Genetic Engineering and Biotechnology Division, Biochemistry Department, Biophysics Group, National Research Center; Head of Rheumatology Department, Air Force Hospital

Abstract: Osteoarthritis is a common cartilage condition and a major cause of pain and disability in older adults. Osteoarthritis most often occurs at the ends of the fingers, thumbs, neck, lower back, knees, and hips. Osteoarthritis hurts people in more than their joints: their finances and lifestyles also are affected. Magnetic susceptibility, dielectric relaxation in the frequency range 100 KHz up to 10 MHz of Hb molecule of osteoarthritic patients receiving anti inflammatory drugs were compared to those received drugs and subjected to soft laser emitted from He-Ne laser with two IR diodes. In addition SOD and whole blood ATP concentration enzyme were measured. The dielectric results indicated that the molecular shape tends to deviate from the non spherical form in patients treated with non steroidal anti inflammatory drugs, to spherical one in those receiving soft laser as an additive drug. Low power laser has significant ability to decrease the pain and suffering of arthritis as well as reducing the disease symptoms. Side effects of medications were reduced in patients received cold laser as a complementary drug. [Journal of American Science 2010;6(5):142-152]. (ISSN: 1545-1003).

Keywords: Osteoarthritis, dielectric properties, soft laser, hemoglobin, magnetic susceptibility.

Introduction

Osteoarthritis (OA, also known as degenerative arthritis, degenerative joint disease), is a group of diseases and mechanical abnormalities results from many metabolic, genetic, chemical, and mechanical factors (Valdes and Spector, 2008), involving degradation of joints (Brandt et al., 2008), including articular cartilage and the subchondral bone next to it. Clinical manifestations of OA may include joint pain, tenderness, stiffness, creaking, locking of joints, and sometimes local inflammation, OA is the most common form of arthritis (Brandt et al., 2009) and a major cause of impaired mobility and disability for the ageing populations (Kokebie and Block 2008; Lozada 2009). The greater the degree of inflammation, the greater the complaint of stiffness (Lin EHB et al., 2003). There are a number of drugs under development for symptomatic and disease modification, and several studies are also evaluating alternative therapies. There are several drugs on the market whose clinical effectiveness and long-term safety still need to be determined. This assessment is especially important since OA requires long-term disease management and the disease primarily affects people over the age of 60 who are most prone to drug toxicity, and for whom the potential for drug interactions are high. Information on the impact of the disease to society and the cost of disease management (including pharmacological and non-pharmacological treatments) needs to be re-evaluated. (Bradley et al., 1991; Stamm et al., 2002; Watkins et al., 2006; Towheed et al., 2006; Zhang et al., 2007).

At present, there is no cure for OA. The management of OA is broadly divided into non-pharmacological, pharmacological, and surgical treatments. Surgical management is generally reserved for failed medical management where functional disability affects a patient’s quality of life. Pharmacological management includes control of pain and improvement in function and quality of life while limiting drug toxicity. Experts in this field suggest that appropriate therapy for OA combines one or more pharmacological agents with exercise, weight loss and physical therapy (i.e. non-pharmacological therapy) (Song et al., 2006).

The therapeutic aim is to treat pain, maintain motor strength, joint range of movement, mobility and therefore function (Dieppe PA, 2004; Dominick et al., 2004; Foster NE, et al., 2007; Reichenbach S., et al., 2007). Strategies include a pharma-cological and non-pharmacological approach. Surgical intervention requires strict indications (Rozendaal RM, et al., 2008; Sawitzke AD, et al., 2008; Zhang W, et al., 2008). While medicines, injections, and surgery all have their place and are valuable, there is still a need for...
potentially useful adjunctive modalities that might speed up recovery and reduce pain faster (Messier SP, et al., 2000; Goldkind L, and Simon LS, 2006).

Lasers for treating osteoarthritis are approved by the FDA (Kipshidze N, et al., 2000), and there are a number of surveys that point to the laser's effectiveness. Low – energy lasers are now widely used to treat a variety of musculoskeletal conditions. Although controlled evaluation of these treatment is limited, quite enthusiastic claims are made for pain, arthritic and wound healing applications. Since these devices are safe, easy to use, and relatively inexpensive. (Ozdemir F., et al., 2001; Stergioulas, A., 2004; Ozcelik O., et al., 2008; and Kuhn A, et al., 2009)

Low level therapeutic laser, better known as phototherapy, is a relatively new form of treatment. Its premise is that certain wavelengths of light have effects on living tissue. This effect is termed “photobiomodulation.” (Markovic AB, et al., 2006; Huang, Y.Y et al., 2009). Certain wavelengths of light at certain intensities (or irradiance to use the technically correct term) delivered by laser, LED or another monochromatic source may affect tissue regeneration, inflammation, or pain. (Gupta AK, et al., 1998; Schubert, V, 2001; and Bjordal JM, et al., 2006).

Laser treatment, unlike traditional surgical methods, is non-invasive and leaves no scarring. Laser treatments are often preferred over medicinal treatment, as lasers do not have the side effects pain pills often do. (Karu, T; 1999; Minatel DG, et al., 2009; Lapchak PA, et al., 2010). Laser therapy was introduced as a non-invasive treatment option for osteoarthritis. The effect produced by laser therapy is not thermal (heat) instead, it has to do with photochemical reactions in cells (Albert, Y. and Banerjee 1975; Karu T, 1988; Lohr NL, et al., 2009).

Many of the pharmacological agents used in the treatment of osteoarthritis can interfere with the various aspects of the inflammatory response. However, deform abilities is still occurred with low rate to some extent. Searching for new trends of treatments to achieve the therapeutic aim of the maximum benefit with minimal toxicity was the aim of the present study.

Material and methods

This study was conducted on 60 osteoarthritic patients, with age range from 47 to 76 years old. They were classified into two subgroups according to the type of treatment received. $G_1$ (25 patients, 15 females and 10 males) treated with non steroid anti inflammatory drugs. $G_2$ (35 patients, 20 females, 15 males) treated with non steroid anti inflammatory drugs and subjected to soft laser produced from mid laser infra red medical instrument. Patients received laser sessions along four weeks every other day. We irradiated the trigger points, access points to the joint, and striated muscles adjacent to relevant nerve roots. Patients were subjected to soft laser and detailed clinical examination in the Air Force Hospital. Blood samples were collected from the patients once after the last session of laser irradiation.

All patients were subjected to detailed clinical history, past history and laying stress on compliant of patients, onset and course of diseases, the pattern of joint involvement and extra articular affection. Pregnant women and patients suffering from other inflammatory diseases were excluded. A pulsed diode laser, He-Ne mid laser with IR manufactured by space laser SRI was used. Turin with continuous emission visible light 632.8 nm wavelength (Out put power 5 mw, output divergence after lens 60 mRad), in coaxial associated with 2 infra red diodes of wave length 904 nm, each with the following specification:

1-Infra-red laser emitters:

Peak output power = $5 \times 10$ w. Average output power = $5 \times (0.3 + 5)$ mw. Pulse width 180 nsec. Pulse frequency min. 200 Hz - Max. 4000 Hz. Output beam divergence 70 m Rad.

Number of diodes = 5

2- I.R. Handles:

Peak power = 10 W. Average output power = 3 mW (min.). Pulse duration 180 nsec. Pulse frequency 4000 Hz. Output beam divergence 70 mRad.

Magnetic susceptibility of hemo-globin is measured using the well known Alert method (Takizawa and Horie, 1986). The force excreted on the sample tube in the magnetic field is determined with a commercial semimicro-balance. This rests upon a mechanical stage, adjustable in two directions, which permits adjustment of the sample between the shoes. Thermal disturbances of the magnetic field (3 to 10 KG) are provided by a water-cooled Wiess magnet. The air gap is 3.8 cm. Fluctuations in the laboratory supply direct current voltage frequently call for a special supply for the magnet. The alternating current supply is fed via a magnetic stabilizer (constant voltage transformer) to an adjustable transformer and rectifier in a two-way rectifier stage. The magnet current can be controlled by
the regulating transformer. The components of the magnetometer are:

1- AC source
2- Thermocouple
3- Variable transformer with control
4- Two-way rectifier
5- Magnet
6- Semi-micro balance
7- Power supply for the heating jacket
8- Magnetic constant voltage supply.

Calculation:
Volume magnetic susceptibility is given from:

\[ K_v = \frac{\Delta S}{W} \cdot \frac{W}{\rho} + \left(1 - \frac{\Delta S}{W} \cdot \frac{W}{\rho} K_w \right) \]  \ldots (1)

Where
- \( K_v \): volume magnetic susceptibility
- \( \Delta S \): weight change of the sample in and outside the field
- \( \Delta W \): same parameter of the water
- \( W \): weight of sample
- \( W \): weight of water
- \( \rho \): density of sample
- \( d \): density of water
- \( K_w \) is the volume magnetic susceptibility of water at the temperature of the measurements.

\[ K_w = 0.72145 \times 10^{-6} - 0.000108 (t-20) \times 10^{-6} \]  \ldots (2)

\( K_v \) is the volume magnetic susceptibility of air which is 0.029 \times 10^{-6}

Molar magnetic susceptibility is given from:

\[ \text{Molar Mag. Sus.} = K_v \times MW \]  \ldots (3)

Determination of hemoglobin oscillator strength is done by using a spectrophotometer UV-Visible 240 Shimadzu (200-700 nm) at room temperature. The extinction coefficient at the wavelength ranged from 310 to 700 nm are taken and then oscillator strength per molar heme was calculated on the following equations:

\[ f = \frac{2.303MC}{N_A \varepsilon} \cdot N_v \left( \frac{3}{N_v + 2} \right)^2 \int \varepsilon \vartheta \nu \]  \ldots (4)

\[ = 1.44 \times 10^{-19} \times 0.841 \int \varepsilon \vartheta \nu \]  \ldots (5)

\[ = 1.44 \times 10^{-19} \times 0.841 \times 3 \times 10^{10} \times \ln \lambda \times \varepsilon \]  \ldots (6)

Super oxide dismutase (SOD) and Adenosine triphosphate (ATP) enzymes activities were measured spectrophotometrically. The reagents used were RANSOD by RANDOK kits (Randox .Crumlin.UK). The instrument used was a double beam spectrometer (UV Model 2410, shimadzu, Japan).

Dielectric Measurements:
The dielectric dispersion for 5% aqueous solution of Hb was measured at 25°C in frequency range 0.1 and 10 MHz for SLE patients compared to normal control using a Loss Factor meter type 1033, RFT, Funkwerk Erfurt. Gerny. The Hb samples were measured by the cell type pw 9510/60, manufactured by Philips. The sample cell has two squared platinum black electrodes each having an area of 0.8x0.8 cm² with an intermediate distance of 1 cm. The cell with the sample is kept at 25°C ± 0.1 in a temperature controlled incubator Kottermann type 2771 Germany. The value of \( \varepsilon' \) (Relative permittivity of the sample in the cell) was calculated at each frequency from the constant \( K \) (the cell constant that depend on the cell dimensions) and \( C_o \) (The residual capacitance) and the measured values of C, also the loss tangent (tan \( \delta \)) was obtained from the measured values of the resistance R and C in farad as:

\[ \tan \delta = \frac{1}{2\pi f RC} = \frac{\varepsilon''}{\varepsilon'} \] the dielectric loss \( \varepsilon'' \) was calculated from the relation \( \varepsilon'' = \varepsilon' \tan \delta \), the conductivity (\( \sigma \)) was then calculated from the relation

\[ \sigma = 2\pi f \varepsilon'' \varepsilon_0 = \frac{C}{K} \]

For spherical macromolecules the dielectric relaxation time depends on the viscosity of the liquid \( \eta \) and its absolute temperature \( T \). Viscosity measurements of each Hb solution was carried out with an ostwald viscometer at concentration of 5% and 25 °C bi-distilled water was used first at fixed volume to pass through certain height of the Ostwald’s capillary, then the efflux of water \( t_2 \) is determined three times and an and an average value was taken also the averaged efflux times \( t_1 \) for both \( G_1 \& G_2 \) were determined, then the viscosity coefficient \( \eta_2 \) of each sample was calculated as

\[ \eta_2 = \frac{\eta_1 (f_1 t_1)}{f_2 t_2} \]

Where \( \eta_1 \) is the viscosity coefficient of water, \( f_1 \) and \( f_2 \) are the densities of water and solute molecules respectively.

Data were analyzed statistically by using the common T-test.
Results

Whole body ATP concentration revealed a significant increase in patients treated with anti-inflammatory drugs and irradiated with soft laser $G_2$ as compared to those received anti-inflammatory drugs $G_1$. Highly significant decrease in the concentration of Super oxide dismutase activity was observed in $G_1$ as compared to $G_2$.

Table 3 illustrates the values of the static $\varepsilon_s$ and infinite $\varepsilon_\infty$, dielectric constant, dielectric increment, cole-cole, the relaxation time $\tau_\beta$, viscosity coefficient $\eta$ in poise and molecular radius in nm for $G_1$&$G_2$. The molecular radius of Hb ($r$) was calculated from the data of relaxation time $\zeta_\beta$ through $\tau_\beta = \frac{4\pi^3\eta}{k\zeta_\beta}$. 

---

Fig. (2) Variation of relative permittivity ($\varepsilon'$), (°); dielectric loss ($\varepsilon''$), (°); conductivity (S), (°) with frequency for 5% aqueous G2 Hb solution at 25°C.
The results indicated that the radius of Hb molecule decreased as well as the relaxation time in $G_2$ compared to $G_1$. The dielectric increment ($\Delta \beta$) per gm per liter was calculated from

$$\tau_\beta = \frac{\varepsilon_1 - \varepsilon_\infty}{C}$$

where $C$ is the concentration of Hb solution in gm/liter. The results of the dielectric increment indicated a higher value in $G_1$ compared to $G_2$. Figures 3, 4 show cole-cole plot ($\varepsilon''$ vs $\varepsilon'$) for ($G_1$, $G_2$) respectively. From these figures, the values of the cole-cole parameter ($\alpha$) for all samples are deduced and given in table 3, these results revealed that there is a wide distribution of the relaxation times of Hb molecules of $G_1$ compared to $G_2$. The curve fitting analysis has shown that, the cole-cole model gave a better fit for the dielectric data.

Fig. (3) : Cole-Cole plot of patients treated with non steroid anti-inflammatory drugs

Fig. (4) : Cole-Cole plot patients treated with ant-inflammatory drug and subjected to soft laser
Discussion

The present study represents a preferable improvement due to the line of interaction treatment by using common anti inflammatory drugs coupled with cold laser in the treatment of osteoarthritis disease.

Oscillator strength is a characteristic constant that reflects the total light absorption of an electronic transition. It provides quantitative information on the electronic states of the hemeprothetic group. Significant decrease in oscillator strength of hemoglobin of osteoarthritic patients subjected to soft laser (G₂) as compared to those treated with anti inflammatory drugs (G₁) confirm the stabilization of hemoglobin as a folding process (Freedman DE, et al., 2010).

Since the ferric atom in any form of chemical binding has an odd number of electrons. Thus, the increment of magnetic susceptibility of hemoglobin of osteoarthritic patients G₁ compared to those receiving soft laser G₂ seems to be related to a degree of oxidation instead of oxygenation (Regan E, et al., 2005).

SOD in general is known to be produced within the RBC by the spontaneous oxidation of oxy hemoglobin of isolated Hb chains, and in particular would appear to be an indicator of disease response (Regan EA, et al., 2008).

The inhibitory effect of low power laser on the emergence of chemotactic factors, which appeared as decrement SOD concentration in the RBC of G₂ compared to G₁. Another possibility is that a low power laser may interfere with the effect of chemical mediators or super oxide induced by inflammation causing re absorption of exudates and facilitating the elimination of algogenic substances (Cho HJ, et al., 2004; Benedicenti S, et al., 2008; Hegedus B, et al., 2009).

An abnormal release of activated species of oxygen in RBC, is believed to be responsible for extensive cellular damage such as the Hb precipitation as Hinz bodies and peroxidase of erythrocyte membrane. Damage by oxygen free radicals within the RBC is prevented by curpo-zinc. SOD, this enzyme catalyzes the dismutation of O₂⁺ by forming O₂ and H₂O₂ which is subsequently catabolized by catalase and / or glutathione peroxidase (Gen Dent, 2008; Yamaura M, et al., 2009; Rubio CR, et al., 2009).

The photochemical and / or photo physical process of low power laser irradiation on cells, appeared from the increase of ATP in blood of patients exposed to soft laser (G₂) compared to (G₁) (Blanco FJ, et al., 2004; Kassák P, et al., 2006; Toncheva A, et al., 2009).

Light is absorbed by enzymes in the mitochondria, which activates the respiratory chain by accelerating the electron transfer in the redox pairs in some sections of the respiratory chain, which promotes proton influx through ATP synthetase. This may result in enhanced ATP synthesis. These changes then initiate a cascade of molecular events leading to a final cellular response, suggested that irradiation with a different wave length (specially 904 nm) could initiate the same final cellular response at a different point in the sequence of molecular events. It is believed that the small changes in concentration of adenine nucleotides (ATP, ADP and AMP) induce considerable changes in cellular metabolism since the nucleotides act as allosteric effectors (activators and inhibitors) of the several key enzymes of energy metabolism (Kujawa J, et al., 2004; Kocer I, et al., 2007).

Dielectric relaxation technique, gives more useful informations about some biophysical properties of the molecule such as the relaxation time ζ, the shape of the molecule and the viscosity coefficient η. The variation of the conductivity S as a function of frequency can be considered as another viewpoint for treating the dispersion data in the β region. It was shown that at high frequency end, the conductivity curve is still elevated for G₂ while flattening appeared in patients treated with anti-inflammatory drugs(G₁).

It is clear from the dielectric relaxation data in table 3, that both the relaxation time κ and radius of the Hb molecules increased for G₁ as compared to G₂. The shift towards lower or higher frequencies f₂, as indicated from the β dispersion in fig (1-4) is attributed to changes in molecular radius. Since smaller molecules have shorter relaxation times and hence larger critical frequencies (Debye, P., 1929; K.S Cole, and R.H Cole. 1941; Srivastova, A, et al., 1997; Samiha T. Bishay. 2000; De Morais NC, et al., 2009).

There is a marked increase in the dielectric increment for G₁ as compared to G₂, it may be presumed that the activity of the disease may result in the variation of the dielectric increment.
Theoretical treatment of the dielectric relaxation data to calculate the Cole–Cole parameter $\alpha$ illustrates another form of the conformational changes in the hemoglobin, the values of $\alpha$ show a very wide distribution of relaxation time. Cole-Cole plot ($\varepsilon''$ vs $\varepsilon'$) is nearly semi circle. The shape of Hb molecule tend to shift from the non spherical form to spherical one (Fig; 3,4) i.e. a decrement in the unfolding process in G$_{2}$ as compared to G$_{1}$. The change in the tertiary structure of Hb molecule results in a change in its molecular shape from non spherical form (G$_{1}$) to nearly spherical form in G$_{2}$ with different values of the parameter $\alpha$.

These conformational changes may be attributed to direct effect of laser on Hb molecules, or to an indirect effect with many enzymes systems related to Hb functions in erythrocyte. There is a hypothesis that cell components may be re-oriented by the linear polarization of laser and as a result its metabolic may becomes activated (Obay BD, et al., 2008; Karu, TI, 2008; Chow, RT et al., 2009).

The indirect effect of soft laser, on Hb conformation may be through interaction with these erythrocyte enzymes. Reaction rate of H$_2$O$_2$ decomposition by catalase increased may therefore reduce the extent of the side reactions that are destructive to the protein moiety, preserving the stable (native) tertiary structure of hemoglobin molecule. The magnitude of this effect therefore enhanced with the laser irradiation. (Lubart R, et al., 2006; Tumilty, et al., 2009).
