Cheeses made with modified mesophilic starter bacteria and probiotic *Lactobacillus*, as adjunct culture were found to have delicate pure taste, clean typical aroma, larger number of eyes and normal elastic consistency (Ta1, Ta2 and Tb2) Fig. 3. The increased eye formation was probably due to the higher number of citric acid fermenting bacteria (leuconostics or leuconostoc and *Str. diacetilylactis* together also enclosed in the curd. Similar results have been reported (Møller *et al.*, 2009). During the ripening of cheese, proteolysis is the most important pathway for flavour development. Short peptides and free amino acids are necessary for flavour development and are dependent on the extent of proteolysis. Gomes and Malcata (1998) reported that the high flavour scores of semi-hard goat cheese made with *B. lactis* and *L. acidophilus* strain Ki were associated with high levels of proteolysis. In addition, Flávia *et al.*, (2005) they reported that *L. paracasei* had a positive effect on the sensory Minas fresh cheese and its a great potential as a functional food.

# Gap Analysis for Protected Areas of Andhra Pradesh, India for conserving biodiversity

C. Sudhakar Reddy

Forestry and Ecology Division, National Remote Sensing Centre, Indian Space Research Organisation, Balanagar,  
Hyderabad -500 625, India  
[drsudhakarreddy@gmail.com](mailto:drsudhakarreddy@gmail.com)

**Abstract:** A gap analysis was carried out to assess the Protected Area (PA) network system in Andhra Pradesh, India. The decisive factors of vegetation type distribution, elevation and endemism was used to determine the representativeness of PA system. In Andhra Pradesh, vegetation cover occupies 23.03% of geographical area and distributed in Coastal Plains, Deccan Plateau and Eastern Ghats. There are 27 PAs for conservation in Andhra Pradesh. The total area protected for biodiversity is about 12,555 km<sup>2</sup> or 4.56% of geographical area of Andhra Pradesh. Of the three physiographic regions, Eastern Ghats represents very high area under PAs which was estimated as 7811.38 km<sup>2</sup> followed by Deccan plateau of 3526.89 km<sup>2</sup>. Three main forest types (semi evergreen forests, thorn forests and dry evergreen forests) missing in the existing PA network were identified. Moist deciduous forests of Eastern Ghats of northern Andhra Pradesh were under-represented in PAs. The land area in an elevation range of 900m-1527m was not included in PA network. Of the 103 species of endemics, 64 species were not included in PA system. Many PAs are experiencing threat from invasive species, forest fires, grazing pressure etc. There is a need to consider for possible ways for effective conservation and to extend the present PA network system in India.

[Journal of American Science 2010;6(11):472-484]. (ISSN: 1545-1003).

**Keywords:** gap area; vegetation; protected area; semi evergreen forests; Andhra Pradesh; India

## 1. Introduction

International treaties call for the conservation of biodiversity in all its manifestations including ecosystem level diversity. Conservation biology is concerned with developing the scientific support for conservation policy and management decisions. Conservation efforts have focused on maintaining biodiversity through establishment of networks of protected areas. Protected areas (PAs) are the priority centers of biodiversity and wildlife conservation. The criteria of biodiversity inventory, vegetation type distribution, topographic variability, climatic gradient and biotic pressure are basic stuff in conservation planning. These surrogates can be effective at representing other aspects of biodiversity, such as ecological uniqueness, species distributions, species diversity and contiguous intact natural habitats (Kirkpatrick and Brown, 1994, Wessels *et al.* 1999). Conservation planning exercises also call for data on the distribution of PAs. But many PA systems across the world were chosen based on socio-economic and aesthetic criteria (Oldfield *et al.* 2004). Gap analysis is a comprehensive approach for assessing conservation needs. The gap analysis has been undertaken by few researchers (Hunter and Yonzon, 1993; Fearnside and Ferraz, 1995; Powell *et al.* 2000; Scott *et al.* 2001; Bon and Gaston, 2005)

India is one of the mega-diversity nations in the world. India has 590 PAs (ca. 500 wildlife sanctuaries and 90 national parks. PAs of India cover 156,700 km<sup>2</sup>, roughly 4.95% of the total geographical area (<http://en.wikipedia.org.2010>). There is a pressing requirement to identify gap areas of high biological richness to declare new Protected Areas in India. Spatially explicit inventories of vegetation types and land cover permit comparisons between particular vegetation distributions and distributions of land cover, land-cover change, expected changes and issues of protected areas. With the current trend of increasing rate of deforestation and loss of habitats in densely populated developing countries, there is a urgent need to generate database which is available for planning, decision making and further objective oriented requirements. Satellite remote sensing along with Geographic Information System (GIS) provides a cost and time effective solution to collect, process and integrate database in an effective manner. In the present study, an attempt was made to identify 'gap areas' in PA network of Andhra Pradesh, India which covers a major part of Deccan Plateau, Eastern Ghats and East Coast regions by integrating spatial and non spatial databases.

## 2. Material and Methods

The study was conducted in Andhra Pradesh, is the largest State of southern India. The State of Andhra Pradesh (The land of Telugu people) is situated in the middle of eastern half of the Indian Peninsula lying between  $12^{\circ} 41' - 19^{\circ} 54' N$  latitudes and  $76^{\circ} 46' - 84^{\circ} 45' E$  longitudes. It is bounded by the Bay of Bengal in the east, Tamil Nadu in the south, Karnataka in the west, and Maharashtra, Chhattisgarh and Orissa in the north. Administratively, Andhra Pradesh has 23 districts which were grouped into three zones: (1) *Circars or Coastal Andhra* with nine districts, i.e. East Godavari, Guntur, Krishna, Nellore, Prakasam, Srikakulam, Vizianagaram, Visakhapatnam and West Godavari (2) *Rayalaseema* with four ceded districts, i.e. Anantapur, Chittoor, Cuddapah and Kurnool (3) *Telangana* (Deccan or erstwhile Nizam's Dominions of Hyderabad State) with 10 districts, i.e. Adilabad, Hyderabad, Karimnagar, Khammam, Mahabubnagar, Medak, Nalgonda, Nizamabad, Rangareddy and Warangal.

Geographically, the State is categorized into three regions, namely: (1) the *Coastal Plains* (along the east coast, a low-lying area from Srikakulam to Nellore) mainly of agricultural land and mangroves (2) the *Eastern Ghats*, forming a chain of discontinuous range of hills along the coast with good vegetation, and (3) the *Deccan Plateau* consisting of agricultural lands, scrub and deciduous forests, which cover part of Kurnool (excl. Nallamalais), Anantapur districts (excl. Nigidi hills) and the major part of Telangana. The total forest cover of the State is  $44,419 \text{ km}^2$ , which occupies 16% of the total geographical area of  $275,068 \text{ km}^2$  (FSI, 2003). The highest peak in Andhra Pradesh is Sambarikonda (1527 m), found in RV nagar range of Visakhapatnam district.

Preparation of vegetation type and land use map was accomplished through visual interpretation of multi-season IRS P6 LISS III images as part of project on "biodiversity characterization at landscape level" (Reddy et al. 2008). The protected area information was accessed from the Protected Areas Database (Anonymous, 2007). In the present study vegetation type information, elevation data (<http://www.landcover.org/data/srtm/>) and endemism was used to determine 'gap areas' for Protected Areas network (Reddy et al. 2006).

### 3. Results

In Andhra Pradesh, vegetation cover occupies 23.03% of total geographical area. While forest cover of the State is estimated as  $44,334 \text{ km}^2$ . The area under forest cover is proportionately 16.12% of total geographical area (Table 1). The forest types found in Andhra Pradesh are Semi

Evergreen, Moist Deciduous, Dry Deciduous, Dry Evergreen, Thorn, Teak mixed, Bamboo mixed, mangrove, riverine forest, woodland, savannah and forest plantation (Table 2). Most abundant forest type was Dry Deciduous forest (Fig. 1) which comprises 73.36% of the total forest area, followed by Moist Deciduous forest of 10.98%. Scrub/shrub land occupies significant area, which is about 6.54% of total geographical area of State. There are about 18,443 wetlands, accounts for  $11,572.50 \text{ km}^2$  (4.21%) of total area of State.

Table 1. Areal extent of Vegetation and Land Use of Andhra Pradesh, India

Sl.no.	Class	Area (km <sup>2</sup> )	% of Area

Savannah	862.92	1.95
Grand total	44334	100

#### 3.1 Total coverage of PAs

There are 27 PAs declared for conservation in Andhra Pradesh, comprising 22 wildlife sanctuaries and 5 national parks (Table 3; Fig.2). The areas of the individual PAs range from 1.42 to  $3,568 \text{ km}^2$ . Taking into account the wildlife sanctuaries and

national parks, the total area protected for biodiversity is about 12,555 km<sup>2</sup> or 4.56% of geographical area of Andhra Pradesh. Of the 63,349.5 km<sup>2</sup> of natural vegetation in State, 11,773 km<sup>2</sup> (18.6%) of area was under PA network. Of the three physiographic regions, Eastern Ghats represents very high area under PAs which was estimated as 7811.38 km<sup>2</sup> (62.2% of total PA) followed by Deccan plateau of 3526.89 km<sup>2</sup> (28%). Altogether an area of 1287.83 km<sup>2</sup> (10.3%) was demarcated for PA system in coastal plains. Nagarjunasagar Srisailam Tiger Reserve is largest tiger reserve of the country, occupies 28% of the total PA of Andhra Pradesh. Of the five PAs of coastal plains, Nelapattu wildlife sanctuary is smallest with an area of 4.58 km<sup>2</sup> and Kolleru is largest with an area of 308.55 km<sup>2</sup>. Of the eight wildlife sanctuaries in Deccan Plateau (Telangana), Pakhal (860.2 km<sup>2</sup>) and Eturnagaram (803 km<sup>2</sup>) are occupying 47.42% area. The PA area under grassland and wetlands are accounted as 6.14 km<sup>2</sup> and 782.1 km<sup>2</sup> respectively.

Table 3. Protected Areas of Andhra Pradesh and representation of Vegetation types

Grand total	12555	100		

### 3.2 Coverage by vegetation type distribution

The semi evergreen forests of Andhra Pradesh were not covered under PA network. Semi evergreen forests were seen only in the northern parts of Andhra Pradesh above an elevation of 900m to 1500m and found in Chintapalle, Gudem, Lankapakala, Sambarikonda, Upper Sileru, Sapparla hills of Visakhapatnam, Dummakonda, Maredumilli, Peddakonda hills of East Godavari. Total area covered by this forest is 1,585.4 km<sup>2</sup> (3.58% of total forest area). The mean annual rainfall in semi evergreen forests is high as compared with other forest types, which is in the range of 1300mm-1700mm.

Moist Deciduous forests are found extensively in Eastern Ghats of northern Andhra Pradesh region, parts of Khammam, Warangal, Adilabad, Gundlabrahmeswaram of Nallamalais and Talakona RF in Chittoor district. The area coverage is about 4,865.85 km<sup>2</sup> (10.98% of total forest area). These forests were exists between elevation of 600m to 900m and mean annual rainfall of 1000mm-1300mm. Moist deciduous forests of East Godavari, Visakhapatnam, Srikantham, Vizianagaram and West Godavari districts and Mothugudem of Khammam district were unique and not present in PA network. Sal mixed deciduous forests of parts of Srikantham (Seethampet and Donubayi) and Vizianagaram districts also significant and can be prioritized for protection.

The dry deciduous forests are conspicuous throughout Andhra Pradesh with supremacy in Telangana and Rayalseema districts. It occurs at an altitude of around 200m-600m. It is spreading over an area of 32,524 km<sup>2</sup> (73.36% of total forest area). Dominance of species differs across different regions. Red Sanders (*Pterocarpus santalinus*) is gregarious species and forms Red Sanders mixed forest in Seshachalam hills of Cuddapah and Chittoor districts. Teak and Bamboo often occurs gregariously and characterize similar associations of dry deciduous

forests. Even though, 20 PAs were represented in dry deciduous forests, still forests like Nigidi hills of Anantapur, Mahadevpur-Kaleshwaram of Karimnagar, Narsapur of Medak, Manchippa of Nizamabad and Chathakonda, Venkatapuram of Khammam need to be considered in view of their community distinctness, geographical situation and topographic variability.

Thorn forests are prevails mostly in Anantapur, Chittoor, Cuddapah, Kurnool and Nalgonda districts. This is characteristic of the dry areas with low rainfall and high temperatures. There is no any PA for thorn forests. The forests of Erramalais of Kurnool, parts of Palakonda hills of Cuddapah and Nagalapuram hills of Chittoor can be prioritized for conservation. Dry Evergreen forest is a unique forest shows dominance of deciduous elements and small leathery-leaved evergreen trees with short trunks and the dense shrubby undergrowth. Dry evergreen forests of Vinukonda range of Guntur district and Kondapalle of Krishna district need to be considered for PA network.

Mangroves are unique systems of east coast, distributed mainly in East Godavari, West Godavari, Krishna, Guntur and parts of Prakasham districts. Total area covered by mangroves is 329 km<sup>2</sup>. The major area of Mangrove was under protection in Coringa wildlife sanctuary and Krishna wildlife sanctuary. Grasslands are mostly found in Rollapadu sanctuary and environs of Kurnool district and in hill tops of Eastern Ghats of northern Andhra Pradesh. Grasslands of Dummakonda and Peddakonda of East Godavari and Gudem, Sapparla, Sileru and Sambarikonda of Visakhapatnam are potential areas for PA network.

### 3.3 Coverage by Elevation

Most of Andhra Pradesh (91.73%) is covered by land with an elevation of <600 m (asl) but only 3.76% of this area corresponds to PA status (Table 4), (Fig. 3). The land between elevation of 300-600m represents 2% of area coverage under PAs. The proportion of PA is very less (0.80%) in an elevation range of 600-900m. However, about 75% of the land between elevation of 900m and 1527m in Eastern Ghats of northern Andhra Pradesh has vegetation cover, but there is no single PA. The geographical area of elevation above 900m occupies 3598.72 km<sup>2</sup> (1.31% of total TGA) need to be considered for declaration of 'Biosphere Reserve'. Coastal plains were received consideration of forest managers and important wetlands of international/national importance were included in PA network.

Table 4. Proportion of PAs with reference to elevation range and geographical area of Andhra Pradesh

Elevation Range	Geographic area (km <sup>2</sup> )	% of geographic area	% of PA network
<100	63156.85	22.96	0.44
100-300	91065.96	33.11	1.32
300-600	98110.11	35.67	2
600-900	19136.18	6.96	0.8
>900	3598.72	1.31	0
Total	275068	100	4.56

### 3.4 Coverage by Endemism

Endemism is a special criterion in conservation of any area. The word '*endemic*' is ascribed to any taxon, which has a restricted distribution. Because of their narrow distributional zonation, endemic species became important target for global conservation efforts. Of the 27 Protected Areas in Andhra Pradesh, Sri Venkateshwara wildlife sanctuary/national park, Nagarjunasagar-Srisailam tiger reserve, Gundlabrahmeswaram wildlife sanctuary, Sri Lankamalleshwara wildlife sanctuary, Peninsula Narasimha wildlife sanctuary and Pakhal wildlife sanctuary represents endemic species (Table 5). Sri Venkateshwara wildlife sanctuary represents 24 endemic species, which are edaphically and climatically adapted to occur in small ecological refugium. So, there is an urgent need to elevate the status of Sri Venkateshwara wildlife sanctuary and national park as 'Seshachalam Biosphere Reserve'. Of the 103 species of endemics, 64 (62%) species were not included in PA network. Of the 45 red listed (threatened) species, 24 (53%) were not covered in PA network. The upper hills of Visakhapatnam district represents 27 endemic species and seven endangered species, needs immediate concern.

#### 4. Discussion

Most PA systems around the world have a tendency to over-represent highland areas (Fearnside and Ferraz, 1995; Powell et al. 2000; Scott et al. 2001) and the study results show a different pattern for Andhra Pradesh. Study found that there is no PA in the elevation above 900m, which is representing semi evergreen forests, moist deciduous forests and savannah. The area above 900m elevation harbours 29 endemic species.

Total PA coverage was low when compared with the commonly used target of 10% (Miller, 1984) with only 4.56% of geographical area of the Andhra Pradesh having PA status. But total proportion of PAs with reference to natural vegetation infer 18% of the area was included under conservation. The analysis of vegetation type distribution reveals that dry deciduous

forests were represented in 20 PAs, where as moist deciduous forests were noticed in two PAs only (Gundlabrahmeswaram and Papikonda). The percentage of PA above 600m, need to be expanded in view of varied vegetation types, species diversity and terrain complexity. Three main vegetation types of State (semi evergreen forests, thorn forests and dry evergreen forests) missing in the existing PA network were identified. Moist deciduous forests of Eastern Ghats of northern Andhra Pradesh were under-represented in PA system (Fig. 4). Gap analysis also determined the number of endemic and threatened plant species currently not protected. Considering vegetation type distribution, elevation and endemism, Upper Godavari and Upper Visakha hills (Eastern Ghats of northern Andhra Pradesh) can be prioritised to the status of 'biosphere reserve' along

with Seshachalam hills (Eastern Ghats of southern Andhra Pradesh). Many PAs have low levels of protection with multifarious threat from invasive species, habitat degradation, forest fires, grazing, illegal extraction of wood, shifting cultivation etc. Deciduous forests are vulnerable ecosystems because of very high economic potential. According to the Directorate of Revenue Intelligence, Govt. of India, the smuggling of Red Sanders wood from Sri Venkateswara Wildlife Sanctuary to South East Asia has emerged as a significant area of concern. During 2003-04, the Directorate of Revenue Intelligence had seized 151 MTs of Red Sanders wood valued at Rs.6 crores (approx.) in the illegal market in India. During 2004-05, 347 MTs of Red Sanders valued at Rs.13.88 crores (approx.) was seized. During 2005-06, the smuggling of Red Sanders continued and 449 MT of Red Sanders valued at Rs. 17.98 crores was seized (<http://www.dri.nic.in>). Pranahita wildlife sanctuary of Adilabad district, had witnessed loss of forest cover of 248 ha area during 1993-2004 (Giriraj et al. 2007). In PAs of Andhra Pradesh, aggressive colonization by invasive plant species (*Hyptis suaveolens*, *Lantana camara*, *Chromolaena odorata*, *Prosopis juliflora*, *Ageratum conyzoides*, *Cassia tora*, *Cassia uniflora*, *Parthenium hysterophorus*) are posing survival threat to native biodiversity. Aquatic habitats also suffering by invasion of *Eichhornia crassipes*, *Alternanthera philoxeroides*, *Ipomoea carnea*, *Typha angustata*, *Pistia stratiotes* etc (Reddy, 2008).

Analysis of endemism also provides a strong platform for the necessity of new protected areas to safeguard unique biodiversity of Andhra Pradesh. To save the biodiversity from human interference, we need to resolve for strong conservation efforts. Consequently, there is need to consider ways to create a network of continuums of Protected Areas in India.

The advent of the remote sensing has made it possible to prepare precise vegetation type maps. The study demonstrated the usefulness of information of vegetation types, elevation and endemism for the conservation prioritisation. The study suggests for declaration of new PAs in semi evergreen forests, moist deciduous forests, dry evergreen forests and under-represented vegetation types. Further, it is recommended that the habitats of endemic species can be preserved by appropriate conservation planning.

#### **ACKNOWLEDGEMENT**

I am grateful to Dr. V. Jayaraman, Director, NRSC, Dr. P.S. Roy, Deputy Director, NRSC and Head, Forestry & Ecology Division, NRSC, Hyderabad for suggestions and encouragement. Thanks are due to Sri P.S. Rao, Additional Chief Conservator of Forests, Andhra Pradesh Forest Department for inspiration and support and to Global

Land Cover Facility Programme, University of Maryland for SRTM data. The present work is carried out as part of national project on "Biodiversity characterization at landscape level using satellite remote sensing and GIS" with financial support of Department of Space and Department of Biotechnology, Government of India.

**Abstract:** Machine Learning and Data Mining are applied to language datasets in order to discover patterns for English and other European languages, Arabic language belongs to the Semitic family of languages, which differs from European languages in syntax, semantic and morphology. One of the difficulties in Arabic language is that it has a complex morphological structure and orthographic variations. This study is conducted to examine knowledge discovery from AL-Hadith through classification algorithm in order to classify AL-Hadith to one of predefined classes (books), where AL-Hadith is the saying of Prophet Mohammed (Peace and blessings of Allah be upon him (PBUH)) and the second religious source for all Muslims, and because of its importance for Muslims all over the world knowledge discovery from AL-Hadith will make AL-Hadith more understandable for both Muslims and nonmuslims.

**Keywords:** AL-Hadith, classification, stem, feature, class, expansion, training set.

## 1. Introduction

Information Retrieval (IR) is the discipline that deals with retrieval of unstructured data, especially textual documents, in response to a query, which may itself be unstructured like sentence or structured like Boolean expression. The need for effective methods of automated IR has grown in the last years because of tremendous explosion of the amount of unstructured data (Greengrass, 2000).

Text mining is a class of what is called nontraditional (IR) strategies (Kroeze, et al., 2003). The goal of these strategies is to reduce the required effort from users to obtain useful information from large computerized text data sources. Also text classifications (TC) is a subfield of data mining which refers generally to the process of deriving high quality of information from a text, which is typically derived through the dividing of patterns and trends through methods such as statistical pattern learning.

However; text classification is one of the most important topics in the field of natural language processing (NLP), where the purpose of its Algorithm is to assign each document of text dataset to one or more pre-specified classes. More formally if  $d_i$  is a document of set of documents  $D$  and  $\{c_1, c_2, \dots, c_n\}$  is the set of all classes, then text classification assigns one category  $c_j$  to a document  $d_i$  and in multi-subjects classification  $d_i$  can be assigned to more than one class from a set of classes.

Text classification techniques are used in many applications, including e-mail filtering, mail routing, spam filtering, news monitoring, sorting through digitized paper archives, automated indexing of scientific articles, classification of news stories and searching for interesting information on the web (Khreisat, 2006).

Also, an important research topic appears in this field called Automatic text classification (ATC) because of the inception of the digital documents. Today, ATC is a necessity due to the large amount of text documents that users have to deal with (Duwairi, 2006).

According to the growth of text documents and Arabic document sources on the web, information retrieval becomes an important task to satisfy the needs of different end users; while automatic text (or document) categorization becomes an important attempt to save human effort required in performing manual categorization.

In this paper, a knowledge discovery algorithm for AL-Hadith is proposed in order to classify it to one of predefined classes (books), this algorithm consists of two major phases; the training phase and Classification phase. Experiments will be conducted on a selected set of AL-Hadith from Al-Bukhari book, where thirteen books were chosen as classes in order to run these experiments. The evaluation of the proposed algorithm is carried out by comparing its results to Al-Bukhari classification.

This paper is organized as follows; related work is represented in section 2, while section 3 represents the proposed classification system, and section 4 analyze experiments and results, finally section 5 demonstrates conclusion.

## 2. Related Work

Most of nowadays classifiers were built for English or European languages. For example, Zhang (2004) builds a Naïve Bayes (NB) classifier, which calculates the posterior probability for classes then the estimation is based on the training set that consists of pre-classified documents, in his system testing phase the posterior probability for each class is computed then the document is classified to the class that has the maximum posterior probability.

Isa, et al. (2008) explore the benefits of using enhanced hybrid classification method through the utilization of the NB classifier and Support Vector Machine (SVM). While Lam, et al. (1999) built a neural network classifier addressing the classifier drawbacks and how to improve its performance.

Bellot, et al. (2003) propose an approach that combines a named entity recognition system and an answer retrieval system based on Vector Space model and uses some knowledge bases, while Liu, et al. (2004) focus on solving the problem of using training data set to find representative words for each class, also (Lukui, et al. 2007) explore how to improve the executing efficiency for classification methods.

On the other hand, Yu-ping, et al. (2007) propose a multi-subject text classification algorithm based on fuzzy support vector machines (MFSVM).

In the Arabic language field, AL-Kabi, et al. (2007) present a comparative study that represents the efficiency of different measures to classify Arabic documents. Their experiments show that NB method slightly outperforms the other methods, while AL-Mesleh (2007) proposes a classification system based on Support Vector Machines (SVMs), where his classifier uses CHI square as a feature selection method in the pre-processing step of text classification system procedure.

El-Halees (2006) introduces a system called ArabCat based on maximum entropy model to classify Arabic documents, and Saleem et al. (2004) present an approach that combines shallow parsing and information extraction techniques with conventional information retrieval, while Khreisat (2006) conducts a comprehensive study for the behavior of the N- Gram Frequency Statistics technique for classifying Arabic text document.

Hammo, et al. (2002) design and implement a Question Answering (QA) system called

QARAB.EL-Kourdi, et al. (2004) build an Arabic document classification system to classify non-vocalized Arabic web documents based on Naïve Bayes algorithm, while AL-Kabi, et al. (2005) represent an automatic classifier to classify the verses of Fatiha and Yaseen Chapters to predefined themes, where the system is based on linear classification function (score function), and (Hammo, et al. 2008) discuss the enhancement of Arabic passage retrieval for both diacritized and non-diacritized text, they propose a passage retrieval approach to search for diacritic and diacritic-less text through query expansion to match user's query.

## 3. Proposed Classification System

The proposed system consists of four phases; first one is the preprocessing phase. Second phase is the training phase where the learning database is constructed which contains the weights of features representing a class. The input for this phase is a set of pre-classified documents. Third phase is the classification phase in which the resulted training database of previous phase is used with the classification method to classify targeted Hadith, also a query expansion occurs in this phase and the output of it will be the class (book) of targeted AL-Hadith. Finally, data analyzing and evaluation phase. These phases are shown in figure 1. We can define the corpus that contains a set of Ahadith (plural of AL-Hadith) as in definition 1.

### Definition 1: Corpus Definition

Suppose corpus  $C = \{H_1, H_2, H_3, \dots, H_n\}$ . Where  $H_i$  represents the  $i$ th tested Hadith in  $C$ ,  $n$  is the number of tested Hadith in the  $C$  and  $i: 1 \dots n$ .

Suppose  $H_j = \{w_1, w_2, w_3, \dots, w_m\}$ . Where  $w_d$  represents the  $d$ th word in AL-Hadith  $H_j$ ,  $m$  is the number of words in  $H_j$  and  $d: 1 \dots m$ .

Figure 2 shows an example of Hadith from the book of food that will be used in the illustration of each step of the proposed system.

### 3.1 Preprocessing phase

In this section the preprocessing techniques are introduced, preprocessing will be conducted on each Hadith used in the training and testing sets. This stage is necessary before the classification phase can be applied to discover knowledge from AL-Hadith and it consists of several sub phases:

1. **Removing Sanad:** this process is done manually and aims to remove Sanad which is a part of AL\_Hadith that refers to the chain of names of persons who have transmitted AL-Hadith.
2. **Tokenization:** which aims to divide AL\_Hadith into tokens (words); AL-Hadith tokenization was

- easily resolved since each token can be identified as a string of letters between white spaces.
3. **Removing punctuation and diacritical marks:** removing diacritical and punctuation marks is important since those marks are prevalent in Ahadith and have no effect on determining AL\_Hadith class.
  4. **Removing stop words:** Stop words are words that found in AL-Hadith and have no discriminative meaning (AL-Kabi, et al., 2005). In the proposed system a list of stop words is built manually and it consists of Arabic pronouns, prepositions, names of people (companions of Prophet Mohammed) and places were mentioned in AL-Hadith corpus. Then after removing stop words from AL\_Hadith, the remaining words (terms) are considered as features.
  5. **Stemming:** In this step the stems of features are extracted, stem extraction implemented is considered as light stem extraction which depends on removing some prefixes or suffixes from the word to relate the word to its stems, we used the stemming algorithm proposed by (Al-Serhan, et al., 2003). The result of stem extraction was filtered to eliminate the incorrect (roots less than three characters). The resulted stems will be used in the query expansion process which will be discussed in details in section 3.3.2, Table 1 shows all steps of preprocessing for AL-Hadith that is presented in figure 2.

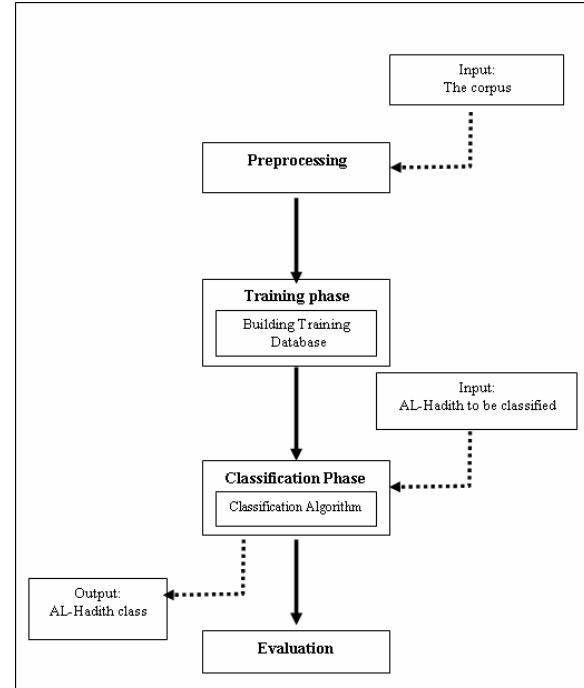

Figure 1. An overview of proposed system phases.

حدثى اسحق بن ابراهيم: أخبرنا روح بن عبادة: حدثنا ابن أبي ذئب، عن سعيد المقيرى، عن أبي هريرة رضي الله عنه:  
 أنه من بقوم بين أيديهم شاة مصلية، فدعوه، فأبى أن يأكل وقال: خرج رسول الله صلى الله عليه وسلم من الدنيا ولم يشبع من خبز الشعير.

Figure 2. Example of AL-Hadith from the book of food.

Table1. Results of preprocessing phase steps for AL-Hadith in figure 2

Step	Result of the step
Removing Sanad	أنه من بقوم بين أيديهم شاة مصلية، فدعوه، فأبى أن يأكل وقال: خرج رسول الله صلى الله عليه وسلم من الدنيا ولم يشبع من خبز الشعير.
Tokenization	{“أنه”, “مر”, “يقوم”, “بين”, “أيديهم”, “شاة”, “مصلية”, “فدعوه”, “أ”, “فأبى”, “أن”, “يأكل”, “وقال”, “خرج”, “رسول”, “الله”, “صلى”, “الله”, “عليه”, “ وسلم”, “من”, “الدنيا”, “ولم”, “يشبع”, “من”, “خبز”, “الشعير”, ”! ”}
Removing Punctuation and Diacritical Marks	{ انه , مر , بقوم , بين , ايديهم , شاة , مصلية , فدعوه , فابى , ان , يأكل , وقال , خرج , رسول , الله , صلى , الله , عليه , وسلم , من , الدنيا , ولم , يشبع , من , خبز , الشعير }
Removing Stop Words	{ مر ، بقوم ، ايديهم ، شاة ، مصلية ، فدعوه ، فابى ، يأكل ، خرج ، الله ، صلى ، عليه ، وسلم ، الدنيا ، يشبع ، خبز ، الشعير }
Stemming (valid stems)	{ ايدي ، دنيا ، شعير }

### 3.2 Training Phase

Supervised classification exploits the predefined training documents that belong to specific class to extract the features that representing a class.

Therefore, every class will have a feature vector representing it, and then these features will be reduced using one of the features selection

techniques. Feature vectors will be used later by the classification algorithm in the testing phase.

Supervised classification has its difficulties; one main problem is how to be sure that trained document actually belongs to a specific class. In this study this problem is resolved by conducting it on a set of AL-Hadith that has been classified by the famous AL-Hadith scientist AL-Bukhari who gave us a good base to evaluate the proposed algorithm.

Training phase consists of two main stages; first one is executed once to produce Inverse Document Frequency (IDF) matrix for the corpus while the second one is executed for each training set.

### 3.2.1 Corpus IDF Matrix

After conducting the preprocessing phase a list of features for each Hadith in the corpus is produced and will be used in the classification process. Building the IDF matrix for AL-Hadith

corpus is done only one time and it will be used in the classification process every time the IDF value for a feature is needed. The IDF value for a given feature is computed according to equation (1).

$$\text{IDF}_i = \log \left( \frac{N}{DF_i} \right) \quad (1)$$

Where

N: number of Ahadith in the corpus.

DF<sub>i</sub>: Number of Ahadith in the corpus containing feature i.

Fewer documents containing a given feature will produce a larger IDF value and if every document in the collection contains a given feature, feature IDF will be zero, in other words the feature which occurs in every document in a given collection is not likely to be useful for distinguishing relevant from non-relevant documents. Table 2 shows the IDF matrix structure.

Table 2. Corpus IDF matrix.

Feature	Pre-defined Classes(Books)					
	Book1	Book2	Book3	....	Bookc	Feature redundancy
Feature1	Log (N/DF <sub>1</sub> )	log (N/DF <sub>1</sub> )	log (N/DF <sub>1</sub> )	.....	log (N/DF <sub>1</sub> )	([DF <sub>1</sub> ]/N)*100

### 3.2.2 Weight calculations for training sets features

The proposed system depends on using a set of Ahadith as training documents to extract representative words for each book (class) to compute their weights. The weight of a given feature in a given document is calculated as (TF×IDF) because this weighting schema combines the importance of TF and IDF at the same time, and the features training weights is computed according to equation (2).

$$TW_{bi} = TF_{bi} \times IDF_i \quad (2)$$

Where:

TW<sub>bi</sub>: feature i training weight in training set b.

TF<sub>bi</sub> : feature i frequency in training set b.

IDF<sub>i</sub>: feature i inverse document frequency calculated earlier (IDF matrix).

Features that will be considered to calculate their training weights must satisfy the feature redundancy threshold 45, that's mean that feature redundancy must be less than 45.

Table 3 shows training weights for features in the training set b in general, while Table 4 shows training weights for features in a training set from the book of food.

Table3.Training weights for features in training set b.

Table 4. Training weights for features in a training set from the book of food.

The book of food (training set No.1)			
Feature	IDF	TF	TW
يأكل	1.80	8	14.39
الدنيا	1.84	1	1.84
شاة	1.97	4	7.90
مر	2.12	1	2.12
ابدیهم	2.22	1	2.22
خنزير	2.34	4	9.37
فأبى	2.42	1	2.42
الشعير	2.52	2	5.04

### 3.3 Classification Process

The classification process consists of four steps as shown in Figure 3. First step is computing query weights where feature's weight in targeted AL-Hadith is found. Second step is the expansion process where the stems are used to expand the query. Third step is calculating the similarity coefficient for each feature in AL-Hadith to be classified, and the final step is finding the cumulative similarity for AL-Hadith over the predefined classes (books).

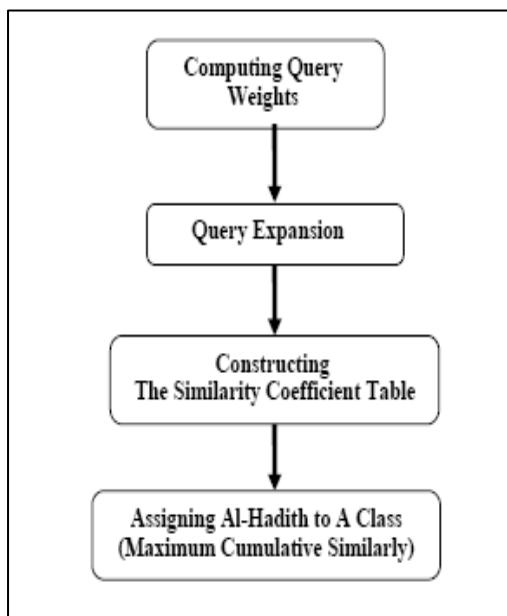

Figure 3. Classification process steps

#### 3.3.1 Computing Query Weights

A feature weight in the query (specific Hadith) is calculated according to equation (3) :

$$Q_h W_i = TF_{hi} \times IDF_i \quad (3)$$

Where:

$Q_h W_i$ : feature i weight in AL-Hadith h (Hadith to be classified).

$TF_{hi}$  : feature i frequency in AL-Hadith h

Bookb			
Feature	IDF	TF	TW
Feature1	IDF1	TFb1	$TWb1 = TFb1 * IDF1$
Feature2	IDF2	TFb2	$TWb2 = TFb2 * IDF2$
Feature3	IDF3	TFb3	$TWb3 = TFb3 * IDF3$
Feature4	IDF4	TFb4	$TWb4 = TFb4 * IDF4$
.....			
Feature n			$TWbn = TFbn * IDFn$

$IDF_i$ : inverse document frequency calculated by equation (1).

Query weights as shown in Table 5 will be computed for each feature in AL-Hadith to be classified. Feature frequency (TF) depends on AL-Hadith features occurrence while Inverse document frequency (IDF) is a global value referenced from IDF matrix.

Table 5. Query Weights Table for Mined Hadith

No.	Feature	IDF	Feature Redundancy	TF	QW
1	الدنيا	1.84	1.44	1	1.84

15	يأكل	1.80	1.59	1	1.80
16	يشبع	2.64	0.23	1	2.64

#### 3.3.2 Query Expansion

The process of query expansion depends mainly on using the stems of features to expand the searching area. The stems for all features in the training set and AL-Hadith to be classified were produced in the preprocessing phase.

In the expansion process the newly added stems in the expanded training set will have the same weights for its origin feature. In other words, if we have the couple  $\{(W, S), (W, TW)\}$  where S is the stem of word W and TW is the training weight for W from the training weights Table then the weight for stem S will be the same weight of W.

The same procedure is applied to stems in expanding the query set where stem S will have the same weight of its origin word W from the query

weight Table. The extended query weights for AL-Hadith sample are shown in Table 6.

Feature	Pre-defined Themes			
	Book1	Book2	...	Book13
Feature1	Sim1=Q <sub>b</sub> W <sub>1</sub> *T <sub>1</sub> W <sub>1</sub>			Q <sub>b</sub> W <sub>1</sub> *T <sub>13</sub> W <sub>1</sub>
Feature2	Sim2=Q <sub>b</sub> W <sub>2</sub> *T <sub>1</sub> W <sub>2</sub>			Q <sub>b</sub> W <sub>2</sub> *T <sub>13</sub> W <sub>2</sub>
Feature3	Sim3=Q <sub>b</sub> W <sub>3</sub> *T <sub>1</sub> W <sub>3</sub>			Q <sub>b</sub> W <sub>3</sub> *T <sub>13</sub> W <sub>3</sub>
Feature4	Sim4=Q <sub>b</sub> W <sub>4</sub> *T <sub>1</sub> W <sub>4</sub>			Q <sub>b</sub> W <sub>4</sub> *T <sub>13</sub> W <sub>4</sub>
Feature5	Sim5=Q <sub>b</sub> W <sub>5</sub> *T <sub>1</sub> W <sub>5</sub>			Q <sub>b</sub> W <sub>5</sub> *T <sub>13</sub> W <sub>5</sub>
Feature n	Sim n=Q <sub>b</sub> W <sub>n</sub> *T <sub>1</sub> W <sub>n</sub>			
	$\sum_{i=1}^n \text{Sim}$			

### 3.3.3 Constructing the Similarity Coefficient Table

In the proposed system the cosine similarity coefficient is used, where the similarity between two documents (document (D) & query (Q)) is actually the cosine of the angle (in N-dimensions) between the 2 vectors and can be calculated according to equation (4) (Baarah, 2007):

$$\text{sim}(D, Q) = \frac{\sum_{i=1}^n (w_{di} \times w_{qi})}{\sqrt{\sum_{i=1}^n w_{di}^2} \sqrt{\sum_{i=1}^n w_{qi}^2}} \quad (4)$$

Where  $w_{di}$  denote the query feature and n is the number of feature in the query Hadith.

Table 7 shows similarity coefficient for features in the mined AL-Hadith in general, while Table 8 shows the similarity coefficient for features in AL-Hadith illustrated in figure 2 against the training set from the book of food shown in section 3.2.2.

Table 6. Extended query weights table for mined Al-Hadith

Table 7. similarity coefficient for features for mined Hadith in general.

### 3.3.4 Assigning AL\_Hadith to a class

After constructing the similarity coefficient table for AL-Hadith to be classified against the predefined classes, the cumulative similarity weights for mined Hadith will be found against each of those classes. The cumulative similarity values indicate common features between AL\_Hadith to be classified and the predefined books.

After finding the cumulative weight for the mined Hadith with correspondence to each predefined book (class), AL-Hadith will be assigned to the book with the maximum cumulative weight, because maximum cumulative weight is an indication of larger common features between the training set and the mined AL-Hadith features set.

Table 8. Similarity coefficient for features in the example Hadith against training set from the book of food.

## 4. Experiments and Results

In this section, an overview is given for AL-Hadith corpus content that is used in this study to run the experiments of the proposed classifying algorithm, and details of experiments are also illustrated.

#### 4.1 Content of AL-Hadith Corpus

AL-Hadith corpus that is used in running the experiments consist of thirteen books (classes). Ahadith were taken from Sahih AL-Bukhari which is the most well known Hadith book all over the Islamic world and the most trusted Hadith book for researchers in this field. Twelve of those books were included in AL\_Kabi (2007) study and the Book of the (Virtues of the Prophet and His Companions) is added to the experiment in this study with 143 additional Ahadith.

Table 9 shows statistical information of books included in the experiments along with its name in English and Arabic as it was used by AL-Bukhari in his Sahih. The testing corpus has 1321 Hadith distributed over 13 books (classes).

Table 9. List of books in AL-Hadith corpus

Book (Class)Name	اسم الكتاب	Doc No.	No. of distinct features after stop words removal
The Book of Faith	كتاب الإيمان	38	938
The Book of Knowledge	كتاب العلم	76	1946
The Book of Praying	كتاب الصلاه	115	2137
The Book of Call to Praying	كتاب الأذان	38	574
The Book of the Eclipse Prayer	كتاب الكسوف	24	715
The Book of Almsgiving	كتاب الزكاه	91	2267
The Book of Good Manners	كتاب الأدب	225	5258
The Book of Fasting	كتاب الصوم	107	1905
The Book of medicine	كتاب الطب	92	1895
The Book of Food	كتاب الطعام	91	1894
The Book of Pilgrimage (Hajj)	كتاب الحج	231	4885
The Book of Grievance	كتاب المظالم	40	906
The Book of the Virtues of the Prophet and His Companions	كتاب المتفق	143	3410

#### 4.2 Classification Methods Applied to AL-Hadith Corpus

One of the researches in AL-Hadith classification field is done by (AL-Kabi, et al., 2007), in which AL-Kabi did not mention an accurate description of AL-Hadith corpus or the stop words list used in their experiments. Therefore, in this study an implementation for their classification algorithm on the corpus used is done.

The following subsections represents in details the three methods have been implemented in this study.

**4.2.1.AL-Kabi method :** this method was proposed by AL-Kabi and his Colleagues on AL-Hadith classification(AL-Kabi, et al., 2007). This method is based mainly on using the stems of Ahadith words to calculate the IDF, the weighting of the feature in training phase and the classification process.

**4.2.2. Word based classification (WBC):** this method uses the words of AL-Hadith after going through the preprocessing phase without stemming stage. The words occurrences after preprocessing are used in the calculation of IDF and in the weighting process. Stems of the words are not used in this method neither in building the training database nor in applying the classification algorithm.

**4.2.3. Stem expansion classification (SEC):** It is the proposed method in this study. In which words and stems are used. Words are used in IDF and features weighting calculations for both training and query sets, but stems are used in query expanding process, the expansion process was discussed in details in section 3.3.2.

#### 4.3 Experiments Specifications

Hadith corpus that is used in this study consists of 1321 Hadith distributed over thirteen books (classes). The system is considered as supervised classification since training sets are used to apply learning algorithm to build the leaning database which will be used for the classification algorithm.

In the experiments author uses (90%) of each Ahadith class as training set while the rest (10%) of each class is used as testing set for the classification system. Of course, for each class the (10%) Ahadith in the testing set are not included in the training set of Ahadith and the training phase calculation.

For each class five testing – training sets combination are chosen to run SEC algorithm, which means that for each class five separable experiments will be run, which gives variation for system testing.

It is important to mention that the same training - testing sets combination is used with the other two classification methods (AL-Kabi's,WBC) which is an important aspect to insure fair comparison among different methods against the proposed one.

#### 4.4 Performance Measurements

In order to demonstrate the efficiency of any classification algorithm, measurements are needed to compare the proposed system's outcome with others. The most popular measurements in text classification algorithm are recall, precision and F-measure that are used in this study.

Recall and precision based on the concept of relevance. Precision is defined as the ratio of relevant documents retrieved to all documents retrieved while Recall is defined as the ratio of relevant items retrieved to all relevant items in a corpus.

There are obvious trade-off between recall and Precision. If the system retrieves all the documents in a corpus then the system will retrieve all relevant documents in the corpus, in this case the recall will be perfect.

On the other hand, since there are only small proportions of documents in a collection that are truly relevant to the given query, retrieving everything will give a very low precision (Greengrass, 2000).

Because of this trade-off between recall and precision a combination of good precision and good recall is needed. In the best case we would like to retrieve all the relevant documents and to discard non-relevant documents, this combination of recall and precision is found in F-measure (Harmonic mean). Precision, recall and F-measure are calculated according to equation presented by (Al-Mesleh, 2007) as follows

$$\text{Precision (P)} = A / (A + B)$$

$$\text{Recall (R)} = A / (A + C)$$

$$\text{F-measure (Harmonic mean)} = (2 \times P \times R) / (P + R)$$

Where the meaning of parameters used in recall and precision calculations are shown in Table 10.

Table 10. Recall and Precision Parameters.

System says...	In reality, the document is...	
	Relevant	Irrelevant
document is relevant	A	B
document is irrelevant	C	D

#### 4.5 Comparisons and Results Analysis

In this section we introduce the comparisons between SEC and the other two methods (AL-Kabi's and WBC), in order to show the preference of the proposed system over AL-Kabi's and WBC method.

##### 4.5.1 Stem Expansion vs. Word based classification

The proposed system (SEC) outperform WBC for 11 out of 13 books in precision, while WBS achieve better precision for The Book of Grievance and the book of Knowledge as shown in Figure 4 . This result is predicted because using the stem expansion phase gives a large morphology variation for the words that can resulted in retrieving more documents that belong in reality to other classes.

The proposed algorithm (SEC) overcomes the side effect of expanding the query using

stemming, by the weighting strategy adopted in the system, where stems in the expansion phase are giving the same weights of its original word in AL-Hadith.

SEC achieved precision value of 1 for The Book of Call to Praying and enhances the precision of 11 classes by 45% in average.

As shown in Figure 5 SEC achieves better F\_measure values for all classes against WBS method and enhances the F\_measure by 49% in average.

##### 4.5.2 Stem expansion vs. AL-Kabi classification

After implementing AL-Kabi's method for the same training -testing sets used to examine SEC, comparisons are conducted as shown in Figure 6 and 7.

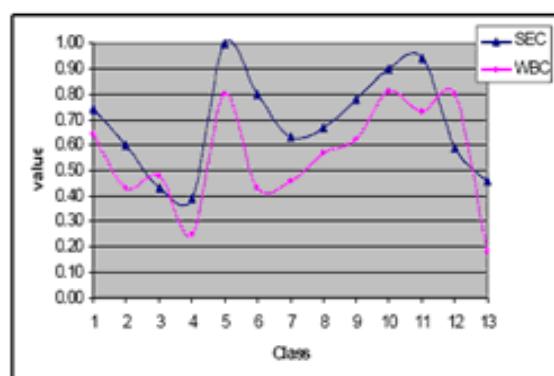

Figure 4. Precision comparison for stem expansion vs. word based classification.

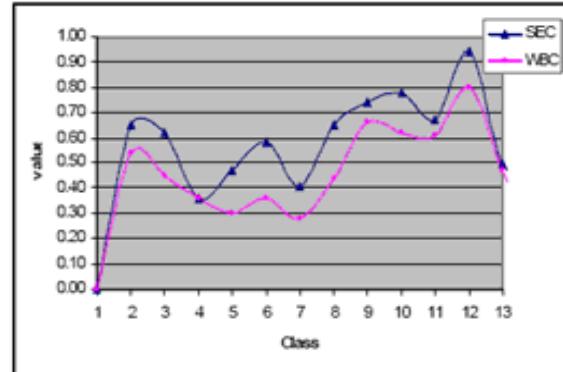

Figure 5. F\_measure comparison for stem expansion vs. word based classification.

Figure 6 represents the precision graph of the two methods, where AL-Kabi's method achieved better precision for The Book of Knowledge and The Book of Grievance, while SEC out performed AL-Kabi's method in 11 out of 13 classes.

This behavior can be justified by the fact that those two books have small number of Ahadith and since the experiments are conducted on Ahadith in a closed domain (Sahih AL\_Bukhari), author

believes that if those classes have larger number of Ahadith the superb of SEC will appear.

In addition AL-Kabi used the stem of words for term weighting in the preprocessing phase, which means that term frequency used in the training process will be the number of the stems occurrence in the training set. In contrary, in SEC the words occurrences is used for the weighting process in preprocessing phase while the stems are used in the expansion process for both training and testing sets.

Since stem expansion is used for both the training and testing sets in the proposed system, more

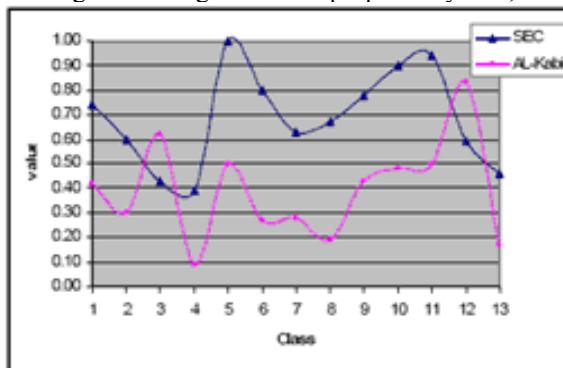

Figure 6. Precision Comparison for Stem expansion vs. AL-Kabi's classification

non-related documents are presented to be retrieved, which justifying AL-Kabi's method achieves better precision for two classes out of thirteen classes . As Shown in Figure 7, SEC method outperformed AL-Kabi F\_Measure in all the 13 classes.

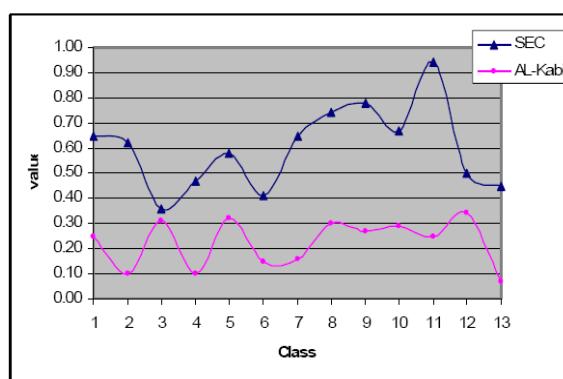

Figure 7. F\_Measure comparison for stem expansion vs. Al-kabi's classification.

## 5. Conclusions

Arabic language is considered as one of the languages that will never distinguish and few researches were made on Arabic corpus linguistics. However, it is the official language of twenty Middle Eastern and African countries and is the religious language of all Muslims, regardless of their origin.

A classification method called Stem Expansion is proposed in this study, in order to discover knowledge from AL-Hadith by assigning each Hadith to one book (class) of predefined classes. SEC is considered as supervised classification method.

In this study a corpus containing 1321 Hadith from thirteen books from Sahih AL-Bukhari is selected and each Hadith is assigned to one class. Sahih AL-Bukhari is used as the base for deciding the correctness of classification results.

The results of the proposed system (SEC) are compared with the results of two methods; one proposed by AL-Kabi and the other is word based classification technique (WBC). The comparison shows that SEC was better against WBC and AL-Kabi in recall for all classes while WBC and AL-Kabi achieve better precision for only two out of thirteen classes, and SEC achieves better F\_Measure for all the thirteen classes against the other two methods (WBC and AL-Kabi).

The results show that SEC performed better in classifying AL\_Hadith against existing classifications methods (WBC and AL-Kabi) according to the most reliable measurements (recall, precision, and F\_Measure) in text classification field.

## Efficacy of some Biocontrol Agents on Reproduction and Development of *Meloidogyne incognita* Infecting Tomato

Moussa Lobna\* and Hanaa Zawam\*\*

\*Soils, Water & Environment Research Institute, Agricultural Research Centre (ARC), Giza, Egypt,

\*\* Plant Pathology Research Institute, Agricultural Research Centre (ARC), Giza, Egypt

[mlobnamy@yahoo.com](mailto:mlobnamy@yahoo.com), [hn\\_zawam@yahoo.com](mailto:hn_zawam@yahoo.com)

**Abstract:** Three rhizobacteria and two yeasts isolates were used as biocontrol agents against *Meloidogyne incognita* in laboratory and greenhouse. The used biocontrol agents were identified as *Bacillus amyloliquefaciens*, *Brevibacterium otitidis*, *Sanguibacter inulinus*, *Candida incommunis* and *Wicherhamiella domercqiae*. They inhibited the egg-masses hatching *in vitro* and exhibited strong nematicidal activity by killing the second stage juveniles of *Meloidogyne incognita* to various degrees in greenhouse. The most effective treatment was the complete culture of the four biocontrol agents (propagules and filtrate) suppressed galls and egg-masses formation by 100% *Br. otitidis* reduced galls and egg-masses by 43.7 and 52.19 %, respectively compared with the untreated control. The microorganisms used in greenhouse test reduced nematode populations in the rhizosphere and promoted the growth of tomato plants over the control treatment.

**Key words:** Biocontrol; *Meloidogyne incognita*; tomato; Rhizobacteria; yeast

### 1. Introduction:

The root-knot nematodes cause serious damage to important crops world-wide resulting in significant loss of revenue. Resistant cultivars, crop rotation, soil fumigation and chemical nematicides have been used traditionally, for management of the root-knot nematodes. Unfortunately, longevity and slow degradation rate of chemical nematicides created potential environmental and human health concerns, which have forced researchers to find other safe and efficient methods for nematode control. Several soil microbes which produce an array of biologically active compounds can serve as potential biological control agents. Plant growth-promoting rhizobacteria (PGPR) have been identified as an important biological control agent (Johnsson et al., 1998).

A group of important natural enemies of nematode pests, nematophagous bacteria exhibit diverse modes of actions including parasitizing, competing for nutrient uptake, inducing systemic resistance of plants, promoting plant health, producing toxins, antibiotics or enzymes. They act synergistically on nematodes through the direct suppression of nematodes, promoting plant growth, and facilitating the rhizosphere colonization and activity of microbial antagonists (Tian et al., 2007).

Chitinases and glucanases lyse microbial cells and these enzymes have been implicated in the reduction of deleterious and pathogenic rhizosphere microorganisms, creating an environment more

favorable for root growth (Leong, 1986).

Chitin, a glucosamine polysaccharide, is a structural component of fungal cell wall, shells of insects, various crustaceans and nematode eggs. In egg shells of tylenchoid nematodes, chitin is located between the outer vitelline layer and the inner lipid layer and may occur in association with proteins (Bird and Bird, 1991). The breakdown of this polymer by chitinase can cause premature hatching which results in fewer viable juveniles (Mercer et al., 1992).

Bacteria and fungi are also capable of producing lytic enzymes such as chitinases,  $\beta$ (1,3) glucanases, cellulases, lipases and proteases. Some of these enzymes are involved in the breakdown of fungal cell wall by degrading its constituents, such as glucans and chitin, resulting in the destruction of pathogen structures or propagules. Biocontrol bacteria producing protease (Dunne et al., 1998) and chitinase (Rossi et al., 2000) were capable to suppress several plant diseases. The degradation products released can be used by the biocontrol agent to proliferate. Several bacterial proteases have been shown to be involved in the infection processes against nematodes (Tian et al., 2006).

A variety of nematophagous bacterial groups were isolated from soil, host-plant tissues, beside nematodes, their eggs and cysts (Meyer, 2003). They affected nematodes by variety of modes including parasitism, production of toxins, antibiotics or enzymes, hindering the nematode plant-host

recognition, competing for nutrients, inducing systemic resistance of plants and promoting their health. These bacteria had a wide range of suppressive activities on different nematode species, including free-living and predatory nematodes as well as animal and plant parasitic nematodes (Siddiqui and Mahmood, 1999). The objectives of the present study were to impact bioagents that suppress root-knot nematodes and to evaluate the potent antagonistic strain in controlling meloidogyne infesting tomato planted under greenhouse conditions.

## 2. Materials and Methods

### 2.1. Samples

Tomato seedlings (Castel rock) were provided from Horticulture Research Institute (Agric. Res. Center -ARC, Giza, Egypt). The experimental soil was collected from the ARC farm, Giza, Egypt. The soil texture was sandy clay characterized by an EC (2.32 dSm-1), pH (7.9) and available N, P & k of 57.35, 6.76 and 110 mg kg soil-1, respectively. The soil analyses were conducted by the methods described by Page et al. (1982). Five potential bio-control agents of which three bacterial strains of *Bacillus amyloliquefaciens*, *Brevibacterium otitidis* and *Sanguibacter inulinus* and two yeast strains of *Wickerhamiella domercqiae* and *Candida incommunis* were previously isolated by Moussa et al. (2006) and Moussa (2007). These microorganisms were tested *in vitro* and *in vivo* for their effect on controlling *Meloidogyne incognita* which causes the root-knot nematodes.

### 2.2. Biocontrol microorganism propagation on laboratory scale

Both bacteria and yeast strains were cultured individually in 250 ml Erlenmeyer flasks containing 100 ml king's B broth medium as described before by King et al. (1954). Incubation was in a shaker incubator at 28 °C and 150rpm min-1 for 24 hours. The obtained culture suspension contained 107cfu/ml

### 2.3. Nematode larvae extraction

The extraction of juveniles from the soil was accomplished using Jenkins's method (Jenkins, 1964). They were counted under the stereoscopic microscope and data were expressed as juveniles per ml of soil.

### 2.4. Nematode eggs extraction

Nematode Eggs were recovered from excised roots by agitation in 0.5% sodium hypochlorite solution (Jenkins, 1964). The total number of eggs was counted under a stereoscopic microscope and expressed as number of eggs per

gram root.

### 2.5. Nematode stock culture

Nematode population of *M. incognita* was maintained on tomato plants cv. super marmand in a green house at 25 -27 °C. Plants were infested at 2-3 leaves stage by adding egg-masses to roots then covered with soil. After 60 days nematode egg-masses collected from roots by a needle, put in Petri dishes and put it in incubator for hatching at 25°C. The hatched juveniles were collected daily for seven days to laboratory experiment and green house testes.

### 2.6. Screening of antagonisms against egg-masses and juveniles nematodes *in vitro*

Five ml from the complete culture, culture filtrate and culture suspension of strain cells of each biocontrol agent were added to five egg-masses of *M. Incognita* (hand picked) in Petri-dishes (5cm). One Petri dish containing same egg-masses number received 5 ml distilled water to serve as control. Each treatment was applied in three replicates. The nematode percentage inhibition was recorded after 3 days.

The same procedure was applied to test the effect of each biocontrol agent suspension on controlling nematode juveniles. One ml of nematode suspension containing 500 individual juveniles was placed in 8 ml glass vial and completed to 5 ml with each bioagent. Each treatment was held in three replicates. The nematode percent mortality was recorded after 48 hours under a stereoscopic microscope. Morphological changes in eggs and juveniles were observed on an inverted microscope found in Cell Manipulation Lab.

Nematode specimens were examined microscopically through phase contrast system using Olympus IX-70 inverted research microscope equipped with 100W Philips halogen lamp for maximum illumination. The objective phase contrast lens used was of 40X power (LCPlanFI40XPh) while the magnification selector knob was 1.5X power. Observation was carried out using frosted filter, color temperature conversion filter (LBD) and the green interface filter (IF 550) Magnification index: 40X (phase contrast lens) x 5X (built in lens) x 1.5X (magnification selector knob) x 2.5X (camera magnification) = 750X.

### 2.7. Effect of biocontrol agents against *M. incognita* using plastic cups

After 7 days of cultivation the tomato seedlings in steam sterilized sand, 500 freshly hatched juveniles of *M. incognita* poured around the roots of tomato seedlings and also, the different treatments of five biocontrol agents were added. Two

controls were maintained, one with nematode suspension in water and another in the media used for bioagents growth. All treatments replicated three times. After 60 days the plants were uprooted and the roots were washed free from the adhering sand particles. Number of galls, number of egg-masses, number of free nematodes in soil and also the plant weight were determined.

#### 2.8. Effect of biocontrol agents against *M. incognita* under greenhouse conditions

A pot experiment was conducted to explore the effectiveness of the five biocontrol agents to reduce the population density of root-knot nematode juveniles and eggs. Three week old tomato seedlings (*Lycopersicon esculentum*) were transplanted in pots (25cm) which were previously filled with 4kg sandy clay soil. Pots were divided into thirteen groups each comprises six replicates.

The treatments included the bioagents *Bacillus amyloliquefaciens*, *Brevibacterium otitidis*, *Sanguibacter inulinus* and two yeast strains of *Wickerhamiella domercqiae* and *Candida incommunis*. They were individually incorporated into the soil at the rates of 4 ml and 8 ml per pot (10<sup>7</sup> cells/ml). This practice was repeated two times every 15 days. Pots were then, watered weekly twice. Fertilization was practiced after cultivation as Super phosphate (15% P<sub>2</sub>O<sub>5</sub>) at a rate 460 kg/Hectare. Nitrogen Fertilizer was added 35 kg/Hectare (Ammonium sulphate 20.5% N) and potassium Sulphate (48% K<sub>2</sub>O) at a rate 115 kg/Hectare recommended by the Ministry of Agriculture. Prior to biocontrol agent addition, the transplanted tomato seedlings were infested with *M. incognita* by using 500 freshly hatched juveniles that were poured around the roots of tomato seedlings (7 days after tomato transplanting).

After 60 and 120 days from tomato transplantation, the developed plants in each pot were uprooted. The roots were then washed to get rid of the adhering sand particles and to determine numbers of galls, egg-masses and free nematodes in soil.

The tomato rhizosphere soil was collected to determine microbial activity by using the fluorescein diacetate hydrolysis (FDA) method as described by Schnurer and Rosswall (1982), total fungl count on potato dextrose agar (Difco, 1985), total diazotrophs bacteria (Hegazi et al. 1998), chitinase activity in soil (Rodriguez-Kabana et al., 1983), protease activity in soil (Wright and Reddy, 2001) and also fruits weight.

Throughout the pots experiment, the following treatments were statistically arranged in a completely randomized design:  
Control (without root-knot nematodes and bioagents).  
Control + *M. incognita*.

Soil + *M. incognita* + media used for growing bioagents.  
Soil + *M. incognita* + *Bacillus amyloliquefaciens* (4 ml/ pot).  
Soil + *M. incognita* + *Bacillus amyloliquefaciens* (8 ml/ pot).  
Soil + *M. incognita* + *Brevibacterium otitidis* (4 ml/ pot).  
Soil + *M. incognita* + *Brevibacterium otitidis* (8 ml/ pot).  
Soil + *M. incognita* + *Sanguibacter inulinus* (4 ml/ pot).  
Soil + *M. incognita* + *Sanguibacter inulinus* (8 ml/ pot).  
Soil + *M. incognita* + *Wickerhamiella domercqiae* (4 ml/ pot)  
Soil + *M. incognita* + *Wickerhamiella domercqiae* (8 ml/ pot).  
Soil + *M. incognita* + *Candida incommunis* (4 ml/ pot).  
Soil + *M. incognita* + *Candida incommunis* (8 ml/ pot).

#### 2.9. Statistical analysis

The data were analyzed by ANOVA using SPSS version 12 statistical software (SPSS Inc. chicago, Illinois). Differences between treatments were determined by Duncan's Multiple Range Test (DMRT) at 5% significance level. Data Collected were subjected to the statistical analysis according to the standard methods recommended by Gomez and Gomez (1984) using the computer program (Costat). The differences between the mean values of various treatments were compared by Duncan's multiple range test (Duncan, 1955).

### 3. Results:

#### 3.1 Effect of biocontrol agent treatments on *M. incognita* egg-masses *in vitro*

*Meloidogyne incognita* inhibition as affected by five biocontrol agents were studied and presented inTable1. Obviously, the inhibition of nematode egg hatching was affected by the treatment type. In general, the maximum inhibition percentage was mostly achieved by using the yeasts complete culture, as it reached 100% with both *Candida incommunis* and *Wickerhamiella domercqiae*, while by using the suspension of the cells it reached 97.79and 89.91%, respectively.

The treatment with the culture filtrates only of either yeasts suppressed hatching by 79.81 and 96.09%, respectively. On the other hand, the lowest inhibition percentage (72.97%) was achieved by *B. amyloliquefaciens* suspension of microbial cells.

The morphological change of *M. incognita* eggs and juveniles was examined using an inverted microscopy during 7 days of incubation with each microorganism. Deformation of juveniles and eggs that occurred as shown in Figure1. (A) to (E) and (F) to (J), respectively and their untreated controls are represented in Figure2. (A) and (B), respectively. Some eggs appeared to be destroyed, but no inhibition was observed with the water control. Observation through the inverted microscope demonstrated that the microorganisms widely attached to the eggs and juveniles of *M. incognita*.

### 3.2 Effect of biocontrol agents on development of *Meloidogyne incognita* infecting tomato roots *in vivo*

The following experiment was conducted to evaluate the five biocontrol agent treatments previously tested in suppressing root-knot nematode infection and nematode population densities under greenhouse conditions as a pre-field test.

The data presented in Table 2. revealed the highly significant response to the effect of variable treatments to tomato including *B. amyloliquefaciens*, *Brevibacterium otitidis*, *Sanguibacter inulinus*, *Candida incommunis* and *Wickerhamiella domercqiae* which suppressed galling compared to untreated control.

The number of juveniles extracted from roots, number of galls and also number of egg-masses were 100% reduced by the complete culture of all treatments except for *Brevibacterium otitidis* treatment which showed lower suppressive effect, whereas, the tomato plant weights were increasingly improved.

4. Effect of biocontrol agent treatment on the numbers of nemtode, gall and egg masses after 60 days of cultivation

Among the microbial antagonists used as alternative nematicides, the biological control agents showed limitation in nematode abundance and increased tomato plant weight and height.

Data in Table 3.revealed that all treatments suppressed galling up to 100% compared to the untreated control expect those treatments with *Brevibacterium otitidis*, 8 ml/pot, and *Candida*

*incommunis* at 4.8 ml/pot and media which reduced gall formation with 87.27%, 63.6%, 81.82% and 29.6%, respectively.

The same trend was observed when testing the parameter of egg-masses number and number of juveniles extracted from soil. In case of development in plant parameters, Figure3. shows the highest shoot length being achieved when treated with *Brevibacterium otitidis* 8ml / pot treatment, while the lowest one was with the media treatment. The highest shoot weight was achieved as revealed in Figure 4.

also with *Brevibacterium otitidis*, 8ml / pot treatment, while the lowest was with the *Wickerhamiella domercqiae* at 4 ml /pot treatment.

#### 4.1 Effect of biocontrol agent treatment on the numbers of nemtode, gall and egg masses at harvest time

The inoculation with nematode alone resulted in extensive galling on roots of tomato at harvest. Treatments with the experimental microorganisms reduced the gall formation at harvest as shown in Table 4. Decline in gall formation was from 436 to 16 due to *Sanguibacter inulinus* at 8ml/pot in comparison with untreated control, followed by *B. amyloliquifaciens* at (8ml/pot) and *Candida incommunis* at (8ml/pot). Egg masses production was successfully inhibited due to the application of all microorganisms. The *Sanguibacter inulinus* at

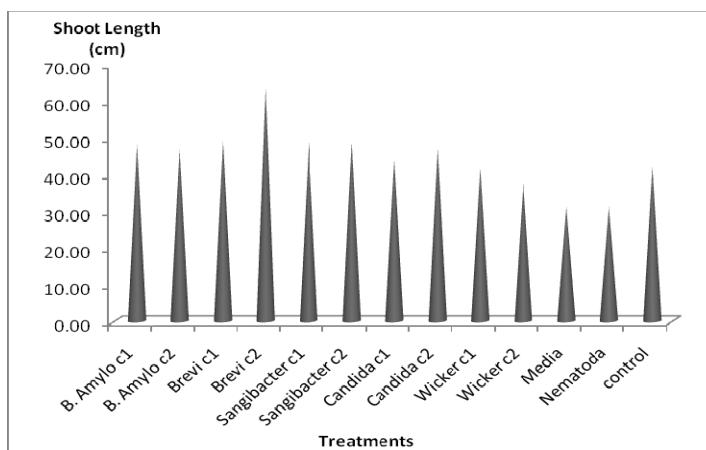

8ml/pot gave the maximum decline in the egg masses, followed by *B. amyloliquifaciens* (8ml/pot) and *Candida incommunis* at 4.8ml/pot and the lowest was with media treatment.

The soil root-knot nematode populations were significantly affected by treatments with microorganisms, as the percent decrease in them was greater than that in galls or egg-masses. The highest decrease in nematode juveniles (n/250 cm<sup>3</sup> soil) occurred with *Brevibacterium otitidis* (8ml/pot) and *Wickerhamiella domercqiae*(8ml/pot) compared to the control infected with nematode. Nevertheless, the nematode development stages inside the root system decreased descending from 7% with *Wickerhamiella domercqiae* at (8ml/pot) to 15% with either *Candida incommunis* (4ml/pot) or *B. amyloliquifaciens* (4ml/pot) compared to with control.

C1=4ml/pot., C2=8ml/pot., P1=60days after cultivation, P2=90days after cultivation, P3=120 days after cultivation, NDS: Nematode development stage.

At harvest, both plant shoot length and weight increased with all the used microorganism treatments compared to nematode infested plant as shown in Figure 5. The highest shoot length (76 cm) being achieved when treated with *Sanguibacter inulinus* at 4ml / pot treatment, followed by (70.67cm) achieved with either *Brevibacterium otitidis* 8ml / pot treatment and *Wickerhamiella domercqiae* 4ml / pot treatment compared to the untreated control (64.67cm), while the lowest one was with the media treatment (47.67cm).

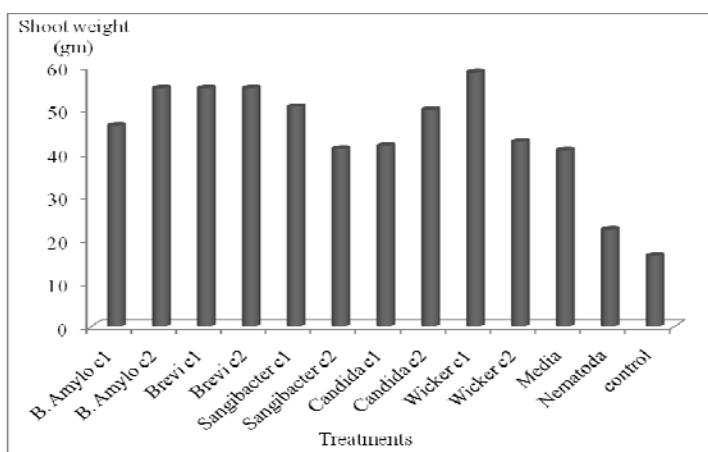

The highest shoot weights were with *Wickerhamiella domercqiae* using first concentration (58.67gm) and *B. amyloliquifaciens* (8ml/pot) recorded (52.33gm) , while *Sanguibacter inulinus* (4ml/pot), *B. amyloliquifaciens* (4ml/pot), *Brevibacterium otitidis* (4ml/pot) and *Wickerhamiella*

*domercqiae* (8ml/pot) recorded 50.67, 46.33 and 42.67gm, respectively, as shown in Figure 6. The lowest shoot weights were 22.33gm obtained from plants infected with nematodes or 16.33 gm obtained from non- infected plants.

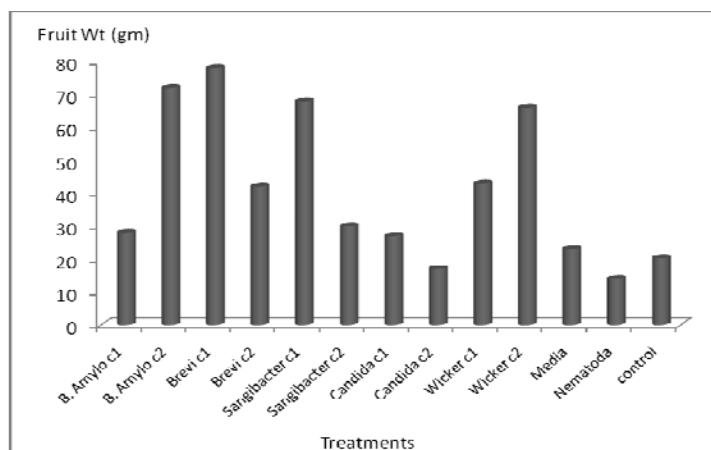

Fruit weights varied significantly due to the used treatments, as the highest fruit weights were obtained with *Brevibacterium otitidis* (4ml/pot), *B. amyloliquifaciens* (8ml/pot), *Sanguibacter inulinus* (4ml/pot) and *Wickerhamiella domercqiae* (8ml/pot) to be 78, 72, 68 and 66 gm respectively, while the lowest fruit weights were obtained from plants infected with nematode (14 gm) and for non-treatment with *Candida incommunis* (8ml/pot) (17 gm) as shown in Figure 7.

#### 4.2 Microbial enzymes detected in rhizosphere during plantation periods

The total microbial activity was assessed by measuring fluorescein diacetate (FDA) hydrolysis releasing fluorescein under the action of microbial enzymes such as proteases, lipases and esterases (Green et al, 2006). The effect of the biocontrol agents activities including bacteria and yeasts added to tomato rhizosphere on fluorescein diacetate compared with that of the controls 1 and 2, beside that of soil amended with media were investigated

through the growth stages of tomato. Data in Table 5. indicate the frequency in the amount of fluorescein resulting according to treatment type. The significant differences indicated that not only the type of treatment affected the activity calculated but both the concentration of the biocontrol added and the intervals of sampling. The *Sanguibacter inulinus* achieved the best activity measured after 90 days using 8ml/pot. All soil rhizosphere treated with those biocontrol agents gave more activity than those untreated (control 1, 2 and that with media only).

**Table 5. Effect of different treatments on microbial activity in soil measured as fluorescein diacetate hydrolysis.**

#### 4.3 Effect of bioagents on diazotrophic bacteria in soil rhizosphere

The diazotrophic bacteria capable of utilizing atmospheric N<sub>2</sub> as their soil nitrogen source (N-fixer) are commonly associated with plants to achieve phyto -nitrogen balance, are affected by soil rhizosphere microflora including the bioagents under study. This experiment was performed to evaluate the effect of bioagents on N-fixing population. As shown in Figure 8, the highest bacterial number among the nitrogen fixing population tested was recorded with *Sanguibacter inulinus* (8ml/pot after 45 days). Along all samples tested, the whole nitrogen fixers' numbers were the maximum after 45 days of cultivation. Obviously, five of the treatments tested (*Bacillus amyloliquifaciens* C1 and C2,

*Brevibacterium otitidis* C2, *Sanguibacter inulinus* C2 and *Wickerhamiella domarcqiae* C1) decreased the diazotrophic bacterial numbers throughout the whole period (120 days). On the other hand, the other five treatments tested (*Brevibacterium otitidis* C1, *Sanguibacter inulinus* C1, *Wickerhamiella domarcqiae* C2, *Candida incommunis* C1 and C2) decreased the diazotrophic bacterial numbers after 90 days but their numbers increased after 120 days. After 45 days the nitrogen fixers' numbers in the soil samples treated with the bioagents exceeded that in the control 1, 2 and that treated with medium. Concerning those untreated, the nematodal presence in the control 2 affected negatively the nitrogen fixers' numbers than those in control 1 with no nematodal invasion.

**Figure 8. Effect of bioagent on Nitrogen fixer bacterial number.**

#### 4.4 Chitinolytic and proteolytic activity criteria in tomato rhizosphere during biocontrol treatments

Data presented in Table 6. And7. shows the influence of different biocontrol agents on excretion

of microbial chitinase and protease, respectively in soil infested with root knot-nematode *M. incognita*. Apparently, the most efficient bioagent in producing chitinase was *Candida incommunis* added at

concentrations of 4ml and 8ml/pot in the second period, followed by the bioagents *Brevibacterium otitidis* and *Wickerhamiella domercqiae* at concentration (4ml, 8ml/pot) in third period. Other less effective bioagents varied in accordance to their type, concentration applied and incubation period in soil. Egg masses production was successfully inhibited due to the application of all microorganisms. The *Sanguibacter inulinus* at 8ml/pot gave the maximum decline in the egg masses, followed by *B. amyloliquifaciens* (8ml/pot) and *Candida incommunis* at (4.8ml/pot) and the lowest with media treatment. The bioagent *B. amyloliquefaciens* showed maximum proteolytic activity at a concentration of 4ml/pot in the third period. Lower protease activity was detected when applying *Brevibacterium otitidis* (4ml/pot, first

period) followed by *Candida incommunis* 8 and 4 ml/pot in the third period). Other bioagent actions decreased dramatically.

#### 4.5 Total number of fungi in rhizosphere soil

Total numbers of fungi were affected by the biocontrol agents added. Their numbers were negatively pronounced with all treatments when compared to control 1 and 2 at first period, while all treatments in the second and third periods decreased fungal numbers as shown in Figure 9. Addition of these two species to the soil seeded with kidney bean and infested with the pathogen increased the percentage of control plants. This was carried out through the process of antibiosis (secretion of antifungal compounds).

#### 4. Discussion:

*Meloidogyne incognita* inhibition was affected by the treatment type. The maximum inhibition percentage 100% was mostly achieved by using the complete culture of both *Candida incommunis* and *Wickerhamiella domercqiae*. Similar results were obtained by Shawky et al. (2006) who reported that all the bioagent candidates *Bacillus subtilis*, *Saccharomyces uvarum* and *Saccharomyces ludwigii* proved harmful to *M. javanica* juveniles, egg masses and numbers of galls but the effect magnitude differed from one candidate to another. Jung et al. (2002) showed that *Paenibacillus illinoiensis* had caused 2.5% reduction in egg hatching on the first day and by seventh day there were no hatching eggs found from the 78 eggs/ml used. Mohamed et al. (2008) indicated that the application with the yeast isolates *Pichiagluijillier mondii*, *Pachytrichospora transvaalensis* and *Candida albicans* treatments significantly reduced the number of juveniles *in vitro* after both 24h and 48h. The lethal action of toxic compounds produced by microorganisms on egg *in vitro* noted by Meadows et al. (1989) deserves further exploration.

The morphological change of *M. incognita* eggs and juveniles agreed with the study of Westcott and Kluepfel (1993). They reported that chitinases produced by PGBR was more potent in attacking the eggs rather than the cuticle of *M. incognita*. This might have resulted from the direct damage to the eggs caused by the bacterial or yeast chitinase activity. Also, Mercer et al. (1992) reported that the bacterial lytic enzymes interferes with the egg hatching of *M. hapla* that might had lysed the egg shell including various lipolytic, proteolytic and chitinolytic enzymes, causing an aberrant change in

egg shape and egg rupture.

*In vivo*, the results of evaluating the five biocontrol agent treatments may be referred to the fact that most rhizobacteria act against plant-parasitic nematodes by means of metabolic by-products, enzymes and toxins. The effects of these toxins include the suppression of nematode reproduction, egg hatching and juvenile survival, as well as the direct killing impact on nematode itself (Siddiqui and Mahmood, 1999).

Cronin et al. (1997) reported that purified commercial chitinase inhibited the egg hatching of potato cyst nematode *Globodera rostochiensis* *in vitro* up to 70%. On the other hand, Yong et al. (2004) reported that genus *Sanguibacter* produced chitinase efficiently, hindering the pathogenesis of locusts. Both protease and collagenase had adverse effects on larval motility *in vitro*, when larvae were treated with the enzymes prior to inoculation, protease-treated larvae caused a significant decrease of 40 % in galling (Galper et al. 1990). Rossi et al. (2000) reported that several bacterial proteases have been shown to be involved in the infection processes against nematode. *B. amyloliquefaciens* has been developed to control plant parasitic nematodes on tomato, bell pepper and strawberry (Meyer, 2003). Huang et al. (2005) reported that eggshells of root-knot nematode might be lysed by bacteria that produce various lipolytic, proteolytic and chitinolytic enzymes. These reports indicated that chitinase produced by soil bacteria was associated with the inhibition of egg hatching of root knot nematode. The present results showed the most efficient bioagent in producing chitinase was *Candida incommunis* added at concentrations of 4ml and 8ml/pot in the second period and the bioagent *B. amyloliquefaciens* showed

maximum proteolytic activity at a concentration of 4ml/pot in the third period this agrees with above reports.

Both plant shoot length and weight increased with all the used microorganism treatments compared to nematode infested plant. At harvest, present results showed that *Brevibacterium otitidis* affected the plant showing the highest shoot length and fruit weight, while *Wickerhamiella domerciae* achieved to the plant the highest shoot weight at specific concentrations. Shawky et al. (2006) found that adding any of the antagonistic bacteria had increased the endophytic strains like *Sanguibacter sp.* increased biomass production of plants in the shoot part and good biomass yield. Also, *B. amyloliquefaciens* strain has been shown to induce growth promotion in tomato seedling and reduce severity of diseases caused by several pathogens and elicitation of induced systemic resistance, additionally reduced gall incidence by root-knot nematodes in tomato plants and resulted in increased yield (Kokalis-Burelle and Dickson, 2003). YU et al. (2002) found that *B. amyloliquefaciens* strains produced Iturin A2 molecules that have been used as biocontrol agents to suppress fungal plant pathogens. Also Hiradate et al. (2002) found that those molecules included seven  $\alpha$ - amino acids and one  $\beta$ -amino fatty acid and Iturin A which were produced as a mixture of up to eight isomers.

*Candida incommunis* was reported for its ability to produce IAA and phosphate solubilization that aid in microbial nutrition besides its ability to produce siderophores that acts as antifungal agents that aid in bacterial enrichment (Hassanin et al. 2007). These actions might affect positively the diazotrophs during the third period (120 days) in the present study.

Total numbers of fungi were affected by the biocontrol agents added. These results agree with that of Chen et al. (2006). They reported that *B. amyloliquefaciens* produced lipopeptides, surfactins, bacillomycin D and fengycins as secondary metabolites mainly of known antifungal activity. Similar results were reported by Turner and Messenger (1986), who estimated the ability of *Brevibacterium* to produce phenazine compounds acting as antibiotics. *Candida incommunis* is characterized by its ability to produce siderophores as antifungal agents and inhibitory effects on the growth of the fungal pathogen *Fusarium oxysporum*, according to Hassanin et al. (2007).

Addition of these two species to the soil seeded with kidney bean and infested with the pathogen increased the percentage of control plants. This was carried out possibly through the process of antibiosis (secretion of antifungal compounds).

## 5. Conclusion:

Through this study, clear evidence was presented that the most effective biocontrol treatment was the complete culture (propagules and filterate) of the four biocontrol agents mentioned *Bacillus amyloliquefaciens*, *Brevibacterium otitidis*, *Sanguibacter inulinus*, *Candida incommunis* and *Wickerhamiella domerciae*. These biocontrol agents suppressed galls and egg-masses formation of *Meloidogyne incognita* by 100% and promoted the growth of tomato plants over the control treatment. Therefore, these biocontrol agents can substitute the use of the nematicides used in tomato fields.

## Phytochemical and Elemental Analysis of *Acalypha wilkesiana* Leaf

\*Madziga, H. A.<sup>1</sup>, Sanni S.<sup>2</sup> and Sandabe U. K.<sup>1</sup>

<sup>1</sup>Department of Veterinary Physiology, Pharmacology and Biochemistry, Faculty of Veterinary Medicine, University of Maiduguri, Nigeria. <sup>2</sup>Department of Veterinary Pharmacology, University of Abuja, Nigeria.

[hannamadziga@yahoo.com](mailto:hannamadziga@yahoo.com)

**ABSTRACT:** Phytochemical and Elemental determination of *Acalypha wilkesiana* was conducted. The result of the Phytochemical analysis of the aqueous leaf extract of *A. wilkesiana* revealed a high presence of carbohydrates, Tannins and Flavonoid, a moderate presence of Phlobatannins, Saponins. Alkaloids and Cardiac glycosides and minute quantity of Terpenes and Steroids. Anthraquinone derivatives was not present. The Elemental analysis showed presence of chloride, sodium, potassium, calcium, iron, magnesium, zinc copper and manganese in moderate quantity while cadmium and lead were not detected. It is therefore concluded that the aqueous leaf extract of *A. wilkesiana* contains Pharmacologically useful active principles elements. Thus the aqueous leaf extract of the plant could play vital roles in health and disease.

**Key words:** *Acalypha wilkesiana*, aqueous leaf extract , Phytochemical analysis, Elemental analysis

### INTRODUCTION

*Acalypha wilkesiana* Muell Arg (copper leaf) is a plant from the family Euphorbiaceae. The genus *Acalypha* comprises about 570 species (Riley, 1963), a large proportion of which are weeds while the others are ornamental plants. The plants are found all-over the world especially in the tropics of Africa, America and Asia. The weeds are wild and can be found growing everywhere, while the ornamental species must have been introduced into West Africa from other parts of the world and are cultivated as foliage plants in gardens and greenhouses (Abiodun, 2005). It's a fast growing evergreen shrubs which provides a splash of colour in the landscape with bronze red to muted red, the leaves appear as heart shaped with combination of colour like green, purple, yellow, orange, pink or white depending on cultivation.

Some of the species are well known in traditional medicine and a few have actually appeared in the homeopathic pharmacopoeia of United States (1941) and India (1971). *A. wilkesiana* was reported to be used in the treatment of hypertension, especially in Managing the abnormal sodium and potassium metabolism that accompany hypertension (Ikewuchi et al, 2005).

However few studies have mentioned the phytochemical constituents and elemental studies of *A. wilkesiana*. Akinde (1986) reported the presence of sesquiterpene, monoterpenes, triterpenoids and polyphenols. Adesina et al (2000) reported the presence of gallic acid, corilagin, geranin, quercentin, 3-O-rutinoside and Kaempferol in the leaves of *A. wilkesiana*.

In another study, Oladunmoye (2006) reported the presence of saponins, tannins, anthraquinan and glycoside in the leaves of *A. wilkesiana*. *A. wilkesiana* has antibacterial and antifungal properties (Akinde, 1986, Alade and Irobi, 1993; Adesina et al, 2000, Ogundaina 2005, Oladunmoye 2006).

The leaves of *A. wilkesiana* are popularly used in the north eastern Africa in the treatment of skin infections. This study is therefore designed to investigate the phytochemical and elemental constituent of *A. wilkesiana* obtained from Maiduguri, Nigeria.

### MATERIALS AND METHODS

#### Plant collection and identification

Fresh leaves of *A.wilkesiana* were collected in the month of June from University of Maiduguri staff quarters. It was identified and authenticated by a botanist from the Department of Forestry, University of Agriculture Makurdi, Benue State. The Plant was then air dried under room temperature for two weeks after which it was pulverized using wooden mortar and pestle.

#### Aqueous Extract Preparation

The powdered sample (200g) was mixed with 1 litre of distilled water in a round bottom flask. A reflux condenser was attached to the flask and inserted with a heating mantle. The mixture was reflux for one hour and filtered with Watman filter paper No. 1. The reflux was done twice again using new distilled water at each stage. The filtrate was then evaporated to dryness using oven at 50°C to a dark viscous substance. The yield was 22.85% w/w.

The resultant extract was concentrated and stored in a specimen bottle at room temperature until used.

### Determination of the Phytochemical constituent

The extract was evaluated for the presence of Carbohydrate, tannins, flavonoids, phlobatannins, cardiac glycosides, saponins, alkaloids, terpenes, steroids and anthraquinone using simple qualitative and quantitative methods of Trease and Evans (1989) and Sofowora (1993).

### Determination of the elemental constituent of *A. wilkesiana* leaf.

Air dried sample (15grams) of *A. wilkesiana* was put in a labeled crucible and heated in a hotspot furnace at 550°C for 3 hours. The sample was removed and cooled in a dessicator. Half (0.5) gram of the ashed sample was digested in a 250mls beaker with 20cm<sup>3</sup> of aqua-regia (mixture of HCl and HNO<sub>3</sub> in a ratio 3:1) and 10 cm<sup>3</sup> of 30% H<sub>2</sub>O<sub>2</sub> was added. The beaker was then covered with watch glass and heated on a hot plate at 90°C for about 1 hour so that the volume is reduced to 2cm<sup>3</sup> in Fume cupboard until a clear digest was obtained. The content was then filtered after cooling and deionized water added and made up to 100mls in volumetric flask. The

elemental analysis was done using Sp-9-single beam atomic absorption spectrophotometer (Philip/pye Unicam Ltd, England). The elemental concentrations were determined by a standard calibration curve method (Sunderman, 1973; Kolthoff and Elving 1976).

### RESULT

The result of the Phytochemical analysis obtained from the aqueous leave extract of *A. wilkesiana* indicated that carborhydrates, tannins and flavonoids were highly present in the extract. Phlobatanins, cardiac glycosides, saponins and alkaloids were present in medium quantity while terpenes and steroids occurred in minute quantity. Anthroquinone were not present in the extract. (Table 1).

The result of the elemental analysis of the leave of *A. wilkesiana* showed a very high concentration of chloride, sodium and potassium ions. Calcium, iron, magnesium and zinc were in medium concentration while copper and manganese were in minute concentration. Lead and cadmium were not detected. (Table 2).

## DISCUSSION

The Phytochemical test result indicated the presence of carbohydrate in the extract; carbohydrate is reported to have numerous roles in living things, such as the storage and transport of energy (starch, Glycogen) and structural components (cellulose in plants, chitin in animals). Additionally carbohydrates and their derivatives play major roles in the working process of the immune system, fertilization, pathogenesis, blood clotting and development (Maton *et al.*, 1993).

The presence of tannins in the aqueous extract of *A. wilkesiana* leaf implies that the extract can be pharmacologically useful as astringents. Tyler (1988) reported that the astringent activity of tannins

is by precipitating proteins, thereby protecting the underlying tissue leading to improvement of wound healing.

Tannins inhibit microbial proliferation by denaturation of enzymes involved in microbial metabolism (Awosika, 1991). Tannins also have shown potential antiviral (stephone *et al.*, 2004 and Lin *al* *et* .,2004), antibacterial (Akiyama *et al* .,2001and Funatogawa *et al.*, 2004) antiparasitic and anticancer effects (Bhagavathi *et al.*,1999; Ling-lihy *et al.*,2000 and Susumu *et al.*, 2005,) Tannins including gallo and ellagic acid (epigallitannins) are inhibitors of HIV replication. Flavonoids have been referred to as nature's biological response modifiers because of its ability to modify the body's reaction to

allergies, viruses, and carcinogens. They show anti-allergic, anti-inflammatory microbial and anti-cancer activity (Yamamoto and Gaynor , 2002 ). However some research indicated that only small amount of flavonoids are necessary to see its medical benefits. Taking large dietary supplements provides no extra benefit and may pose some risks (David stauth, 2007). Cardiac glycosides have been used in the treatment of congestive heart failure, constipation, edema and microbial infections (Robinson, 1967 and Franstisk, 1991). It may be possible that the aqueous extract of *A. wilkesiana* could be useful in the treatment of this ailment since it contains cardiac glycoside.

In dogs and cats, cardiac glycosides are indicated for their negative chronotropic effect in supraventricular arrhythmias such as atrial fibrillation. They slow the rate of impulse conduction through the A.V. node and allow the ventricular rate to fall below the atrial and so restore more efficient pumping (Aliu, 2007). Saponins have expectorant properties which have been used in the treatment of upper respiratory tract infection (Trease and Evans, 1989). They also have antibacterial activities (Birk and Petri, 1980) thus have been used in the treatment of microbial infections.

Alkaloids are pharmacologically useful. They are the local anaesthetic, CNS stimulant (Cocaine, nicotine, coffiene, etc), analgesic e.g. Morphine and antimalarials e.g. guanine (<http://en.wikipedia.org/wiki/Alkaloid>). Steroids (anabolic steroids) have been observed to promote nitrogen retention in Osteoporosis and in animals with wasting illness (Aliu, 2007).

The result of the elemental analysis of the aqueous extract of *A.wilkesiana* indicated the presence of macro and micro nutrients. Macro nutrients such as sodium, potassium and calcium regulate the fluid balance of the body and thereby influence cardiac output (Sanni , 2007). Restriction of sodium intake or an increase in Potassium intake exert remarkable anti-hypertensive effect (Schroever , 1976). Calcium ions plays an important physiological and biochemical processes such as neuromuscular excitability blood coagulation, secretary processes etc (Sanni, 2007).

Proper extracellular fluid and periosteal concentration of calcium and phosphate ions are required for bone mineralization (Robert *et al.*, 2000).

Elements such as iron, zinc and manganese are essential because they are important in several enzyme reactions as co-factors (Robert *et al.*, 2000). Potassium has an oxidizing effect, it act as astringent and can destroy organic poisons especially alkaloids (Aliu, 2005).

## CONCLUSION

This study shows that *A. wilkesiana* contains pharmacologically active principles and elements which are used extensively in chemotherapy and which are useful in health and disease in humans and animals. Therefore the aqueous extract of this plant could be of immense medicinal value.

**Abstract:** This study was conducted to evaluate the effect of feeding buffalo cows on ration supplemented with two levels from iodine (I) during late pregnancy (three months before parturition) and postpartum period (six months after parturition) on nutrients digestibility, some blood constituent, birth weight of their offspring, Concentrations of immunoglobulin in colostrums, milk (yield and composition) and reproductive parameters. Eighteen buffalo cows (2-4 lactations) in late pregnancy period were selected to carry out the experimental work. The animals were divided into three similar groups (6 female buffaloes in each). Concentrate feed mixture (CFM), berseem hay (BH) and rice straw (RS) were given to animals as a control ration ( $I_0$ ) without supplementation, while the other groups  $I_1$  and  $I_2$  received the control ration with iodine at levels of 0.3 and 0.5 mg I per kg DM intake /h/d, respectively. Results indicated that supplementation ration of buffalo cows with different levels of I had improved the digestibility of all nutrients, TDN, DCP at pre and post partum, feed efficiency, increased milk yield, 7% fat correct milk yield and its composition. Birth and weaning weight of calves in treated groups were higher than that control group. Immunoglobulin concentration in colostrums indicated higher values with animals feed supplemented rations than those fed the control. Moreover, addition of I improved RBC, WBC, Hb, PCV, plasma total protein, globulin, glucose, T<sub>3</sub> and T<sub>4</sub>. Supplemented rations of buffalo cows with 0.5 mg I/h/d tend to significantly ( $P < 0.05$ ) higher in actual milk yield, 7% FCM yield, fat %, protein %, lactose %, SNF % and TS %, while supplemented with 0.3 mg I/h/d appeared to the same higher trend with no significantly differences. Moreover, better feed efficiency was observed with animals fed supplemented rations. The periods required for fetal membrane expulsion was significantly reduced in  $I_2$  group when compared to  $I_1$  or control groups. Moreover, only control group showed a case of abortion and still birth, while treated dams delivered 100% healthy calves. Buffaloes of group  $I_2$  had the least ( $P < 0.05$ ) calving interval due to the shorter intervals for uterine involution, onset of the 1<sup>st</sup> postpartum heat and days open. Iodine supplementation showed significant differences among groups in studied parameters such as NSPC and CI. Mean period elapsed from calving until placenta drop significantly decreased  $I_2$  than the control group. Generally, it concluded that I supplementation for ration of buffalo cows improved immunity, nutrients digestibility, calves birth weight and increased milk (yield and composition) and showed better feed efficiency as well as higher some traits of reproductive performance.

## 1. Introduction

Buffalos are the most favored milk animal in Egypt, as most Egyptians prefer buffalo milk to cow milk because of its white color, sweet taste and high fat percentage.

Iodine is a key component in the formation of thyroid hormones that contributes to brain development during fetal life and metabolism

thereafter. On the other hand, thyroid hormones are major regulators of development, metabolism and homeostasis. Studies addressed that thyroid hormones influence both aspects of development; growth. A lack of iodine indirectly influences growth rate, milk production and feed consumption. Other deficiency symptoms include poor conception rates, abortions, longer gestation periods and the birth of

dead, weak or hairless calves. Moreover, pregnant animals are more susceptible to iodine deficiency than non-pregnant animals, which in turn increase the incidence of prepartum and postpartum reproductive disorders. Also Lactating dairy cattle require more iodine than beef cattle because approximately 10% of the iodine intake is normally excreted in milk, and this percentage may increase as milk production increases.

NRC (1994, 1998, 2001) reported that the iodine requirements for dairy cows 0.5 mg/kg dry matter (DM). Sanchez (1995) reported that iodine requirement is 0.6 mg /Kg of DM for lactating cows and 0.25 for calves, and growing heifers. Although cattle can tolerate iodine far in excess of their requirements, a level of 50 mg I/ Kg of DM has been suggested as the maximum tolerable level. Who added that low levels of iodine in the diet affect reproduction of cows, causing irregular oestrous cycles, low conception rates as well as desorbed fetuses, abortions, stillbirths or calves may be born blind, weak or with goiter. Male fertility may be also affected, decreasing libido and semen quality. Severe iodine deficiency may reduce milk yield or growth rate. Georgievskii et al. (1990) found that the principal function of iodine is determined by its presence in the thyroid hormones. These hormones are known to regulate basic metabolism, consumption of carbohydrates, proteins and fats, and heat formation processes, and to affect growth, development and the reproductive function. The effect of hormones on metabolism involves synthesis of respiratory and other enzymes, which affect intracellular processes of oxidation, oxidative phosphorylation and protein synthesis. Gaffarov and Saliev (1979) indicated that supplement of iodine for cow rations increased the digestibility of all nutrients. Gasanova (1985) reported that increasing the dietary level of iodine from basal values 0.11-0.16 mg /Kg DM to 0.59 - 0.65 mg / Kg DM improved feed utilization for milk production. Hetzel(1990) reported that iodine deficiency disorders is the term now used, instead of goiter (enlarged thyroid), to denote all the effects of I<sub>2</sub> deficiency on growth and development.

Hoption (2006) reported that thyroidal hormones play a major role in the growth and development of brain and central nervous systems, control of several metabolic processes including carbohydrate, fat, protein, vitamin and mineral metabolism. Iodine deficiency affects reproductive capacity, brain development and progeny as well as growth. Smith and Chase (2004) reported that early research confirmed that nutrition played an important role in reproduction, but in most cases severe

nutritional deficiencies were required to cause reproductive problems. They also said that reproduction is influenced through iodine's action on the thyroid gland. Inadequate thyroid function reduces conception rate and ovarian activity. Lobb and Dorrington (1992) and Monge and Monniaux (1995) reported that the animals suffer from iodine deficiency then ovary become atrophy and decrease the milk production and there will be decrease calcium absorption capacity i.e. low calcium and high phosphorus in blood. Iodine acts on the thyroid gland. Metabolic activity of body also decreases slow growth due to Iodine deficiency. If we supply iodine, increase the function of thyroid gland, maintain the balance of Ca and P level, and increase metabolic activity of body, body weight and animal come in heat early. So hormone will be less effective in Iodine deficient cow. The mechanism by which massage brings back cows ovary to function is not clearly understood, but is probably the result of activation of intrinsic ovarian factors.

Therefore, the present work aimed to study the effect of iodine dietary supplementation on birth weight of their offspring, milk (yield and composition), nutrients digestibility, immunoglobulin status, blood constituents and reproductive performance of Egyptian buffalo's cows.

## 2. Material and Methods

### The experimental procedures:

This study was carried out at EL-Gemmaiza Experimental Station belonging to Animal Production Research Institute, Agricultural Research Centre, Giza, Egypt. Eighteen Egyptian lactating buffalo cows (2-4 lactations) were used in this study. Animals were chosen in late pregnancy period at approximately 90 days prepartum and divided randomly into three similar experimental groups, (6 animals in each group) to evaluate the effect of using iodine in feeding buffalo cows on nutrients digestibility, some blood parameters, birth weight of their offspring, immunoglobulin status, milk yield, milk composition and reproductive parameter. The control ration consisted of concentrate feed mixture (CFM), berseem hay (BH) and Rice straw (RS)which was given to buffaloes, (I<sub>0</sub>) without additives, while the other groups I<sub>1</sub> and I<sub>2</sub> fed the control ration supplemented with two levels of Iodine : 1<sup>st</sup> is 0.5 mg sodium iodide per kg DM intake /h/d (0.3 mg I per kg DM intake /h/d) and 2<sup>nd</sup> is 0.8 mg sodium iodide per kg DM intake /h/d /h/d (0.5 mg I per kg DM intake /h/d)respectively. I were well mixed with some of the ground concentrate feed mixture before feeding. Animals were individually fed according to Kearn (1982). The animals were left

for 4 weeks (as a preliminary period) on the same diet before receiving any samples. The experimental treatments lasted nine months (three months before the expected calving date and continued up to six months of lactation period) to investigate the effect of I supplementation on productive and reproductive performance of buffaloe cows.

#### **Management and feeding:-**

All animals were housed in semi open pens until time of delivery then they were transferred to the maternity unit. Water was offered freely in water troughs except at the milking time. After delivery all buffalo cows were allowed to nurse their calves for only one week postpartum (period of colostrums intake) thereafter, the dams were transferred to the milking unit and milked twice daily at 7a.m and 5 p.m. and they were subjected to the regular managerial practices of the breeding stock. Dams were weighted before and after calving as well as their new born calves were also weight and recorded immediately after calving until weaning (90days). Milk yield was recorded. Composite and representative samples of milk (morning and evening samples) were mixed by ratio of 1% weight of milk and analyzed biweekly for fat, protein, lactose, solids non fat, total solids and ash using Milkoscan apparatus. Energy of milk was calculated by using the formula of Overman and Sanmann (1926) where energy of milk:

$$(Kcal) = 115.3 (2.51 + \text{fat \%}).$$

Actual milk yield was converted into 7% fat corrected milk (FCM) using the formula given by Raafat and Saleh, (1962) as follows:

$$7\% \text{ FCM} = 0.265 \text{ milk yield} + 10.5 \text{ fat yield.}$$

Two digestibility trials were carried out at 60 and 180 days of the feeding trials using buffalo cows from all groups to determine the nutrients digestibility and nutritive value of the experimental rations. Acid Insoluble Ash (AlA) technique according to (Van Keulen and Young, 1977) was used as a marker for the determination of the nutrients digestibility. Digestibility of DM as well as all nutrients was determined with the following equations:

$$\% \text{ Nutrient digestibility} = 100 - (\% \text{ DM digestibility} \times \% \text{ Nutrient in feces}) / \% \text{ Nutrient in feed}.$$

At the 60 and 180 days of the trial, fecal samples were collected from the rectum twice daily every 10 hr at 7:00 and 17:00 hr starting at the 3<sup>rd</sup> day of the collection period. Feed and fecal samples were dried, ground and kept for later analysis. Chemical composition of the different ingredients and feces samples were analyzed according to A. O. A. C. (1990).

#### **Colostrums analysis:-**

Colostrums samples were collected within one hour of parturition (first milking) from each dam at the 1<sup>st</sup>, 2<sup>nd</sup> and 3<sup>rd</sup> day postpartum for immunoglobulin studies. Determination of immunoglobulin's Ig A, Ig M and Ig G in colostrums was applied by Bovine radial immunodiffusion (RID) kit according to the procedure outlined by the manufacturer (The Binding Site Ltd, Birmingham, UK). The principle of the technique was derived from the work of Mancini *et al.* (1965) and Fahey and McKelvey (1965).

#### **Blood sampling:-**

Blood samples were collected biweekly via the jugular vein from each buffalo cows during late pregnancy (LP) and postpartum (PP) period. Count of red blood cell (RBC) and white blood cell (WBC) was determined using haemocytometer, packed cell volume (PCV%) was estimated using micro-hematocrit tube and micro hematocrit centrifuge at 10000 rpm for 5 min, while concentration of hemoglobin (Hb) was carried out using (Super+Ior®, Sahli's method) according to Sahli, (1905). Blood plasma was carefully separated after centrifugation at 4000 r.p.m. for 20 minutes, and then stored at -20 C° until analysis for the different blood parameters. Plasma was used for determination of Glucose (Trinder, 1969), total protein (Armstrong and Carr 1964), blood urea nitrogen (Fawcett and Scott, 1960), albumin (A) (Drury, 1974), cholesterol (Kostner *et al.*, 1979) and triglycerides (Schalm *et al.*, 1975). Direct radioimmunoassay technique was performed for determination of progesterone, (P4) estradiol 17β, triiodothyronine (T<sub>3</sub>) and thyroxin (T<sub>4</sub>) hormones in representative plasma samples. Kits of "Diagnostic Products Corporation, (DCP) Los Angles, USA " with ready antibody coated tubes were used according to the procedure outlined by the manufacturer.

#### **Measurement of reproductive traits:-**

During postpartum period, the reproductive tract was rectally palpated once every two days till 21 postpartum and once every three days after that in order to assess the uterine involution according to El-Fadaly (1978). All experimental buffalo cows were observed twice daily for estrous activity and buffalo cows in heat were inseminated 12 h after estrus detection. Animals were examined for pregnancy by rectal palpation after 50 days of insemination.

Immediately after parturition, the interval elapsed for complete fetal membranes drop (hour) and uterine involution period (day) were recorded. Also, the interval from calving to first detected estrus (day), service period length (day), number of services

per conception (NSPC), days open, pregnancy rate (%) and calving interval (CI/day) were recorded.

#### **6- Statistical analysis:**

Data were analyzed using GLM procedures of the SAS (SAS, 1996). Means were separated by using Duncan's multiple range test (Duncan, 1955).

### **3. Results and Discussions**

#### **Chemical composition of feedstuffs:-**

The chemical composition of CFM, BH and RS (Table 1) are within the normal ranges reported in Egypt by several workers (El-Hosseiny, *et al.*, 2008 and Zeedan, *et al.*, 2008 and 2010).

#### **Nutrients digestibility and nutritive values:-**

Results obtained from Table (2) indicated that digestibility of DM, OM, CF and EE was not influenced by I supplementation at 60 days. While digestibilities of CP and NEF were significantly higher ( $P<0.05$ ) for  $I_2$  than  $I_0$ . Also, nutritive value as TDN was significantly ( $P<0.05$ ) for  $I_2$  than  $I_1$  and  $I_0$ . At 180 days the digestibility of all nutrients and nutritive value (TDN and DCP) tended to significantly ( $P<0.05$ ) increase for the  $I_2$  compared to the  $I_0$ . These results were in agreement with those obtained by Lubin *et al.* (1979), Gasanova (1985) and Lenina (1986). Pattanaik *et al.* (2001) found that digestibility of DM, OM, CP and EE was not influenced by I supplementation and were comparable to the control values during the first metabolism trial (90 days). During the second trial, conducted at 165 days post-feeding, the digestibility of nutrients tended to increase for the I supplemented group  $I_{50}$  compared to the control, but the differences were non-significant. El-Hosseiny, *et al.* (2008) found that supplement of iodine for young camel, the digestibility of nutrients and nutritive value (TDN and DCP) tended to increase, but the differences were non-significant. Also Gaffarov and Saliev (1979) indicated that supplement of iodine for cow rations increased the digestibility of all nutrients.

The improving of digestibility of most nutrients may be due to its effect on rumen bacteria especially rumen proteolytic bacteria and increasing the number of rumen cellulolytic bacteria (Hungate, 1968 and Martinz and Church, 1969). Lawrence and Fowler (1997) reported that thyroid hormones influence the function of most organs and stimulate the basic metabolic rate through regulation of the metabolism of carbohydrates, proteins and lipids. Improvement of TDN and DCP might be due to the higher values of digestibility values of all nutrients by supplementation with different levels of I

supplementation. Hoption (2006) reported that thyroidal hormones play a major role in the control of several metabolic processes including carbohydrate, fat, protein, vitamin and mineral metabolism. On the other hand, Sawal *et al.* (1996) found that digestibility of all organic nutrients decreased with female Gaddi sheep receiving iodine.

#### **Birth weight of born calves and dams:-**

Data of body weight (dams and calves) and daily gain of calves are summarized in Table (3). The dam body weight before parturition; late pregnancy (LP) was insignificant in all experimental groups. The same trend was observed with fetal fluid, but dam body weights after parturition, post-partum (PP) were significant ( $P<0.05$ ). Also, fetal fluid was not significant in all treatments. Percentages of calving loss (CBW + fetal fluid) / DBW before parturition were 9.30%, 9.66% and 10.48 % for groups  $I_0$ ,  $I_1$  and  $I_2$ , respectively. Differences between groups in Calf birth weight (CBW) and CBW / Dam post-partum were significant ( $P<0.05$ ) (Table 3). Group  $I_2$  achieved greater values of CBW / Dam post-partum, calf birth weight, weaning weight, total gain of calf and daily gain of calf than other groups. Improvement percentage was 8.62 and 12.07% for daily gain of calves. The newly born calves from treated dams I showed higher CBW, weaning weight, total gain, daily gain and better vitality in comparison with the control group. Generally the calves from treated dams showed higher CBW, CBW / Dam post-partum, weaning weight, total gain and daily gain than the control group. The supplementation has improved the thyroid function at calving and weaning in the buffaloes, increased the digestion protein, TDN (60 and 180 days), concentrations of immunoglobulin in colostrums, milk protein and milk lactose led to increase the calf birth weight and calf weaning weight. Gilles *et al.* (2009) found that the selenium and iodine administration in prepartum cows may enhance the calf immune defences by improving the maternal mineral status. Sultana *et al.* (2006) found that the highest live weight gain was found in Lugol's iodine treated group (7.09%) followed by iodide salt treated group (5.28%) and common salt treated group (4.94%). They added that the lowest live weight gain was determined in control group (No iodine treatment). They added that the reason why might be due to anabolic effect of iodine on weight gain. Hoption (2006) reported that thyroidal hormones play a major role in the growth and development of brain and central nervous systems, control of several metabolic processes including carbohydrate, fat, protein, vitamin and mineral metabolism. Iodine deficiency affects reproductive capacity, brain

development and progeny as well as growth Lobb and Dorrington (1992) and Monget and Monniaux (1995) reported that the animals suffer from Iodine deficiency then decrease the milk production and there will be decrease calcium absorption capacity i.e. low calcium and high phosphorus in blood. Iodine acts on the thyroid gland. Metabolic activity of body also decreases slow growth due to Iodine deficiency. If we supply iodine, increase the function of thyroid gland, maintain the balance of ca and p level, and increase metabolic activity of body, body weight. Also, Mc Dowell, (2003) and Underwood and Suttle, (2001) found that both hormones have multiple functions in the energy metabolism of cells, in the growth, as a transmitter of nervous stimuli, and as an important factor in brain development. Also, Gasanov (1991) reported that Supplemented (injections of tetravitan and supplements of trivitan, potassium iodide, sodium selenite, calcium triphosphate, proserine, cobalt chloride or zinc sulphate) buffaloes had increased calf birth weight, decreased calving problems, increased milk yield and colostral density, and blood immunoglobulin concentrations. He added that buffaloes were deficient in selenium, cobalt and iodine which affected immune.

#### **Concentrations of immunoglobulin in colostrums:-**

As shown in table (4) concentrations of all Immunoglobulin (Ig) fractions in colostrum of buffaloes showed a descending trend with sequence sampling days after parturition. IgA, IgM and IgG were detected increasing for  $I_1$  and  $I_2$  compared to  $I_0$ . IgG were significantly ( $P < 0.05$ ) in group  $I_2$  in comparison with other groups. The control group  $I_0$  had minimal concentration of IgA, IgM and IgG than other treated groups. The supplementation has improved the thyroid function at calving in the pregnant cows, increased the digestion both protein and TDN at 60 days led to increase immunoglobulin. Northeim *et al.* (1985) reported that the immune status of the newborn calves is dependent upon the passage of immunoglobulins from dams to the calves through the ingestion of colostrum and its subsequent absorption from small intestine. Nocek *et al.* (1984) demonstrated that IgG has been related to pre-weaning growth. Consumption of colostrum is essential to provide animals with the antibodies and other proteins that calves need to stay healthy. The amount of colostrum and immunoglobulin, or IgG consumed determines amount of passive immunity and resistance to disease. When calves consume insufficient amounts of IgG from colostrum within the first 24 hours of life, calves are much more susceptible to developing disease and possibly dying.

A major reason that pre-weaning mortality is higher than optimum (defined as less than 5% of calves born alive) is due to inadequate IgG intake (Quigley, 2005).

Estimates of Ig in the current study are greater than those obtained by Salama *et al.* (1997) who observed that Ig contents in colostrum of Egyptian buffaloes at 24, 48 and 72 hr after calving were 26.1, 20.0 and 16.4 mg/ml in premiparous and 26.0, 14.3 and 10.9 in pluriparous buffaloes. Gasanov (1991) reported that Supplemented (injections of tetravitan and supplements of trivitan, potassium iodide, sodium selenite, calcium triphosphate, proserine, cobalt chloride or zinc sulphate) buffaloes had decreased calving problems, increased colostral density, and blood immunoglobulin concentrations. Who added that buffaloes were deficient in selenium, cobalt and iodine which affected immune.

Generally Subsequently, the amount of IgG in dam's colostrum depended mainly upon prepartum administration of immunopotentiators, and in calves depended mainly upon consumption of colostrum directly after parturition. Also, iodine supplementation may be improved the thyroid function led to increase concentrations of immunoglobulin in colostrums.

#### **Milk yield and composition:-**

Data presented in Table (5) showed that the actual milk, milk composition percentage and yields, 7% fat corrected milk (7% FCM) yield and milk energy (Kcal / Kg milk) of lactating buffalo cows. The actual milk yield (AMY) and 7% fat corrected milk (7% FCM) yield of dairy buffalo cows were significantly ( $P < 0.05$ ) higher of  $I_2$  than that of  $I_0$ . Similar results were obtained by Monastyrev (1980), Gasanova (1986), Kobeisy and Shetaewi (1992), Kobeisy *et al.* (1992) and Allam *et al.* (2003) they reported that addition of I to the ration of lactating cows and buffaloes increased milk production and 4 or 7% fat correct milk yield. Improvement and increasing in milk yield was observed with animal gropes fed supplemented ration with I, being 14.94 % and 28.67% with groups  $I_1$  and  $I_2$ , respectively. The same increasing trend was shown with 7% FCM yield. The respective values were 16.00% and 45.5. Also Golubev and Sedov(1984), Drebickas *et al.*(1993) and Androsova (1994) showed that addition of potassium iodide to ration of lactating cows increase milk production by 10 – 18%.

The increase in milk yield with I supplementation may be due to higher nutrients digestibility at 180 days (Table 2) and increase in  $T_3$  and  $T_4$ . Hoption (2006) reported that thyroidal hormones play a major role in the control of several

metabolic processes including carbohydrate, fat, protein, vitamin and mineral metabolism. Georgievskii *et al.* (1990) reported that the principal function of iodine is determined by its presence in the thyroid hormones. These hormones are known to regulate basic metabolism, consumption of carbohydrates, proteins and fats the effect of hormones on metabolism involves synthesis of respiratory and other enzymes, which affect intracellular processes of oxidation, oxidative phosphorylation and protein synthesis. Also, Lawrence and Fowler (1997) reported that thyroid hormones influence the function of most organs and stimulate the basic metabolic rate through regulation of the metabolism of carbohydrates, proteins and lipids. Gasanova (1985) reported that increasing the dietary level of iodine from basal values 0.11-0.16 mg /Kg DM to 0.59 - 0.65 mg / Kg DM improved feed utilization for milk production.

Percentages and yield milk constituent (fat, protein, lactose, SNF, TS and milk energy) were significantly ( $P < 0.05$ ) higher in groups  $I_2$  than those of  $I_0$  in (Table 5). Allam *et al.* (2003) reported that supplementing ration with iodine significantly ( $P < 0.05$ ) increase percentages fat, protein and energy contents. Angelow *et al.* (1993) reported that the differences between control and iodine (0.2 mg / kg as KI) for daily yield of milk fat and protein were significant. Todorova *et al.* (1995) found that iodine deficiency decreased milk fat, protein yield of ewes. Ehlers *et al.* (1994) observed that there was trend towards higher milk protein yield which was attributed to higher thyroxin for dairy cows given diet supplemented with iodine. Kobeisy and Shetaewi (1992) found that milk fat% and milk TS% increased by iodine supplemented group in Egyptian buffaloes at mid lactation. Kobeisy *et al.* (1992) found that iodine supplementation in ration buffaloes increase percentages milk constituent (fat, protein, lactose and TS) compared the control group. On the other hand, Norouzian *et al.* (2009) pointed that no significant differences observed in all treatment by different level of iodine, for milk yield and milk composition. Also Nudda *et al.* (2009) found that milk yield and composition were not influenced by KI supplementation, but the first level of KI supplementation increased the content of milk fat significantly compared with that of the unsupplemented group.

#### **Feed intake and feed efficiency:-**

Data in Table (6) indicated that lower dry matter intake was obtained for  $I_1$  and  $I_2$  than that of  $I_0$ , with no significant differences among groups. Data presented in Table (6) showed that the DMI decreased with animal groups fed  $I_1$  and  $I_2$ .

Decreasing in DMI might be due decreasing intake of rice straw with there groups because of I supplementation make a favorable effect for animals to get the best ingredient from ration and also might be to higher digestibility and nutrients value for experimental rations. Norouzian *et al.* (2009) found that decrease of dry matter intake related to feeding high levels of iodine but no significant difference was observed between treatments for DMI. These results are in agreement with El-Hosseiny, *et al.* (2008), Allam *et al.* (2003) and Meyer *et al.* (2008) they found that I supplementation had no significant effect on feed intake. Total intake from both TDN and Total DCP showed no significant difference with I supplementation. Results obtained herein are in agreement with that of El-Hosseiny, *et al.* (2008) and Allam *et al.* (2003).

Feed efficiency was expressed as amount of either milk yield or 7% milk yield produced from one kg DM intake. Results obtained in Table (6) showed that the feed efficiency was significantly ( $p < 0.05$ ) higher with animal groups fed  $I_2$  than those fed  $I_0$ , but the differences between groups fed  $I_0$  and  $I_1$  were not significant. Also, differences between groups fed  $I_1$  and  $I_2$  were not significant. Generally, iodine supplementations tend to higher feed efficiency. Improvement in feed efficiency for groups consumed I supplementation might be attributed to lower DM intake and higher milk yield.

The same previous trend was observed with feed efficiency when expressed as 7% FCM/kg DCP, being 8.89, 9.98 and 12.13 for gropes fed rations  $I_0$ ,  $I_1$  and  $I_2$ , respectively. These results are in harmony with Allam *et al.* (2003) and Lenina (1986) they reported that supplements of I for cattle improve feed efficiency compared to control groups.

#### **Blood parameters:-**

Data in Table (7) illustrated that count of (RBC and WBC), Hb and PCV were significantly ( $P < 0.05$ ) increased on LP and PP in treatment. This effect could be due to increased thyroid hormone and functions of hormone in treated animals. These results are in accordance with shcheglov and Gruzdev, (1989), Spiridon and Hebean. (1988) and Zygmunt (1987). Bedi *et al.* (2000) found that hemoglobin tended to increase, but the differences were non-significant by using level of KI. Also, Sultana *et al.* (2006) reported that the total erythrocyte count (TEC), hemoglobin percent and packed cell volume (PCV) were increased on 60 days of post-treatment in all groups (common salt, iodide salt and Lugol's iodine) compared with control group. They added that the variation might be due to effect of iodine formulation on hemopoiesis.

As shown in Table (7) total protein, T<sub>3</sub> and T<sub>4</sub> concentrations in blood plasma of I<sub>1</sub> and I<sub>2</sub> groups were significantly ( $P < 0.05$ ) greater than of I<sub>0</sub> within two stages LP and PP. Shetaewi *et al.* (1991) found that serum proteins tend to be higher in high treatment of KI than low of KI or control treatments. Vsyakikh *et al.* (1992) reported that total protein significantly increased during the second month of lactation in cows receiving KI. El-Hosseiny, *et al.* (2008) showed that serum total protein significantly increased by supplement of iodine. The increase in plasma protein with iodine addition may be due to the increase in protein synthesis, digestion of protein at the 60 and 180 days in Table (2) and increase in T<sub>3</sub> and T<sub>4</sub>. Freeman, (1983) and El-Masry and Habeeb, (1989) reported that the result of the elevation of anabolic hormone secretion that are responsible for utilization of amino acids and other physiological functions related to metabolic rate. Also, Lawrence and Fowler (1997) reported that thyroid hormones influence the function of most organs and stimulate the basic metabolic rate through regulation of the metabolism of carbohydrates, proteins and lipids. On the other hand Kobeisy and Shetaewi (1992) found that serum total proteins was lower ( $P < 0.01$ ) in I supplemented buffaloes compared with control. Pattanaik *et al.* (2001) found that T<sub>3</sub> and T<sub>4</sub> increased by I supplementation compared to control. Kobeisy and Shetaewi (1992) showed that iodine treated buffaloes had 40% higher ( $P < 0.02$ ) serum triiodothyronine than control buffalos. Khushdeep and Randhawa (2004) found that a significant elevation of plasma T<sub>4</sub> concentration in buffaloes treated with 2 ml of iodized (containing 375 mg iodine / ml) subcutaneously in the brisket region. Also, Rose *et al.*, (2007) found that supplementation with I was associated with higher levels of triiodothyronine and thyroxin in the lambs at birth. Norouzian *et al.* (2009) found that average to T<sub>3</sub> were 90.75, 91.125, 99.50 and 104.75 for control, the control diet plus 2.5, 5 and 7.5 mg Potassium Iodide/kg diet DM, respectively, while T<sub>4</sub> were 3.00, 2.675, 3.237 and 2.80 at the same treatments. In these study the increase in T<sub>3</sub> and T<sub>4</sub> concentrations with animals fed I<sub>1</sub> and I<sub>2</sub> treated animals may be due to increasing the availability of I to the thyroid to meet the increasing demand of thyroid hormone during pregnant and lactation period.

No significant difference was observed among different treatments for albumin in LP but significant difference was observed during PP period (Table7). While, significant difference was observed among treatments for globulin during LP and PP period. Also no significant difference was observed among treatments for A / G ratio during LP and PP. The increase in serum albumin and globulin with

iodine addition may be due to the increase in protein synthesis, total protein in blood and digestion of protein at the 60 and 180 days as show in Table (2). Shetaewi *et al.*, (1991) founded that serum albumin tended to be higher in high iodine treatment than low iodine or control treatment. They added that serum globulin tended to be higher in iodine treatment than control treatment. El-Hosseiny, *et al.* (2008) showed that serum albumin no significant by supplement of iodine. They added that globulin was significant by supplement of iodine. On the contrary Kobeisy and Shetaewi (1992) found that globulins was lower ( $P < 0.01$ ) and albumin tended to be lower in I<sub>2</sub> supplemented buffaloes compared with control.

Data in Table (7) illustrated that glucose was significantly ( $P < 0.05$ ) increased with groups fed I<sub>1</sub> and I<sub>2</sub> during PP period and it showed no significant difference during LP period. Bedi *et al.* (2000) reported that serum glucose level was significantly ( $P < 0.01$ ) in goats by using level of KI. Davis *et al.* (1988) found that T<sub>4</sub> injection (20 mg/d) for 4 days during successive 16 days experimental period increased mammary glucose uptake by 45%. Kobeisy and Shetaewi (1992) reported that serum glucose concentration was higher in iodine supplemented buffaloes than in control buffaloes. Draganov *et al.* (1991) found that supplemented diets (iodine, cobalt and copper) increased the concentration of blood glucose by 2.1 and 5.7 %. Vsyakikh *et al.* (1992) revealed that blood glucose significantly increased during the second month of lactating in cows receiving KI compared with control group. These results also probably attributed to the higher of blood plasma glucose and albumin concentration of animals fed iodine supplemented ration as shown in Table (7). It led to an increase in milk lactose synthesis and a consequent increase in milk production. This results may be due to the high demand for energy especially glucose as a main source of energy during late pregnancy. Manston and Allen (1981) reported that reduction in blood sugar level in the late pregnancy and 1 - 2 days after parturition indicates a heavy demand for glucose in late gestation and early lactation. Similar results were reported by El-Malky (2007) who found that Egyptian buffaloes blood glucose was decreased during late pregnancy and increased in the 3 months of postpartum. Significant Triglycerides was observed between treatments in LP and PP in Table (7). Kobeisy and Shetaewi (1992) showed that buffaloes treated with iodine in mid-lactation period had more 67% ( $P < 0.05$ ) triglycerides than control group. On the other hand, Davis, *et al.* (1988) found that was no detectable effect of T<sub>4</sub> injection on plasma triglycerides concentration. Lawrence and Fowler (1997) reported that thyroid hormones influence the function of most organs and

stimulate the basic metabolic rate through regulation of the metabolism of carbohydrates, proteins and lipids.

Also, the effect of treatment on blood urea nitrogen (BUN) was significant ( $P<0.05$ ), whereas treated groups had a higher means compared with untreated group in both pre and postpartum periods. This effect could be due to increased thyroid hormone in treated animals which in turn result in a slight increase in protein catabolism. Kobeisy and Shetaewi (1992) found that serum urea nitrogen tended to be slightly higher in buffaloes treated with I<sub>2</sub> in mid-lactation period compared with control group.

Data in Table (7) showed that cholesterol was lower in I<sub>1</sub> and I<sub>2</sub> than I<sub>0</sub> during LP and PP. It is interesting to notice the reverse relationship between T<sub>3</sub> and cholesterol concentrations that occurred during treatments. Shetaewi *et al.*, (1991) found that serum cholesterol concentration was 15% lower in lambs that received 80 mg KI/head/wk compared with controls. Also, Kobeisy and Shetaewi (1992) showed that cholesterol concentration was 20% less in treated group than that control group for buffaloes in mid lactation period supplemented with I<sub>2</sub> in diet. Kaneko (1980) reported that serum cholesterol was previously used as an index of thyroid function because hypothyroidism is generally associated with an elevation in serum cholesterol. Bergersen (1979) suggested that thyroid hormones increase cholesterol synthesis and enhance the liver's ability to excrete cholesterol in the bile. But the effect on cholesterol excretion is greater than that on cholesterol synthesis; the net result is a decrease in plasma cholesterol concentration. However, serum cholesterol varies with a variety of factors unrelated to thyroid activity such as the nature of the diet, hepatic function and other factors (Kaneko, 1980).

As shown in Table (7) EST 17 $\beta$  concentrations in blood of I<sub>1</sub> and I<sub>2</sub> groups were significantly ( $P<0.05$ ) greater than that of I<sub>0</sub> within two stages (late pregnancy LP and Postpartum PP). Data showed that level of plasma P<sub>4</sub> was lower in treated groups in prepartum period than that in the control group. Concentrations of P<sub>4</sub> tended to change slightly during the postpartum first months where the ovaries are still inactive. This may suggest that the sharp increase of EST17 $\beta$  and decrease of P<sub>4</sub> just before parturition was observed by Gordon (1996). Analysis of variance revealed that prepartum and postpartum P<sub>4</sub> concentration was affected significantly by different experimental groups. P<sub>4</sub> concentration tended to be high in I<sub>2</sub> than I<sub>1</sub> and I in postpartum period. This

finding indicated regression of corpus luteum in all cows at parturition (El-Moghazy, 2003). It is of interest to note that, average P<sub>4</sub> concentration at postpartum period was tends to be high in treated groups than control group. In general, the presented data reflected that treatment lactating buffalo cows on different iodine levels did not affect P<sub>4</sub> profile prepartum and postpartum periods. The diminished levels of P<sub>4</sub> before parturition was also stated earlier by several authors ( Kamonpatana *et al.*, 1981; Perera, 1981) working on buffaloes. Smith *et al.* (1973) reported that the decline of P<sub>4</sub> stimulates the uterus to be under estrogen dominance at a time when coordinated uterine contractions begin in cattle. In contrary, Nanda *et al.* (1981) noticed that P<sub>4</sub> levels in normal pregnant buffaloes remained almost constant from day 60 before calving to the last week of pregnancy. The importance of P<sub>4</sub> drop before onset of calving is to prevent the inhibitory effect of P<sub>4</sub> upon myometrial contraction as well as the release of oxytocin (Batra *et al.*, 1982).

Data illustrate that the level of EST17 $\beta$  increased linearly toward time of parturition in treated and untreated groups of buffalo, however clear differences were detected between both groups, whereas treated groups recorded higher EST17 $\beta$  levels than control group. After delivery, concentrations of EST17 $\beta$  decreased sharply in both groups of buffaloes in comparison with its level during late pregnancy. It seems likely that estradiol concentration in blood increases concomitantly with the decline in P<sub>4</sub> concentration (El- Wardani *et al.*, 1998). Normal expulsion of fetal membranes requires a rise in EST-17 $\beta$  before calving accompanied by a gradual and sustained fall in P<sub>4</sub> (Prakash and Madan, 1986). Moreover, normal calving requires softening and dilation of the cervix, particularly during late pregnancy due to the influence of relaxin and estrogen when P<sub>4</sub> dominance declines and uterine prostaglandin production is increasing (Taverne, 1992). This, P<sub>4</sub> decline is accompanied by a gradual increase in PGF<sub>2 $\alpha$</sub>  until 24 h before calving (Gordon, 1996).

The increase in blood studied constituents may be due to the role of iodine in improving all nutrient digestibility especially CP (Table, 2) of buffalos fed I, and also may be probably led to an increase in the absorption rate from the digestive tract, thus blood constituents of the supplemented animals reflected a corresponding increase of these values. These results are in agreement with Drebickas *et al.* (1993) who found that supplementary iodine improved chemical composition of blood in cows compared with the control diet.

**Reproductive aspects:-**

Mean values of some reproductive traits of the experimental dams are presented in table (8). Prepartum treatment with iodine reduced the period of fetal membrane expulsion compared to the other groups ( $P<0.05$ ). Buffaloes of group  $I_2$  had significant shorter intervals for uterine involution, onset of the 1<sup>st</sup> heat and days open when compared with other groups. In consequence, group  $I_2$  had the least ( $P < 0.05$ ) calving interval ( $367.2\pm24.1$  days). On the contrary to that, the control group  $I_0$  exhibited longer time to attain its uterine involution ( $52.6\pm9.16$  days) or reaching conception date ( $93.2\pm18.28$ ). Buffaloes in group  $I_2$  required only one service to conceive. Gestation periods for groups fed ration containing 0.5 mg I ( $I_2$ ) were relatively less than that of the other groups, presumably due to amelioration in fetal growth imposed by increased metabolism. Group  $I_2$  achieved a smallest value in the number of services per conception followed by groups  $I_1$  and  $I_0$ . It seems that positive impact of iodine treatments were shown on reproduction in buffaloes.

In coincidence with these findings, Sushma-Chhabra, *et al.*, (2007) found that iodine supplementation improved oestrus signs, whereas the onset of oestrus in the treatment group ranged from 4-33 days. Also, iodine treatment groups showed a better conception rate compared to the control group. Mavi and Bahga (2005) found that treatment groups improved reproductive efficiency, whereas eight heifers in the treatment group (44%) exhibited oestrus within 60 days of supplementation and four heifers (22%) conceived. In control group, only one heifer (12.5%) exhibited oestrus and none conceived in the same period. Panchal *et al.*, (1991) found that the overall pregnancy rate in the treated animals (42.17%) was significantly higher than that of the untreated controls (17.05%). Bahga and Gangwar (1989) measuring plasma protein-bound iodine in buffaloes after calving during summer and winter seasons and found that values were lower in summer than in winter, and lower in buffaloes requiring less than 30 days for uterine involution than in those requiring more than 30 days: they were lowest in buffaloes requiring more than 50 days for restoration of ovarian follicular development. Bahga (1989) reported that poor reproductive efficiency, postpartum oestrus interval, service period and number of services for conception were observed in animals in the low plasma protein bound iodine group. Gasanov (1991) reported that supplemented buffaloes with injections of tetravitamin and supplemented of trivitan, potassium iodide, sodium selenite, calcium triphosphate, proserine, cobalt

chloride or zinc sulphate reduced service interval, improved conception to first service.

Sharawy *et al.*, (1987) demonstrated that animals treated with patent thyroid preparation exhibited the highest percentage of heat appearance (86.7%) with 73.3% pregnancy rate, while group treated with supplements of crude iodinated casein revealed that 84.6% came in heat and 69.2% became pregnant and animals treated with potassium iodide revealed that 50% manifested heat while 40 conceived. In sheep, Ferri *et al.*, (2003) reported that 100% of treated ewes mated with treated rams were pregnant vs 37% of the control ewes mated with control rams, also, results demonstrated that iodine supplementation restores fertility of sheep living in iodine deficient areas.

**Pregnancy rate:-**

Table (9) showed that in control group three buffaloes came in heat after 65 days after delivery, three of them ovulated and conceived. In the second group, five animals manifested oestrus after 54 days and were ovulated while four of them got pregnant. In the third group all animals exhibited oestrus signs within 45 days, all were ovulated and all will pregnant (100%). Results revealed higher pregnancy rate in  $I_2$  (100%) than in groups  $I_1$  (66.67%) and  $I_0$  (50.0%). This may in relation to level of iodine supplementation, being better with the high (0.5 mg I per kg DM intake /h/d) than low level (0.3 mg I per kg DM intake /h/d) of supplementation. The marked improvement in pregnancy rate of buffaloes supplemented with iodine in  $I_2$  compared with  $I_0$  is in agreement with the findings of Sharawy *et al.* (1987) who found that treatment with potassium iodide revealed that 50% of the treated animals came in heat while 40% got pregnant. Also, Glotra, *et al.*, (1969) found that significant improvement in relation to heat appearance and pregnancy rate in buffaloes supplied by potassium iodide than in control.

**Health status of delivered calves:-**

As shown in Table (10) the control dams delivered only 4 calves because there was one case of abortion and one case of stillbirth, meanwhile, treated dams delivered 12 healthy calves. The calves from treated dams showed higher body weight, growth rate/day and better vitality in comparison with the control. Likewise, body weight and growth rate/day were higher in newly born calves from  $I_2$  than  $I_1$  and  $I_0$  groups. In addition, no mortality in the 1st month occurred between the newborn calves resulted from iodine treated buffaloes compared to the control group.

Moreover, the control calves showed more severe pneumonia and enteritis as a result of which

2 (33.33%) calves died. The present results support the other views (Mavi *et al.*, 2005) who found that, iodine treatment to late pregnant dams induced better state of reproductive and delivery with no retained placenta or stillbirth in comparison with the control group. The newly born calves were of heavier body weight, better healthy status and highly resistance to disease. The pre and post-partum supplementation with iodine improved the reproductive efficiency of Egyptian buffaloes (Sharawy *et al.*, 1987). Consequently, a high immunoglobulin-G concentration was observed in calves supplemented with iodine. Circulating IgG had been related to pre-weaning growth (Nocek, 1984) as well as long term performance of calves (Wittum, 1995), thus some commercial calf raisers will pay dairy producers a premium for providing calves with serum total protein that exceeds some critical threshold (usually >5.2 to 5.5 g of total protein/dl of serum). Others will reduce the amount they pay to the producer if total protein is too low. Although passive immunity has an important effect on calf health, there are a number of other factors that influence the overall cost of morbidity and mortality on a calf raising operation. These other factors include the level of exposure of calves and level of stress to which calves are exposed. Another critical control point during the calf's life is the first 24 hours. Consumption of colostrum is essential to provide animals with the antibodies and other proteins that calves need to stay

healthy. The amount of colostrum (and immunoglobulin, or IgG) consumed determines amount of passive immunity and resistance to disease. When calves consume insufficient amounts of IgG from colostrum within the first 24 hours of life, they are much more susceptible to developing disease and possibly dying. A major reason that pre-weaning mortality is higher than optimum (defined as less than 5% of calves born alive) is due to inadequate IgG intake (Quigley, 2005). Measuring a calf's level of passive immunity within the first week of life allows the producer to know the effectiveness of the colostrum management and calf feeding program. Because this is so important to the health and survival of the calf, it is an essential part of monitoring the overall heifer operation. However, the importance of achieving adequate levels of colostral immunoglobulins to protect the neonate from enteric disease and septicemia has long been recognized (Robinson, 1988).

#### 4. Conclusion

It could be recommended that using iodine supplementation at level (0.5 mg I per kg DM intake /h/d)) in female buffaloes ration tended to improve the digestion, nutritive values, immunity, milk production, milk composition and Reproductive parameters.

**Table (1).** The chemical composition of feed ingredients and the calculated composition of the Experimental rations.

Items	Chemical composition as DM basis (%)

# Integrated theoretical model to enhance neonatal screening for sickle hemoglobinopathies in the wake of predictive, preventive, personalized and participatory medicine

E. William Ebomoyi, Ph.D., Professor

Department of Health Studies, College of Health Sciences, Chicago State University, Chicago Illinois and he serves as a Consultant in International Health for the American Public Health Association, 9501 South King Drive, Douglas Hall 127, Chicago, Illinois 60628-1598, USA

[eebomoyi@csu.edu](mailto:eebomoyi@csu.edu), 773-995-2527

**ABSTRACT:** This study utilized the integrated theoretical model (ITM) to assess strategies to ameliorate screening for sickle hemoglobinopathies in the age of genomic medicine. Also discussed, is the relevance of predictive, preventive, personalized and participatory interventions. Comparison was made between universal and targeted screening. The international guidelines for neonatal screening were reiterated. The self-efficacy and empowerment of mothers is crucial in ensuring that they effectively participate in the treatment and follow-up of their new-born babies. We emphasized the compliance with the ethical, legal and social implications of newborn screening for genetic diseases.

**Keywords:** integrated theoretical model (ITM); ameliorate; sickle hemoglobinopathies; genomic medicine; neonatal screening; ethical; legal; social; genetic diseases

## Background

Sickle cell disease is a recessive hereditary disorder. "This disease involves the possession of two abnormal allelomorphic genes related to hemoglobin formation, at least one of which is the sickle cell gene, the genotypes constituting sickle disease being SS, Sc, S Thal, SE, SF 'high gene' and SD."(Konotey-Ahulu, 1974). Sickle cell is usually inherited in an autosomal recessive Mendelian pattern. The clinical abnormality caused by sickle cell anemia includes manifestations of severe pain, leg ulcers, and swellings of the joints, pains in the abdomen, arms, fatigue, and sometimes death. For pediatric age, splenic sequestration, sepsis and stroke are more common and carries a high mortality, whereas for adult cohort, eye disease and organ damage and pulmonary hypertension are quite frequent (Calloway, 1977).

The observable differences between sickle cell disease and sickle cell trait (SCT) were discovered 61 years ago. The differences lie in the quantity erythrocytes of sickle cell trait and sickle cell disease and the involvement of greater reduction in the partial pressure of oxygen which is required for a significant quantity of the trait to sickle than to sickle cell disease. In sickle cell trait, a person inherits one normal hemoglobin gene (A) from one parent and one abnormal gene (S) from the other parent. With regards to sickle cell disease two abnormal genes are inherited, one from each parent. Since sickle cell disease is a hereditary disorder, the specific mechanism for this genetic inheritance follows the Mendelian pattern (Kene, 1978).

Regarding hemoglobinopathies, these are conditions that affect the nature and proportion of hemoglobin which individuals have in their red blood cells. Hmoglobinopathies is the clinical term used to describe the presence of abnormal hemoglobin

production in the blood. Although sickle cell disease is the most common hemoglobinopathy in this century, and with innovations in genomic technologies, a litany, of sickle hemoglobinopathies will be genotyped and diagnosed. We reiterate that the success of the Human Genome Project (HGP) in mapping the entire human genome is a triumph comparable to the development of the theory of relativity, and it opened the door to a new branch of biomedical science, genomics. Genomics differs from the more established discipline of genetics in that it examines not only existing characteristics of the genome but also those related to the environment (haplotypes) and biological inheritance. In particular, genomics holds out the potential for early identification of disease and disease risk, preventive strategies, “personalized medicine” and pharmacology (Ebomoyi and Ebomoyi, 2010).

Against this background, the study described here was designed to explore adoption of integrated theoretical model to enhance screening for sickle hemoglobinopathies in the age of genomic medicine, define and accentuate the crucial nature of predictive, preventive, personalized and participatory treatment of patients, assess relevance of universal and targeted screening for sickle hemoglobinopathies, identify international guidelines for neonatal screening, succinctly discuss the ethical, legal, financial and social implications of neonatal screening; emphasizing the empowerment of women and the importance of trait counseling are valid primary preventive initiatives.

#### Integrated Theoretical Model

The two distinct models most applicable in neonatal screening for sickle hemoglobinopathies involve the integration of the Social Cognitive Theory (SCT) into the Health Belief Model (HBM)(Rosenstock,1974). The HBM hypothesizes that health-related actions depends upon individual's view of perceived susceptibility to a disease (X), such as sickle hemoglobinopathies particularly in a society where there is no premarital counseling. This situation is rampant in rural America, South America, Africa, South East Asia and the Mideast. The second issue is the belief that one is susceptible to a disease that is very severe. The classical symptoms of sickle hemoglobinopathies are many and varied. There are specific variants of sickle hemoglobinopathies that are life-threatening while very few variants confer mild distress on patients. At present, there is no known cure for sickle hemoglobinopathies (Ebomoyi, 2009).

The HBM also emphasizes the belief that compliance with health recommendation would be relevant in reducing the perceived threat. This process is dependent on both demographic and structural variables as education; that is, knowledge about the disease and prior contact with it. The cues to actions include mass media campaigns advice from others, illness of family members, magazine articles and reminder postcards from physicians (Maiman and Becker, 1974). Sickle hemoglobinopathies are quite rampant among people of African ancestry and this disease has a frequency of 1 in 8 African-Americans as carrier of the disease and 1 out of 400 carrying the autosomal recessive genes doubly homozygous (Ebomoyi, Cherry, 2010). The likelihood of complying with the recommended actions occurs once the perceived benefits of preventive actions outweigh the perceived barriers (Figure 1) Bandura (1977). (SCT) made two cogent contributions to the HBM. The first is emphasis on several sources of information for acquiring expectations particularly on the informative and motivational role of reinforcement and by observational learning through modeling. A second pertinent contribution is the introduction of the concept of self-efficacy; which means “the conviction that one can successfully execute the behavior required to produce the outcome.”(Bandura, 1977) This integrated model has been used for many screening activities involving genetic services, family health and planning and other behavioral health problems (Bandura, 1977).

In United States, neonatal screening for hemoglobinopathies has been well established in many of the urban tertiary health care centers. At present the screening for hemoglobinopathies occurs in 43 states and in the District of Columbia, Puerto Rico and the virgin island Screening is now well established by the State Department of Laboratory and Federally mandated Newborn screening program. Implementation occurs in the hospitals where all newborns are screened for hemoglobinopathies and other disorders. Annually, screening at States' level has identified over 2000 infants with sickle diseases and additional 50,000 newborn with sickle cell trait (Day et al; 1977). Once identified, children having the disease are automatically referred to their pediatrician of record or hematologist as identified by the State Newborn screening program. In Louisiana and many other states, a medical social worker develops a follow-up plan to encourage mothers of children with sickle cell to participate in health education activities to facilitate compliance with both prevention and other medical interventions.

With existing stringent budget, not many States have followed this intervention quite religiously. Day et al,(1977) remarked that national standard have not been established for follow-up of the neonates with the heterozygous condition. Besides, several factors contribute to the unsatisfactory counseling activities at state level because screening program have shoestring budget, and prompt identification and follow-up services for sickle cell patients is given low priority.<sup>12</sup> This statistics pinpoint that trait counseling and primary prevention against the sickling genes has not been intensified. Therefore, educated and affluent expectant mothers of African ancestry must utilize their self-efficacy and empowerment initiatives to encourage their counterparts to participate in neonatal screening and comply with routine medical regimen and demand that the program needs to be accorded higher priority. We must emphasize that among rural expectant mothers who use the services of traditional birth attendants, the benefits of neonatal screening could be ignored to the detriment of their newborns.

#### Predictive, Preventive, Personalized and Participatory Interventions

In the era genomic medicine these 4p's constitute precision medicine. According to Dr. Elias Zerhouni (2010), The former director of the National Institutes of Health(NIH), the new medicine must anticipate and interrupt the disease process, thereby preventing the patient from being overwhelmed by the actual disease burden. The Institute of System Medicine (ISM) (2010) defined (1) predictive approach as the development of probabilistic health projection for a person based on their DNA and protein expression. (2) preventive medicine is the creation of interventions or therapeutic that will prevent a disease that an individual is assessed to have a high probability of developing. Regarding sickle hemoglobinopathies, trait counseling of young adults of child-bearing age is one technique of making primary preventive strategy most effective. (3) Personalized medicine refers to treating individuals based on their unique human genetic variations. For example, what are their sequenced DNA and haplotype characteristics? (4) Participatory medicine implies a patient's active, informed involvement in their medical choices, treatment, and acting in partnership with their health care providers. Educated mothers of children who enroll their newborn in the neonatal screening program must ask pertinent questions about the various variances of hemoglobinopathies (FA, FAS, FS, FSC, FSA, FSD, FS OArab, FC, FAE). Questions such as the meaning of these variances of sickle

hemoglobopathies, what is the degree of severity of these diseases? At what age do the indeterminate cases become either a trait or disease? Clinically, at what time will FS convert either to SS or AS?

The mother must be able to confirm when her child can be placed on 250 milligram of oral penicillin, and what are the benefits and side effects of such prophylactic treatment and follow. Will her child be placed on this treatment plan throughout his or her pediatric age? What are the options for her regarding career choices, sporting activities and whether there could be any cognitive deficits in their newborn babies?

Many technological gadgets relevant to neonatal screening have been developed in recent times. Some of the developed technologies used to enhance personalized medical care were the 454 life sequences manufactured by Roche Diagnostics (Brandford, CT), chromatography and electrophoresis, gene amplification, capillary analysis, polymerase chain reaction tests, microarray sequencing, and iso-electric focusing. These state-of-the-science approaches and bioinformatic technologies have the potential to provide significant insights into disease manifestation in individual patients and clinical differences at the molecular level. Such knowledge will enable the physician to tailor treatment to the precise needs of patients.

DNA Vision (2010) recently created as increased technological portfolio by using next generation sequence FLX system (Roche) for genome shotgun sequencing, genome re-sequencing, transcriptome profiling and metagenomic and meta-transcriptomics. A comprehensive list of the state of the art technologies required to improve the dissemination of personalized health care services were compiled by Ebomoyi and Srinivasan (2008).

In the era of genomic medicine, the key benefits of predictive, preventive, personalized and participatory interventions to the patient include new abilities to:

- Detect disease at an earlier stage, when it is easier and less expensive to treat effectively
- Stratify patients into groups that enable the selections of optimal therapy
- Reduce adverse drug reactions by more effective early assessment of individual drug responses
- Improve the selection of new biochemical targets for drug discovery

- Reduce the time, cost, and failure rate of clinical trials for new therapies
- Shift the emphasis in medicine from reaction to prevention and from disease to wellness.<sup>17</sup>

Additional benefits of the HGP are the availability of extensive genetic map which has increased the pace by which different genes are localized in the human genome. Medical geneticists are now able to identify susceptible sections of the genome which could be responsible for many disorders as sickle cell.

#### Universal Screening

Recommendations on the issue of universal and targeted screening evolved out of an NIH Consensus Development Conference (1987), on Newborn Screening for Sickle Cell Disease and Related Hemoglobinopathies. The conference involved 400 biomedical scientists, clinicians, public health workers, parents and public representatives. From the “consensus statement” the panel recommended universal screening of all newborns for hemoglobinopathies. As enunciated by the expert panel, programs which focused their screening on specific high-risk segments of a population are fraught with missing people who are inaccurately registered. Owing to complacency among some providers, non-screening of at-risk individuals is encouraged. The Consensus panel cautioned that the health risks to children with sickle cell disease and related hemoglobinopathies are so grave that concerted efforts are required to identify and enlist every affected child. The panel therefore recommended “that most states adopt a policy of screening all newborns.”(NIH, 1987).

Many states in America have complied with the universal screening policy advocated by the consensus panel; the benefits can be appreciated from the experiences from Florida, Texas, New York and Georgia among others. The data elicited from the University of Miami/Jackson Memorial (UM/JM) Medical Center situated in a large multi-ethnic metropolitan area indicate that it is better to test all newborns for hemoglobinopathies. Because the investigators have consistently shown that it was common to find Hb S and Hb C in infants designated as White Hispanic. This study has revealed the imprecision of using the designation White or Black when screening for sickle cell disease. The need to include certain “White” populations in screening programs has become very important in situations where the possibility of detecting SCD is quite high.

#### Guidelines on neonatal screening

The guidelines recommended by the World Health Organization (2006), for most screening programs worldwide must meet a number of requirements before implementation:

- The condition in question should portray high prevalence
- The condition in question should impose a significant health and economic burden on the population
- The gene in question should be easily and inexpensively tested, the analytical validity of the test should justify screening(WHO, 2006)

#### Screening in the Age of Genomic Medicine

Newborn screening has become one of the nation’s most successful public health programs. Very well established screening centers now exist in the urban areas. However, an effective mechanism is needed to extend such services to rural areas. In centers with highly qualified medical geneticists, physicians have been able to sequence the DNA of sickle cell patients so as to determine the order of the base pairs on the globin gene of the patient with sickle cell disease and characterize how it differs from the other children without sickle cell.

In compliance with WHO (2006) guidelines, clinical epidemiologist, and Centers for Disease Control and Prevention scientists continue to advise medical laboratory technologists and the screening team to carry out inexpensive test with acceptable sensitivity and specificity. Sensitivity is when the technology indicates that the genetic disease is present, when it is actually present. Whereas, specificity is when the technology indicates the genetic disease is absent when in fact, the disease is not present in the newborn. In the first two to three months of birth there could be a few indeterminate cases of “FS”, “FA”. Sometimes, these few cases turn out to be cases of the heterozygous status of the sickling gene. One must encourage screening centers to accurately compile the results for scientific investigation and reporting.

Dr Francis Collins and others (2010) the current Director of the National Institutes of Health,

and the United States Department of Energy (2004), have cautioned clinicians and providers to be quite sensitive to analytic validity of a test, which focuses on the ability of the genetic test to measure accurately and reliably the genotype of interest. Clinical validity of a test assesses the ability of a procedure to detect or predict the presence or absence of a phenotype, clinical disease or predisposition for a disease. Clinical utility of a genetic test indicates the probability that the test will lead to an improved outcome for the patient. Screening for sickle hemoglobinopathies and other diseases in the United States major hospitals, in the wake of preventive, predictive, personalized and participatory medicine must take into cognizance the ethical, legal, financial and social implications of neonatal screening.

#### Health Education Implications Using the Integrated Model

The integrated model has all the relevant constructs to enable any expectant mother to participate in neonatal screening for sickle hemoglobinopathies. As people of African ancestry, there is the perceived susceptibility to sickle cell disease if one had not participated in premarital screening to ensure that one's partner does not have the trait for sickle cell. Since there is no known cure for the disease, the perceived seriousness of the diseases is quite authentic bearing in mind that the classical signs and symptoms of the diseases are life-threatening and costly to managed. Participation in screening is to enable people engage in primary preventive behaviors. The integration of the social cognitive theory into this model further augment the predictability of this model by insisting that we use persuasion and copious information and motivations to focus on one's self-efficacy to carry-out the preventive behavior. Therefore, among high school students of child-bearing age, health education intervention must reinforce counseling students about premarital genetic screening. Efforts must be devoted by educators to intensify trait counseling so as to reduce the frequency of the deleterious gens in the society. The education of women and their empowerment can be most useful in avoiding being impregnated by partners with the allele of any hemoglobinopathies.

#### The Ethical, Legal, Social Implications

With the availability of cutting edge biotechnology and genomic science, it is prudent to predict that genetic variation within the human genome can be characterized and genotyped for many ethnic groups. Through the use of molecular techniques, and genomic techniques scientists expect to detect increasing number of genetic diseases. Therefore, there is the urgent need to train more scientist with the capabilities to provided the relevant genomic services.

#### **Acknowledgement**

The information used in this study is a component of neonatal screening conducted with Professor Flora F Cherry (Retired) at the Tulane Medical Center, School of Public Health and Tropical medicine. I am very grateful to Dr. Cherry for serving as my preceptor and for her commitment to the success of our neonatal screening for sickle hemoglobinopathy in New Orleans Louisiana.

# Mixed Infection of Bovine Viral Diarrhea Virus, Mycoplasma Species and Mannheimia Haemolytica in Calves Showed Chronic Pneumonia with Reference to the Histopathological Findings of the Affected Lungs

Hanaa, A. Ghoneim\*, Naglaa, I. Hassan, Hanaa, A. Elhalawany and A.M.Nabih

Animal Reproduction Research institute (ARRI) Giza, Egypt

\*hanaeg2002@yahoo.com

**Abstract:** A total of 100 nasal swabs as well as blood samples were collected from 75 diseased calves suffered from respiratory manifestations and 25 apparently healthy calves of ages ranges from 2-12 month old from three herds. Also 80 clinically pneumonic lung specimens of slaughtered calves were collected from El-warak and El- moneeb abattoir. All were examined to establish the extent of involvement of Bovine Viral Diarrhea (BVDV), *Mycoplasma* species (M. spp.) and *Mannheimia haemolytica* (M. haemolytica) in cases of chronic calf pneumonia. On virological studies, AGPT and commercial ELISA kits were rapid and accurate tests for detection of BVDV antigen. BVDV was isolated on MDBK cell line from Buffy coat, nasal swabs collected from diseased calves and lung specimens. The isolated virus was identified by IFAT using reference antisera. Also 100 serum samples collected from diseased and apparently healthy calves were tested by VNT for the detection of neutralizing antibodies against BVDV. Moreover, on bacteriological investigation, *M. haemolytica* were recovered from lung specimens of slaughtered calves as well as nasal swabs of diseased ones and apparently healthy ones. The isolated strains were biotyped as biotype A (56 isolates, 80 %) and biotype T (14 isolates , 20 %). The resistance of the isolates to most antimicrobial agents was high to ceftiofur, nalidixic acid, gentamicin, oxytetracycline, and cephalexin. While they were highly sensitive to norfloxacin, ampicillin and erythromycin. Although, *Mycoplasma* species recovery rate from the examined nasal swabs of pneumonic calves was (46.67%) relatively higher than that recovered from apparently healthy calves (32.00%), the isolation rate from the examined lung tissues reached to (25.0%). The most prevalent isolated species was *M. bovis* followed by *M. dispar*, then glucose positive, arginine negative species. Considering the mixed infection, results showed that, simultaneous isolation of the three pathogens from nasopharyngeal swabs of the examined pneumonic calves was relatively high (12.00%), followed by simultaneous isolation of BVDV& *Mycoplasma* sp as well as *M. haemolytica* & *Mycoplasma* sp. (9.33%). On the other hand, there was simultaneous isolation of both BVDV and *M. haemolytica* from nasopharyngeal swabs of (8.00%) out of the examined pneumonic calves. Examination of 80 clinically pneumonic lung tissues of slaughtered calves that were collected from abattoirs revealed that, a high percentage (17.50%) of examined lung tissues colonized both *Mycoplasma* sp. and *M. haemolytica* together. On the other hand, simultaneous isolation of the three pathogens was detected in (3.75%). However, simultaneous isolation of both BVDV and *Mycoplasma* sp. as well as BVDV and *M. haemolytica* was recorded in (2.50%) of examined lung tissues. Regarding histological studies of lung tissue specimens, there were five types of pneumonia distinguished according to types of necrosis, and cellular infiltrations in relation to microbial isolation, Caseonecrotic bronchopneumonia, 3.75%, Fibrino-necrotizing bronchopneumonia 12.5% ,Acute and chronic fibrinosuppurative bronchopneumonia 13.75%. In conclusion *M. bovis* showed two necrotic patterns, where an original focus of coagulative necrosis evolves with time into caseous necrosis ended by fibrosis.

## 1. Introduction:

Bovine respiratory tract disease is a multifactorial disease complex and has been one of the most serious problems due to their high mortality and economic losses in calves. This respiratory

disease complex involving several viruses one of these is the bovine viral diarrhea virus. On the other hand, severe respiratory tract disease in cattle is associated with concurrent infections of viruses and bacteria which resulted in suppress the host immune

responses leading to the disease complex. The bacteria that play prominent roles in this diseases complex are *Mannheimia haemolytica* type A, *Mycoplasma* spp as *Mycoplasma bovis*, and *Mycoplasma dispar* ( Srikumaran et al., 2007). The occurrence and severity of pneumonia may depend on a series of complex interactions between infectious agents and stress factors as adverse climatic conditions, weaning, transportation, environmental factors and immunological status of the calf (Martin et al., 1982 and Kiropes et al., 1988). Certain BVDV strains can cause primary respiratory disease and mild respiratory disorder in calves (Archambault et al., 2000 and Baule et al., 2001). The clinical presentation varied according to the age of the affected animal ( Jacob et al.2010 ). A synergistic role of BVDV in bovine respiratory disease occur by increasing pathogenicity of both viral and bacterial concomitant infection; this has been attributed to immunosuppressive effects of BVDV on the host (Potgieter, 1997). The immune suppressive effect of acute BVDV infections is due to strong affinity of the virus for immune competent cells which may be destroyed or functionally impaired which enhance the clinical disease of other pathogens and play an important role in multiple infectious diseases (potgieter, 1997).

*Mycoplasma bovis*, *M. dispar*, *M.bovirhinis* and *Ureaplasma diversum* are four species of mycoplasma that have been established as being of importance as causes of pneumonia in housed calves, based on pathogenicity studies and frequency of association with the disease (Nishimoto and Yamamoto, 2002). *M.bovis* is responsible for at least a quarter to third of calf pneumonia (Nicholas and Ayling ( 2003 )). Moreover, Haines et al. (2001) reported an increase in cases of antibiotic-resistant pneumonia and fibrinous polyarthritis in which *M. bovis* and BVDV infection were frequently detected.In addition *M.bovis* is considered as an emerging cause of mortality in feedlot cattle and is associated with bronchopneumonia and arthritis (Gagea et al , 2006 b).

*Mycoplasma dispar* is regularly isolated from pneumonic calves but is also found causing mild superficial and asymptomatic infections of the respiratory mucosa (Howard and Taylor 1983). Moreover, it is a proven cause of pneumonia and has been reported in cases of mastitis and was isolated from the lungs and nasal cavities of pneumonic cattle (Muenster et al., 1979). Nishimoto and Yamamoto (2002) reported a case of respiratory mixed infection of *Mycoplasma dispar*, *Manheimia haemolytica* and *pasteurella multocida* of a calf with nine months age. They concluded that, *M. dispar* is presented as the causative agent for pneumonia.

It has been suggested that cattle with primary mycoplasmal infection undergo immunosuppression (Potgieter, 1995), which might predispose to secondary infection with virus or bacteria (Shahriar et al., 2002). Also, Howard et al. (1978) concluded that, mixed infections of mycoplasmas and other microorganisms certainly lead to enhanced disease.

Pneumonic pasteurellosis due to *Mannheimia haemolytica* is one of the most important disease complexes causing economic loss in the cattle feedlot industry. It is responsible for the largest cause of mortality in calves farms in Egypt. Shipping fever pneumonia of calves is precipitated by stress-inducing conditions such as shipping, viral infections, inhalation of diesel fumes and overcrowding Frank (1989). Moreover, stress also resulted in nasopharyngeal overgrowth of bacteria, including *M. haemolytica* which results in more bacteria reaching the lungs via inhalation of infected droplets. Cell proliferates under stressful conditions and are eroded in large numbers into lung alveoli, where they cause the disease (Frank, & Briggs. 1992). In addition, respiratory viruses can damage the ciliated epithelium (Andrews & Kennedy, 1997) and compromising the normal defense mechanisms these allowing *M.haemolytica* to colonize the lung. Several mechanisms have been proposed to explain the phenomenon of viral-bacterial synergism in respiratory infection. These include selection of pathogenic form of bacteria, reduced efficiency of lungs in clearing bacteria, depressed phagocytosis or bactericidal potential of alveolar macrophages, depression of ciliary activities and suppression of the immune response (Sharma et al., 1990).

The present study aimed to establish the extent of involvement of BVDV, Mycoplasma species and *M.haemolytica* in cases of chronic calf pneumonia. Also, to determine the most prevalent isolated causative agent from the nasopharyngeal specimens of the examined calves in affected herds as well as from the calves' pneumonic lung tissues that collected from abattoir. Furthermore, to throw light on the most pronounced histopathological findings of the affected lung tissues accompanied by each pathogen.

## 2. Materials and methods

### Animal and samples:

A total of 100 nasopharyngeal swabs were collected from calves of ages ranged from 2 up to12 months old, from which 75 calves were suffered from respiratory manifestations, recumbency, anorexia, abdominal respiration as well as from their closely contact apparently normal calves (25 calves) from three herds at El-kalubia governorate, Misr-

Alexandria road and at the 10<sup>th</sup> of Ramadan city as shown in table (1). The samples were collected during winter (November, up to April).

**Table (1): Number of examined pneumonic as well as closely contact apparently normal calves from the three examined herds**

Herd No.	Pneumonic calves	Closely contact normal calves	Total
<b>Herd 1</b>	35	12	47
<b>Herd 2</b>	22	7	29
<b>Herd 3</b>	18	6	24
<b>Total</b>	75	25	100

Two nasopharyngeal swabs were collected aseptically from each examined calf, one sample for *Mycoplasma species* isolation in sterile screw capped tubes containing enriched heart infusion (HN) broth as a transport medium. Another swab was collected on nutrient broth for *Mannheimia haemolytica* cultivation.

More over two blood samples were collected from each examined calf one for serum separation for serodiagnostic tests and the other sample on anticoagulant and the buffy coat were separated for virus isolation and identification. Also, two blood films were freshly prepared from each examined calf for diagnosis of *Mannheimia haemolytica*. On the other hand, 80 clinically pneumonic lung tissue specimens of slaughtered calves were collected from El-warak and El-moneeb abattoirs, the gross pathological lesions were recorded and representative portions from each pneumonic lung were chosen. Lung tissue specimens were immediately immersed in 10% neutral buffered formalin solution meanwhile the other samples were packed individually in plastic bags and transferred directly to the laboratory in thermos tank with ice packs for virological, mycoplasmal and bacteriological examination. At the laboratory, the naked eye examination of the collected lungs were recorded, and a loopful of deep lung tissues after burning of its surface by very hot spatula were cultured on enriched heart infusion (HN) broth and subsequently on its corresponding agar plates for *Mycoplasma species* isolation, another loopful was inoculated in brain heart infusion agar supplemented with 5% defibrinated sheep blood, blood agar and macconkey agar for *Mannheimia haemolytica* cultivation.

#### Virological examination:

Agar gel precipitation test (AGPT) according to Hanel (1993). Samples (Buffy coat, nasal swabs and

lung tissues) were tested against standard reference positive hyper immune sera, the agar was used in concentration 1% in PBS and reaction was incubated for 24-48 h at 37°C in Co<sub>2</sub> incubator and examined for the presence of precipitin line.

#### Institute pourquier ELISA kits:

These kits were used for detection of NSP2-3 of the bovine virus diarrhea/ mucosal disease virus (BVDV).

#### Inter predation of the results:

Calculate for each sample the S/P ratio (in %) S/P = OD of sample – OD of negative control/of positive control – OD of negative control X 10 if sample S/P % < or = 25% are considered to be from animals that are not carrier to BVDV. If sample S/P % is between 25 %-30% are considered to be doubtful. If sample S/P % = or > 30% are considered from animals carrier to the BVDV.

#### 3- Cell culture:

Continues cell line of median Darby Bovine kidney cells (MDBK) was used for trials for isolation and propagation of BVDV from (Buffy coat, nasal swabs and lung tissues) which was positive in ELISA test. And also used in virus neutralization test, the cell proved to be free from non-cytopathic strains of BVDV. Monolayer cell line was grown in Eagles MEM supplemented with 10% fetal calf serum. The cell was obtained from virology department Animal Health Research Institute (AHRI). The collected samples after preparation were subjected for virus isolation via propagation on MDBK cell line according to the method described by Clark et al., (1984). Inoculated cells were incubated at 37 °C and were examined daily for 5 days post incubation for three successive blind passages, CPE changes being to appear at the fourth passage.

#### 4- Indirect immuno fluorescent technique (Indirect IFAT):

The (IFAT) was used on the inoculated cell culture with cytopathic effect (CPE) to identify the (cp BVDV), it was used also on inoculated cell culture without CPE to detect (ncp BVDV). The indirect IFAT was carried out according to OIE standers (1992).

#### 5- Enzyme conjugates:

Anti-bovine fluorescence isothiocyanate conjugate was supplied by Sigma immune chemicals used in IFAT.

#### Reference positive immune sera:

Standard reference positive bovine hyper-immune serum of BVDV was supplied by virology department AHRI.

#### 7- Virus neutralization test:

It was conducted for detection of specific BVDV neutralizing antibodies in cattle serum samples according to OIE (2004).

#### Isolation and Identification of Mycoplasma species:

The aseptically collected nasal swabs were cultured onto enriched heart infusion (HN) broth and then streaked onto the corresponding agar medium which prepared as described by Freundt (1983) for Mycoplasma species isolation. Naked eye examination of the collected lung tissue specimens were recorded, and a deep part of each lung tissue was cut into small pieces (1mm thick.), inoculated immediately in HN broth medium and shaken with a vortex. Three 10-fold dilutions were made according to the method described by Taoudi et al., (1985) and a loopful of each sample was streaked onto agar plates. All the plates were incubated at 37°C in a humid jar, under 10% CO<sub>2</sub> tension for 72 hours.

#### Identification of Mycoplasma isolates:

Genus determination: was performed using digitonin sensitivity test according to Freundt et al., (1973).

Biochemical characterization: The isolates were biochemically identified by glucose fermentation test as described by Erno and Stipkovits, (1973) and arginine hydrolysis according to Barile (1983).

Serological identification: It was carried out by growth inhibition (GI) test according to Clyde, (1964). The isolates were serologically examined against rabbit antisera of Mycoplasma bovis, M.bovigenitalium and M. dispar.

Serological test: Serum samples from all examined calves were tested for the presence of M.bovis or M.dispar antibodies by indirect haemagglutination (IHA) test according to Cho et al., (1976). The results were interpreted

#### Bacterial isolation and identification.

#### Cultural and biochemical identification:

Nasal swabs which immersed in nutrient broth and a loopful of deep lung tissues after burning of its surface by very hot spatula were cultured on brain heart infusion agar supplemented with 5% defibrinated sheep blood, blood agar and Macconkey agar. Plates were incubated at 37°C for 24 hours (Kodjo, et al. 1999). Bacterial identification was assessed by:

#### **The observation of the colonial morphology**

Gram staining and biochemical identification includes oxidase, catalase, urease tests, triple sugar iron agar, motility tests and indol tests (Atlas, 1997; Baily and Scotts, 1998 and Topley and Wilson, 1998).

#### Blood films Staining:

The freshly prepared blood films from examined calves were stained with Leishman stain and examined under oil immersion lens for detection of Gram-ve bipolar bacilli.

#### Biotyping of isolated M.haemolytica:

Biotyping of isolated M.haemolytica was applied depending on L-arabinose, trehalose, D-xylose, lactose and salicine fermentation tests (Biberstein et al., 1990).

#### Antimicrobial susceptibility test (Sensitivity test):

The susceptibilities of isolates to antimicrobial agents were determined by using the disk diffusion method according to the NCCLS Guidelines (2002). The antimicrobial disk used are Ampicillin, Amikacin, Ceftiofur, Cephaloridine, Cephalexin, Erythromycin, Norfloxacin, Oxytetracycline, Pencillin G, Streptomycin and Nalidixic acid.

#### Pathological examination:

Pneumonic lung specimens were taken immediately from the slaughtered calves and immersed in 10 % formalin. The fixed specimens were trimmed, washed and dehydrated in ascending grades of alcohol, cleared in xylene, embedded in paraffin. The embedded samples were sectioned at 3–5 µm thickness, stained with Haematoxylin-Eosin stain and, when necessary, with special stain (Giemsa stain and Periodic acid schiff (PAS) (Bancroft and Marilyn, 2002). The slides were examined using light microscope.

#### **3. Results and Discussion:**

##### Virological results and discussion:

As shown in table (2) the Buffy coat of pneumonic calves showed higher percentage of viral detection by ELISA test (92.00 %) than by AGPT (36.00 %). Also, detection of BVDV from nasal swabs by ELISA test (76.00 %) was higher than AGPT (25.33 %). Although, BVDV could not be detected by AGPT either in the buffy coat and nasal swabs of apparently healthy calves, the virus was detected in small numbers by ELISA test in buffy coat and nasal swabs (4.00 % and 12.00 % respectively). While BVDV was detected in lung tissues in higher percentage by ELISA test (25.00 %) than by AGPT (6.25 %).

In this study AGPT was used as a simple and rapid method for BVDV or antigen detection in collected samples (, nasal swabs and lungs) which reported by (Hanel, 1993; Hosny et al., 1996 and Nahed et al., 2004). Results of AGPT are low if compared with other tests due to the low sensitivity of the test or type of sample collection. Commercial Pourquier ELISA kit (antigen capture ELISA) gave rapid and accurate detection of BVDV antigen in the same original samples.

An antigen capture ELISA was developed and proved its specificity, sensitivity and accuracy (Gottschalk et al., 1992). Also, (Donis, 1995 reported that antigen detection ELISA for BVDV was usefully mainly in confirming enteric, respiratory and reproductive diseases. Many authors described the

importance of ELISA in testing program of animals BVDV (Sandvik et al., 1997 and Ferrari et al., 1999).

ELISA test was improved by the use of monoclonal antibodies which were specific to BVD viral proteins and we could detect most if not all BVDV strains (Sandvik, 1999) . In our study we use kits with specific monoclonal antibodies directed to NSP2-3 (NSP-3 associated with lytic activity of the cytopathic strain) which increased the application of ELISA for detection of BVDV strains and offered sensitivity equivalent or higher than virus isolation, this also recorded by (Ferrari et al. 1999; Cavirani et al., 2000 and OIE2000). Also, Aymen, (2002) proved that commercial ELISA kits are valuable in antigen detection.

**Table (2): Comparison AGPT and ELISA test for detection of BVD antigen in the diseased, apparently healthy and slaughtered calves.**

State of animal	Sample tested		+ve by AGPT (%)	+ ve by ELISA (%)
	Type	No .of samples		
<b>Diseased Calves</b>	Buffy Coat	75	27 (36.00%)	69 (92.00%)
	Nasal swabs	75	19 (25.33%)	57 ( 76.00%)
<b>Apparently healthy calves</b>	Buffy Coat	25	0 (0.00%)	1 (4.00%)
	Nasal swabs	25	0 (0.00%)	3 (12.00%)
<b>Slaughtered calves</b>	Lung tissues	80	5 (6.25%)	20 (25.00%)

**Table (3): Isolation and identification of BVDV from diseased, apparently healthy and slaughtered animals which were positive by ELISA test.**

State of animal	Sample tested		No. of samples with CPE	Virus identification by IFAT
	Type	No.		
<b>Diseased calves( 75 )</b>	Buffy Coat	69	24 (34.78%)	24 (34.78%)
	Nasal swabs	57	19 (33.33%)	13 (22.81%)
<b>Apparently healthy calves</b>	Buffy Coat	1	0 (0.00%)	0 (0.00%)
	Nasal swabs	5	0 (0.00%)	0 (0.00%)
<b>Slaughtered calves (80)</b>	Lung tissues	20	10 (50.00%)	7 (35.00%)

Table (3) represented the isolation of BVDV from samples positive by ELISA, out of 150 samples, 53 (35.3 %) gave signs of CPE for BVDV on the cell. These samples were then subjected for identification by indirect immunofluorescent technique (IFAT) to detect non- cytopathic BVDV, where 44 (29.3 %) were positive results (Fig. 1). MDBK cell line is considered the most common cell culture system for

virus isolation and propagation (Allam, 2000). In the present study, MDBK cells were used for three successive blind passages for samples positive by ELISA,. These samples were then subjected for identification by indirect immunofluorescent technique (IFAT) to detect non- cytopathic BVDV, where 24 (26.5%) were positive results in table (3). Edwards, (1990) and Brock (1991) reported that the

conventional diagnosis of Pestivirus is based on direct detection of the virus in the clinical samples by using cell culture method followed by immunofluorescence. Also, reported that accurate diagnosis of BVDV infection depend upon isolating the virus from blood or nasal swabs or tissue samples from affected animals in diagnostic laboratory which agrees with our results (Haines et al., 1992; Abd- El Rahim and Grunder, 1996).

The virus multiplication was detected by immunofluorescent technique that revealed diffuse or granular intracytoplasmic fluorescence in infected cells, also IFAT was used for identification of BVDV cell culture (Munoz et al., 1996; Tsuboi and Imada, 1999 and Zabal et al., 2000). the samples positive by ELISA kits and did not isolate or identify by IFAT may be due to BVDV present in those negative samples FA complexes with antibodies rendered it non infectious for cell cultures ( Palfiet et al., 1993 ). Improper handling or storage of the samples,

instability BVDV, Also ELISA can detect both BVDV and antigen.

BVDV specific antibodies in apparently healthy and diseased animals in serum samples by using VNT were shown in table ( 4 ) which revealed that , 50 serum samples ( 66.7 % ) were positive in titer range ( 1/8- 1/64 ) while 5 serum samples ( 20 %) of the apparently healthy animals were positive in a titer ( 1/4 – 1/16 ).

Serological examination of serum samples applied for detecting antibodies specific to BVDV is a useful tool for herd screening and BVDV prevalence and monitoring BVDV free herd status (Houe et al., 1995) VNT was carried out of detection of specific neutralizing antibodies for BVDV in both diseased and apparently healthy animals. Antibody tests were useful in assessing the status of animal groups as a part of disease control. VNT is the most common serologic test used as a reference method for BVDV tests (OIE, 2004).

**Table (4): Results of BVDV specific antibodies in apparently healthy and diseased calves in serum samples by VNT.**

State of animal	No. of tested sera	No. of +ve	% of +ve	Average titer
Diseased calves	75	50	66.7%	1/8-1/64
Apparently healthy calves	25	5	20%	1/4-1/16
Total No.	100	55	55%	

#### Mycoplasma results and discussion:

Several species of *Mycoplasma* may be isolated from calves with pneumonia, but only a few of these species are considered pathogenic. Respiratory pathogenic *Mycoplasma* spp. include *M. dispar*, *M. bovis*, *M. bovirhinus*, *M. bovigenitalium*, *Ureaplasma diversum*. As shown in Table (6) ,*Mycoplasma* species recovery rate from examined nasal swabs of pneumonic calves were (46.67%)

relatively higher than that recovered from apparently healthy calves (32.00%). ter-Laak et al. (1992) isolated *M.bovis* from 20% of pneumonic lungs from fattening calves but only from a small number of apparently healthy calves. Tschoop et al. (2001) confirmed the importance of *M.bovis* as an agent of respiratory disease where 50% of 400 calves introduced to infected fattening sites developed respiratory disease attributable to *M.bovis*.

**Table (5): Recovery rate and the Identified *Mycoplasma* species from examined pneumonic as well as apparently healthy calves and lung tissues**

samples	No. examined	No. +veMycoplasma (%)	Identified sp. No. (%)

Recovered <i>Mycoplasma</i> sp. (%)	IHA antibodies ( $\geq 1/160$ )	Recovered <i>Mycoplasma</i> sp. (%)	IHA antibodies ( $\geq 1/160$ )
<b><i>M. bovis</i> 23/75(30.67%)</b> <b><i>M. dispar</i> 7/75 (9.33%)</b>	<b><i>M. bovis</i> 30/75(40.00%)</b> <b><i>M. dispar</i> 9/75(12.00%)</b>	<b><i>M. bovis</i> 5/25(20.00%)</b> <b><i>M. dispar</i> 2/25 (8.0%)</b>	<b><i>M. bovis</i> 4/25 (16.0%)</b> <b><i>M. dispar</i> 3/25 (12.00%)</b>

Serological identification of the thirty five mycoplasma isolates that were obtained from the examined pneumonic calves by growth inhibition (GI) test revealed that the most prevalent isolated species was *M. bovis* (65.71%) followed by *M. dispar* (20.00%). These results were nearly similar to that reported by Gagea *et al.* (2006a, b) who isolated *M. bovis* in a rate of 82%. Haines *et al.* (2001) detected *M. bovis* in the lungs and joints of feedlot cattle with chronic pneumonia and arthritis. They suggested that *M. bovis* should be considered as a principal pathogen in chronic unresponsive pneumonia of feedlot cattle. Unfortunately, a total of 5 isolates (14.29%) couldn't be serologically identified and showed biochemical reactivity as glucose positive and arginine negative which may be *M. bovirhinis* or *M. bovoculi*.

In the present study, only 7 isolates out of 35 mycoplasma isolates from the examined pneumonic calves were identified as *M. dispar* (20.00%). Bitsch *et al* (1976) isolated *M. dispar* from pneumonic calf lungs in a higher percentage 56%. Moreover, Shahriar *et al.* (2002) isolated *M. bovis*, *M. dispar* *M. arginini*, *M. bovirhinis*, BVDV, *Haemophilus somnus* and *pasteurella multocida* from the lungs of calves with chronic pneumonia.

On the other hand, the recovered *Mycoplasma species* from the apparently normal calves were only 8 isolates. The most prevalent identified species was *M. bovis* (62.50%), followed by 2 isolates (25.00%) as *M. dispar*. The least identified sp. (12.50%) was glucose positive and arginine negative. Mycoplasma *dispar* is a proven cause of pneumonia and has been reported in cases of mastitis but can be isolated from the lungs and nasal cavities of healthy and pneumonic cattle (Øystein *et al.*, 2009),

Mycoplasma species could be isolated from 20 out of 80 examined lungs in a percentage of (25.0%). These results were coincides with the findings of Byrne *et al.* (2001) who isolated *M. bovis* with ranges from 13 to 25% of pneumonic lungs of dairy and fattening herds and from 30% of calf herds with pneumonia. Also, with the results of Tend *et al.* (2004) who screened 34 cattle for the presence of

*Mycoplasma species* and reported that the recovery rate of *M. bovis* was 25.2 %.

In the present study, a total of 20 mycoplasma isolates were obtained from examined lung tissues. The most prevalent identified species was *M. bovis* (70.0%) followed by *M. dispar* (20.0%) and the least recovered isolate was glucose +ve and arginine negative (10.0%). This result supported by the conclusion of Nicholas *et al.*, (2000) where *M. bovis* is a major component of calf pneumonia complex. Moreover, stated that, over a third of lungs were infected with *M. bovis* while the rest contained a combination of *M. bovis* with *P. multocida* and /or *H. somnus*. Also, an alteration in the lungs were chiefly due to mycoplasma infection and the remaining bacteria contributing to complications in the pneumonic process Buchvarova and Vesselinova (1989). *M. dispar* was isolated from pneumonic calf lungs (Gourlay and Leach, 1970), which had cytopathic effect on bovine fetal tracheal organ cultures Thomas *et al.*, (1986).

Serum samples were examined by IHA test for the presence of *M. bovis* or *M. dispar* antibodies ,n= number of examined calves

As shown in table (6) showed that, the indirect haemagglutinating *M. bovis* antibodies( $\geq 1/160$ ) were detected in the blood serum of (40.00%) of pneumonic calves higher than the recovery rate (30.67%). While the blood serum of (12.00%) of the examined pneumonic calves showed high titer ( $\geq 1/160$ ) against *M. dispar*, the recovery rate of the organism from their nasal swabs reached to 9.33%. Gagea *et al.*, (2006 b) explained these findings that cases with specific antimycoplasmal antibodies in their serum but negative by mycoplasmal isolation represented acute or primary infection. Sachse *et al.* (1993) stated that the variation between mycoplasma isolation and serological response may refer to the stage or duration of infection. Pfutzner and Schimmel (1985) explained this finding that, *M. bovis* was transmitted from mastitic cows to their calves, infected their respiratory system and remained viable and infective up to sexual maturity when it could be isolated from their genital tract. Nicholas et al (2000) stated that using both mycoplasma isolation and

serological detection of the specific antibodies against the isolated species concurrently is expected to maximize the diagnosis of mycoplasma. Nicholas and Ayling, 2003 added that, serological detection of *M. bovis* antibodies is often a more reliable diagnostic method as the antibody levels remain high for many months. They concluded that the presence of specific antibodies indicates that the infection is invasive.

Considering the closely contact apparently normal calves, the results showed that, while the recovery rate of *M. bovis* from their nasal swabs reached to 20.0%, the detection of *M. bovis* antibodies in their blood sera was relatively lower (16.0%). In the present study, the detected IHA antibodies in the blood serum of apparently normal calves may be due to maternal immunity or latent infection due to the close contact with the diseased calves. This finding was discussed previously by Gagea *et al.* (2006b) who stated that, *Mycoplasmas* can be introduced in a herd by subclinical *Mycoplasma* carriers. These cattle shed the organism through nasal discharge for months to years without showing clinical signs. This finding is coincides with that of Jasper 1977) who stated that, in mycoplasma infected herds, it is usually to find animals have titer against mycoplasma in their serum without any history of illness. These animals may acquire partial immunity from prior exposure to mycoplasma infection. Moreover, Justice *et al* (2010) stated that, one of the currently documented routes of transmission of *Mycoplasma* spp. is through direct animal contact.

On the other hand, *M. dispar* specific antibodies were detected in the blood sera of (12.00%) out of the examined apparently healthy calves, whereas the organism was recovered from only 8.00% of their nasal swabs. Cho *et al.* (1976) observed that IHA results provided a more accurate diagnosis of

Mycoplasma herd infection than culture isolation and/or growth inhibition. They added that, IHA test is considered sensitive, reliable and highly specific and the titers were high in the infected or previously infected animals compared with the recently infected animals which may not show any titer. Nicholas and Ayling, 2003 added that, serological detection of *M. bovis* antibody is a true choice when antibiotics have been used extensively on examined herds. They stated that, animals in which *M. bovis* or *M. dispar* found only in the nasal passages without clinical symptoms were rarely seroconverting. Jurmanova *et al.* (1982) and Uhua *et al.* 1990) stated that the isolation of mycoplasma species from the prepuce of bull or vagina of cows without clinically apparent disease, usually didn't lead to high antibody titer in their blood sera perhaps as a result of superficial localization of the o

#### Bacteriological results and discussion :-

*Mannheimia haemolytica* (M.heamolytica) is a gram negative coccobacilli, non-motile, non-spore forming, facultative anaerobe from the family *Pasteurellaceae*. It is a normal inhabitant of the nasopharynx of healthy animals, but it is not a normal inhabitant of the bovine lung (Abdullah *et al.*, 1992 and Rice *et al.*, 2008). As shown in table (7), 29 *M.haemolytica* (38.60%) were isolated from 75 diseased calves and 37 (46.30%) isolated from 80 lung tissues of slaughtered calves hile only 4 isolates were detected from 25 apparently healthy calves (16%), under certain predisposing factors as shipping, rearing, transportation, overcrowding, mycoplasma infection and viral infection, *M.heamolytica* may shifting from being commensally to pathogen form (Confer *et al.*, 1995).

**Table ( 7 ) : Occurrence of *M.haemolytica* isolates in diseased , apparently healthy and slaughtered calves.**

State of animals	Type of samples	Total No. of sample	No. of +ve	% of +ve
Diseased calves	Nasal swabs& Blood films	75	29	38.60%
Apparently healthy calves	Nasal swabs& Blood films	25	4	16 .00%
slaughtered calves	Lung tissues	80	37	46.3%
<b>Total</b>		180	70	38.89 %

As shown in table ( 8 ), Fifty six ( 80 % ) of the isolated *M.haemolytica* were biotyped as biotype A and 14 *M.haemolytica* ( 20 % ) were biotyped as biotype T table ( 8 ) . These results revealed that *M.haemolytica* biotype A was the most frequently associated with shipping fever, adisease of beef

cattle, which characterized by fibrinous pleuropnemonia , the same results were reported by Ewer *et al.*2004 and Ilhan and Keles,2007 )

As shown in table (9), Antimicrobial susceptibility tests revealed that most of *M. haemolytica* biotype A was highly sensitive to

norfloxacin followed by ampicilline and erythromycin (75%, 65%, and 60% respectively) and highly resistant to ceftiofur, nalidixic acid, gentamicin, oxytetracycline, and streptomycin (90%, 85%, 75%, 65%, and 60% respectively). On the other hand most of *M. haemolytica* biotype T was highly sensitive to norfloxacin and erythromycin (92.86%, 71.43% respectively) and highly resistant to cephalaxin, nalidixic acid, oxytetracycline, and

streptomycin (85.71%, 78.57%, 64.29% and 64.29% respectively). These results were nearly similar to that mentioned by Esaki et al. (2005) and catry et al. (2005), and disagree with Mevius and Hartman (000) and Berge et al. (2006). The differences between our results and others may be attributed to many factors: misusing of antibiotics, individual physiological variation and differences in pathogenicity of the isolates and geographical localities.

**Table (8): Biotyping of isolated *M. haemolytica***

No. of total <i>M. haemolytica</i> isolated	Biotype A		Biotype T	
	No.	%	No.	%
70	56	80	14	20

Mixed infection of *BVDV*, *M. haemolytica* and *Mycoplasma species*

As shown in table (10), simultaneous isolation of the three pathogens from nasopharyngeal swabs of the examined pneumonic calves was relatively high (12.00%), followed by simultaneous isolation of *BVDV* &*Mycoplasma sp* as well as *M. haemolytica* and *Mycoplasma sp.* (9.33%). On the other hand, there was simultaneous isolation of both *BVDV* and *M. haemolytica* from nasopharyngeal swabs of (8.00%) out of the examined pneumonic calves. The present isolation data of *Mycoplasma species* from examined herds based on the previous isolation of mycoplasma from these herds which may indicate that chronic mycoplasmal infection may predispose the animals to infection by other pathogens. This explanation coincides with that of (Howard et al. (1978) who stated that, the immunosuppression resulted from mycoplasmal infection enhanced the susceptibility of the animal to infection

with other microorganisms. They added that mixed infection of mycoplasmas and other microorganisms certainly lead to enhanced disease. Additionally, Shahriar et al. (2002) reported co-infection with *BVDV* and *M. bovis* in feedlot cattle with chronic pneumonia. They concluded that cattle with primary mycoplasmal infection undergo immunosuppression which might predispose to secondary infection with other pathogens. They suggested that the synergism between *Mycoplasma* and other agents may complicate the disease condition. On the other hand, Trautwein et al. (2002) concluded that mycoplasmal infection may be able at least to exacerbate a disease condition that is probably initiated by other pathogen. Although the source of respiratory viral infection is not always obvious. It is likely that a proportion of calves acquired infection from their dams early in life. Haines et al. (2001) reported that *M. bovis* was detected in the lungs and joints of 80% of cases, while *BVDV* and *M. haemolytica* in 40 and 23%

respectively of these cases. Significant antibody titer to *M. bovis* were detected in half of 55 pneumonic examined, of which only 7 had rising titer to viral pathogens as bovine viral diarrhea virus (Nicholas and Ayling, 2003). However, *Mycoplasma sp.* only were recovered in a higher percentage (16.00%) than

the isolation rate of *M. haemolytica* only (9.33%) and the least recovered pathogen was BVDV only (2.67%). *Mycoplasma* infection might persist than other bacterial infection because many strains are resistant to antibiotics commonly used in the treatment of pneumonia (Thomas *et al.*, 2003).

**Table (10): Simultaneous recovery of BVDV, *M. haemolytica* and *Mycoplasma species* from examined nasopharyngeal swabs and lung tissues**

Infectious agent	State of calf		Lung tissues
	Diseased n= 75	Apparently normal n=25	n=80
BVDV only No.(%)	2 (2.67%)	0(0.00%)	0(0.00%)
<i>Mycoplasma sp.</i> Only No.(%)	12(16.0%)	5(20.0%)	1(1.25%)
<i>M. haemolytica</i> only No.(%)	7 (9.33%)	1(4.0%)	18(22.50%)
BVDV & <i>Mycoplasma sp.</i> No.(%)	7(9.33%)	0(0.00%)	2(2.50%)
BVDV & <i>M. haemolytica</i> No.(%)	6(8.00%)	0(0.00%)	2(2.50%)
<i>Mycoplasma sp.</i> & <i>M. haemolytica</i> No. (%)	7(9.33%)	3(12.00%)	14(17.50%)
BVDV& <i>Mycoplasma sp.</i> & <i>M. haemolytica</i> No. (%)	9(12.00%)	0(0.00%)	3(3.75%)

Regarding the closely contact apparently normal calves, there was simultaneous isolation of *Mycoplasma sp.* and *M. haemolytica* detected in (12.00%) of examined samples. Mixed infections of *M. dispar* and *M. haemolytica* have been demonstrated in field cases of calf pneumonia (George, St. *et al.*, 1973; Fatma *et al* (2008)). The frequent association of *M. bovis* infection with *M. haemolytica* or *P. multocida*, singly or in combination, suggests synergism between these pathogens (Gagea *et al.*, 2006a and Max ,2007). They added that *M. bovis* might colonize and perpetuate the lung lesions that were initiated by *M. haemolytica* or *P. multocida*, even if infection with these pasteurellaceae are cured by antibiotic therapy and host immunoinflammatory response Robert *et al* ( 2000 ).

On the other hand, the isolation pattern of each pathogen alone revealed that, while the *Mycoplasma sp.* could be detected in a higher percentage (20.0%) than the recovery rate of *M. haemolytica* (4.00%), BVDV couldn't be isolated from all examined apparently normal calves either alone or in combination with other pathogen.

Examination of 80 clinically pneumonic lung tissues of slaughtered calves that were collected from abattoirs revealed that, a high percentage (17.50%) of examined lung tissues colonized both *Mycoplasma sp.* and *M. haemolytica* together. This result coincides with the findings of Gagea *et al.* (2006a). On the other hand, Simultaneous isolation of the three pathogens together was detected in (3.75%) of examined lung tissues. However, simultaneous isolation of both BVDV and *Mycoplasma sp.* as well

as BVDV and *M. haemolytica* was recorded in (2.50%) of examined lung tissues. Shahriar *et al.* (2002) could detect *M. bovis* and BVDV antigens by immunohistochemical (IHC) staining in the lung tissues of calves with chronic Pneumonia in a percentage of 91% and 44% respectively. At the level of isolation of each pathogen alone from the examined lung tissues, the results revealed that, while *M. haemolytica* was recovered in a higher percentage (22.50%) than the recovery rate of *Mycoplasma sp.* only (1.25%), BVDV couldn't be recovered alone.

#### Pathological results & discussion:

Pneumonia is a major cause of death and economic losses to the calves industry. Recognizing the patterns of pneumonic lesions of the various types of pneumonia is important for correct diagnosis and interpretation of the lesions (Roger & Anthon, 2010). Bovine atypical interstitial pneumonia (AIP) is a multifaceted disease. It often complicated with bacterial, viral, or mycoplasmal organisms, Alan, (2010). In this work we studied the pneumonic lesions in naturally occurring bovine viral diarrhea virus (BVDV) associated bronchopneumonia and the relationship of this condition with mycoplasma spp. infection and *M. haemolytica*. Five types of pneumonia were distinguished according to etiological agents associated with (BVDV), either single or multiple they were:

#### 1-Caseonecrotic bronchopneumonia:

Represented 3.75% of tissue samples (3 of 80). Isolated organisms where as shown in table (12)

*Mycoplasma bovis* (*M.bovis*) mixed with (BVDV) with Sever ++++

**Table (11) Results of histopathological Examination demonstrate types, and percentages of pneumonia in the examined pneumonic lung tissues:**

Mixed pneumonia				Non mixed	
Type of pneumonia	Caseonecrotic bronchopneumonia	Fibrinonecrotizing bronchopneumonia	Acute and chronic fibrinosuppurative bronchopneumonia:	Interstitial pleuro-pneumonia	Serofibrinous pleuro-pneumonia
Isolated organisms	<i>M.bovis</i> ,& BVDV	<i>M.heamolytica</i> & BVDV	<i>M.dispar</i> &, <i>M.heamolytica</i> & BVDV	<i>M.bovis</i>	<i>M.heamolytica</i>
Degree.	Sever ++++	Less sever +++	Moderate ++		
No. of cases	3/80	2/80	2/80      9/80 without BVDV	6/80	25/80
%	3.75%	2.50%	2.50 %      11.25%	7.50%	31.25%

#### Gross lesions:

Dark red patches with interstitial edema and emphysema. In two cases there was multifocal sequestral formation in the form of circular, raised yellow foci of dry friable, caseous material. The intervening tissue in these areas was atelectatic. There was accumulation of fibrin on the pleural surface. Previous findings observed were nearly similar to those observed by Gagea *et al* (2006 b), and coincide with those observed by Jones *et al*. (1997); Calvin *et al.* (2008); Radaelli *et al.* (2009) and Fulton *et al.* 2009)

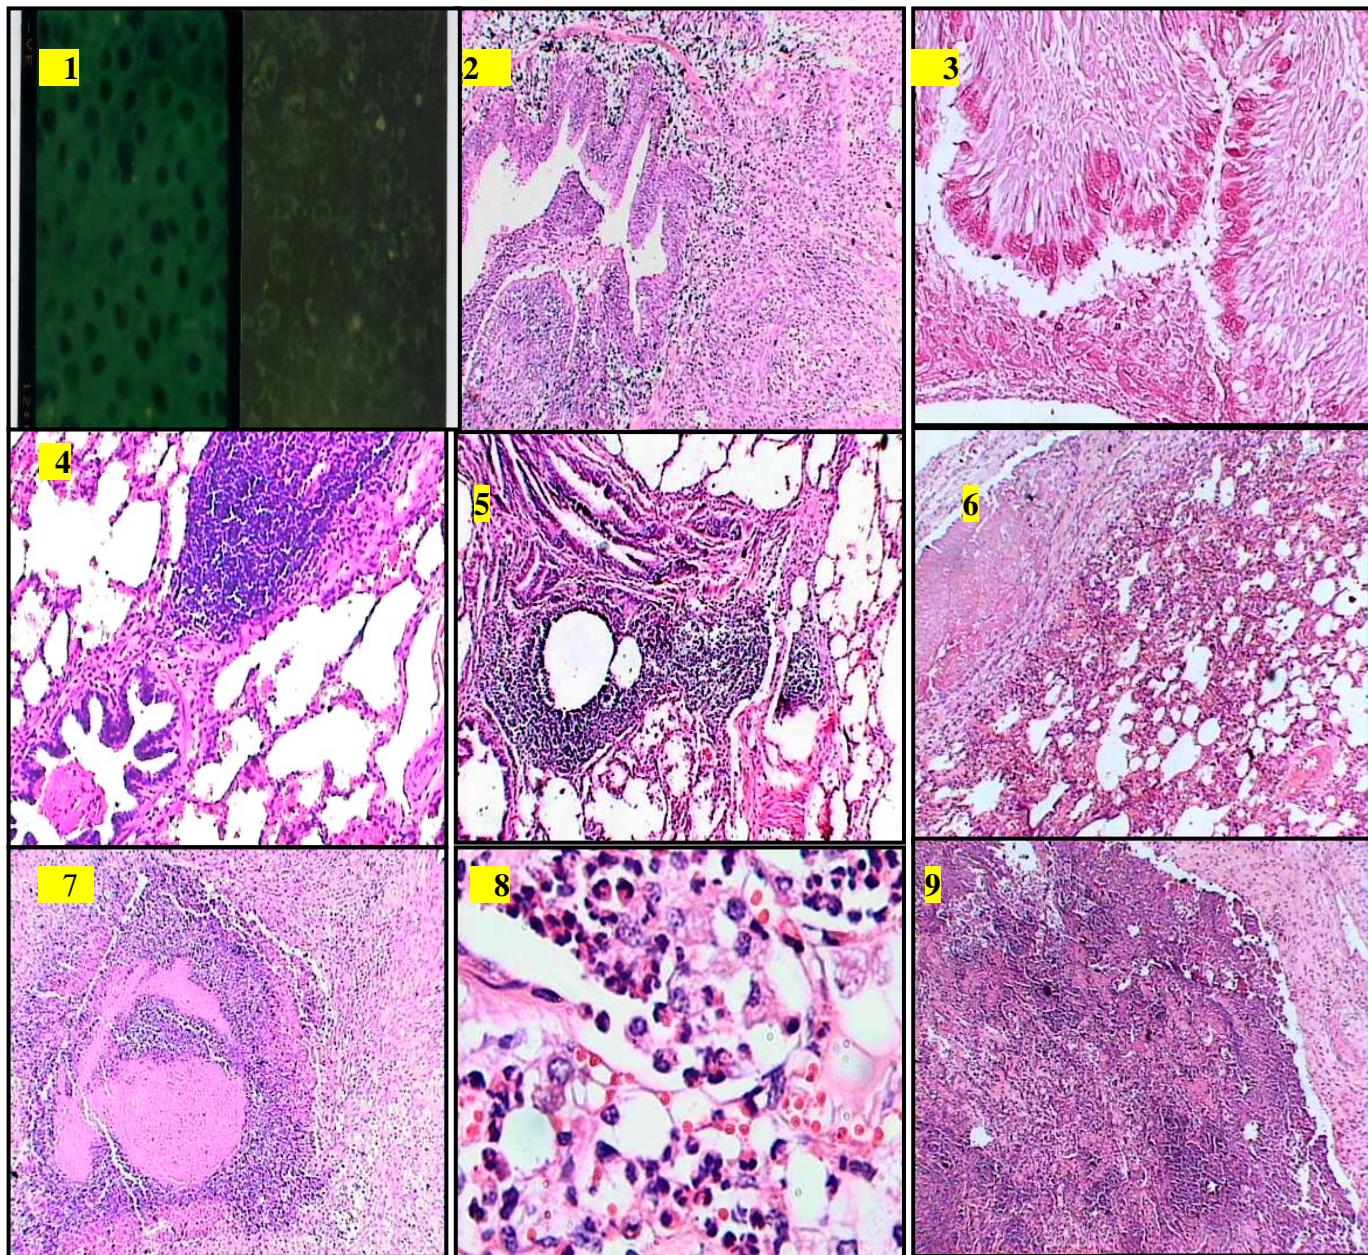

#### Histopathology:

The bronchiolar epithelium lining showed necrotic changes with loss of cilia or exfoliation of ciliated cells within bronchial lumen (Fig.2). Goblet cell hyperplasia also noticed and was confirmed with (PAS) stain (Fig. 3). This noticed hyperplasia considered as an inflammatory response to the development of mycoplasma specific antibodies and immune complexes resulted from persistent mycoplasmal infection. Such response acting on the respiratory epithelium and goblet cell precursors, (Zhang *et al.* 2006 and Aurora *et al.* 2006).

The peribronchial associated lymphoid tissue (BALT) showed marked proliferations and hyperplasia (Fig. 4). More over there were edema, per alveolar, perivasculär, peribronchial and per bronchiolar mononuclear cellular infiltrations (Fig.5). The Pulmonary blood vessels were engorged with blood, some of them showed fibrin thrombi with lymphocytic infiltrations, pleurisy, Interstitial pleuropneumonia (Fig. 6) with pronounced thickened alveolar walls. Previously mentioned findings were the remarkable findings of mycoplasmal infection,

were coincide with those described by (Mohamed & Abdelsalam, 2008, Fulton *et al.* 2009 and Alan, 2010). Such changes explained by Jubb *et al.* (1993); Macgavin & Zachary , (2007) as the infection which brings about immune suppression caused by BVD virus then ciliary dysfunction in addition to unregulated production of Tumor necrosis factor  $\alpha$  (TNF $\alpha$ ) barrel with the development of inflammation and increased vascular congestion so widening of vascular wall pores ,which followed by fibrin escapes from blood to pulmonary tissue under the effect of bacterial toxins and increased procoagulant activity, furthermore fibrin is chemotactic to leukocytes.

Foci of coagulative necrosis with intensely eosinophilic cytoplasm also were seen (Fig.7). These foci were delineated by a zone of neutrophils and macrophages, encircled by fibroblasts (Fig.8). Other areas showed diffuse casious necrosis (Fig.9). Mycoplasma was demonstrated with Giemsa stain in the vascular wall, interstitial tissue and inside alveoli. The latter necrotic foci which noticed microscopically was explained by Hum *et al.* (2000); Edy & Joachim, (2001) and Steven *et al* .(2003) as massive presence of *M.bovis* produce necrotizing factors as protease enzyme ,hydrogen peroxide and a complex polysaccharide toxin. Necrotizing factors are resulting in destruction of the pulmonary epithelium and vascular endothelium, which leading to initiation of thrombus, ending by pulmonary infarctions with inflammatory reaction followed by severe oxidative damage of tissues. This explains the Presence of bluish green mycoplasma colonies on wall of pulmonary blood vessels.

**(Fig : 1 ) :** Normal MDBK non infected cells ( A ) and infected MDBK cells ( notice Specific intracytoplasmic fluorescent ) ( B ).

**(Fig : 2 )** bronchiole showing necrosis & exfoliation of lining cells into the lumen (H&E) x4

**(Fig : 3 )** bronchiole showing marked goblet cell hyperplasia noticed with (PAS) x4

**(Fig : 4)** hyperplasia of peribronchiolar lymphoid tissue ( H&E) x10

**(Fig :5)** perialveolar ,perivasicular , and peribronchiolar mononuclear cellular infiltrations ( H&E) x4

**(Fig : 6)** interstitial pleuropneumonia ( H&E) x4

**(Fig : 7)** caseous necrosis with calcifications (H&E) x4

**(Fig:8)** alveoli filled with neutrophils and macrophage with congested perialveolar vessels (H&E) x40

**(Fig : 9)** diffuse caseous necrosis with calcifications with in center (H&E) x4

In the present study two patterns of pulmonary necrosis were noticed, the most common pattern was caseous necrosis; the second and least common pattern was coagulative necrosis,. The previous finding were highly consistent with those the reported by (Lopez & Martinez, 2002; Khodakaram & Lopez 2004 and Mohamed & Abdelsalam 2008).They speculated that an original foci of coagulative necrosis progress with time into caseous necrosis with proliferation of granulation tissue .This variation in severity, development of disease during infections may be regarded to the environmental factors (Gulliksen *et al.* 2009) Variable surface protein antigens Vsp of *M. bovis* were demonstrated in lungs of calves by (Buchenau. *et al* 2010) . In which Vsp together with immunological factors may contribute to the chronicity of pulmonary disease. The BVDV role in those lesions were due to its stimulation of cytokines hypersecretion such as interferon TNF, (Bielefeldt *et al.* 1989;Jacob *et al.* 2010).

#### 2-Fibrino-necrotizing bronchopneumonia :

Represented 2.5% of tissue samples (2of 80) as shown in table (12) .Isolated organisms where. *M. haemolytica* and *Bovine viral diarrhea virus* BVDV. +++ With less Severity.

#### Gross lesions:

Lung tissue was pale flabby with multiple focal grayish areas of consolidation.

#### Histopathology:

Bronchiolar epithelial cells showed loss of cilia and necrosis with desquamation within the lumen (Fig.10). Marked peribronchial lymphoid tissue hyperplasia was seen. Some alveolar lumens were filled with faint eosinophilic fibrin network intermingled with mononuclear cells, mainly lymphocytes, plasma cells and histiocytes (Fig. 11). Other alveoli contained cellular exudates consisted mainly of mononuclear cells. Multifocal coagulative necrosis were detected as homogenous strongly eosinophilic areas surrounded with mononeuclear cells and neutrophils ( Fig. 12) .Oat cells and coccoid bacteria were colonized at the periphery of necrotic foci. Other foci showed congested capillaries with perivascular lymphocytic infiltration and emphysema. Pleura showed fibrinous exudate, with lymphocytic infiltrations.

The gross and microscopical findings were coordinate with (Mohamed & Abdelsalam, 2008; Jean *et al* .(2008) ; Fulton *et al.* 2009), and attributed by Jeyaseelan and Sreevatsan (2002) to the *M. haemolytica* virulence factors such as leukotoxin

which is the main virulence factor that is associated with lung lesions and secreted by all *M. haemolytica* serotypes Jeyaseelan, and Sreevatsan (2002); .At high concentrations it induces leukocyte lysis, resulting in the nuclear streaming of necrosis (Cudd *et al.*,2001 ; Bojesen *et al.*, 2007 ; Wollums *et al.*, 2009).Another important virulence factor Lipopolysaccharide,( LPS) is synergistic with leukotoxin to induces oxidative burst of pulmonary alveolar macrophages and may inhibit the production of neutrophilic granulocyte, A polysaccharide-rich capsule is resistant to phagocytosis by neutrophils and macrophages, Also it assists in attachment, and alter neutrophil function. Furthermore Neuraminidase which increases the adhesion of the bacterium to the respiratory epithelium (Wollums *et al.*, 2009). Bovine respiratory viruses increase affinity to *M. haemolytica*, and other respiratory pathogens, by infecting ciliated epithelium and reducing mucociliary clearance. Another reason for extensive pulmonary necrosis is the secretion of maximum amounts of cytokines by alveolar macrophages, Malazdrewish *et al.* (2004); Macgavin & Zachary ,(2007) .

#### 3- Acute and chronic fibrinosuppurative bronchopneumonia:

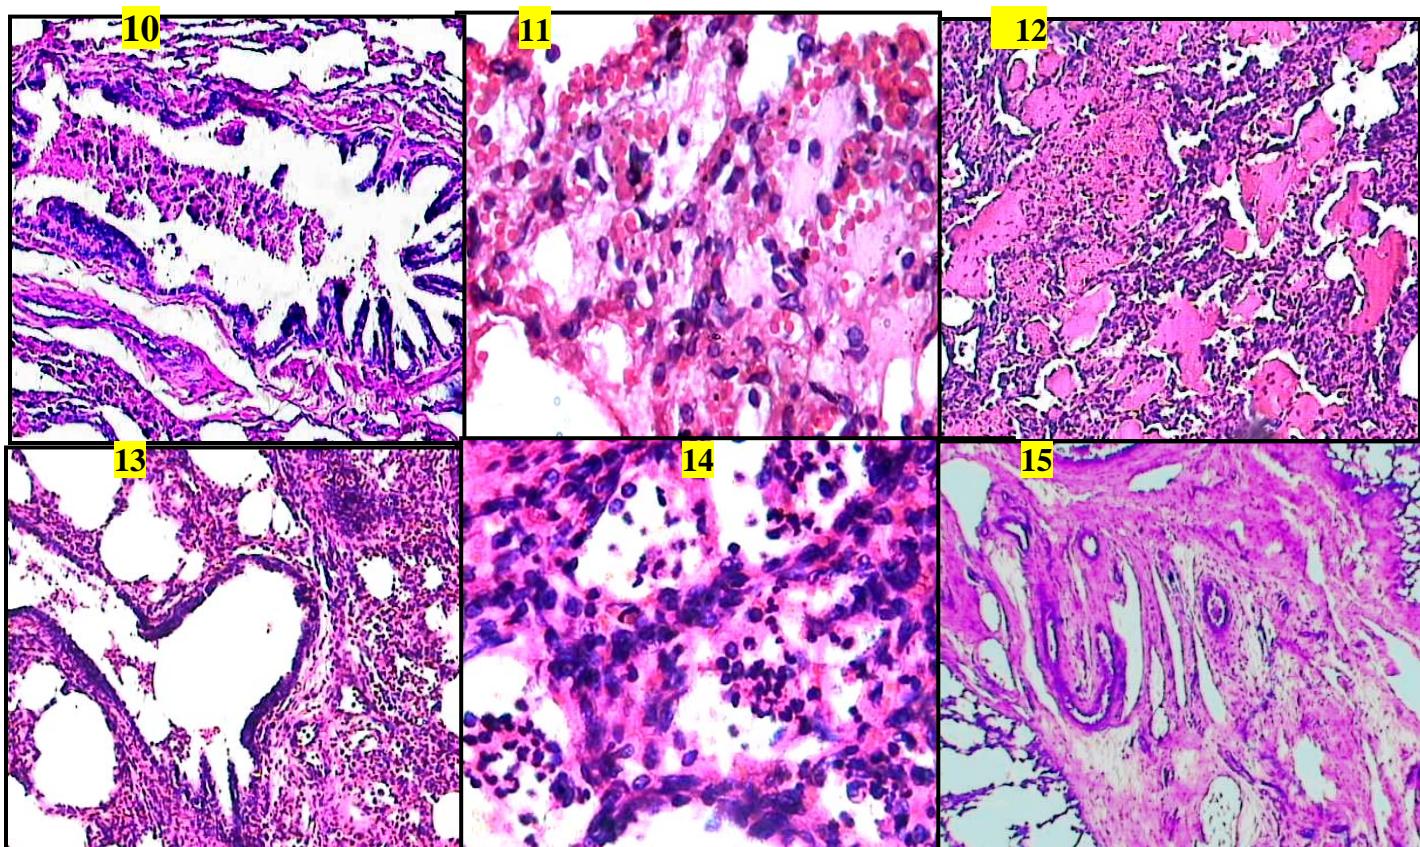

Represented 13.75% of tissue samples ( 11of 80) as shown in table (12) and isolated organisms were *M. haemolytica*, *M. dispar* and (BVD). With Moderate ++

#### Gross lesions:

The affected areas were deep red and consolidated. Pleural showed fibrosis with fibrin adhesions was evidenced. Pulmonary parenchyma showed foci of suppuration irregularly shaped and, delineated by a grayish rim.

#### Histopathology:

Bronchiolitis, bronchiectasis were seen in most cases of this category (Fig. 13) Alveoli showed atelectasis and necrosis with macrophage , neutrophils , fibrin, or both, and streaming of nuclear chromatin to form oat cells, foci of coagulative necrosis typical of *M. haemolytica* pneumonia( Fig. 14).Pleura showed aggregations of neutrophils with edema and congestion. A process of chronic fibrosis was seen with granulation tissue formation (Fig: 15). Within interstitial tissue histiocytes, plasma cells and lymphocytes were also noticed.

(Fig :10 ) Bronchiolar epithelial lining showing loss of cilia and necrosis with desquamation into the lumen (H&E) x10

(Fig :11) alveolar lumen with exudates of fibrin network intermingled with mononuclear cell mainly histiocytes ,lymphocytes , plasma cells and ,monocytes ( H&E) x40

( Fig : 12) multifocal coagulative necrosis as homogenous strongly eosinophilic areas infiltrated with mononeuclear cells ( H&E) x10

( Fig :13) Bronchiolar necrosis, intrabronchiolar neutrophils, bronchiolitis (H&E) x10

( Fig :14) Alveoli showing necrosis with neutrophils, and streaming of nuclear chromatin to form oat cells. (H&E) x40

( Fig :15) Pleura showing thickening with fibrous and granulation tissue proliferation (H&E) x10

Those neutrophil influx with alveolar necrosis and minimal bronchiolar necrosis were specific picture to *M. dispar* , and were agreed with Linda & Reggio, (2002) ; Jeyaseelan, and Sreevatsan (2002); Ajuwape *et al.* (2003) ; Ewer and Wieler 2004) ; Ilhan & Keles, 2007 and Fulton *et al.* (2009). Leukocytes within the alveoli and bronchioles undergo necrosis but retain a ghost-like outline with hyper-eosinophilic cytoplasm and fragmented nuclei (Caswell and Archambault, 2008). Studies using *M. dispar* indicate the pathogenesis of *Mycoplasma* pneumonia in calves involves degeneration and impairment of ciliated respiratory epithelial cells, thereby predisposing the lung to secondary infection with additional pathogens (Almeida & Rosenbusch,

1994). Coinfection of *M. hemolytica* with viruses resulting in complex infection after long-distance transportation and coldness (Jean *et al.* 2008).induced a moderate increase in the lesion severity ( Gourlay &Houghton, 1995 ). But only when calves were infected with *M. bovis* prior to infection with *M. hemolytica*. *M. bovis* pneumonia in calves is typically more severe when multiple pathogens, including *M. hemolytica*, (Bucharova & Vesselanova, 1989; Gregg *et al* 2010 ).

4-Non mixed pneumonia:

A- Interstitial pleura- pneumonia:

Represented 7.5 % (6 of 80) cases and isolated only mycoplasma species, lung tissue

showed interstitial lobar pneumonia, thickening interstitial tissue, desquamations of bronchiolar epithelium with in lumen. In addition to perivasculär ,perialveolar lymphocytic cuffing those findings coincide with those observed by,( Rodriguez et al., 1996).Those lesions regarded to mycoplasma toxins.

#### B- Serofibrinous pleuropneumonia :

Found in 31.25% cases, represented 25/80 and the isolated organism was only *M.haemolytica* This type represent the higher percentage, this illustrated by (Thomas et al.2002;Caswell and Williams 2007) as *M. hemolytica* are the most common organisms commensally of the bovine nasopharynx which, during stress can overcome host defense mechanisms establishing infection in the lower respiratory tract .Lung tissue showed widespread accumulation of, fibrin mash intermingled with neutrophils, macrophages . Airway Lumina and interlobular septae were distended with serofibrinous exudates. Those observations were caused by *M. hemolytica* toxins and nearly similar to those of (Larsen et al . 2001).

#### 4. Conclusion

Viral agents are usually considered the primary pulmonary pathogen, capable of destroying the respiratory epithelial lining to a degree allowing other agents to colonize. In addition to acute BVDV infections or persistent postnatal BVDV infections, undergo immunosuppression through destroying of immune competent cells of the host. The latter increases the susceptibility of these animals to secondary bacterial infection and increasing pathogenicity of concomitant diseases, that is why mycoplasmal and manhaemial infection may able to exacerbate a disease condition and initiated by other pathogen. Other theory suggested that, the viral and mycoplasmal agents are the primary infections and the bacterial gents are there as the secondary invaders.and these two suggestions supports our view.

<sup>2</sup>Phoniatric Unit, ENT Department, Cairo University, Cairo Egypt.

<sup>\*</sup>dressamaziz@msn.com

**Abstract:** Objectives: the aim of this study was to evaluate the efficiency of denture adhesives in improving phonation in complete denture wearers and to compare the efficacy of three different types of denture adhesives. Methodology: Fifteen completely edentulous patients with flat mandibular ridge shared in this study, complete denture was constructed for each patient according to the conventional method. Phonetic analysis was performed in the Phoniatric Unit via both Perceptual and Acoustic techniques to compare the efficacy of three chemically different denture adhesives (Super corega, Fittydent and Fixodent) on Arabic phonemic production. Results: a marked improvement in patients' articulation after application of the denture adhesives was reported, perceptually and acoustically, where the Fixodent denture adhesive gave the highest values. Conclusion: Whenever possible, denture adhesives should be used to improve retention and articulation. The polymethylvinyl ether malate-based adhesives (Fixodent) are strongly recommended as a highly reliable type of denture adhesives.

[Essam Adel Aziz, Azza Adel Aziz Dina Essam Eldeen Ibrahim and Ali Eldeen Mohammed Ahmed. Comparative Study between Different Denture Adhesives in Improving Phonation in Complete Denture Wearers. Journal of American Science 2010;6(11):556-561]. (ISSN: 1545-1003).

**Keywords:** Different Denture; Adhesives; Improving Phonation; Complete Denture Wearer

### 1. Introduction:

Residual ridge resorption is considered a major oral disease which could occur despite of careful prosthetic handling<sup>(1)</sup>. One of the most undesirable effects of residual ridge resorption is compromised denture retention which is considered a real challenge in complete denture therapy. There is always a question asked by the patients even in their own minds when they are seeking a prosthetic therapy which is "Is this denture going to be retentive?" Patients are asking for retention during talking, laughing, speaking, and for sure eating, regardless the condition of their remaining tissues (alveolar ridge height and soft tissue condition)<sup>(2,3)</sup>. Improving retention in cases of residual ridge resorption could be achieved via either surgical and/or prosthetic treatment. Surgical treatment may be in the form of vestibuloplasty<sup>(4)</sup>, ridge augmentation<sup>(5)</sup>, endosseous dental implants<sup>(6)</sup>. Anatomic, systemic and / or financial limitations could interfere with the surgical techniques described for flat ridge cases<sup>(7)</sup>. Denture adhesives had been used to aid in complete denture retention long time ago<sup>(8,9)</sup>. Wilson et al.<sup>(10)</sup> reported that 30% of the patients wearing dentures used denture adhesives. Another study declared that out of the 20% of the adult population in US who wear dentures at least 22% used denture adhesives<sup>(11)</sup>. Slaughter et al.<sup>(12)</sup> reported that the use of denture adhesives is considered suitable, adjunctive and effective treatment modality in removable

prosthodontics. Denture adhesives are commonly composed of three main components<sup>(13)</sup>:

a - basic adhesive substance such as methyl cellulose, sodium carboxy methyl cellulose, hydroxy methyl cellulose and/or synthetic polymers such as polyethylene oxide, acrylamides and polyvinylmethylether Maleic Anhydride.

b- Antimicrobial agent: such as hexachlorophene, sodium borate, ethanol and sodium tetraborate.

c- Preservatives, flavouring agents, wetting agents and plasticizers.

Many studies reported the effect of denture adhesives on improvement of mastication,<sup>(14-16)</sup> but their effect on Pronunciation of different phonological sounds is still lacking.

### 2. Materials and methods:

Fifteen patients (10 females and 5 males) were selected from the outpatient prosthodontic clinic, faculty of Oral and Dental Medicine, Cairo University. Their ages were ranging from 54 to 73 years with a mean age of 61.5 years. They were all completely edentulous with flat mandibular ridge, construction of complete dentures was carried out according to the conventional method. Phonetic assessment for the fifteen patients was carried out in the Phoniatric unit, faculty of medicine, Cairo University via both perceptual (subjective) and acoustic analysis (objective) methods in five phases:

Phase 1: before denture delivery while the patients were still unrestored completely edentulous.  
 Phase 2: two weeks after the final denture inspection.  
 Phase 3: two hours after application of the denture adhesive type 1 (Super corega) which is based on Carboxymethyl cellulose (CC).  
 Phase 4: this was done one week later, two hours after the application of adhesive type 2 (fittydent) which is based on Sodium Carboxymethyl cellulose and polyvinylacetate.  
 Phase 5: this was done one week later, two hours after the application of adhesive type 3 (Fixodent) which is based on sodium Carboxymethyl cellulose and polymethylvinylether maleate.

Application of each type of denture adhesive type was done on clean fitting surface according to the manufacturer recommendation (Figure 1).

**Figure (1), Application of the denture adhesive of the lower complete denture.**

#### Phonetic assessment:

I- Subjective perceptual assessment of different Arabic phonemes using the Arabic Articulatory Test (AAT).<sup>(17)</sup> Consonant sounds were sampled in initial, middle and final positions of words. The patients' products were tape-recorded and the test was transcribed on line followed by analysis of the recorded tape to verify the on-line transcription.  
 II- Objective acoustic assessment from a wide-band spectrogram display, using the Computerized Speech Lab (CSL) Kay model 4300, (Figure 2). Acoustic analysis of the perceptually-detected mostly affected phonemes (/s/, /ʃ/, /z/, /f/) was performed in the initial and the terminal-word positions. The full word was displayed on the screen and then the target sound was zoomed in. The segment was visually and auditory verified to ensure that both the beginning and the end of the sounds were included. Cursors were placed at the initial and the terminal of the target phonemes. The following acoustic parameters were analyzed: 1-Average energy in (dB), which

reflects the sound volume over a period of time. 2-Average duration in (mSec), which reflects the time required to produce a given speech sound. Subjects were instructed to repeat target words containing the consonants which appeared to be affected during perceptual assessment. The words were put in a carrier phrase (say .....again) to ensure a standard way of utterance.

Data were presented as mean and standard deviation (SD) values. Analysis of variances with repeated measures ANOVA was used and Bonferroni's test for pair-wise comparisons. The significance level was set at  $P \leq 0.05$ .

**Figure (2) Computerized speech lab (CSL).**

#### 3. Results:

Results of the perceptual assessment using Arabic Articulatory Test<sup>(17)</sup> revealed that only four fricatives were mostly affected from the whole 23 tested Arabic phonemes; they were /s/, /ʃ/, /z/ and /f/, in 100% of completely edentulous patients. The same phonemes were affected after wearing the dentures without denture adhesives in all the patients. Marked perceptual improvement in phonemes was noticed after application of every adhesive type; 100% of patients improved in /s/ sound, 95% in /ʃ/ sound, 100% in /z/ sound and 100% in /f/ sound, however, there was no perceptual difference in phonetic improvement between the three types of adhesives.

Adhesive type 1: (Super corega) which is based on Carboxymethyl cellulose (CC).

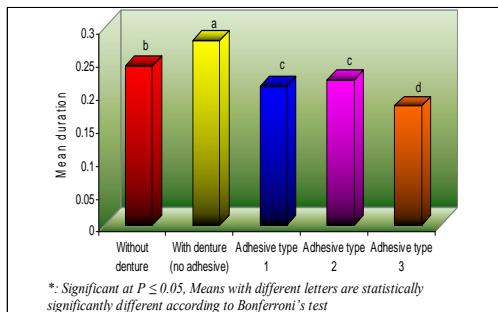

Adhesive type 2: (fittydent) which is based on Sodium Carboxymethyl cellulose and polyvinylacetate.

Adhesive type 3: (Fixodent) which is based on sodium Carboxymethyl cellulose and polymethylvinylether maleate.

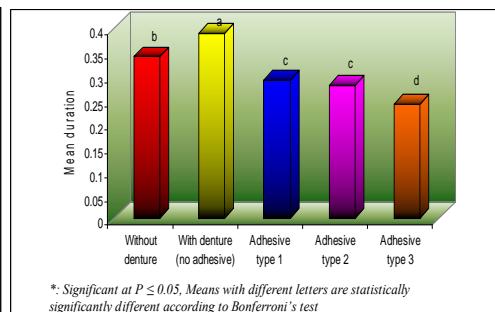

**Table (1): The total duration of the tested phonemes (/s/, /ʃ/, /z/, /f/) in initial and terminal-word positions in patients; without dentures, with dentures without adhesive and with three types of denture adhesives.**

Groups	Duration of initials in (m sec)		Duration of terminals in (m sec)	
	Mean	SD	Mean	SD
<b>Patients Without denture</b>	<b>0.24<sup>b</sup></b>	<b>0.03</b>	<b>0.34<sup>b</sup></b>	<b>0.03</b>
<b>Patients With denture (no adhesive)</b>	<b>0.28<sup>a</sup></b>	<b>0.02</b>	<b>0.39<sup>a</sup></b>	<b>0.04</b>
<b>Patients With denture With Adhesive type 1</b>	<b>0.21<sup>c</sup></b>	<b>0.03</b>	<b>0.29<sup>c</sup></b>	<b>0.04</b>
<b>Patients With denture With Adhesive type 2</b>	<b>0.22<sup>c</sup></b>	<b>0.02</b>	<b>0.28<sup>c</sup></b>	<b>0.02</b>
<b>Patients With denture With Adhesive type 3</b>	<b>0.18<sup>d</sup></b>	<b>0.04</b>	<b>0.24<sup>d</sup></b>	<b>0.03</b>

Means with different letters are statistically significantly different according to Bonferroni's test ( $P \leq 0.05$ ).

\*: Significant at  $P \leq 0.05$ . Means with different letters are statistically significantly different according to Bonferroni's test

\*: Significant at  $P \leq 0.05$ . Means with different letters are statistically significantly different according to Bonferroni's test

**Figure (3) Duration of initials.**

Results of the total duration of the acoustically tested phonemes (/s/, /ʃ/, /z/, /f/) in the initial and the terminal-word positions, as seen in Table (1), Figure (3,4) revealed a highly significant increase in the mean duration in patients with denture without adhesive (which showed the highest mean duration among the five groups) compared to patients without denture. There was a highly significant decrease in the mean duration value in patients with denture with adhesives compared to patients without denture.

**Figure (4) Duration of terminals.**

There was no significant difference in the mean duration in patients with adhesive type 1 compared to patients with adhesive type 2. There was a highly significant difference in the mean duration in patients with adhesive type 1 and adhesive type 2 compared to patients with adhesive type 3, which showed the lowest total mean duration value of the tested phonemes, both in initial and terminal-word positions.

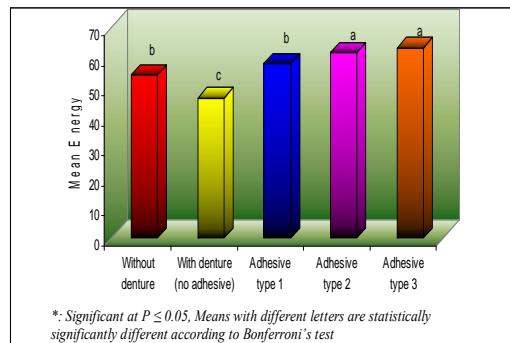

**Table (2): The total energy of the tested phonemes (/s/, /ʃ/, /z/, /f/) in initial and terminal-word positions in patients; without dentures, with dentures without adhesive, and with three types of denture adhesives.**

Groups	Energy of initials in (dB)		Energy of terminals in (dB)	
	Mean	SD	Mean	SD
<b>Patients Without denture</b>	<b>54.28<sup>b</sup></b>	<b>3.44</b>	<b>45.11<sup>d</sup></b>	<b>4.21</b>
<b>Patients With denture (no adhesive)</b>	<b>46.73<sup>c</sup></b>	<b>4.12</b>	<b>40.61<sup>e</sup></b>	<b>3.38</b>
<b>Patients With denture With Adhesive type 1</b>	<b>57.90<sup>b</sup></b>	<b>3.21</b>	<b>50.43<sup>c</sup></b>	<b>4.12</b>
<b>Patients With denture With Adhesive type 2</b>	<b>61.65<sup>a</sup></b>	<b>2.89</b>	<b>54.76<sup>b</sup></b>	<b>3.86</b>
<b>Patients With denture With Adhesive type 3</b>	<b>63.33<sup>a</sup></b>	<b>3.69</b>	<b>57.21<sup>a</sup></b>	<b>4.18</b>

Means with different letters are statistically significantly different according to Bonferroni's test ( $P \leq 0.05$ ).

Adhesive type 1: (Super corega) which is based on Carboxymethyl cellulose (CC).

Adhesive type 2: (fittydent) which is based on Sodium Carboxymethyl cellulose and polyvinylacetate.

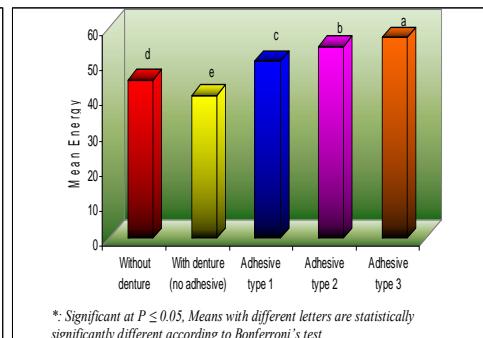

**Figure (5), Energy of initials**

The results of the total energy of the acoustically tested phonemes (/s/, /ʃ/, /z/, /ʒ/) in initial and terminal -word positions, as shown in Table (2), figure(5,6) revealed that patients wearing dentures without adhesives showed the lowest mean energy value among the five groups, both in the initial and the terminal-word positions. A highly significant difference in the mean energy values was found in patients without denture compared to patients wearing dentures without adhesives. There was insignificant difference in the mean energy in patients without denture compared to patients wearing denture with adhesive type 1 in the initial-word position. There was a significant increase in the mean energy of phonemes in patients with adhesive type 2 compared to adhesive type 1, both in the initial and the terminal-word positions. There was a further significant increase in the mean energy in patients with adhesive type 3 compared to type 2 in the terminal -word position.

#### 4. Discussion:

Perceptual Phonetic assessment of patients revealed that patients' articulation while they were edentulous was slightly deviated from normal, with defects in fricative phonemes (/s/, /ʃ/, /z/, /ʒ/), this may be attributed to a poor accommodation with the new situation. After wearing the denture without adhesives, there was a marked deterioration in the articulation. This is in accordance with Banknson and Byrne<sup>(18)</sup> who reported that loose dentures will not allow the tongue to function normally and this in turn will affect speech. This is also in agreement with Rothman<sup>(19)</sup> who clarified that pronunciation disturbance affecting fricative sounds could result from the direct influence of the artificial teeth and

Adhesive type 3: (Fixodent) which is based on sodium Carboxymethyl cellulose and polymethylvinylether maleate.

**Figure (6), Energy of terminals**

palate on the air flow as well as from different tongue positions and movements, as the tongue contacts specific parts of the teeth, alveolar ridge or the palate during each consonant pronunciation. Emily et al<sup>(20)</sup> clarified that consonant sounds are affected by the presence of poor retentive prosthetic appliance, and Ana Petrovic<sup>(21)</sup> found that unsatisfactory upper and lower dentures affect articulation markedly.

In the past, dentists used to think that the use of denture adhesives refers to poor dental skills as denture adhesives were thought as a solution for ill fitting denture<sup>(22,23)</sup>. Nowadays this philosophy was changed. The use of denture adhesives is highly recommended with patients seeking for extra retention demands that can't be achieved by the routine protocol of complete denture construction<sup>(24)</sup>. Denture retention and stability were significantly improved with the use of denture adhesives due to the bond created between the denture base and the underlying supporting tissues.<sup>(25)</sup>

Despite of the ability of the perceptual assessment to declare the improvement in the perceptually perceived phonemes in patients wearing dentures with adhesives than in those wearing dentures without adhesives, yet it couldn't differentiate the improvement between the different adhesive types. Therefore, acoustic assessment was performed as an objective assessment method for evaluating the most perceptually affected phonemes detected by the Arabic articulation test<sup>(17)</sup> which were the following fricatives; /s/, /ʃ/, /z/, /ʒ/, tested in initial and terminal- word positions.

Phonetic assessment for patients after applying adhesive type 1 revealed significant decrease in duration and significant increase in energy which reflected a better articulation, that may

be attributed to obvious improvement of lower denture retention as retention affects masticatory efficiency, phonation as well as self confidence as reported by Fujimori et al.<sup>(26)</sup>

Two hours after applying adhesive type 2(which combine both carboxy methylcellulose and polyvinylacetate), acoustic studies revealed that there was a significant decrease in the duration and a significant increase in the energy in comparison to adhesive type 1 (carboxy methylcellulose based type). This was in accordance with Panagiotouni et al<sup>(16)</sup> who concluded that fifty -dent denture adhesive gave a significant high scores on CC based adhesive type 1, when the degree of retention and retention duration were considered, due to the presence of polyvinylacetate adhesive material in combination with CC. This was almost the same results obtained by Berg et al<sup>(27)</sup> who declared that polyvinylacetate works as a powerful adhesive material but it works only on dry surface so carboxy methylcellulose acts as a sponge and absorbs saliva. Acoustic assessment for fricatives /s/, / ʃ /, / z / and / ʃ / in initial and terminal- word positions, 2 hours after applying the third denture adhesive type (which combines both polymethylvinylether maleate plus Carboxymethylcellulose) revealed a significant decrease in duration and increase in energy, which improved the articulated phonemes, in comparison to adhesive type1 and type 2. This is because polymethylvinylether maleate is a durable powerful adhesive and Carboxymethylcellulose gives a rapid initial bond. This was in accordance with Psillakis et al<sup>(28)</sup> who tested Fixodent denture adhesive and concluded that using denture adhesive (fixodent) subjectively improves speech and chewing ability. This was also in accordance with Ozcan et al,<sup>(29)</sup> who clarified that bite force until denture dislodgement was increased for both old and new dentures after the use of denture adhesive based on polymethylvinylether maleate plus carboxymethyl cellulose (kukident) and this improvement lasted for 6 hours after application of the denture adhesives.

## 5. Conclusion:

This study clarified that the use of the denture adhesives markedly improves articulation in complete denture wearers as evidenced by both subjective and objective speech assessment, mainly due to their valuable effect on denture retention. The polymethylvinylether maleate-based adhesive Compound (Fixodent) gives the best results than Carboxymethyl cellulose-based denture adhesives (Supercorega) and Carboxymethyl cellulose plus Polyvinylacetate-based adhesive (fiftydent) as evidenced by the improvement in the acoustic features of the tested Arabic phonemes.

# Assessment of Working Memory in Normal Children and Children Who Stutter

**Hazem Aboul Oyoun<sup>1</sup>; Hossam El Dessouky<sup>2</sup>; Sahar Shohdi<sup>\*2</sup> and Aisha Fawzy<sup>2</sup>**

<sup>1</sup>Otorhinolaryngology, ENT Department, Faculty of Medicine, Cairo University. Cairo, Egypt

<sup>2</sup>Phoniatrics, Phoniatic Unit, ENT Department, Faculty of medicine, Cairo University. Cairo, Egypt    sshohdi@hotmail.com

**Abstract:** The aim of this study is to assess working memory (WM) abilities in normal children and Children Who Stutter (CWS) then to compare the results in order to detect if WM deficits have a role in the development of stuttering. 30 normal children and 30 children who stutter were subjected to WM recall abilities tests and nonword repetition tasks. The WM recall tests included recall of word sets different in length and rhyming, digit span, letter sequences and picture-number test. The nonword repetition test was used to assess phonological encoding through measuring number of phonological errors produced on repeating the task, and to measure the reaction time. The children who stutter (CWS) had performed poorly on some working memory tests compared to the control group. Conclusion: Children who stutter may have diminished ability to recall nonwords and some of working memory abilities and that further investigation into this possibility may shed light on the emergence and characteristics of childhood stuttering.

[Hazem Aboul Oyoun; Hossam El Dessouky; Sahar Shohdi and Aisha Fawzy. Assessment of Working Memory in Normal Children and Children Who Stutter. Journal of American Science 2010;6(11):562-569]. (ISSN: 1545-1003).

**Key words:** working memory; children who stutter; nonword repetition; phonological encoding, phonological errors, reaction time.

## 1. Introduction:

Stuttering has been described as a speech motor disorder that disrupts the timing and/or coordination between the respiratory, laryngeal, and vocal tract symptoms of speech (Van Lieshout et al., 2004). It is true that people who stutter suffer from some overt phenomena like tense movements of face, jaw and occasionally extremities; however it is also important to investigate where these phenomena came from (Kawai, 2008).

Recently working memory has been implicated in the development of stuttering. Working memory is universally recognized as neurocognitive system that provides temporary storage and processing of incoming information. Baddeley (2003) envisioned working memory as a multicomponent neurocognitive system that includes a central executive, visuospatial sketchpad and phonological loop. The phonological loop includes short term storage and rehearsal of incoming verbal information to enable comprehension. Phonological encoding during speech planning involves retrieving phonological material from storage to build articulatory plans (Levelt, 1989). Working memory is considered critical to phonological encoding (Gathercole and Baddeley, 1993) and vital to higher level cognition (Rosen and Engle, 1997).

One prominent theory which is the covert repair hypothesis of Postma and Kolk (1993) assumes that

stuttering arises because inefficient or slow phonological encoding leads to an increase in covert repairs to the phonological plan, particularly when the individual is intent on speaking at a rate exceeding the compliance of the phonological encoding mechanism.

Cognitive models of speech production, such as that proposed by Levelt and colleagues (1999), provide a useful framework to consider the linguistic processes that might be deficient in stuttering. A number of studies have explored the hypothesis that retrieving semantic and/or phonological information for the purposes of linguistic encoding might be a source of deficit or delay in stuttering (Newman and Bernstein-Ratner, 2007). However these studies have produced mixed findings

The aim of this study is to assess working memory (WM) abilities in normal children and Children Who Stutter (CWS) then to compare the results in order to detect if WM deficits have a role in the development of stuttering.

## 2. Subjects and methods:

### Subjects

Participants in this study were 30 normal children (group 1) and 30 children with stuttering (group 2). All children ages were between 5 and 13 years. The two groups were matched in age and gender. Each group was further subdivided according

to children's age into 2 subgroups; A) 15 Children with ages ranging between 5 and 9 years. B) 15 Children with ages ranging between 9 and 13 years. Mean age of children who stutter (CWS) was 7.51; while the mean age of the control children was 7.93. They were all selected from the outpatient clinic, Phoniatric unit of Kasr El Aini Hospital and with following exclusion criteria: No history &/or presence of delayed language development, dyslalia, mental retardation, hearing impairment, psychological problems or neurological problems. The study was done in the period from 2008-2009.

### Methods

All participants were subjected to the following protocol of assessment:

#### History taking and patient examination:

Including personal, perinatal, natal, postnatal developmental history and any history of childhood illness together with general, neurological, local and ENT examination.

#### Psychometric evaluation:

- a. Stanford Binet test (4<sup>th</sup> version) (Thorndike et al., 1986). All selected participants were of average IQ (IQ≥ 85)
- b. Illinois psycholinguistic test (Kirk et. al., 1969): Only 3 items were selected (psycholinguistic age, auditory sequential memory and visual sequential memory). These were selected to test other memory abilities rather than working memory.

The Assessment protocol of Disfluency used in Phoniatric Unit, Cairo University (Shohdi, 1999): to assess disfluency and severity of stuttering.

#### Battery of assessment of working memory (WM):

All tasks were recorded using an audiotape (National Rx- CW30F) for documentation.

#### A. WM Recall Tasks:

- 1- Recall of short versus long word sets: to assess the efficiency of retrieval of phonological sequences of different length.
- 2- Recall of similar versus dissimilar word sets: to assess the efficiency of retrieval of phonological sequences with different rhyming. The word sets were presented verbally by the experimenter. Children had to remember the words in the same order in which they were presented. For a trial to be considered correct, all words in that sequence had to be remembered in the correct order. Testing continued as long as the child managed to correctly repeat at least one of the two trials at a particular list length.
- 3-Digit span versus letter sequences: Sequences of digits and letters graded from 3 to 10 were administered verbally provided not to be in a

sequential order. Ten digits between 1 and 10 were used. Ten letters were also used (not sequential).

- 4- Picture-number test (Ekstrom et al., 1975): This test was used to address the visuospatial component of WM. Some modifications to the original test were done to be suitable for the examined age range. It was graded from 3 to 10 picture-number tests, it was presented visually for 60 seconds then the child was asked about the missing numbers associated with the presented pictures. The total score was given according to the maximum number of correct missing numbers recalled and associated with the correct presented pictures.

The purpose of assessment of WM recall abilities is to explore the role of verbal WM and its operations in the development of stuttering.

#### B. Non-Word Repetition tasks:

Non-word repetition was considered to be a phonological short term memory task, in which the phonological forms of the stimuli are unfamiliar thus requiring children to code new phonological sequences and maintain them in phonological memory. By repeating nonwords the speaker relies on the storage component of the phonological loop without the complicating effects of prior lexical knowledge (Gathercole et al., 1994). A list of 40 non-words was administered (20 bisyllabic and 20 trisyllabic non-words).

The participants were examined in a quiet setting on two sessions. Three examples of nonwords were given by the examiner and the child was asked to repeat each. Once the child appeared to be comfortable with the setting and understanding to the task, the 40 non-words were presented verbally by the examiner using the microphone of the Computerized Speech Lab. (Kay model 4300) in order to measure the reaction time using spectrographic analysis. The task was also recorded using an audiotape. Then the recording task was transcribed and analyzed for detection of (A) Phonological errors and (B) Disfluency. Reaction time (RT) was considered as the time between the end of the examiner's stimulus and the beginning of the child's response to detect if stutterers differ in their speed of phonological encoding. For the Phonological errors, the responses were scored as either correct or incorrect. All phonemes within a non-word had to be produced correctly for the response to be scored correct. Response of CWS were judged as either correct (no phonological error) or incorrect (presence of phonological error). The total number of phonological errors of the 40 non-words for all the participants was calculated. For disfluency, the response of CWS were judged as either fluent or disfluent. The number of disfluently

produced responses was then calculated for each nonword and across all the task items. Disfluency was measured in order to test its relation with phonological errors on the nonwords repetition task.

#### Statistical Analysis:

Data was analyzed by Microsoft office 2003 (excel) and Statistical Package for Social Science (SPSS) Version 10. Parametric data was expressed as mean and standard deviation while parametric data was expressed as number and percentage of the total. Student's t-test was used to compare between the 2 test groups. Measuring the mutual correspondence between two values was done using the Spearman correlation coefficient.

### 3. Results and Discussion:

#### Psychometric evaluation:

a. Stanford – Binet test (4<sup>th</sup> version) (Thorndike et al., 1986): There was no significant difference between controls and stutterers for all the test items except the *memory for sentences* was significantly better in controls (mean =84.53; SD= 8.42).

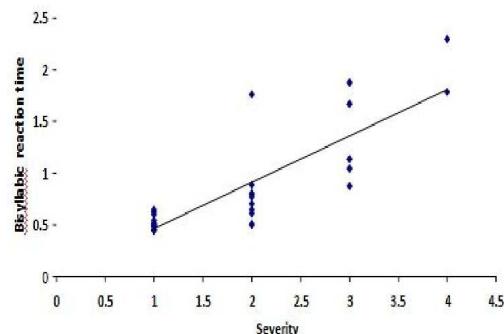

b. Illinois Psycholinguistic test (Kirk et al., 1969)

There was no significant difference between controls and stutterers regarding the tested items of the Illinois test.

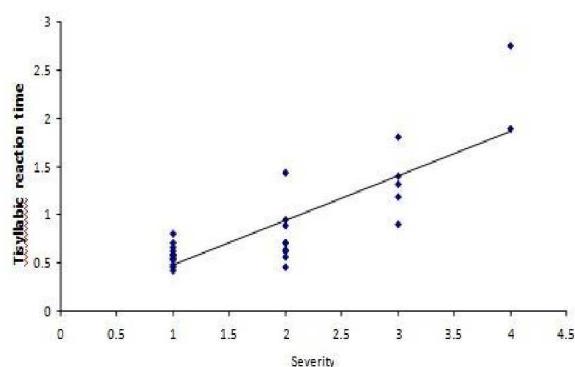

#### Disfluency:

Results showed that there were 13 children with mild stuttering, 10 children with mild to moderate stuttering, 5 children with moderate stuttering and 2 children with moderate to severe stuttering.

The correlation between severity of stuttering and reaction time of both bisyllabic and trisyllabic nonwords showed a highly significant +ve correlation ( $r$  value=0.825 and 0.827 respectively) (Figure 1 & 2).

**Figure (1): The correlation between severity of stuttering and reaction time of bisyllabic nonwords.**

between the age and recall of short word sets, long word sets, dissimilar word sets, letter sequences and

picture-number tests showed a highly significant +ve correlation (Table 1).

**Table (1): The correlation between age and WM recall tasks in controls and stutterers**

	Control age ( r value )	Significance	Stutterers age ( r value )	Significance
<b>Recall of short word sets</b>	<b>0.397</b>	S	<b>0.501</b>	<b>HS</b>
<b>Recall of long word sets</b>	<b>0.366</b>	S	<b>0.591</b>	<b>HS</b>
<b>Recall of similar words</b>	<b>0.517</b>	<b>HS</b>	<b>0.378</b>	S
<b>Recall of dissimilar words</b>	<b>0.397</b>	S	<b>0.501</b>	<b>HS</b>
<b>Digit span</b>	<b>0.401</b>	S	<b>0.382</b>	S
<b>Letter sequences recall</b>	<b>0.492</b>	<b>HS</b>	<b>0.513</b>	<b>HS</b>

WM: working memory, HS: highly significant, S=significant

Both controls and stutterers showed a highly significant better recall of short (controls: mean = 5.40; SD = 1.19, stutterers: mean = 5.00; SD = 1.08) than long word sets (controls = 3.83; SD= 0.83 and stutterers= 3.67; SD= 0.66), dissimilar (controls: mean = 5.40; SD= 1.19 and stutterers: mean= 5.00; SD= 1.08) than similar word sets (Controls: mean=3.53; SD=0.73 and stutterers: mean=3.43; SD=0.73 ), Digit span (controls: mean= 5.93; SD= 1.41 and stutterers: mean =5.03; SD=1.27) versus Letter-sequences (Controls: mean=4.57; SD=1.33 and stutterers: mean=3.97; SD= 1.10).

**Table (2): Number of phonological errors in bisyllabic nonwords and trisyllabic nonwords between controls and stutterers.**

		Controls	Stutterers	P VALUE
<b>Phonological errors</b>	<b>Bisyllabic nonword</b>	4	32	0.000002**
	<b>Trisyllabic nonword</b>	35	61	0.006**
<b>P VALUE</b>		0.000**	0.002**	

\*\* = highly significant p value ( $\leq 0.01$ )

There was no significant difference in the number of phonological errors in bisyllabic nonwords between controls (subgroup A, aged 5-9 y) and controls (subgroup B, 9-13y). While control subgroup A showed a highly significant more number of phonological errors than control subgroup B in trisyllabic nonwords.

Stutterers (subgroup A, aged 5-9 y) had a highly significant more number of phonological errors than stutterers (subgroup B, aged 9-13 y) in both bisyllabic and trisyllabic nonwords.

#### Disfluency:

There was no significant difference in the number of disfluencies between bisyllabic and trisyllabic nonwords in the stutterers ( $p=0.292$ ).

#### B) Nonword Repetition Tasks:

##### Phonological Errors (PEs):

Stutterers had a highly significant more phonological errors compared to the controls in both bisyllabic and trisyllabic nonwords repetition task.

There were a highly significant more number of phonological errors in trisyllabic nonwords than in bisyllabic nonwords in both the controls and the stutterers.

Stutterers subgroup A had a highly significant more number of disfluencies in both bisyllabic and trisyllabic nonwords compared to stutterers subgroup B ( $p=0.002$  and  $0.000$  respectively).

There was no significant difference between the number of phonological errors and the number of disfluencies in stutterers in both bisyllabic and trisyllabic nonwords ( $p=0.155$  and  $0.436$  respectively).

#### Nonwords Reaction Time (RT) (Table 3)

There was a highly significant longer reaction time in the stutterers than the controls for both the bisyllabic and trisyllabic nonwords repetition tasks (mean of bisyllabic RT in control group= $0.56$ ; SD= $0.12$ ; mean of bisyllabic RT in stuttering group= $0.85$ ; SD= $0.51$ ) and (mean of trisyllabic RT in

control group=0.58; SD= 0.14; mean of trisyllabic RT in stutterers=0.88; SD= 0.53).

Neither the controls nor the stutterers showed significant difference between reaction time

for both bisyllabic and trisyllabic nonwords repetition task.

**Table (3): Reaction time of bisyllabic and trisyllabic nonwords in controls and stutterers**

		Controls		Stutterers		<b>P VALUE</b>
		<b>Mean</b>	<b>SD</b>	<b>Mean</b>	<b>SD</b>	
<b>Non-word repetition</b>	<b>Mean BRT</b>	0.56	0.12	0.85	0.51	0.005**
	<b>Mean TRT</b>	0.58	0.14	0.88	0.53	0.006**
	<b>P value</b>	0.504	0.841			

(SD=Standard deviation; BRT= Bisyllabic Reaction Time; TRT= Trisyllabic Reaction Time)

\*\* = highly significant p value ( $\leq 0.01$ )

### 3. Discussion:

Psychometric evaluation:

Stanford-Binet test:

Testing different memory abilities showed no significant difference between controls and stutterers except for memory for sentences as controls showed a slightly better performance and that may be explained by the fact that sentences are more complex than words and convey more grammatical complexity which can increase the mental load on stuttering memory recall abilities.

Illinois Test:

There was no significant difference between controls and stutterers in visual as well as auditory sequential memories.

Severity of stuttering:

Correlation between severity of stuttering and reaction time in both bisyllabic and trisyllabic nonwords showed a significantly +ve correlation. This means that with increase in the severity of stuttering, the time needed for encoding and phonological processing increases.

Working memory recall tests:

The present study showed no significant difference between controls and stutterers in various recall tasks, however the stutterers showed poorer performance in picture-number test than controls and that could be explained that this task put more pressure and demands on their mental and recall abilities due to time pressure during the task.

There was a highly significant ability to recall short word sets than recall of long word sets in both stutterers and controls. This can be attributed to the fact that short words have less articulatory duration

and less phonological complexity and that short articulatory duration allows rapidly spoken words to be rehearsed more frequently. Words that are rehearsed more frequently are less likely to decay before an entire sequence of them can be recalled (Baddeley, 1986). And it could also be explained by what Caplen et al., 1992 had hypothesized that the word-length effect stems from speech planning rather than overt or covert articulation and that speech planning are influenced by the phonological complexity of words, as indexed by number of phonemes and syllables. Comparing the results of recall of dissimilar words versus recall of similar words, both controls and stutterers showed better performance in recall of dissimilar words than recall of similar words. Typically, sequences of phonologically similar words are remembered less well than sequences of dissimilar words (Schweickert et al., 1990). The phonological similarity effect supports the phonological loop model's assumption that verbal information is represented in a modality-specific phonological store rather than in another type of storage system. Comparing the results of digit span versus letter-sequence tests in both controls and stutterers, it was clear that both groups had better performance in digit span than in recall of letter sequences. This could be explained by the fact that children especially the younger ones are more familiar with digits than with letters.

A correlation between age and various recall parameters in both control and stuttering groups showed a significant +ve correlation in both groups. Some researchers showed that brain maturation increases with increase in age. Structural neuroimaging studies show that regions of parietal and especially frontal cortex undergo changes well

into adolescence and early adulthood. These studies suggest that the brain systems underlying WM and thus WM undergo changes well into adolescence and regions are activated when children and adults retain information in WM. Behaviorally, WM undergoes substantial growth over the course of development. For example, counting and listening span increase from 7 to 13 years of age (Siegel and Ryan, 1989), and digit span increases from 4-5 items at 4-5 years of age to 5-7 items at 14-15 years of age (Conklin et al., 2007).

#### Non-Word Repetition Task:

##### Phonological errors (PEs)

The number of phonological errors in controls was lower than stutterers. This could be attributed to the poor rehearsal and storage abilities of children with stuttering. The findings of the present study goes with the Covert Repair Hypothesis assumption that building a phonological output representation, is realized through the association of phonemes with slots in a metrically defined frame. Normally, if a slot in the frame needs to be filled, the phoneme that has the highest activation level at the critical time point is selected. In a person who stutters, however, activation spreading is slow. This means that when a specific slot needs to be filled, it is likely that competition among candidate phonemes has not settled. Consequently, a misselection may occur. Many such misselections are pre-articulatory detected and repaired, which yield interruptions and restarts in overt speech, if one couldn't do these covert repairs, the overt phonological errors would be produced.

Both controls and stutterers also produced more errors in trisyllabic than bisyllabic nonwords. The more the length of the nonwords, the more difficulty in encoding, rehearsal and storage. Present findings are also similar to those reported by Montgomery (1995), in children with specific language impairment (SLI). He found that children with SLI performed significantly worse than language-matched typically developing peers on three syllable non-words. At the 3 syllables, the CWS showed more difficulty with the task, as do many children with SLI.

On comparing the result of the number of phonological errors in bisyllabic and trisyllabic nonwords between the two control age subgroups, it was found that no significant differences between both groups as regards number of phonological errors in bisyllabic nonwords, but it showed that group (A) aged between 5-9 years produced more errors in trisyllabic nonwords than group (B) aged between 9-13 years. As regards the two stutterers' age subgroups, group (A) showed more errors than group (B) in both bisyllabic and trisyllabic nonwords. These

results suggest that phonological ability of children improves when they grow older.

#### Disfluency

Comparing the number of disfluencies between bisyllabic and trisyllabic nonwords in stuttering group, there was no significant fluctuation in fluency as nonwords increased in length. Thus, it would appear that even though CWS had greater difficulty (i.e., producing PEs) in the two and three syllable nonwords than their normally fluent peers, these difficulties did not manifest themselves in children's fluency. And thus, the poor performance of CWS in nonwords repetition task as regards the phonological errors was not related to speech production difficulties (speech disfluencies) but the results cannot be considered conclusive as the majority of the CWS were of mild and moderate degrees of severity. However, the finding is consistent with both Hakim and Ratner (2004) and Anderson et al (2006) that revealed no significant fluctuation in fluency as nonwords increased in length. On contrary, an older literature on stuttering in adults has documented that disfluencies should increase with increasing word length (Soderberg, 1966 and Wingate, 1967).

Comparing the number of disfluencies of bisyllabic and trisyllabic nonwords between the two stutterers' age subgroups, there was highly significant difference as group (A) produced more disfluencies than group (B) in both bisyllabic and trisyllabic nonwords. However there is no evidence that disfluency increases in young age.

Comparing the number of disfluencies and number of phonological errors in bisyllabic and trisyllabic nonwords in stutterers, no significant difference was found. The results were in accordance with Wolk et al (2000) who indicated that frequency of disfluency on syllables with phonological errors was similar to those produced without errors. According to them, it may have been predicted that more disfluency would occur during instances of phonological errors. One explanation for the results is that the two disorders (stuttering and disordered phonology) may indeed be separate entities. Although stuttering and phonological errors may co-occur in the same child, they may not interact in the same syllable.

#### Reaction Times (RTs)

Comparing the results of reaction time of bisyllabic and trisyllabic nonwords between the controls and the stutterers, it was found that the stutterers had longer reaction time in both bisyllabic and trisyllabic nonwords than the control group, although, that only fluent productions were selected to measure the reaction time. And that led us to the

prediction that children who stutter may take more time for phonological encoding than normal children. These results were in agreement with the results of the study by Kolk et al (1991) who suggested that individuals who stutter may demonstrate impairment in their phonological encoding mechanisms. This assumption leads to the prediction that the activation of target phonemes is somewhat delayed for people who stutter, resulting in a relatively long period of time when target phonemes are in competition with other phonemes. But the results did not match with the results of Bakhtiar et al (2008) who found no significant difference between the two groups regarding reaction time in both bisyllabic and trisyllabic nonwords. They assumed that the defect might be in the other parts of linguistic processing but not phonological ones.

The comparison of reaction time between bisyllabic and trisyllabic nonwords in both controls and stutterers showed insignificant difference. Lack of significance may be attributed to the small sample size and the difference could be significant with more increase in nonwords syllabic length. The result of the present study is in agreement with the results of Bakhtiar et al (2008).

The present study showed no difference between controls and stutterers in recall tasks, except picture-number test. This could be explained by that their prior lexical knowledge about the words and the semantic content of these words facilitated their recall.

The results of this study are in agreement with the Covert Repair Hypothesis in that the children with stuttering produced more phonological errors than normal children and they had longer reaction time. This may support the assumption of the Covert Repair Hypothesis of the presence of a phonological encoding deficit and that leads to the prediction that the activation of target phonemes is somewhat delayed for people who stutter, resulting in a relatively long period of time when target phonemes are in competition with other phonemes. The Covert Repair Hypothesis assumed that when disfluency is suppressed, overt speech errors should increase in frequency and the more overt stuttering, the less phonological errors should be observable; however, this was not proved in this study. The relation between disfluencies and phonological errors is still query waiting for further investigation.

#### **4. Conclusion:**

In accordance with several studies, it was found that performance of CWS on phonological memory tasks lag to some degree behind that of normal children. Further research in this area may shed light on the emergence and characteristics of childhood

stuttering and that can lead to new approaches for the management of stuttering.

## CHEMICAL STUDIES ON 3,6-DICHLOROPYRIDAZINE

Mohamed H. Sherif, Gamal A. Ahmed, Adel A. Elbahnasawy and Eman O. Helal

Department of Chemistry, Faculty of Science, Zagazig University, Egypt  
[meahsherif@hotmail.com](mailto:meahsherif@hotmail.com)

**ABSTRACT:** Reaction of 3,6-dichloropyridazine (**1**) with acid hydrazides, p-toluene sulfonylhydrazine, anthranilic acid derivatives and ammonium hydroxide afforded the compounds (**2a,b**), (**3**), (**4a,b**) and (**5**) respectively. Compound (**5**) reacted with aromatic aldehydes yielded the Schiff's bases (**6**) and (**7**). Compound (**6**) reacted with anthranilic acid derivatives and gave (**8**). Also, compound (**1**) easily reacted with 2-chlorobenzylamine, sodium azide and thiosemicarbazide afforded the compounds (**9**), (**10**) and (**11**) respectively.

[Mohamed H. Sherif, Gamal A. Ahmed, Adel A. Elbahnasawy and Eman O. Helal. CHEMICAL STUDIES ON 3,6-DICHLOROPYRIDAZINE. Journal of American Science 2010;6(11):570-574]. (ISSN: 1545-1003).

**Keywords:** 3,6-dichloropyridazine; acid hydrazides; p-toluene sulfonylhydrazine; anthranilic acid derivative; ammonium hydroxide

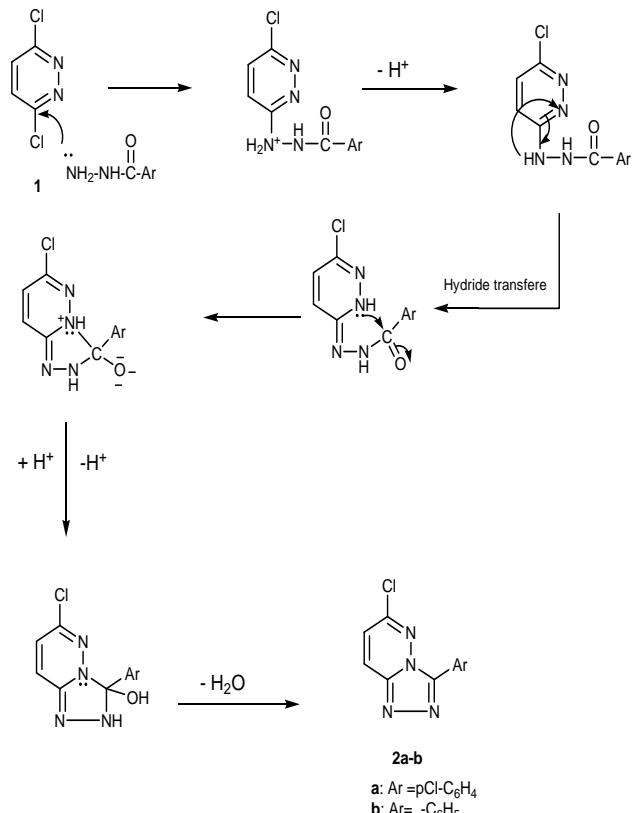

### 1. Introduction

Pyridazine derivatives continue to attract considerable attention due to the wide range of their biological activity (Yamada et al., 1981) and (Easmon et al., 2001). 3,6-disubstituted pyridazine (**1**) had a bioactive effect and was considered to be an appropriate starting material for pyridazine derivatives. It was well known that selective mono-substitution of single chlorine atom in (**1**) can be achieved when (**1**) was allowed to react with oxygen (Parrot et al., 1999) and (Huang et al., 2003), sulfur (Parrot et al., 1999), nitrogen (Rabisson et al., 2003) and (Ding et al., 2002) and o-halogen nucleophiles (Goodman et al., 1999), (Hamdouchi et al., 2003) and (Tye et al., 2006). Heterocyclic thiosemicarboxamide (pyridine and diazines) have shown an inhibitory effect on the acidity of gastric secretions (Van Hoeven et al., 1975), (Yamanoto et al., 1995) and (Pagni et al., 2000). The second important pharmaceutical property was an action against mycobacteria in particular against mycobacterium tuberculosis (Luo et al., 2004), (Caumul et al., 2005) and (Al-Awadi et al., 2007).

### 2. Results and discussion

When 3,6-dichloropyridazine (**1**) was allowed to react with acid hydrazides, namely (p-chlorobenzoylhydrazine and benzoylhydrazine) it gave the triazolopyridazine derivatives (**2a,b**) which were elucidated from their correct spectral data (Table 1).

The mechanism of reaction could be as:

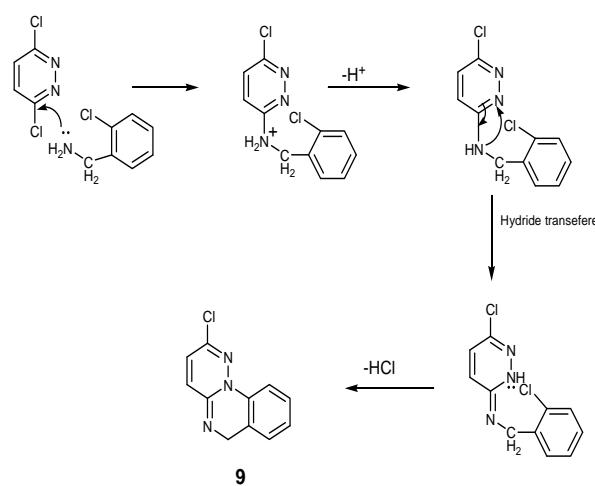

Also, compound (**1**) easily reacted with p-toluenesulfonylhydrazine afforded the compound (**3**). On the other hand, when compound (**1**) was reacted with anthranilic acid derivatives yielded the tricyclic compounds (**4a,b**).

Compound (**1**) easily reacted with ammonium hydroxide solution which formed the 3-amino-6-

chloropyridazine (5) which condensed with aromatic aldehydes, (namely, 3,4,5-trimethoxy benzaldehyde and m-nitrobenzaldehyde), and gave the Schiff's bases (6) and (7) respectively. Reaction of compounds (6) and (7) with anthranilic acid derivatives gave compounds (8a,b) (scheme 1).

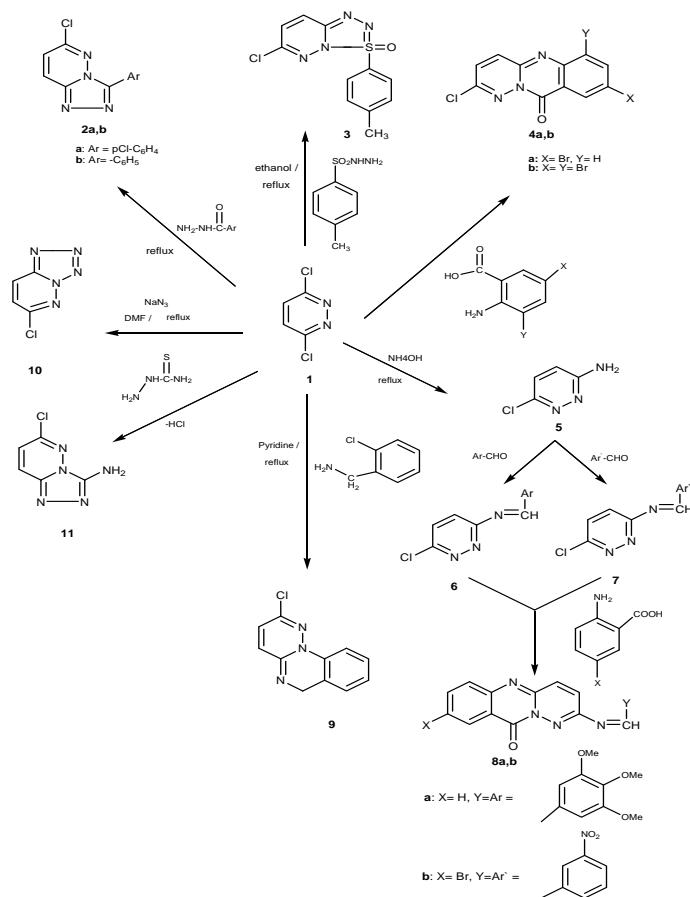

Reaction of compound (1) with O-chlorobenzylamine in pyridine afforded the tricyclic compound (9). The structure of (9) was confirmed from (1) of correct weight ( $M/e = 217$ ) and  $^1H$  NMR spectrum (Table 1). The mechanism of reaction could be as:

On the other hand, when compound (1) was allowed to react with sodium azide afforded the chlorotetrazolopyridazine derivative (10) (scheme 1). The structure of (10) was elucidated from the correct spectral data (table 1), and the mass spectrum showed a base peak at ( $M/e = 151$ ). Reaction of compound (1) with thiosemicarbazide in ethanol afforded compound (11). The chemical structure of compound (11) was confirmed from the correct spectral data (Table 1).

### 3. Experimental

All melting points were uncorrected and were determined on Gallenkamp electric melting point apparatus. IR spectra (KBr discs) were recorded on a FT/IR-400 spectrophotometer (Perkin Elmer).  $^1H$  NMR spectra were recorded on a varian-300 (DMS-d6) solution. Chemical shifts were reported as  $\delta$  values relative to tetramethylsilane (TMS) as internal reference. The mass spectra were run at 70 ev on a varian MAT 711 mass spectrometer.

**Scheme 1**

#### 1. Reaction of compound (1) with acid hydrazides; formation of compounds (2a,b).

A mixture of compound (1) (0.01 mole) and acid hydrazides, namely (p-chlorobenzoylhydrazine and benzoylhydrazine) in absolute ethanol (20 ml) was heated under reflux for 7 hours. The solid product obtained upon cooling, was filtered off, dried, and crystallized from ethanol to give compounds (2a,b) as white crystals (Table 1).

#### 2. Reaction of compound (1) with p-toluenesulfonylhydrazine; formation of compound (3).

A mixture of compound (1) (0.01 mole) and  $p$ -toluenesulfonylhydrazine in absolute ethanol (20 ml) was heated under reflux for 7 hours. The solid product obtained upon cooling, was filtered off, dried, and crystallized from ethanol to give compound (3) as white crystals (Table 1).

**Table (1): Physical and spectral data of the prepared compounds.**

### 3. Reaction of compound (1) with anthranilic acid derivatives; formation of compounds (4a,b).

A mixture of compound (1) (0.01 mole) and anthranilic acid derivatives (namely 5-bromoanthranilic acid and 3,5 dibromoanthranilic acid) (0.01 mole) in absolute ethanol (20 ml) was heated under reflux for 7 hours. The solid product obtained upon cooling, was filtered off, dried, and crystallized from ethanol to give compounds (4a,b) as white crystals (**Table 1**).

### 4. Reaction of compound (5) with aromatic aldehydes; formation of schiff's bases (6) and (7).

A mixture of compound (5) (0.01 mole) and aromatic aldehydes (namely, 3-Nitrobenzaldehyde and 3,4,5-trimethoxy benzaldehyde) (0.01 mole), in glacial acetic acid (20 ml) was heated under reflux for 7 hours. The solid product obtained upon cooling, poured on water, filtered off and crystallized from ethanol to give compounds (6) and (7) respectively as white crystals (**Table 1**).

### 5. Reaction of compound (6) with anthranilic acid derivatives; formation of compounds (8a,b).

A mixture of compound (6 and / or 7) (0.01 mole) and anthranilic acid derivatives in absolute ethanol (20 ml) was heated under reflux for 7 hours. The solid product obtained upon cooling, was filtered off, dried, and crystallized from ethanol to give compounds (8a,b) as white crystals (**Table 1**).

### 6. Reaction of compound (1) with o-chlorobenzylamine; formation of compound (9).

A mixture of compound (1) (0.01 mole) and o-chlorobenzylamine (0.01 mole) in pyridine (20 ml) was heated under reflux for 7 hours. The solid product obtained upon cooling, poured on ice , neutralized with HCl, and the precipitated solid was filtered off, washed with water, dried and crystallized from ethanol to give compounds (9) as brown crystals (**Table 1**).

### 7. Reaction of compound (1) with sodium azide; formation of compound (10).

A mixture of compound (1) (0.01 mole) and sodium azide (0.01 mole) in DMF (20 ml) was heated under reflux for 7 hours. The solid obtained upon dilution with water, filtered off and crystallized from benzene to give compounds (10) as white crystals (**Table 1**).

### 8. Reaction of compound (1) with thiosemicarbazide; formation of compound (11).

A mixture of compound (1) (0.01 mole) and thiosemicarbazide hydrochloride (0.01 mole) in absolute ethanol (20 ml) was heated under reflux for 7 hours. The solid product obtained upon cooling, was filtered off, dried, and crystallized from ethanol to give

compounds (11) as white crystals (**Table 1**).

**Abstract:** The purpose of this paper is to describe the citizen's attitude toward local government and its relationship with level of participation. Participation in local government issues, requires a favorable attitude towards local government, councilors and councils' performance in terms of efficiency. The paper is based on the study of citizens' attitude towards local government, which was carried out in Torbat Hedarieh city, Iran. The analysis of data uses Pearson correlation to determine the relationship between variables involved. The findings revealed that two level of ladder participation (Tokenism and Citizen-power) have positive and significant relationship with attitude, while Non-participation level of ladder participation has negatively significant relationship with attitude. The findings of the study imply that those respondents who have positive attitude toward local government, councilors and council performance, would have the higher tendency to be actively involved in higher levels of participation, whereas who have negative attitude toward local government, would put less effort in higher levels of participation.

**Keywords:** Citizen attitude, Citizen participation, Local government, social exchange.

## 1. Introduction

There is consensus among scholars, which attitude toward local government is regarded as effective factor to people's participation in local government. Some scholars generally agree that positive attitude toward local government encourage citizens participation in council matters (Kosecik & Sagbas, 2004, Suzanne et al, 2007). As local governments become increasingly important in citizens' everyday lives, the investigation of public attitude toward local government is vital for success of future council programs and reforms. Without regular and systematic analysis of public attitude, viable local government policies will become more difficult to design and implement in the future.

The development of local government is ensure people's involvement in local government matters, thus, promoting people's participation in local government is important. Aldashev (2003) considers participation as a social behavior, and Rishi (2003) added attitude as a central element in social behaviors and argued that attitude is imperative for making change of the behaviors. According to Rishi (2003) social actions of people or their personal program are directed by their attitudes, if the attitude of people is positive toward an event or an action, it is more likely, that they divert their behavior in more meaningful way (Rishi, 2003). Similarly, if local people have positive attitude towards local government, it is more likely that they support the local government issues as well as participating more

in local government matters. Thus, understanding the citizen attitude can help to access the degree/level of citizen participation in council issues. The main objective of this study is to describe the relationship of citizen's attitude toward local government and level of people's participation in local government, on the basis of social exchange theory. The paper attempts to establish a relationship between social exchange theory, attitude of citizens and level of people's participation. This research is important because up to present moment, there has been very little research or discussion focusing upon the attitude toward local government and its relationship with level of participation in council matters. And also in this study, the participation of people in local government is linked with theory of social exchange. The theory of social exchange has been given only limited attention in participation in local government literature, even though it has been extensively used in other areas such as; tourism (Aref, et al, 2009), and agriculture (Bagherian, et al, 2009).

## 2. Literature Review

Citizen participation is considered as an important factor for successful and prosperity of local government. Citizen's participation in local government produce more efficiency in programs as well as promote good governance (Lowndes et al, 2001, According to Aref et al, (2009), without community participation, there are obviously no accountability, no development, and no program. Ashley & Roe, (1998) describe community participation as a spectrum from passive to active involvement to full local participation, where there is active community participation and venture ownership. Meanwhile, some scholars such as; Pretty (1995), Oakley (1991), Johnson (1982), and Wandersman (1987), provided a typology of participation, but the most suitable typology adopted in urban issues is Arnstein ladder. According to Arnstein; participation is a process that enables "have-nots" citizens, those who are excluded from decision-making process, to be included in future. It is the strategy that have-notes involve in sharing-information, and join to set priorities and goals. The Arnstein's ladder has eight rungs and each rung corresponding to the extent of citizens' power in determining the plan and/or program. The eight rungs are categorized into three categories. The bottom rungs of the ladder are manipulation and therapy. These two rungs describe level of non-participation, which the real objective is not to enable people to participate in planning, but to enable power-holders to educate the participants. The following categorization involves three levels of tokenism;

informing, consultation, and placation. In this level citizens may indeed hear or be heard, but under these conditions they lack power to influence decisions (Arstein 1969). It is the illusion of a voice without the voice itself. The highest level of ladder is citizen-power, which include; partnership, delegated power and citizen control. In this level, citizen control all issues and win the majority of decision-making seats.

Todays, Local government are well placed to play a crucial role in enhancing citizen's participation and enabling local communities to participate in decision-making process (Mariana, 2008).

Local government is an essential component of administrative systems of all modern societies, which look for the improvement of public services and provide the situation for reaching/achievement good governance values at local level (Kosecik and Sagbas, 2004). Local government provides opportunities for public participation, and ensures effective and efficient public service delivery (Stoker, 1996: 6). Public participation at local level is achieved only if local people have an interest in local government affairs. The efficiency and effectiveness of local government is ensured when local people or citizens participate in the decision-making process of local government and keep local government under control (Kosecik and Sagbas, 2004, Jerry and David 1996). Local government will make better decisions and will have greater impact on their communities, when they increase the frequency, diversity and level of engagement of local people. Citizen involvement in local government will produce more public-preference decision making on part of administrators and better appreciation by the larger community among the public (Stivers 1990, Oldfield 1990, Box 1998).

These attitudes about the benefits of participation in local government are evaluated by citizens. The evaluation of the benefits and costs of local government by citizens link this study with social exchange theory.

This theory asserts that people develop attitudes toward others and things based on the benefits they could obtain while those activities assuming to increase benefits will be positive support and activities assuming to be costly will tend to be perceived negatively (Napier & Napier, 1991). Social exchange theory argues that all human relations are formed by the use of a subjective cost-benefit analysis. For social exchange when the costs and benefits of a relationship are equal, the relationship is defined as equitable. The concept of equity is fundamental in social exchange theory.

In Homans' (1958) view, who is the initiator of the theory, the social behavior is an exchange of goods, material goods and also non-material goods, this can be symbols of approval or prestige. Blau,

(1964) also notes that individuals can also enter into and maintain relationships, they can satisfy their own interest as long as they are sure that the benefits outweigh the costs.

**Tbale 1: level of citizen participation in local government**

Levels	Types	Characteristics
Citizen-power	Citizen control	This range is the highest level. Citizens have the degree of power (or control) which guarantees the participation in governing a program from citizens (Arnstein, 1969).
	Delegated power	Citizen participation is performed through negotiations between citizens and authorities, this results in positive role the citizens played in partial decision making with the authority over a particular plan or project (Arnstein, 1969).
	Partnership	power is in fact redistributed through negotiation between citizens and power-holders (Arnstein, 1969).
Tokenism	Placation	<i>Placation</i> is a stage that citizens begin to have some degree of influence though tokenism is still apparent (Arnstein, 1969).
	Consultation	people are invited to give their suggestions, this rung of the ladder is still a sham since no assurance is offered. Concerns and ideas of citizens will not be taken into consideration (Arnstein, 1969).
	Informing	authorities inform citizens of their rights, However, more emphasis is put on a one-way flow of information (Arnstein, 1969).
Nonparticipation	Therapy	With respect to group therapy, masked as citizen participation, should be on the lowest rung of the ladder because it is both dishonest and arrogant (Arnstein, 1969).
	Manipulation	Based on so-called citizen participation, people are placed on rubber stamp advisory committees (Arnstein, 1969).

**Source:** Sherry Arnstein, 1969.

Prekumar and Ramamurthy (1995) declared, social exchange theory has been used by some researchers as a theoretical framework to investigate the community relationships that are not based on the economical aspects, rather than they are based on non-economical aspects, such as power, trust, interdependency, and the like. Therefore, this theory is not only for exploration of the economic relations, rather it can be used for exploration of non-economic and social relationships. Prekumar and Ramamurthy (1995) stated social exchange theory provides the base for the study of relationships between groups

and organizations in community (Prekumar and Ramamurthy 1995, p. 306). According to social exchange theory, the outcomes of an collective/organization's behavior will be related to the responsive behavior of the other participants within the relationship (Son et al. 2000). The main issue of this viewpoint is that the relationship between community groups does not necessarily need to be directly related to any economic outcomes (Hallen et al. 1991, Humphreys et al. 2001). Humphreys et al. (2001) postulate that social exchange theory is a appropriate base for studying

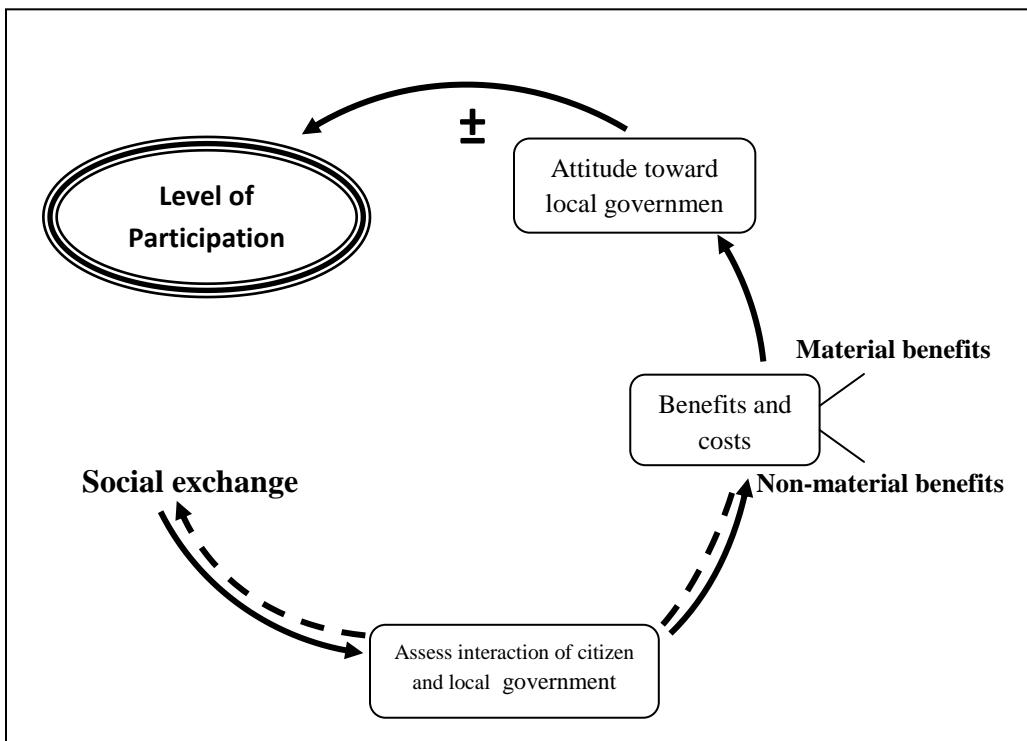

non-profit relationships. So, in terms of people's participation in local government, the social exchange theory is adopted to investigate the social aspects of relationships between citizens and local government. According to Ledingham (2001) Citizens tended to participate in local government, when they perceive that local government is providing benefits for local people, acting in the best interest of local people, and dedicating resources to support matters of importance of citizens in the exchange relationship between people and local government. He added Citizens expect mutual interactions with local government, they seek a balance between social costs of interaction with their local government. Ledingham and Bruning (2001) concluded: "To be effective, relationships need to be seen as mutually beneficial, based on mutual interest between an organization and its significant publics". People cannot be expected to present positive attitude toward local government if the benefits and costs of local government is not equal for them.

An attitude is a hypothetical construct that represents an individual's degree of like or dislike for an item. Attitudes are generally positive or negative views of a person, place, thing, or event- this is often referred to as the attitude object (Bagherian, et al., 2009). Attitudes are generally viewed as a kind of disposition toward various aspects of the world including persons, events and subjects. It has been generally believed that attitude change is necessary before other behavioral modifications can be effected (Zainuddin, 1977).

Kosecik & Sagbas (2004) found that there is a relationship between citizens' attitude toward local government and level of participation in local government affairs. Stevenson (2007) found that people with positive attitude toward local government are more likely to participate in local government. Rishi (2003) outlined that understanding of attitudes is one of the central concerns in social life and is relatively crucial in bringing the desired change in the behavior. Collective and personal actions of people are directed by their attitudes. Attitudes make it possible to predict and control the behavior, which ultimately is useful to implement program successfully. Kosecik & Sagbas (2004) in

their study found, public attitude affects public participation and that is an essential element for increasing participation in local government. The positive attitude toward local government can make local people more active and eager to participate in activities that are related to local government. According to Hiskey and Seligson (2003) there is link between performance of local government and citizen attitude, he demonstrates as a first step, performance of local government affect citizen attitude toward council. It is unlikely that performance of local government affect citizen attitude but does not influence their level of participation (Hiskey and Seligson, 2003). Aspden and Brich (2005) demonstrated that there are a number of factors and issues that affect the publics' attitude towards participation in local affairs and decision-making. Their demonstration consist of the; citizen interest and understanding of local government, citizens satisfaction for their involvement, citizen trust to local government and its members, and previous experience of voluntary participation (Aspden and Brich, 2005). A better understanding of citizen attitude is necessary if councilors are to address the very real problems of apathy of citizens that hinder public participation, and if they are maximize the impact and effectiveness of participation (Lowndes, et.al, 2001). Public attitude toward local government might differ according to certain variables such as, age sex, education, occupation, and income (Kosecik & Sagbas, 2004). These variables have considerable influence in citizen attitude toward local government and consequently in their participation in council affairs.

According to the above figure, the social exchange theory is used to illustrate that citizens assess their interaction and cooperation with local government based on benefits and costs that its brings to them. Participation occurs when the cost of participation is low and the benefit of participation is high, and consequently it makes positive attitude toward participation in local government. But if the costs outweigh the likely benefits, no interest to participation.

**Figure 1; Cycle of social exchange theory, attitude toward local government and level of participation**

### 3. Research Design

The study was carried out on 400 citizens in Torbat Heydarieh. Torbat Heydarieh is located in the east north of Iran in Khorasan Razavi province; it is 1005km far from Tehran (capital of Iran). In Iran, the size of council range is between five and fifteen depending on population. Since the population of Torbat Heydarieh is less than 200'000, so, the members of local government are seven (the Constitution of Islamic Republic of Iran). In some big cities, local government has established neighborhood councils due to increase in public participation for achievement of its targets. Neighborhood councils are subset of local government, which try to close the members of local government to local people and recognize their problems. In Iran among the cities with less than 200,000 populations, Torbat Hedarieh was the first city that established neighborhood council, for increasing public participation and improving the issues. According to Ghanizadeh (1999) "in Iran, neighborhood councils by attraction of public participation have could given assistance to local government in executive issues".

The study used survey design in which questionnaire was used to collect the data. Questionnaires are well-established methods of collecting data within social science research (Dillman, 2000). Questionnaire survey is a useful tool of research that are related to community participation (Shin, 2004). A questionnaire is a data instrument that each respondent fills out as part of participating in research study (Johnson & Christensen, 2004). The respondents were 400 citizens, where each citizen as respondents was chosen randomly.

In this study Cluster Sampling was used. This is type of random sample that use multi stages and is often used to cover wide geographic areas. Cluster sampling was chosen because we believe through that, we can select a proxy for community that they represent the voice of people. The population of this research will be all of the inhabitants include men and women and 17 above years who live in Torbat Hedarieh. Eleven questions were developed based on the literature review of the measurement of attitude toward local government. The respondents were asked to insure these questions which were constructed to gauge their attitude

toward local government, councilors and its efficiency. The questionnaire was piloted tested to have its content validated by several reviewers of Persian background. Statements for citizen attitude were tested for their validity using Cronbach's alpha. The respondents in pilot study had diverse demographic characteristics, especially with regards to community.

To test the proposed objective, this research was used statistical statics such as Pearson correlation and descriptive statistic. Pearson correlation was employed to measure the degree of relationship between variables involved (the attitude toward local government and levels of participation). Pearson correlation statistic is a statistical technique to measure the strength of the association that exist between two quantitative variables (Ary et al., 1996). In statistics, correlation (often measured as a correlation coefficient) points to the strength and direction of a linear relationship between two variables that has been determined randomly (Aref and Redzuan, 2009). And, Descriptive analysis was employed to determine level of people participation. In this study participation is a composite variable, consisting of three level, namely, nonparticipation (5 items), tokenism (7 items), and citizen power (9 items). The study used Likert-scale to measure every item. In the analysis, the citizen attitude was correlated with the three levels of participation in order to determine the strength of their relationships. Meanwhile, means and standard deviations are the descriptive statistics that were used to describe the basic features of these variables.

#### **4. Result and Discussion**

As have been mentioned above, the main objective of the study is to determine the relationship between citizens' attitude toward local government and level of participation. Pearson correlation was used to identify these relationships. Table 1 shows the findings of the study in relations to means and standard deviations of studied variables. For the three variables related to level of participation (nonparticipation, tokenism and citizen power), the data reveal that generally, the mean scores of nonparticipation level is higher than tokenism and citizen-power. This is reflected by the means of every level – nonparticipation level ( $M = 20.26$ ,  $SD = 3.12$ ), tokenism level ( $M = 17.27$ ,  $SD = 3.93$ ), citizen-power level ( $M = 15.91$ ,  $SD = 4.8$ ). These findings imply that participation in nonparticipation level is more frequent than tokenism and citizen-power. Moreover, the standard deviations show that there are relatively small deviations (differences)

between respondents (citizens) in terms of their participation in each level. Meanwhile, the mean of citizens' attitude in regard to local government is relatively moderate ( $M = 27.03$ ,  $SD = 7.90$ ). It implies the majority of citizen have relatively moderate attitude toward local government, councilors and its performances.

The second analysis for this paper focuses on the relationships between the attitude toward local government and the level of participation based on Arnstein ladder. The results of the analysis are shown in table 2. The correlation between citizen attitude and nonparticipation level is found to be negatively significant ( $r = -.414$ ,  $N = 400$ ,  $P = 0.000$ ). Meanwhile, the correlation between citizen attitude and the level of tokenism is found to be positively significant ( $r = .323$ ,  $N = 400$ ,  $P = 0.000$ ), as well as the correlation between citizen attitude and citizen power is positive and significant ( $r = .385$ ,  $N = 400$ ,  $P = 0.000$ ).

When comparing the nonparticipation, tokenism and citizen-power levels of participation with attitude toward local government descriptively, Non-participation level has a negative relationship with attitude. - Since this level is unrealistic and superficial and its real objective is not to enable citizens to participate in planning (Arnstein, 19969), this relationship is understandable. Because whatever attitude towards local government is positive, Participation will be increased. And it can surpass non-participation level to reach higher levels, i.e Tokenism and Citizen-Power - . However, Tokenism and Citizen-Power levels have positive relationship with attitude. It confirmed the assumption that participation will be increased when the attitude of local people be positive toward local government, its efficiency, and its services (Aspden and Brich, 2005).

The findings from this study supported the previous studies in terms of citizen attitude toward local government and their participation in local government. The findings also are consistent with the past studies that have been concluded by Stevenson (2007) and Suzanne et al (2007). Most of these studies evaluated citizen attitude toward the local government and services that are provided by it, and the role of citizen attitude in participation.

In addition study indicated that those people who had positive attitude toward program more likely to participate in program. These findings also are consistent with results of Rishi (2003), Shahroudi and Chizari (2008), Vicente (2008) and Asadi *et al.* (2009) in their research that found significant

relationship between attitude and level of participation.

**Table 2: Means and Standard Deviation of the studied variables**

Variables	Means	Standard Deviation
Level of nonparticipation	20.26	3.12
Level of tokenism	17.22	3.93
Level of citizen-power	15.91	4.8
Attitude toward local government	27.03	7.90

**Table 3: Correlation Matrix Analysis of Attitude toward Local government and Levels of Participation (n=400)**

Variable	X	Y <sub>1</sub>	Y <sub>2</sub>	Y <sub>3</sub>
X- Attitude toward local government	1.00			
Y <sub>1</sub> - Non-Participation level	-.414**	1.00		
Y <sub>2</sub> - Tokenism level	.323**	.418**	1.00	
Y <sub>3</sub> - Citizen-Power level	.385**	-.491**	.493**	1.00

\*\* Correlation is significant at 0.01 level

## 5. Conclusion

By using social exchange theory framework, this paper attempts to illustrate the relationship between attitude towards local government and the level of participation. This theory helps to create a clear understanding about the relationship between perceived attitude and support for local government matters.

This study aimed at examining citizen attitude to local government and its relationship with level of participation, based on the findings of the questionnaire carried out in Torbat Hedarieh city, Iran. The basic argument about this study was that citizen's participation is the most important part of local government, which enhanced efficiency and effectiveness of council issues. The efficiency of the performance of local government is ensured if citizens participate in decision-making process and hold local government accountable. If citizens are not interested in local government and remain passive, it is not expected that the responsibilities of local government to the citizens will be undertaken.

From the study, it is found that there is linear relationship between level of participation and citizen attitude. It can be concluded that, if citizen attitude toward local government is positive, it is more likely that citizens are willing to participate in council affairs. Also, according to literature and other researches, attitude is one of the most important and effective factors for participation in local

government, which play a significant role in encouraging citizens to participate. Therefore the result of this study indicates main recommendation, that is; focus on measures which are believed to improve citizen attitudes to local government. The findings of this study have an implication on understanding the role of attitude in participation in local government. It is suggested that the good performance of local government make a positive attitude toward local government among citizens or local people. Consequently local government can receive a support from local communities. As, local government is important to citizens in daily lives, positive attitude toward local government can encourage them to engage in council issues. However the creation of such attitude toward local government in Iran has always been challenged, because, people would rather consider local government as a governmental organ than public and non-governmental organ, level of public knowledge about the functions of local government, and lack of efficient and expertise among councilors.

# Algal Abundances and Growth Performances of Nile Tilapia (*Oreochromis niloticus*) as Affected by Different Fertilizer Sources

M.A. Elnady\*, H.A. Hassanien, M.A. Salem and H. Marian Samir

Department of Animal Production, Faculty of Agriculture, Cairo University, Giza , Egypt .

\*[melnadyahmed@yahoo.com](mailto:melnadyahmed@yahoo.com)

**Abstract:** The experiment was designed to study the effect of different fertilizer sources (chemical fertilizer, organic fertilizer or combined chemical +organic fertilization) on plankton abundances , growth performances of Nile tilapia juveniles and water quality parameters in concrete tanks compared to feeding fish at satiation .The average secchi disk readings were shallower in the chemical and combined fertilizer treatments compared to those of the ration and organic fertilizer treatments as a result of increased algal density and abundances. Ammonia and orthophosphate concentrations in the chemical and combined fertilizer treatments were higher with an increase in algal growth, abundance. Within fertilizer treatments, the daily weight gains of Nile tilapia reared in the chemical and combined fertilizer treatments (0.43 and 0.5 g/fish/day, respectively) were significantly higher than those reared in the organic fertilizer treatment (0.32g/ fish/ day). This indicated that the use of chemical fertilizer in a fertilization program is superior in increasing fish growth compared to that of the organic fertilizer .It can be concluded that Nile tilapia juveniles can obtain major nutritional requirements for growth( 48% of its total feed requirements) from feeding only on algae during this stage of growth. Results of the current experiment recommended that organic fertilizer should not be used as sole source in fertilizer programs and should be combined with chemical fertilizer in order to produce good algal growth necessary for the nourishment of farmed fish.

**Key words:** Fertilizers, manure, algae, plankton, Nile tilapia.

## 1. Introduction:

Pond fertilization through organic and inorganic sources has become a management protocol in aquaculture (Bhakta et al., 2006). Almost all extensive and the majority of semi- intensive aquaculture operations in Asia are dependent on the use of chemical fertilizers and organic manures (De Silva and Hasan, 2007). The purpose of pond fertilization is to augment fish production through autotrophic and heterotrophic pathways (Jha et al., 2008). Natural food supply is enhanced by using organic and inorganic fertilizers and low-cost supplemental feeds derived agricultural by-products (Halwart et al., 2002). It is well known that high fish yield can be achieved by higher abundance of plankton in culture system (Jha et al., 2004). Teferi et al.(2000) found that Nile tilapia was essentially planktivorous. Moreover, small tilapia filtered significantly more phytoplankton than larger individuals (Turker et al., 2003).

Chemical fertilization of ponds effectively stimulated primary productivity and mean chlorophyll a concentration (Green et al .,2002) and application of medium amount of chemical fertilizers ( urea and TSP) as pond inputs has been proven to

produce up to a three- fold increase in fish yield (Pant et al., 2002). Pond fertilization practices using animal wastes are widely used in many countries to sustain productivity at low costs (Gupta and Noble, 2001; Majumder et al., 2002) since soluble organic matter supplied to ponds by using manure stimulate phytoplankton growth (Sevilleja et al., 2001). Moreover, it increases biomass of zooplankton and benthic organisms (Atay and Demir, 1998). Consequently, animal wastes lead to increased biological productivity of ponds through various pathways, which result in an increase in fish production (Dhawan and kaur, 2002).

The study was designed to explore whether chemical fertilizer (nitrate and phosphate) is superior to organic fertilizer (pigeon manure) in promoting natural food abundance and fish growth compared to the combined use of both chemical and organic fertilizer in rearing tanks.

## 2. Materials and methods

The current experiment on growth performances of Nile tilapia (*Oreochromis niloticus*) was conducted at the Fish Culture Research Unit, Faculty of Agric.,

Cairo Univ., Egypt. The experiment was performed in outdoor concrete tanks (2.0 x 1.2 x 1.0m each).

The experiment consisted of four treatments with three replicate tanks per treatment as follows:

1-The chemical fertilizer treatment included a weekly application of ammonium nitrate ( $\text{NH}_4\text{NO}_3$ , 33%N) at 2 g / $\text{m}^2$ /week and superphosphate ( $\text{P}_2\text{O}_5$ , 15.5%P) at 2 g / $\text{m}^2$ /week.

2-The organic fertilizer treatment included a weekly application of dry pigeon manure at a rate of 16 grams dry matter/ $\text{m}^2$ / week (40 grams/ tank/ week).

3-The combined fertilizer treatment included the application of both chemical fertilizers (ammonium nitrate at 2 grams/  $\text{m}^2$ / week + superphosphate at 2 grams/  $\text{m}^2$ /week) and pigeon manure fertilizer (16 grams dry matter/  $\text{m}^2$ /week) in the same tank.

4-The ration treatment included the application of commercial diet (30% crude protein) as fish feed administrated to satiation, six day per week. The experiment lasted 90 days.

The growth performance parameters of juveniles were measured in terms of total length, body weight, specific growth rate, weight gain, daily weight gain and condition factor .Fish growth data were estimated using average individual weight and length to the nearest 0.1 g and 0.1 cm, respectively. The daily weight gain was determined using the formula  $(\text{DWG}) = (\text{WT}_F - \text{WT}_I) / T$  where  $\text{WT}_F$  = final fish weight (g),  $\text{WT}_I$  = initial fish weight (g) and  $T$ = growing period (days) between initial and final weight. Specific growth rate (% body weight day $^{-1}$ ) was calculated using the formula:  $\text{SGR}=(\ln \text{WT}_F - \ln \text{WT}_I) \times 100 / T$ . The condition factor of fish was calculated from the formula  $K= \text{WT}_F / L_F^3 \times 100$  where  $\text{WT}_F$ = final fish weight (g),  $L_F$  =the final total length (cm).

Water from each tank was tested once a month for temperature ( $\text{C}^\circ$ ), secchi disk visibility (SD), PH, ammonium ( $\text{NH}_4$ ), and orthophosphate – phosphorus ( $\text{PO}_4\text{-P}$ ). All determinations were carried out in the Water Research Laboratory, Ministry of Irrigation, Qanater Khayria, Egypt .Chemical analyses were carried-out according to the Standard Methods, American Public Health Association (APHA, 1993).

Statistical analyses were performed using one way analysis of variance (ANOVA) and Duncan's multiple range test to determine differences among treatment means at a significance level of 0.05. Means (X) and standard deviations (S.D.) were calculated accordingly. Statistical tests on parameter

values were conducted using (SAS INC, 1992) computer software.

### 3. Results and Discussion:

As shown in table (1), the average water temperatures during the experimental period were 28.6, 29.1, 29.7 and 28.7  $\text{C}$  in chemical, organic, combined and ration treatments, respectively. This indicated that average water temperatures in all treatments were optimal for fish growth and algal production. Tilapia is known to increase their growth rate when water temperature is above 25  $\text{C}^\circ$ , with optimal growth rate taken place when water temperature is 25-30  $\text{C}^\circ$  (Boyd, 1990).

The overall average of total ammonia concentration in tank water during the experimental period indicated that the chemical fertilizer treatment had an over abundance of ammonia (0.708 mg / l ) followed by combined fertilizer (0.623 mg / l ), ration (0.475 mg / l ) and organic fertilizer (0.381 mg / l ) treatments, respectively. The shallow secchi disk readings during the experiment in the chemical fertilizer and combined fertilizer treatments ( 22.9 and 27.1 cm, respectively) were due to the effect of over- abundance of ammonia in water which increased algae growth. This resulted in an increase algae turbidity (concentration) and shallower secchi disk readings in those treatments.

Although organic fertilizer may be consumed directly or as manure- derived detritus after heterotrophic microbial activity, the role of manure or manure – derived detritus as a source of food for fish is not universally known (Knud-Hansen et al., 1993). Manure is a costless fertilizer that stimulate the development of natural foods especially phytoplankton and zooplankton (Lan et al.,2000). Animal wastes lead to increased biological productivity of ponds through various autotrophic (algae production) and heterotrophic (bacterial production) path-ways, which result in an increase in fish production (Orhibhabor and Ansa, 2006).

Plankton levels ( phyto- and zooplankton) were significantly higher and fish growth was significantly more in manured ponds ( Dhawan and kaur,2002). When comparing different treatments, zooplankton was significantly higher in manured ponds (Kumar et al., 2005) and the highest density of zooplankton was obtained from pond water that had high concentration of nitrogen and phosphorus salts (Lan et al., 2000). Organic manures contain almost all the essential nutrient elements (Jana et al.,2001) that stimulate the growth of plankton ( Wurts,2000 ; Ansa & Jiya,2002; Kadri & Emmanuel,2003) and consequently, manure contains considerable quantities of nutrients for fish production (Gabriel et al., 2007).

Ammonia production in tank water of the three fertilizer treatments was mainly through the decomposition of dead algal by bacterial activity and the mineralization of algal protein into ammonia by fish and aquatic animals. According to Ludwig(1999) when organic fertilizers are added to pond they are decomposed by bacteria , releasing ammonia and phosphates which are rapidly utilized by phytoplankton and other bacteria (Jha etal., 2008). The three fertilizer treatments enhanced algal production and decomposition in their tanks and led to the accumulation of ammonia over time in the fertilized tanks .The high build up of ammonia concentration in the chemical fertilizer and combined fertilizer treatments was due to the increase in the intensity of algal production, followed by bacterial decomposition of dead algae in the sediment. Dead algae are mineralized to ammonia by bacterial action in the presence of aerobic conditions (Hargreaves, 1998).

Mineralization of organic matter in sediment and the consequent regeneration of nutrients at the sediment-water interface in aquaculture ponds is important as a source of ammonia to the water column (Hargreaves, 1998). A simulation model describing ammonia dynamics in commercial catfish ponds estimated that 25 to 33% of the ammonia supplied to the water column was derived from the sediment (Hargreaves, 1997). As shown in Table (1), the chemical fertilizers stimulate the natural productivity, through photosynthesis, whereas animal manures provide, upon decomposition, nutrients for both autotrophs and heterotrophs (Nguenga el al., 1997).

The high ammonia concentration in the ration treatment (0.475 mg/l) was caused by the mineralization of dietary protein into ammonia during metabolism by fish and aquatic animals. Normally 40-90% of the nitrogenous wastes, resulting from the metabolism of dietary proteins is excreted by fish and shrimp as ammonia from the gills and in urine (Goddard, 1996).Most of this ammonia is excreted passively in the unionized form from the gills.

Phytoplankton is known to absorb ammonia readily at higher rate compared with nitrate (Boyd, 1990).Ammonia is known to be utilized by phytoplankton during the process of protein synthesis (Kumar et al., 2005). The major sources of ammonia in pond water are the direct excretion of ammonia by fish (Tucker and Boyd, 1985) and microbial decomposition in the sediments .In catfish ponds, daily feed addition during the warmer months results in inputs of 200 – 400 mg N/m<sup>3</sup>/day and 30-60 mg P/m<sup>3</sup>/ day (Massout, 1999). Nitrogen and phosphorus salts are known to be major nutrients required for the primary production of plankton in pond water (Kumar et al. 2005).

Total ammonia concentration (TAN) was a major factor that affected algae concentration and production in water during the experimental period.

This is in agreement with Padmavathi and Ptasad (2007) who indicated that high PH and ammonia levels are associated with algal blooms. Higher total ammonia concentrations in the chemical fertilizer and combined fertilizer treatments were correlated positively with higher algal abundances (shallower secchi disk readings).As shown in table (1), the lower total ammonia concentrations in the organic fertilizer and ration treatments produced lower algal abundances compared to other treatments. This indicated a lower efficiency of organic fertilizer in respect to ammonia production in water .The present results are in accordance with Green et al. (2002). Organic fertilizer should not be used as sole source in fertilizer programs and should be combined with chemical fertilizer in order to produce good algal growth necessary for the nourishment of farmed fish.

Orthophosphate (PO<sub>4</sub> – P) was significantly higher ( $p < 0.05$ ) in the chemical and combined fertilizer treatments compared to those of the organic fertilizer and ration treatments (table 1). The overall mean of orthophosphate concentrations were 0.575 and 0.527 mg – P /l for the chemical and combined fertilizer treatments, respectively, while those of the organic fertilizer and ration treatments were 0.295 and 0.18 mg - P/l , respectively. The increased algal abundances in the chemical and combined fertilizer treatments (secchi disk readings = 22.9 and 27.1 cm, respectively) were also due to the higher concentrations of orthophosphates in those treatments.

Fluctuations of environmental factors in relation to growth of *Tilapia mossambica* exposed to single superphosphate indicated that fish growth was dependent upon the plankton organisms .The harvest weight of fish was significantly positively correlated with the phosphate, available phosphorus and calcium carbonate (Sarkar and Konar, 1989). Soluble reactive phosphorus and total phosphorus concentrations were both correlated with fish production (Wudtisin and Boyd, 2005).

Averages orthophosphate (PO<sub>4</sub> – P) concentrations were 0.295 and 0.187 mg/l PO<sub>4</sub> – P in the organic fertilizer and ration treatments, respectively, which were much lower than those of other treatments (table 1). This lowered the photosynthetic rate and algal abundance in those treatments (secchi disk readings were 39.8 and 36.1 cm, respectively) and negatively affected growth rate of fish in the organic fertilizer treatment since algae is food material for fish. These results were consistent with Wudtisin and Boyd (2005).

Sources of orthophosphate ( $\text{PO}_4^{3-}$ -P) in ration treatment were primarily a product of dietary phosphorus metabolism by fish through excretory processes .Kund-Hansen et al. (1993) evaluated the functional role of chicken manure for Nile tilapia *Oreochromis niloticus* production in central Thailand. Regression analysis suggested that chicken manure P was about 10% effective as TSP-P at increasing net fish yield (NFY). Simple economic comparisons discourage the purchase of chicken manure as a source of soluble N and P for increasing algal productivity in Thailand (Knud- Hansen et al., 1993).

Because of low N and P content and high oxygen consumption, organic fertilizer alone is unlikely to provide adequate nutrients for algae and sufficient oxygen for fish. To stimulate the growth of

food organisms for fish in aquaculture ponds, a combined use of inorganic and organic fertilizer is recommended, but the amount of organic fertilizer should be determined with care to avoid water quality deterioration ( Qin et al., 1995).

As shown in table (1), early morning pH in concrete tanks were significantly high ( $p<0.05$ ) in the chemical fertilizer treatment (8.5) than those of the combined fertilizer (7.86) or ration (7.63) treatments. This may be due to the higher algal growth and production in the chemical fertilizer treatment compared to other treatments. The pH of water increases when plants are rapidly removing carbon dioxide from water for use in photosynthesis (Boyd, 1990).

**Table (1). Averages of water quality parameters in experimental tanks under different fertilizer treatments.**

Parameter Treatment	chemical fertilizer	organic fertilizer	combined fertilizer	ration treatment
Water temperature (C°)	28.6 <sup>a</sup> ± 0.8	29.1 <sup>a</sup> ± 1.2	29.7 <sup>a</sup> ± 1.5	28.7 <sup>a</sup> ± 0.7
Total ammonia (mg-N/l)	0.708 <sup>a</sup> ± 0.18	0.381 <sup>b</sup> ± 0.16	0.623 <sup>ab</sup> ± 0.19	0.475 <sup>ab</sup> ± 0.09
Early morning pH	8.5 <sup>a</sup> ± 0.4	7.46 <sup>b</sup> ± 0.51	7.86 <sup>ab</sup> ± 0.25	7.63 <sup>b</sup> ± 0.45
Orthophosphate (mg-P/l)	0.575 <sup>a</sup> ± 0.03	0.295 <sup>b</sup> ± 0.04	0.527 <sup>a</sup> ± 0.1	0.18 <sup>b</sup> ± 0.03
Secchi disc depth (cm)	22.9 <sup>a</sup> ± 6.3	39.8 <sup>c</sup> ± 5.6	27.1 <sup>ab</sup> ± 2.6	36.1 <sup>bc</sup> ± 4.7

-a,b,c means with different superscripts among treatments are significantly different( $p < 0.05$ ).

The least early morning pH (7.46) was observed in the organic fertilizer treatment ( $p<0.05$ ). This was due to the negative effect of the organic manure on the pH value of water. In this case, heterotrophic activities of aerobic bacteria reduces pH through respiration (Boyd, 1990). Early morning pH in the combined fertilizer and ration treatments were significantly lower ( $p<0.05$ ) compared to that of the chemical fertilizer treatment. This may be due to their higher organic inputs (diet or manure inputs) and the increased heterotrophic activities by aerobic bacteria on these inputs .Organic manure and dietary wastes decompose and serve as a continuous source of carbon dioxide (Boyd, 1990) and when carbon dioxide accumulates in water ,water pH declines.

The higher early morning pH reflected higher algal production and increased photosynthetic activities that resulted in higher algal concentration and abundances .These results are in accordance with

Padmavathi and Ptasad (2007)who elucidated the fact that high PH levels were associated with algal blooms

.In intensive aquaculture, high density algal blooms can lead to high water pH (Pote et al., 1990) and the relationship of photosynthesis and respiration to pond pH has been well documented by Tucker & Boyd (1985) and Boyd (1990) who reported that autotrophic activity increases water pH through  $\text{CO}_2$  absorption, while heterotrophic activity decreases water pH through respiration.

The average secchi disk readings were significantly lower ( $p<0.05$ ) in the chemical and combined fertilizer treatments (22.9 and 27.1cm, respectively) compared to those of the ration and organic fertilizer treatments (36.1 and 39.8 cm, respectively).This was due to the increased algal density and abundance in the chemical and combined fertilizer treatments compared to other treatments. The ammonia and orthophosphate concentrations in

the chemical and combined fertilizer treatments were significantly higher ( $p < 0.05$ ), increasing algal growth, abundances and biological turbidity of water reducing water visibility in those treatments.

The secchi disk visibility data indicated that the chemical and combined fertilizer treatments had good algal abundances and were better considering sound water quality management applied in fish farming. Semi-intensive aquaculture ponds often develop dense phytoplankton population ( chlorophyll A  $> 250 \text{ mg/m}^3$  and secchi disk visibility  $< 20 \text{ cm}$ ) in response to a high rate of nutrient input (Hargreaves, 1998). In addition, monthly net fish yield of *Oreochromis niloticus* was strongly correlated to secchi disk depth, total phosphorus and water temperature (Diana et al., 1988).

Concentrations of both ammonia and orthophosphate salts required to increase algal growth were least in the organic and ration treatments. This lowered algal abundances and increased secchi disk visibility depth in those treatments. The ration treatment did not receive any fertilizers consequently, algal abundance (turbidity) was lower and secchi disk reading was higher in that treatment.

Algae were the major source for Nile tilapia nutrition in the fertilized tanks, and the decreased secchi disk visibilities in the fertilizer treatments indicated a good potential for fish nutrition. Jamu et al (1999) reported that secchi reading is commonly used by aquaculture pond managers as an indicator of algae concentration in pond water. Almazan and Boyd (1978) found a high degree of correlation between phytoplankton abundances, secchi disk visibility, gross productivity and chlorophyll "a" content.

During this investigation, an over-abundance of algae (required for fish nutrition) in the chemical and combined fertilizer treatments over those of organic and ration treatments was detected. Algae or manure or both were the major sources of fish nutrition in the fertilizer treatments, while both diet (30% crude protein) and algae were the sources of fish nutrition in the ration treatment.

In fish farming practices where fish nutrition depend largely or entirely on natural food produced by fertilization programs, levels of algal abundances (reflected by secchi disk readings) are positively correlated with fish yield (Dhawan and Kaur, 2002). Ponds used for intensive fish culture are normally turbid with algae which grows in response to additions of fertilizer or fish feed (Boyd, 1990; Green et al.,2002). Ponds which received applications of fish feed also had abundant phytoplankton growth because roughly 75 percent of the nutrients in feed are excretory products during the process of metabolism (Boyd, 1979).

When secchi disk visibility is shallower, this reflects a high algal abundance in the photic zone which is positively correlated with fish growth and nutrition (Abbas and Hafeez-Ur-Rehman, 2005). Secchi disk visibility is commonly used by aquaculture pond managers as an indicator of phytoplankton concentration (Jamu et al. , 1999 ; Wudtisin & Boyd ,2005) . It is well known that Nile tilapia could obtain more than 50% of its nutritional requirements from feeding only on algae and zooplankton, especially during the Juvenile stage of growth (Turker et al., 2003). Consequently, using low cost fertilization programs can highly reduce nutritional requirements for dietary ration (Abbas and Hafeez – Ur-Rehman, 2005).

Kumar et al. (2004) demonstrated that a mix of manure and organic fertilizers was successful in fish culture. Such a combination of fertilizers promotes both autotrophic and heterotrophic organisms in the pond and enables better nutrient management as well as maintenance of water quality (Kumar et al.,2002).Recent studies have shown that the combined use of inorganic and organic fertilizers is effective in productivity improvement in earthen ponds ( Grozev et al., 2001 ; Kumar et al. ,2004 ; Afzal et al. ,2007 ; Jha et al. , 2008).Moreover, the combined use of inorganic and organic fertilizers is effective in maintaining phytoplankton and zooplankton population in rearing ponds (Qin & Culver ,1992 ; Afzal et al. , 2007) .

The least algal abundances ( $p < 0.05$  ) was observed in the organic fertilizer treatment .This was due to the decreased efficiency ( $p< 0.05$ ) of organic fertilizer in promoting algal growth and abundances compared to other fertilizer treatments. The decreased organic fertilizer efficiency in promoting algal abundances was due to its lower dose (  $2.3 \text{ gm/m}^2/\text{day}$  ) in the present study and lower content of phosphorus compared to that of chemical fertilizers. Moreover, bacterial activity on decomposable organic fertilizer ( manure ) consumes a high proportion of ammonia (TAN) and phosphate released in water during the process of manure decomposition .Those ammonia and phosphate are necessary components for bacterial growth on manure particles. This process, in addition to the lower phosphate content of manure, lowered the organic fertilizer (manure) efficiency in promoting algal growth and abundances compared to those of other fertilizer treatments. It is well known that phosphorus play a major role in promoting algal growth and abundances in water of aquaculture ponds ( Wudtisin and Boyd,2005).

Algal abundances in the ration treatment (artificial diet to satiation) were of low magnitude and were enhanced by the direct excretion of ammonia and phosphate by fish as a result of dietary

protein metabolism (Boyd, 1990). Nile tilapia juveniles were feeding on both diet and plankton in the ration treatment.

Because of low N and P content and high oxygen consumption, organic fertilizer alone is unlikely to provide adequate nutrients for algae and sufficient oxygen for fish (Kumar et al., 2004) , consequently, to stimulate the growth of food organisms for fish in aquaculture ponds, a combined use of inorganic and organic fertilizer is recommended ( Jha et al ., 2008).

It is concluded that the use of combined (chemical + organic) fertilizer promoted algal growth and abundances necessary for the nutrition of Nile tilapia. These fertilizer programs are of low costs and can enhance fish production in semi – intensive farming systems.

As shown in table (2) , average body weight of Nile tilapia Juveniles increased from 38.6- 42.6 grams at the start of the experiment to 81.3, 71.0 , 85.5 and 119.0 grams at the end of the experiment for the chemical fertilizer, organic fertilizer, combined fertilizer and ration treatments, respectively.

Final weight of Nile tilapia fed at satiation was heavier than those raised in the combined fertilizer treatment by 39.2%. Better growth performances of Nile tilapia in the ration treatment was achieved as a result of feeding on both algae and prepared diet compared to those reared in the fertilizer treatments which were feeding mainly on algae or manure or both.

Fish growth was influenced by the presence of natural food (Pant et al., 2002). Fish growth is slower on plankton feeding alone because larger fish lack the capacity to acquire sufficient ration even in ponds with high plankton stocks. Moreover, feeding is begun as a supplement to plankton forage, and soon becomes the dominant nutritional source, and rapid, near optimal growth is attained on a ration of approximately 50% of satiation amounts ( Szyper et al .,1996).

The present results indicated that Nile tilapia juveniles can obtain major nutritional requirements for growth (more than 48% of its total feed requirements) from feeding only on algae during the juvenile stage of growth compared to that of ration treatment where dietary inputs were offered. Based on analyses of stomach content, up to half the food intake of tilapia in intensively fed ponds was natural food, which indicated its substantial contribution to tilapia growth (Lim, 1989). Evaluation of the growth performance of major carps in fertilized ponds supplemented with feed, indicated that primary productivity (i.e. plankton ) contributed 57.4 % towards the increase in fish yield (Aziz et al .,2002) .

As Nile tilapia derives most of their nutrition from phytoplankton (Colman and Edwards, 1987), a strong correlation between algae production and net fish yield was expected (Knud- Hansen and Batterson, 1994; Green et al ., 2002).Most often natural food forms the basis of fish nutrition with artificial supplement (diet) given to increase fish production (O' Grady and Spillett, 1985).

The results confirmed that the best growth of *Oreochromis niloticus* was in the ration treatment (1.25% per day), followed by fish in the combined fertilizer treatment (0.81% per day).Comparing different fertilizer treatments ,the chemical fertilizer and combined treatments had significantly higher specific growth rates (0.81 and 0.71% per day, respectively) than that of organic fertilizer treatment (0.57% per day ).

Growth of fish was significantly increased by the increases in level of natural food (Pant et al., 2002 and 2004). In addition, some fish derive a high proportion of their food from plankton organisms, rather form supplement (i.e. artificial diet) and these fish maintain rapid growth even though they compete poorly for supplement (Wahlam and Shephard, 1988). Consequently, organic and inorganic fertilizations can produce high plankton abundances to be capable of supporting fish growth ( Jha et al., 2008).

As shown in table (2) , net fish yield increments in fertilizer treatments ranged 0.64- 1.0 gram /m<sup>2</sup>/day (equivalent to 6.4-10.0 kg fish weight/ ha/day) and were significantly lower (p<0.05) than that of the ration treatment fed at satiation which averaged 1.78 gram / m<sup>2</sup>/ day( equivalent to 17.8 kg fish weight/ ha/ day). The lowest (p< 0.05) net fish yield increment (0.64 gram / m<sup>2</sup>/ day) was observed in tanks fertilized with organic manure which was equivalent to 6.4 kg fish weight/ ha/ day.

Maximum manuring rate recommended in earthen ponds are 50 grams dry manure per square meter per week (Nyandat, 2007).Ponds fertilized with four levels of chicken manure (12.5, 50 and 100 g dry weight/ m<sup>2</sup>/ week) during 149 day experiment for Nile tilapia, yielded from 4.9 to 15.7 kg fish weight/ ha/ day (Kund – Hansen et al., 1991). Net fish yield was correlated to both net primary productivity and chicken manure fertilization .This is agreement with Dhawan and Kaur (2002) and Jha et al. (2008). Zhu et al. (1990) reported that the average net fish yield (different species of carp) in many experiments, was 10.2 kg/ha/day over a growing period of 150-200 days.

A significant increase in Nile tilapia production attained in the combined fertilizer treatment indicated that the combined use of chemical and organic fertilizers promoted fish

production (10.0 kg/ha/day) above that attained either by single use of chemical fertilizer (8.6 kg/ha/day) or

organic manure (6.4 kg/ha/day). These results are in

**Table (2) .Averages of growth performance parameters of Nile tilapia juveniles under different fertilizer treatments.**

Parameter Treatment	chemical fertilizer	organic fertilizer	combined fertilizer	ration treatment
Initial weight (grams/fish)	42.6 <sup>a</sup> ± 2.9	42.6 <sup>a</sup> ± 4.1	40.6 <sup>a</sup> ± 2.9	38.6 <sup>a</sup> ± 0.4
Final weight (grams/fish)	81.3 <sup>b</sup> ± 10.1	71.0 <sup>c</sup> ± 6.3	85.5 <sup>b</sup> ± 15.6	119.0 <sup>a</sup> ± 10.5
Weight gain (grams/fish)	38.7 <sup>b</sup> ± 8.3	28.4 <sup>c</sup> ± 4.4	44.9 <sup>b</sup> ± 13.6	80.4 <sup>a</sup> ± 10.5
Daily weight gain (g/fish/day)	0.43 <sup>b</sup> ± 0.09	0.32 <sup>c</sup> ± 0.4	0.5 <sup>b</sup> ± 0.15	0.89 <sup>a</sup> ± 0.12
Condition factor	1.66 <sup>bc</sup> ± 0.19	1.48 <sup>c</sup> ± 0.22	1.74 <sup>b</sup> ± 0.39	2.12 <sup>a</sup> ± 0.13
Specific growth rate (% per day)	0.71 <sup>c</sup> ± 0.1	0.57 <sup>d</sup> ± 0.07	0.81 <sup>b</sup> ± 0.15	1.25 <sup>a</sup> ± 0.1
Net yield (gram/ m <sup>2</sup> /day)	0.86	0.64	1.0	1.78

-a,b,c means with different superscripts among treatments are significantly different( p < 0.05).

accordance with Kumar (2004), Terziyski et al.(2007) and Afzal et al . (2007).

High nutrient inputs led to a two - fold increase in monthly net adult yield (9.0 kg/ha/d) over low input ponds (4.5 kg/ha/d) and there was a significant difference in net adult yield and biomass between organically (11.2 kg/ha/day) and inorganically (9.0 kg/ha/day) fertilized ponds at high nutrient loading ( Diana et al. ,1991).Increased fertilization rate resulted in larger fish yields and higher primary production (Dhawan and Kaur, 2002; Kumar et al., 2002; Jha et al.,2004).

Green et al. (1989) compared yields of tilapia (*O. niloticus*) in sets of ponds receiving chicken litter, cow manure or chemical fertilization. The added nitrogen was equal in all three treatments. Chemical fertilization and cow manure supported similar fish yields, 8.0 and 8.6 kg/ha per day, respectively. The yield with chicken manure was 11.7 kg/ha per day.

When net fish yield increment in the ration treatment was compared to those of the fertilizer treatments, the importance of algae as a source for tilapia nutrition during medium size stages was evident. Increasing algal growth and abundances in the chemical and combined fertilizer treatments caused an increase in growth of Nile tilapia at a proportional rate parallel to algae production. There was a positive correlation between net fish yield increment and algal concentration (secchi readings) in rearing tanks.

Organic and inorganic fertilizers are often used in fish ponds to increase pond fertility and to improve fish production (Shrestha & Lin, 1996; Grozev et al, 2001; Terziyski et al., 2007). Popma et al. (1995) described pond management practices, and fish yields for Guatemalan farmers with less than two hectares of land: average total fish yield form non-integrated ponds receiving approximately 500 kg of nutrients /ha- month was 8.4 kg /ha/day. At nutrient loading rates near 1500 kg /ha- month, net fish yields averaged 12.7 kg/ha /day in 6 months. Fish production cycles were usually 4 to 9 months.

In conclusion, the most productive treatment of the experiment was that of tanks fed at satiation, followed by that of the combined fertilizer treatment (17.8 and 10.0 kg/ha /day, respectively). Moreover, when the chemical fertilizer and ration treatments were compared, it was evident that Nile tilapia at medium size range can obtain at least 48% of their nutritional requirements from feeding only on algae.

**Abstract:** This study examined whether, spiritual intelligence (SI) and emotional intelligence (EI) can be considered as predictor for mental health. The present investigation was also to test the moderating effects of age on the relationship of SI and EI with mental health among high school students. The participants in the study were 247 High school students (124 male and 123 female) in the age range of 14-17 years old, at the Gorgan City, north of Iran. Three valid and reliable instruments were used to assess SI, EI and mental health. Descriptive statistics, multiple and moderated regression analysis were used to analyses the data. The result demonstrated that mental health can be influences by SI and EI. In addition, the moderated effect of age on the relationship of SI and EI with mental health was not found.

**Keywords:** Psychology, education, high school students, spiritual and emotional intelligence, mental health

## 1. Introduction

Mental health is vital to the overall health and well-being of adolescents (World Health Organization [WHO], 2004). The WHO conceptualized mental health separate from mental ill-health and defined the concept as: a state of well-being in which the individual realizes his or her own abilities, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to his or her own community. (WHO, 2007, p. 1) Previous studies are clear on the influence of better mental health versus mental ill-health for the individual and society. Individually, mental health affects our expressive, cognitive, perceptive, relational, and coping abilities, undergirding our general health and wellbeing and capacity to integrate into and become productive members of society (Dwivedi & Harper, 2004). Better mental health outcomes in adolescents are characterized by greater adaptation in family, school, and society environment, improved quality of life, and reduced symptoms of psychological disorders (Hoagwood et al., 1996; USDHHS, 1999). Positive mental health is also link to better physical health, increased pro-social behaviors, and participation in less adverse behaviors in adolescence (Resnick, 2000). On a societal level, mental health is perceived as a positive source contributing to asset development individually, socially, and economically (WHO, 2004). Conversely, poor mental health and well-being (i.e. depression, low self-esteem) during the adolescent years can lead to adolescent health risk

behaviors, school failure, physical ill-health, suicide, involvement in juvenile and criminal justice systems, negative life choices, and mental disorders in adulthood (Lewinsohn et al., 1993; Canals, et al., 2002; Trzesniewski et al., 2006; Hjemdal et al., 2007).

There is some evidence that spiritual and emotional intelligence development and spiritual and emotional experiences are helpful for health. At the same time, there is a significant relationship between awareness of spiritual and emotional experiences and health (Hay & Morisy, 1990; Ioannis & Ioannis, 2005). As whole, it seems spiritual and emotional functions including SI, EI and its components can be used as an instrument in relates with individual mental health.

Many authors claimed and reported that there existed a significant relationship between EI and mental health (Goleman, 1995; Salovey & Mayer, 1990; Ioannis and Ioannis, 2005), and SI and mental health (Emmonce 2000; Nobel, 2000). Also, spiritual including SI can be used as a possible instrument to increase individual's mental health (West, 2004). Therefore, the aim of this study was to investigate the link of SI and EI with mental health. In addition, the current study aims at providing more evidence regarding the relationship of SI and EI with mental health condition. In particular, this study examines whether SI and EI affects on mental health functioning.

Emotional intelligence (EI) was originally recognized as having its roots in the concept of social

intelligence (Thorndike, 1920; Salovey & Mayer, 1990; Goleman, 1995). Later, researches provided evidence that the two concepts actually represent interrelated components of the same construct (Salovey & Mayer, 1990; Bar-On et al., 2003; Lane & McRae, 2004). Consequently, this broad construct was accurately referred to as "emotional-social intelligence" (Bar-On, 2006). Based on historical reference, traits such as the capacity to navigate through and to adapt to one's own environment and the possession of social and emotional "skills" are important not only to basic survival, but have implications in the areas of relationships, work, school, and emotional and mental health (Goleman, 1995; Salovey & Mayer, 1990).

The popularity of the concept for the past decades has led researchers to examine its potency in various areas of human functioning. Among the areas with the strongest connections to EI is developmental, educational, clinical and counselling, industrial and organizational psychology. Hence, characteristic or ability EI were related to life success (Bar-On, 2001; Goleman, 1995), life satisfaction and well-being (Martinez-Pons, 1997; Palmer et al., 2002), physical and mental health (Ioannis and Ioannis, 2005), interpersonal relationships (Fitness, 2001; Flury & Ickes, 2001), academic achievement (Van der Zee et al., 2002; Parker et al., 2004), and more.

Today, there has been an increasing interest in how emotional reactions and experiences affect on mental health. For example, it has been claimed that negative emotional states are associated with unhealthy patterns of physiological functioning, whereas positive emotional states are associated with healthier patterns of respond in both cardiovascular activity and immune system (BoothKewley & Friedman, 1987; Herbert & Choen, 1993).

According to Salovey (2001) although suppressing negative feelings is neither a healthy strategy, he suggested that emotions' manifestation has a positive impact on physical health when people are confident about their abilities to regulate them. Moreover, Taylor (2001) argued that if you are emotionally intelligent then you can cope better with life's challenges and control your emotions more effectively, both of which contribute to good physical and mental health. Furthermore, Dulewicz, et al., (2003), examined the role emotional self-management such as stress, distress, morale and poor quality of working life play in everyday life. They demonstrated that EI was strongly correlated with both, physical and psychological health.

Also, considering Gardner's theory, existential intelligence can be define as an ability to find and realize meaning in life (Halama & Strizenec 2004).

Based on this definition, Halama & Strizenec (2004) suggested that the ability to find and realize meaning in life is an important element of SI. Since, SI involves a set of abilities that draw on spiritual resources, it can be concluded that existential and SI is non-identical but mutually related and overlapping construct (Halama & Strizenec 2004). Drawing on Gardner's definition of intelligence, Emmons (2000b) argued that spirituality can be viewed as a form of intelligence because it predicts functioning and adaptation and offers capabilities that enable people to solve problems and attain goals. Earlier, Emmons (1999) defined spirituality as the search for, and the experience of elements of sacred meaning, higher consciousness, and transcendence, SI entails the abilities that draw on such spiritual themes to predict functioning and adaptation and to produce valuable products or outcomes. Zohar & Marshall (2000) stress the utility of SI in solving problems of meaning, value, and those of an existential nature, concurring with Vaughan (2002) and Wolman (2001). Looking at spirituality through the lens of intelligence, Emmons (1999) writes, "SI is a framework for identifying and organizing skills and abilities needed for the adaptive use of spirituality" (p. 163). Hence, SI can be differentiated from spirituality in general, spiritual experience, (e.g. a unitary state), or spiritual belief, (e.g. a belief in God), (Amram, 2007). However, the theory and research of the spirituality and SI were well reviewed by many authors and researchers (Emmons, 1999; MacHovec, 2002; Mark, 2004; Schuller, 2005; Sisk & Torrance 2001; Wolman, 2001; Zohar & Marshall, 2000; Nasel, 2004; Amram, 2009).

## 2. Method

### 2.1. Sample

Two hundred and forty seven Iranian high school students in Gorgan city, north of Iran (124 females and 123 males) were recruited as respondents in this study. Their ages ranged from 14 – 18 years. They were selected by using cluster sampling technique, and their participation was voluntary and anonymously.

### 2.2. Measures

All participants responded to of the three instruments that have been translated to Persian language:

#### 2.2.1. The Integrated Spiritual Intelligence Scale (ISIS, Amram & Dryer, 2008)

Amram & Dryer's Integrated Spiritual Intelligence Scale (ISIS) was reviewed and chosen for measure of SI due to its comprehensive nature and strong psychometric properties (Amram & Dryer,

2008). ISIS is an 83-item long form, and a 45-item short form, self-report and observer-rated instrument containing 22 subscales assessing separate capabilities that are grouped into five main domain scales of spiritual intelligence. Responses are answered a six-point scale ranging from "never or almost never" to "always or almost always". For this study the simple Likert method (1–2–3–4–5–6) was chosen. The measure yields an overall SI scores (range 0–270). The scale has a Cronbach alpha of 0.76.

#### 2.2.2. Emotional Intelligence Inventory, Youth Version (EQ-i YV, Bar-On & Parker, 2000)

Utilized to measure emotional intelligence, the Bar-On Emotional Quotient Inventory: Youth Version (EQ-i: YV) was developed by Reuven Bar-On, Ph.D. and James D.A. Parker, Ph.D., and published by Multi-Health Systems, Inc. (2000). The EQ-i: YV was developed to measure emotional intelligence in adolescent populations, based on the theoretical basis of the Bar-On model of social and emotional intelligence. This 60-item inventory is a self-report instrument designed to measure emotional intelligence in young people age 7 to 18 years. The instrument measures a cross-section of abilities and competencies that constitute the core features of emotional intelligence. Responses are invited on a four-point scale ranging from "very seldom true of me" to "very often true of me". For this study the simple Likert method (1–2–3–4) was chosen. The measure yields an overall EI scores (range 0–240). The scale has a Cronbach alpha of 0.74.

#### 2.2.3. General Health Questionnaire (GHQ 28, Goldberg, 1972; Goldberg & Williams, 1998)

In 1972, Goldberg developed a simple questionnaire, the General Health Questionnaire (GHQ), which is the most widely used instrument for detecting non-psychotic psychiatric "Cases". The GHQ is a self-administered screening questionnaire used to diagnose psychiatric disorders both in primary care and in the community. The main benefits of GHQ are that it is easy to administer, brief, and objective. Several versions of GHQ are available: there is a 60-item version, and shorter versions (comprising 30, 28 and 12 items). The 28-item version (GHQ-28) developed by Goldberg and Hillier (1979) is constructed on a different basis when compared with the other versions. Responses are responded on a four-point scale ranging from "less than usual", to "much more than usual". Of the four possible ways of scoring this instrument (Goldberg & Williams, 1998), for this study the simple Likert method (0–1–2–3) was chosen. The measure yields an overall health scores (range 0–84)

and is composed of four subscales described as somatic symptoms, anxiety and insomnia, social dysfunction and depression. High scores indicate high levels of psychological strain. The measure was found to have an acceptable level of internal consistency reliability ( $\alpha = 0.92$ ). High score on this scale indicate poor general health.

### 3. Results

To attain the main objectives of the present study, the collected data were subjected to a number of statistical analyses by using statistical package for social sciences (SPSS 17.0). Besides, descriptive statistics, multiple and moderated regression analyses was also used in this study.

*3.1. Descriptive statistics;* Table 1 indicates the mean and standard deviations of all the observed variables. Descriptive statistics is worked out to know the pattern of score distribution. A perusal of table 1 reveals that the mean score on SI is 3.93 with the SD of .36, EI is 2.90 with the SD of .29, and on total mental health the mean score was .91 with the SD of .43. (See table 1)

*3.2. Multiple Regression Analysis (MRA);* MRA was conducted to assess the strength of relationship between dependent variable and independent variables. MRA provides an opportunity with little ambiguity to assess the importance of each of the predictors to the overall relationship. The results of regression analysis for the dependent variable (mental health) are presented in table 2. It is clear from the results that the regression analysis indicated both the variables (SI and EI) as a significant predictor of mental health. This table shows that  $R = .640$ ,  $R^2 = .409$ , and  $\{F (2,244) = 48.50 p < .05\}$ . This  $R^2$  value means that 40.9% of the variance in mental health increase is explained by SI and EI. Based on the values reported in the table, the beta coefficient for spiritual intelligence was -.293, and for emotional intelligence was -.413. This means that emotional intelligence is the strongest predictor followed by spiritual intelligence to explain the criterion variable (mental health).

*3.3. Moderated Multiple Regression (MMR);* (MMR) was employed in examining the effects of moderator variable (Age) on the relationships between the independent variable (SI and EI) and dependent variable (mental health). MMR involves two steps. First, it is needed to form two regression equations, one includes the first-order only and a second model include the first-order effects as well as a product term including the moderator variable. In this research, the product term is age. The following

are the two equations formed that derived from the regression procedure by entering independent variables and product term block by block in order to create two models.

Table 3 shows that for model 1,  $R = .640$ ,  $R^2 = .409$ , adjusted  $R^2 = .404$  and  $\{F (2,244) = 48.50 p < .05\}$ . This  $R^2$  means that 40.9% of the variance in mental health increase is explained by SI and EI. Model 1 does not include the product term and, thus, ignores a possible moderating effect of age. To find out whether the potential moderating effect of age on the SI and EI with mental health relationship, we need to interpret the model 2 in table 3.

Model 2 shows results after the product term has entered the equation. As shown in table 3, the addition of the product term resulted in an  $R^2$  change of .000, F change (1,243) = .132, Sig. F change = .717 at the  $p < .05$ . This result do not supported the presence of a moderating effect. In other words, the moderating effect of age explains .0% of variance in mental health above and beyond the variance explained by spiritual intelligence and emotional intelligence. The results suggest that the age is not important moderating factors on relationship between SI, EI and mental health.

#### 4. Discussion

The results in this study found emotional intelligence was significantly and negatively correlated with mental health scores. This finding is in line with (Bar-On, 2002; Palmer et al, 2002; Ioannis and Ioannis, 2005). Also between spiritual intelligence and mental health scores the finding of this study provides evidence to the claims of the previous researchers (Hay and Morisy, 1990; Emmonce 2000; Nobel, 2000; Zohar and Marshall (2000); West, 2004). The results of the Multiple Regression Analyses (MRA) revealed the overall scores of the emotional and spiritual intelligence are statistically significant predictors of mental health in the study. Emotional Intelligence wad found to be the strongest predictor followed by spiritual intelligence for mental health scores. So, the findings of this study supported a positive effect of spiritual and emotional intelligence on students' mental health scores. The overall regression model was successful in explaining approximately 40.9% of the proportion variance explained in mental health scores. Finally, the findings of the results failed to provide evidence for the hypothesis that age has moderating effect on the relationship between two independent variables (spiritual and emotional intelligence) and dependent variable (mental health).

Table 1: Descriptive Statistics of the Independent and Dependent Variable

Variables	N	Minimum	Maximum	Mean	Std. Deviation
Spiritual Intelligence (SI)	247	3.02	4.87	3.9340	.35637
Emotional Intelligence (EI)	247	2.15	3.67	2.9028	.29031
Total Mental Health	247	.04	2.04	.9110	.42770

Table 2: Multiple Regression Analysis of Total Mental Health

Variables	Summary of Regression	Un-std Coefficient B	Un-std Coefficient Std. Error	Std. Coefficient Beta	t	Sig. Value
(constant)		4.063	.248			
Spiritual intelligence		-.352	.076	-.293	- 4.638	.000
Emotional intelligence		-.609	.093	-.413	-6.533	.000
Multiple R	.640					
R Square	.409					
Adjusted R Square	.404					
F-Statistics	84.504					

Note. Predictors: SI & EI. Dependent Variable: Total Mental Health. \*  $p < .05$ .

2	.646b	.410	.402	.33068	.000	.132	1	243	.717

Note. Predictors step 1: Total SI & EI; step 2: Total SI & EI, Students Age. \* p < .05.

## 5. Conclusion

The main purpose of the present study is conducted to explain the role of SI and EI on mental health (somatic symptom, anxiety, social dysfunction and depression) of high school students. The present investigation also was to test the moderating effects of age on the relationship of SI and EI with mental health. In this research, we found that student's mental health can be predicted by SI and EI. In other words, The R-squared of .409 implies that the two predictor variables (SI and EI) explain about 40.9% of the variance in the mental health (dependent variable). Also, this study does not support the presence of a moderating effect of age on link of SI and EI with mental health. In other words, the moderating effect of age explains .0% of variance in mental health above and beyond the variance explained by SI and EI. The result suggests that the age is not important moderating factors on relationship between SI and EI with mental health. These findings suggest that SI and EI are important and should be encouraged in school and students mental health life. Since, combining the concept of spiritual and emotional intelligence in the analyses of multiple regression and moderated regression, a new understanding emerged in this area of psychology. Therefore, this information will be valuable to community counsellors, teachers, school counsellors, and parents, all of whom are concerned with spiritual-emotional development and mental health of the school students, especially those of Iranian population.

## Acknowledgment

We thank the administration officers at all schools of this research sample for giving us information about students in their schools. We also appreciate the contribution of high schools students by participating in this research, thus allowing us to collect the necessary data for the study.

**Abstract:** Nicotine is a major toxic component of cigarette smoke and it is a major risk factor in the development of functional disorder of several organ systems. The natural diet contains a variety of compounds that exhibit protective effects towards different toxicities of nicotine as green tea. Four groups of male Swiss albino mice were divided: untreated control group; Nicotine-treated group (2.5 mg/kg/day); Green tea-treated group (40 mg/kg./day); and Nicotine and green tea treated group interperitoneal administration for successive 28 days. Results showed that disorganization of the seminiferous tubules associated with reduction of spermatogenic cells, leading to widening of lumen of tubules upon nicotine toxicity. Many of seminiferous tubules exhibited degenerative phases of spermatocytes and spermatides as well as missing of sperms and hypo-spermatogenesis. The recorded data in nicotine intoxicated group showed significant and gradual decrease of number of leydig cells throughout all intervals of experiment. In the last, cytogenetically examination demonstrated significant increased in the number of nucleated polychromatic erythrocytes (MnPCE) and decreased in number of polychromatic erythrocytes (PCE) in bone marrow of nicotine-treated animals using micronucleus assay. Green tea treatment reduced number of nucleated polychromatic erythrocytes (MnPCE) and restored number of polychromatic erythrocytes (PCE) to nearly normal. In conclusions, intake of green tea might suppress the toxicity and mutagenic activity of nicotine.

[Azza M. Gawish, Aliaa M. Issa, Aziza M. A., and Sherin Ramadan. Morphometrical, Histopathological, and Cytogenetical ameliorating Effects of Green tea Extract on Nicotine Toxicity of the Testis of Rats. Journal of American Science 2010;6(11):401-411]. (ISSN: 1545-1003).

**Keywords:** Smoking - Nicotine – Fertility – Antioxidants – Green tea

## 1. Introduction:

Smoking has enormous negative health consequences worldwide. Nicotine is a naturally occurring alkaloid found in tobacco plant (*Nicotiana tabacum*) and it is the major constituent of tobacco responsible for the compulsive use of tobacco (Wu *et al.*, 2002). Nicotine and its metabolites are also being investigated and researched for the treatment of a number of disorders as Alzheimer's diseases (Hecht, 2003). Okamoto *et al.*, (1994) recorded the LD<sub>50</sub> of nicotine as (50 mg/kg) for rats and (3 mg/kg) for mice.

Nicotine administration induces changes in gonadal functions and deficiency in sperm maturation and spermatogenesis and has a detrimental effect on the sperm-fertilizing potential of male rats (Reddy *et al.*, 1998 and Yamamoto *et al.*, 1998). Also nicotine was reported to have toxic effects on gonadal functions in males in addition to its role in the lowering testosterone and estradiol levels in the serum (Kavitharaj *et al.*, 1999). Nicotine has been associated with decrease in number of germ cells, germinal cells and increased

chromosomal abnormalities in sperm and with increased the risks of birth defects and neonatal death and genetic mutations in sperm, reduced sperm fertilizing capacity and decreased embryonic implantation rates (Polyzos *et al.*, 2009). Nicotine has a deleterious effect of nicotine on sperm membrane intactness and DNA and apoptosis in mouse leydig cells treated with nicotine were recorded by (Arabi, 2004 and Kim *et al.*, 2005). From human studies; nicotine smoke contains harmful mutagens and carcinogens metabolites; that may induce defective semen quality, nuclear DNA damage of spermatozoa (Arif *et al.*, 2000, De Flora *et al.*, 2003 and Elshal *et al.*, 2009).

Nicotine had been shown to increase the frequency of micronuclei in human gingival fibroblasts and induce DNA strand breaks in human spermatozoa (Arabi *et al.*, 2004). Information on the *in vivo* genotoxicity of nicotine have shown that nicotine induces aneuploidy and polyploidy (Bishun *et al.*, 1972), sister chromatid exchange and chromosome aberrations in bone-marrow cells of mice (Sen *et al.*, 1991). High doses of nicotine

increase the frequencies of premature centromere separation and premature anaphase and reduce the number of oocytes ovulated; however, the results of this study suggested that nicotine does not elevate aneuploidy levels in mouse oocytes (Mailhes *et al.*, 2000). The increased generation of ROS can produce a condition of oxidative stress that can result in the oxidation of lipids, induction of DNA single-strand breakage, inactivation of certain proteins, and disruption of biological membranes (Durak *et al.*, 2002). Increased oxidative stress has been suggested to play a major role in the pathogenesis of several smoking-related diseases such as cancer, cardiovascular and oral diseases (Reibel, 2003 and Sudheer *et al.*, 2007)

Natural antioxidants as polyphenols of green tea extracts have received much attention for treatments of oxidative-stress-related pathological conditions (Park *et al.*, 1998 and Yokozawa *et al.*, 2004). Green tea can suppress the DNA adduction, and hence act as inhibitors of cancer and it is a rich source of polyphenols, which are antioxidants in natural and their ameliorating effect on genital organs were recorded (Ogura *et al.*, 2008). Study on acute effect of green tea extract and its polyphenols constituents, *in vitro* showed stimulated testosterone production by rat Leydig cells and reduced the testicular tissue content of total cholesterol (TC), triglycerides (TG), phospholipids (Fabiano *et al.*, 2009).

Tea polyphenol could inhibit the mutagenicity of chemical mutagens and chromosome aberrations (Shim *et al.*, 1995). The frequencies of sister-chromatid exchange (SCE) in peripheral lymphocytes were study were significantly higher among smokers who were non tea drinkers, than those of non-smokers and smokers who consumed green tea at least two to three cups per day during the past 6 months (Lee *et al.*, 1997). It is possible that consuming high levels of green tea over a long period may reduce the DNA damage caused by tobacco smoking (Liang *et al.*, 2007). Our aim of work is the evaluation of the role of green tea in the protection from the effects of cigarette smoking.

## 2. Materials and methods

### 1-Experimental animals:

The experimental animals used in this study were male Swiss albino mice. Eighty Male Swiss albino mice aged 9 – 12 weeks and weighing 25 -30 gm were used throughout the study. Animals were fed a commercially prepared diet and had free access to tap water. All mice were kept under the same experimental condition, feeding standard diet, and water was available *Adlibitum*.

After one-week acclimatization period, the selected animals of nearly a similar weight were divided into 4 experimental groups so as to keep more or less the same mean body weight within the individual groups. The selected animal groups treated as follows:

1-Nicotine – Treated group: Each mouse in this group was given intraperitoneally (i.p.) dose of 3 nicotine 2.5mg/ kg / day for successive 28 days.

2-Green Tea – Treated group: For successive 28 days each mouse in this group was injected i.p. with freshly prepared green tea extract (40 mg / kg body weight / day).

3-Nicotine-Green Tea -Treated group: Each animal in this group was given i.p. of nicotine (2.5mg/kg/day) at the same dose as group1 concomitantly with green tea extract (40 mg / kg body weight) at the dose as second group for successive 28 days.

4-Control -Treated group: Each animal in this group was injected i.p. with distilled water (1ml/ day) for successive 28 days and handling on the same conditions exactly similar to that of the previously mentioned groups.

### II-Chemicals:

The treated elements in the experiment were nicotine ((*S*)-3-(1-Methyl-2-pyrroli-dinyl) pyridine) and green tea extract. Nicotine was supplied as colorless liquid, obtained from faculty of pharmacy, Cairo University, Egypt. The mean LD<sub>50</sub> for intraperitoneal administration of nicotine to 8-week-old mice was reported as 12.5 mg (Favarro *et al.*, 2003). Green tea extract was supplied in form of tablets obtained from Technomad Groups Company, Egypt, they were soluble in water.

### III- Experimental design:

Five mice from each group were scarified by cervical dislocation at end of 1, 2, 3, and 4 weeks (7<sup>th</sup>, 14<sup>th</sup>, 21<sup>th</sup>, 28<sup>th</sup> days) of the experimental period and decapitation, two femurs are removed and stripped clean of muscle for cytogenetically examination. Also, lung, liver and testes were also sampled and kept in aqueous Bouin for histological, histochemical and morphometrical examinations.

### Experimental analysis:

#### 1--Histopathological examination:

For histopathology and morphometric evaluation, testes of all groups were collected deceiption and fast dissection. They were fixed in aqueous Bouin solution, dehydrated through alcohols, cleared in xylene and then embedded in paraffin wax. According to the method described by

Bancroft and Stevens, (2002). 5 $\mu$  thickness paraffin sections were prepared and mount on clean slides. For histopathological study sections were stained with Ehrlich's haematoxylin and counterstained with eosin. A number of photomicrographs were taken at known magnification.

#### 2-Image analysis:

The data were obtained using Leica Qwin 500 image analyzer computer system (England). The image analyzer consisted of a colored video camera, colored monitor, hard disc of IBM personal computer connected to the microscope, and controlled by Leica Qwin 500 software. The image analyzer was first calibrated automatically to convert the measurement units (pixels) produced by the image analyzer program into actual micrometer units. These measurements were done using an objective lens of magnification 40, i.e. of total magnification 400. Ten readings were obtained in each specimen. Regarding the no of Leydig cells using an objective lens of magnification 40, i.e. of total magnification 400, they were counted using interactive measurement in 10 fields in each specimen. The data obtained were subjected to statistical analysis using Duncan's Test and ONE WAY ANOVA.

#### 3- Micronucleus assay

The most attractive features of the micronucleus assay are rapidly and easily with which in vivo genetic activity can be demonstrated. The first test to be developed and the most commonly used is carried out in mouse bone marrow by scoring micronuclei polychromatic erythrocytes (Heddle, 1973). In this study the micronucleus polychromatic erythrocyte were prepared according to an improved method adopted by (Salamone *et al.*, 1980).

##### a. Harvesting Marrow.

Animals are killed by cervical dislocation, and two femurs are removed and stripped clean of muscle. The marrow is removed by making a small opening at the iliac end of the femur and introducing the pointed shaft of a 2.5-cm safety pin into the femur at the epiphysial end. As the pin is slowly pushed and twisted into the marrow canal, the marrow exudes out the hole at the iliac end. The marrow is placed directly on a slide, and then a drop of fetal calf serum is added. With the aid of the edge of a clean slide, the marrow is mixed with the serum until homogeneous and then is spread as a smear; additional slides from a given animal can be prepared by simply transferring some of the mixed preparation onto other slides. Prepared slides are air-dried, fixed for 5 min in absolute methanol.

##### b- Slide Staining:

After air-drying, the smear were stained for 20 min in May-Grunwald stain in conjunction with the Gimsa stain (May-Grunwald/Gimsa (Schmid, 1975)), this combination consisted of: 3 ml Gimsa (stock), 12 ml May-Grunwald (0.25gm MayGrunwald/100ml methanol), 2 ml 0.1M Na<sub>2</sub>HPO<sub>4</sub>, 4.5 ml 0.1M KH<sub>2</sub>PO<sub>4</sub>, and 51 ml D. Stain was freshly prepared and mixing well before used. After the staining, the slides were washed thoroughly in distal water and left to dry overnight. All glass slides were coded before observation. Examination under oil lense.

##### c- Scoring

1000 polychromatic erythrocytes (PCEs) were scored per animal and the numbers of micronucleated PCEs were recorded. The results were expressed as the average number of micronucleated PCEs / 1000 PCEs. For each sampling time, bone marrow smears from five animals per four / group were used for evaluation. From each animal, 1000 polychromatic erythrocytes (PCE) were scored under the microscope (1000-1250x; Optech, Germany) for the incidence of micronucleated polychromatic erythrocytes (MnPCEs). In addition, the number of PCEs among 1000 total erythrocytes (PCE + NCE) per animal was recorded to evaluate bone marrow cytotoxicity. The ratio of polychromatic to normochromatic erythrocytes (PCE / NCE) was calculated, based on 1000 erythrocytes (PCE / NCE) scored per slide. These ratios were used as a measure of toxicity of test materials.

#### IV- Statistical analysis:

Statistical analyses were carried out using analysis of variance, Duncan's Test and One Way ANOVA (Snedecor and Cochran, 1980). To evaluate the effect in between groups and give a change for multiple comparison in between.

### 3. Results:

#### 1-Histopathological results:

The control untreated male mice testes tissues showed an outer capsule of fibroblastic connective tissue bound normal seminiferous tubules microscopy (Fig 1).

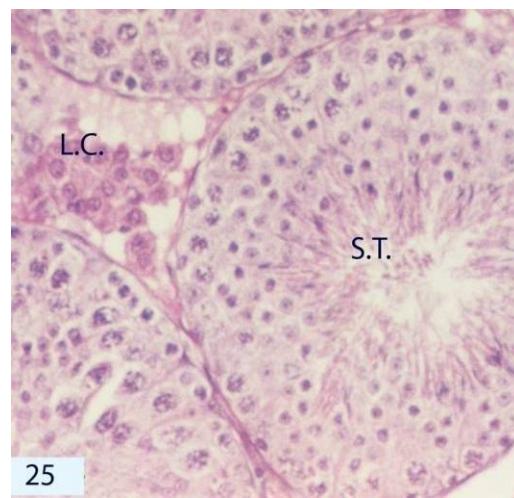

Testis of Swiss albino mice due to interperitoneal and daily injected nicotine treatment at the dose level 2.5mg/kg showed more or less normal testis architecture with complete spermatogenesis and focal decreased in population of leydig cells at the first week of nicotine treatment (Fig2). Along three weeks of nicotine treatment, some seminiferous tubules shows disorganization and atrophy of

seminiferous tubules with widening of its lumen and reduction in sperm count. Other seminiferous tubules had arrest in spermatogenesis. Some spermatogenic cells showed apoptosis especially in 1ry and 2ry spermatocytes. Also, few vacuoles were appeared in some somniferous tubules. Leydig cells were more reduction compared with previous stages and control stage (Fig. 3). Compared with normal group, the animal treated with nicotine for four weeks revealed most of seminiferous tubules had reduction in more than one stage of spermatogenesis such as reduced in

**Fig (1):** Micrograph of testis section of mice in control group showing normal architecture of somniferous tubules (S.T.) .Atypical appearance of mice seminiferous tubules with different cellular association .The tubules had normal progression cells and Leydig cells have normal disruption (L.C.) (H&E., 200X)

number of spermatocytes and spermatid (marked arrest in spermatogenesis) and marked degeneration of the leydig cells and decrease in this cell population (Fig. 4). Histological examination of testis sections of mice treated with green tea at different interval of experimental showed normal architecture (Fig. 7), complete spermatogenesis and maturation of germinal epithelium. Also, animals treated with green tea exhibited normal appearance, regarding size and arrangement of the tubules (Fig8).

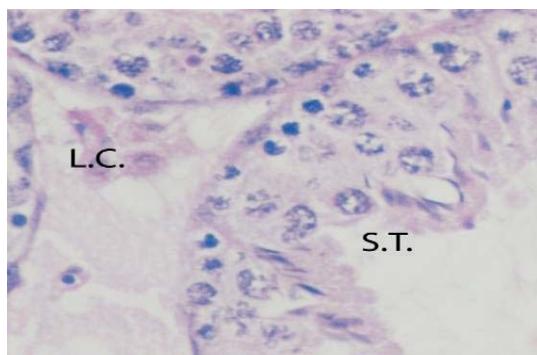

**Fig (2):** Micrograph of testis section treated with nicotine for a week showing complete spermatogenesis (S.T.) and nearly normal testis structure with lower decreased in population of Leydig cells (L.C.). (H&E., 400X)

## 2-Morphometric results:

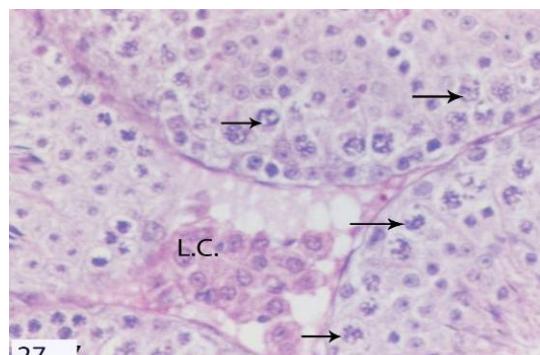

### Number of leydig cells in testis:

Table (1) and Figure (9) represent the variation in the number of leydig cells of testis due to nicotine intoxication and / or green tea protection. In normal group, all Swiss albino mice had normal distribution in nucleus area of liver and no significant changed presented along all interval of experimental.(  $23.40 \pm 1.784$ ;  $23.70 \pm 1.726$ ;  $23.90 \pm 1.940$ ;  $24.60 \pm 2.242$  );. The recorded data in nicotine intoxicated group showed significant ( $P < 0.05$ ) and gradual decrease of number of leydig cells throughout all intervals of treatment of experimental ( $18.10 \pm 2.282$ ), ( $15.30 \pm 1.783$ ), ( $12.40 \pm 1.979$ ) and ( $9.50 \pm 1.462$ ). As compared to control level, nicotine intoxicated group obtained insignificant ( $P < 0.05$ ) decrease of number of leydig cells after first week of treatment ( $18.10 \pm 2.282$  vs.,  $23.40 \pm 1.784$ ) but the

value recorded being highly significant decreased till reached to minimal value at last week of experimental ( $15.30 \pm 1.783$  vs.,  $23.70 \pm 1.726$ ); ( $12.40 \pm 1.979$  vs.,  $23.90 \pm 1.940$ ); ( $9.50 \pm 1.462$  vs.,  $24.60 \pm 2.242$ ). Treatment with green tea prevented the decrease in number of leydig cells in nicotine treated mice with different degree and showed general increase in these cells. As compared to nicotine intoxicated group, the recorded data showed insignificant increased in number of leydig cells after first and second weeks of treatment With continues injection of green tea, till four weeks of experimental showed significant increased in number of leydig cells and highly significant ( $P < 0.05$ ) increased at three and last week of experimental ( $19.50 \pm 2.591$  vs.  $12.40 \pm 1.979$  and  $21.60 \pm 2.390$  vs.,  $9.50 \pm 1.462$ ) were observed compared to control values.

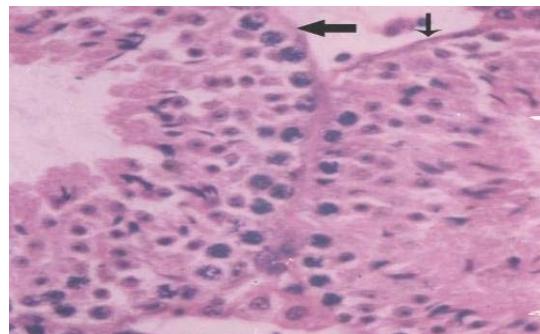

**Fig (3):** Micrograph of testis section treated with nicotine for three weeks showing apyknosis among spermatogenic cells especially necrosis in 1<sup>try</sup> & 2<sup>nd</sup> spermatocytes (thin arrow). (H&E., 400X)

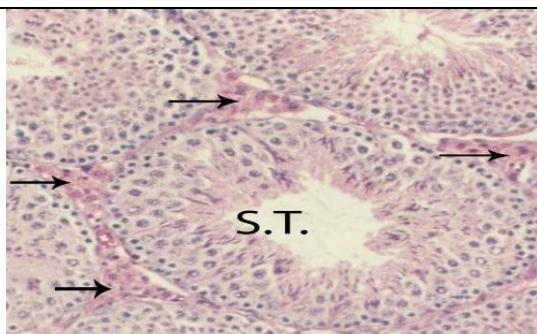

**Fig (4):** Micrograph of testis section treated with nicotine for four weeks showing different degree of damage of seminiferous tubules such as a disorder of systemic arrangement of the stages of spermatogenesis, loss of one or more stages of spermatogenesis (S.T.) and few number of Leydig cells are appeared(L.C.). (H&E., 400X)

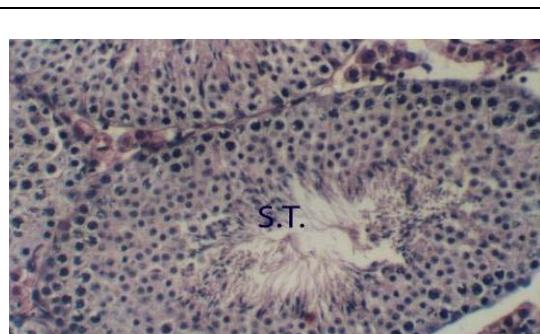

**Fig (5):** Micrograph of testis section treated with green tea concomitantly with nicotine for a week showing almost normal appearance of seminiferous tubules (S.T.) with normal spermatogenic cells and arrangement Leydig cells are more increased, (H&E., 200X)

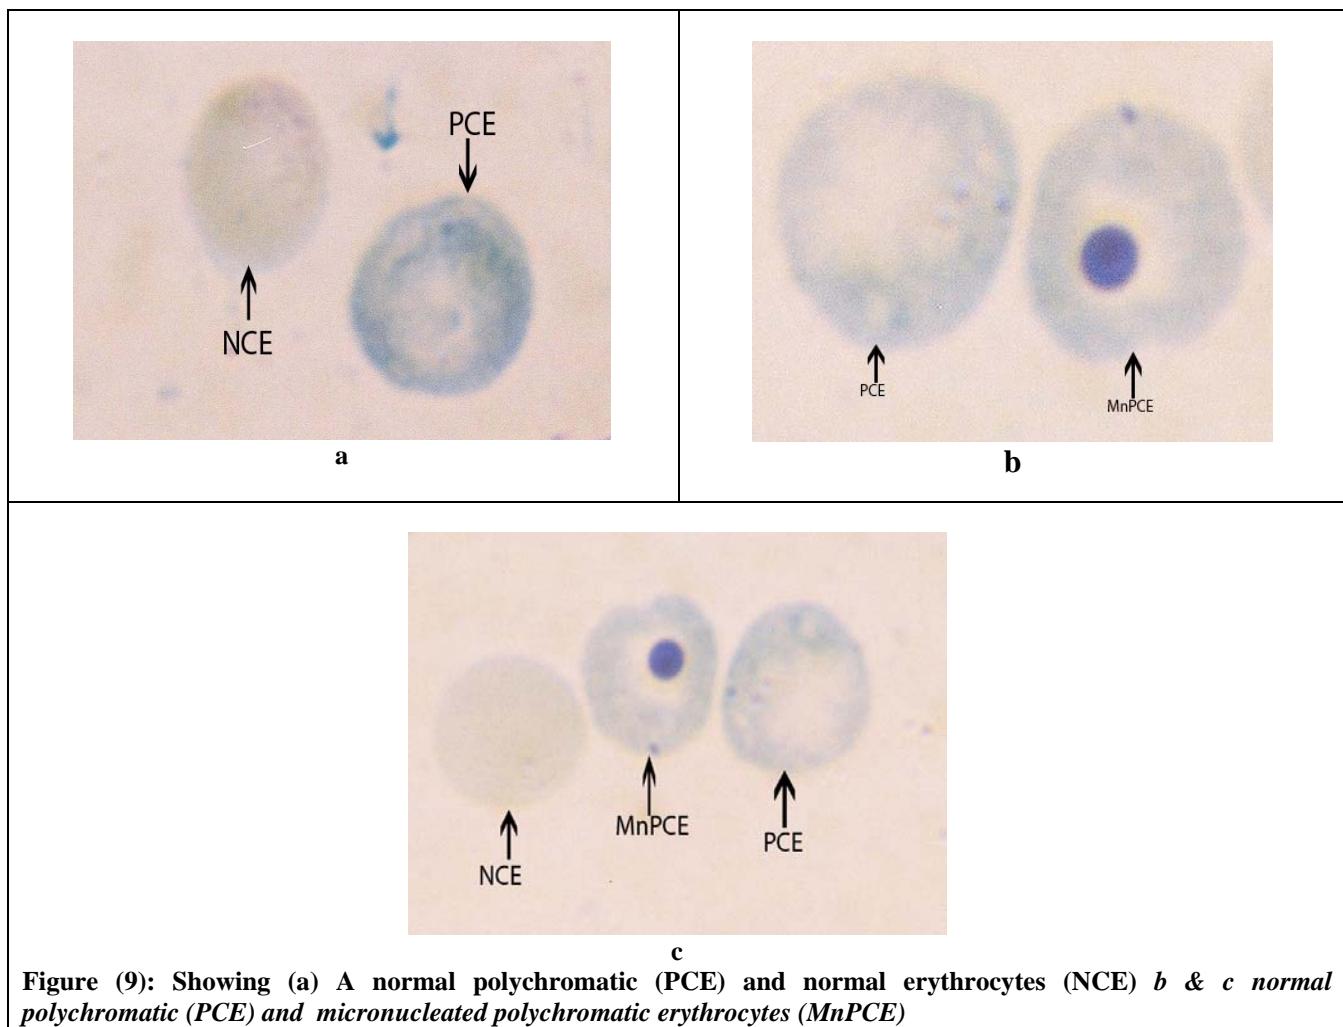

**Fig (6):** Micrograph of testis section treated with green tea concomitantly with nicotine for three weeks showing most of sommiferous tubules

**Fig (7):** Micrograph of testis section treated with green tea concomitantly with nicotine for four weeks showing a little change in architecture of sommiferous tubules with normal and order spermatogenesis (S.T.). (H&E, 400X)

**Fig (8):** Micrograph of testis section treated with green tea showing a normal testis structure, complete spermatogenesis (S.T.) and normal appearance of Leydig cells (arrow). (H & E , 400 X).

**Figure (9): Showing (a) A normal polychromatic (PCE) and normal erythrocytes (NCE) b & c normal polychromatic (PCE) and micronucleated polychromatoc erythrocytes (MnPCE)**

Improvement and protective effect of green tea increased significant and gradually with increased time of administration on nicotine intoxicated group. Individual green tea injection to albino mice showed no significant difference in the number of Leydig cells throughout all the tested experimental period or over all intervals of experimental were attained compared to control level. In conclusion, green tea had obviously improved on nicotine toxicity and Leydig cells back to normal number in male albino mice. As well as, it is showed an amelioration and obviously improvement to the nicotine toxicity effect on area of nucleus in liver, elastic fiber and leydig cells of testis of male albino mice.

### 3-Cytogenetical Results:

The cytogenetic damage induced by intraperitoneal injection of nicotine at ( 1/5 LD<sub>50</sub> = 0.6 mg /kg to mice ) as well as the antimutagenic effects of green tea at ( 40 mg /kg ) treated

intraperitoneal for one, two, three and four weeks with or without nicotine were investigated in bone marrow of male mice utilizing micronucleus assay. Micronucleus test were performed with nicotine and green tea. The % MnPCE in each treatment group as well as the PCE / NCE ratio are shown in tables 1 and 2. Normal polychromatic erythrocytes (PCE), normal normochromatoc erythrocytes (NCE) and micronucleated polychromatoc erythrocytes (MnPCE) showing in photos (1) a, b, and c.

In the present study, The ameliorative effect of green tea is gradual, increased with increased the time of administration of green tea with nicotine when study polychromatic erythrocytes (PCE), PCE/ NCE ratio and Mn-PCEs as shown in Tables 1&2. Treatment of green tea with nicotine was effective in reduction the frequencies of MnPCE in response to the time treatment. When green tea treated with nicotine for one, two or three weeks, the reduction in MnPCE come down to the same range of control

group and the percent of the reduction in group 1, 2, 3 and 4 was 62.5%, 57.1 %, 77.35 % and 81.8 % respectively. Whereas treatment of green tea with nicotine, significantly ( $p<0.05$ ) improved the number

of PCEs and the ratio of PCEs to NCEs were significant ( $p<0.05$ ) enhanced in compared to the control group.

#### 4. Discussion:

Our result showed that disorganization of the seminiferous tubules associated with reduction of spermatogenic cells, leading to widening of lumen of seminiferous tubules upon nicotine toxicity. Many of seminiferous tubules exhibited degenerative phases of spermatocytes and spermatides as well as missing of sperms and hypo-spermatogenesis.

Fávaro *et al.* (2006); Ahmadnia *et al.* (2007) and Yamamoto *et al.* (2007) reported many alterations attributed to the direct cytotoxic effects of nicotine leading to the inhibition of prostaglandin's synthesis and decrease of testosterone which play a functional role in reproduction system of the male mice. Other investigation displayed that nicotine was a CNS depressor that can inhibit the neural stimulus essential for the release of pituitary gonadotrophine (Reddy *et al.*, 1998), which lead to a lack of pituitary gonadotrophins essential for initiating and completing spermatogenesis and steroidogenesis in the testis (Aydos *et al.*, 2001). Destruction of Leydig cells may cause testicular atrophy; gonadal dysfunction, erectile dysfunction, and male factor

infertility were showed by Kim *et al.* (2005). Other studies explained that metabolites of nicotine as cotinine produced dose response inhibition of luteinizing hormone and 3 $\alpha$ -hydroxysteroid dehydrogenase, enzyme stimulated testosterone production (50-70%) (Fávaro *et al.*, 2006).

Aydos *et al.*, (2001) and Ahmadnia *et al.*, (2007) explained that nicotine toxicity may be due to change in the proportion of collagen fibers and contractile myofibroblastic cells, which may prevent the appropriate release of spermatozoa from the germinal epithelium into the lumen.

The oxidative stress of nicotine may cause a peroxidant/antioxidant imbalance in blood cells, blood plasma, and tissues resulting in a decrease in the activity of endogenous antioxidant enzymes (Suleyman *et al.*, 2002). Other researchers reported disruption of spermatogenesis in nicotine treated animals' testes tissues may be modulated by free radical toxicity (El-Sweedy *et al.*, 2007). Also nicotine metabolite cotinine generates free radicals / ROS in tissues in the liver and testes (Kalpane and Menon, 2004), and induces oxidative tissue injury

(Husain *et al.*, 2001 and Argentine & Cicchetti, 2004).

Direct genotoxic effects have been shown in human gingival fibroblasts (Sassen *et al.*, 2005 and Kleinsasser *et al.* (2006) and DNA strand breaks in human spermatozoa in nicotine aneuploidy and polyploidy, sister chromatid exchanges and chromosome aberrations in bone marrow cells of mice (Sen and Sharma, 1991 and Yauk *et al.*, 2007). High doses of nicotine increase the frequencies of premature centromere separation and premature anaphase and reduce the number of oocytes ovulated (Attia, 2007 and Sudheer *et al.*, 2007)

Results concerning the mutagenicity of nicotine in several test systems are contradictory. In the present study, nicotine intoxicated group obtained highly significant and gradual increased of MnPCEs throughout all the tested experimental periods. The statistical analysis of data is also provided. Nicotine treated mice, for one, two, three and four weeks resulted in highly significant alterations of all monitored parameters, but with different intensity and distinctive time trends. Nicotine intoxicated group obtained highly significant and gradual decreased of PCEs and PCEs /NCEs but gradual increased in NCEs throughout all the tested experimental periods.

The differences between the results can be attributed to different drug concentrations and the different genotoxic endpoints considered in the test systems. Different repair capacities of the various cell types used may also explain the discrepancies. The micronucleus technique has been proposed as a useful tool for measurement of genotoxicity (Madhumita *et al.*, 2003) induced by nicotine as it is able to assess both the clastogenic and aneugenic properties of a test compound. The genotoxic effects of nicotine have been shown in human gingival fibroblasts and spermatozoa and damage to DNA may result in mutations and altered cell functions (Kleinsasser *et al.*, 2005 and Ogura *et al.*, 2008).

In the present investigation a significant increase in the levels of NCE, and increased micronuclei frequency in nicotine-treated groups, as indicative of DNA damage, when compared with control group. The results were in a gradient with those reported by Villard *et al.* (1998) who mentioned that nicotine causes *in vivo* DNA single-strand breaks (SSB) in lung and liver of mice and those reported by Sassen *et al.* (2005) who reported that nicotine increases the DNA fragmentation in mini organ cultures. Hassan and Ahmed 2004, proved that green tea were inhibit the induction of Mn-PCEs in bone marrow of mice by 66% and 90%

when treated for one and two weeks respectively. Ayako (2004) suggests that tea catechins are not genotoxic but rather have a preventive effect against reactive oxygen species ROS -induced chromosomal damage at their physiological condition. These useful effects of tea catechins against ROS-induced chromosomal damage may support the cancer-preventing effects of tea constituents (Fujiki *et al.*, 2002).

# Tourism as an Economic Development Tool

Mohammad Taleghani

Assistant professor, Islamic Azad University - Rasht Branch, IRAN.

[Taleghani@iaurasht.ac.ir](mailto:Taleghani@iaurasht.ac.ir)

**ABSTRACT** - Probably, the greatest single deterrent to tourism development is the lack of appreciation and enthusiasm for tourism by civic and business leaders. When tourism is not understood and its benefits are unclear, planning and implementation of measures to improve the industry are often lacking. Notably, global tourism has become the largest industry in the world, with nearly 500 million consumers of tourism services per year spending hundreds of billions of dollars. The industry provides employment to over 100 million people worldwide. Thus, in view of tourism's increasing role in economic activity, the factors affecting its performance should be analyzed. An understanding of these factors is crucial to determine the ways in which national and international financial institutions, NGOs and other entities can play the most value-adding role. This paper provides a brief profile of key factors and trends in tourism and their economic effects at the global, national and regional levels.

**Keywords:** Tourism, Economic Development, Supply and Demand, GDP.

## 1. INTRODUCTION

The most important economic feature of activities related to the tourism sector is that they contribute to three high-priority goals of developing countries: the generation of income, employment and foreign-exchange earnings. In this respect, the tourism sector can play an important role as a driving force of economic development. The impact this industry can have in different stages of economic development depends on the specific characteristics of each country. "Given the complexity of tourism consumption, its economic impact is felt widely in other production sectors, contributing in each case towards achieving the aims of accelerated development" (Davidson, 2004).

A major difficulty in defining the boundaries of the tourism sector is to ascertain what investment costs should be ascribed to the development of tourism. Although heretofore not treated by international agencies as a "sector" in national accounting terms, tourism entails a collection of goods and services that are provided specifically for visitors and would not have been provided otherwise. Because of its interdependence with other sectors of the economy, it is difficult to analyze and plan for tourism. Furthermore, the lack of reliable statistical data hampers identification of the mechanisms by which tourism generates growth, as well as its potential for development.

Yet, in those instances where analysis has been carried out and research has preceded planning, tourism's priority in competing for scarce investment funds has been established. In these cases, long-term programmes for tourism development have been designed.

Nature and heritage tourism development has investment needs that differ, in certain respects, from traditional hotel development. There may be a greater need to improve access to the attraction site or facility, and for a mode of development that does not interfere with a sensitive habitat or historic area (Eadington & Redman, 2001).

## 2. LITERATURE REVIEW

### 2.1 Elements of Supply and Demand

There are primary factors that influence the level of nature and heritage tourism demand, namely; the overall tourism growth, the growth in specialty travel and the increasing awareness and concern for the environment. Each of these factors is in turn influenced by a number of elements. Overall tourism, for instance, is expected to continue to grow more rapidly than the world's economic output as a result of factors, such as population growth, rising incomes and employment, shorter working weeks in many parts of the world and the increasing integration of the world's economies and societies. The rapid growth of specialty travel is fuelled by some of the same factors, but there are a number of additional explanations, such as the boom in outdoor recreation and the new interest in health and fitness. Additionally, environmentalism is one of the elements that has changed people's attitudes on how they should spend their vacations.

### 2.2 The Importance of Location

People with incomes high enough for foreign travel are concentrated in a few countries. Most developing countries are far from the key points of origin. In this regards, countries like Mexico and

some Caribbean islands that are close to the United States and Canada benefit from a comparative advantage. These tourist destinations have reaped early success in promoting their attractions (Murphy, 2003).

### **2.3 Income Elasticity**

In several countries, travel receipts have been the fastest growing export item. The tourism sector represents over two-third of the value of total exports of goods and services from the Bahamas, three-fifth of those from Barbados and over one-third from the Dominican Republic and Jamaica. As national incomes increase, expenditure on travel also increases even faster<sup>1</sup>. As a result of this trend, international receipts from foreign travel have been increasing by nearly 11 percent a year (over eight percent in constant prices) or more than twice the rate of national incomes (Hogan & Mcpheters, 2003).

### **2.4 Decreasing Travel Costs**

There is evidence that tourism demand is also price-elastic, particularly below certain price levels. The two major costs of a trip abroad are transport charges and expenditures in the destination country. For long-distance traffic, air transport is predominant, and the average air transport costs have been declining as well. Where such transport costs constitute a high potential of the total costs of a trip, this decline is of great significance for potential long-distance travel growth.

### **2.5 Public and Private Sector Involvement**

Tourism is mainly a private sector enterprise, but the timely provision of hotel and other visitor services, such as entertainment, food and sport facilities, requires the public-sector participation in the form of infrastructure, promotional support, as well as fiscal and financial incentives, so as to attract private investment to the sector.

### **2.6 Availability of Credit**

Another important factor directly related to tourism facilities is the availability of credit on suitable terms, which is an essential catalyst for sound tourism investment. In some countries, when the private financial system does not provide this credit availability, the public sector has established credit lines for tourism investment.

### **2.7 Tourist Destination Attributes**

<sup>1</sup>- A model developed by the IDB for 17 major source countries gave a weighted average of 1.7 for the income elasticity of tourism demand.

Tourist demand is spurred by innovation in the type of holidays offered (new commodities) and by improvements in transport, accommodations and attractions (quality changes). The tourism sector offers multi-dimensional product that if vigorously promoted, is likely to lead to changes in the pattern of demand and general new demand for services. Yet, as in any other sectors of economic activity, a minimum set of parameters needs to be in place in order to make an investment viable. In this sense, it is important to identify those attributes of a destination area that are necessary to attract tourism projects and make them viable. Such attributes relate to at least six different categories, namely; climate, natural resources, infrastructure, amenities, culture, as well as socioeconomic and political factors. The table below presents these categories with their related attributes (Inskeep, 2008).

An ideal combination of these attributes should result in the form of tourism development that maximizes returns to the economy, the investors and the consumers of tourism services.

### **2.8 Tourism and GDP**

The tourism sector in the Latin American and Caribbean countries contributes significantly to GDP earnings, though this contribution is not reflected in the domestic income and product accounts of most countries. In the Bahamas, tourism accounts for about one-third of GDP and most sectors of economic activity are directly or indirectly linked to it. In Barbados, tourism was the leading economic sector, accounting for 15 percent of the GDP in 2002. In Jamaica, the tourism contribution to GDP was 13.4 percent in 2002, while in Mexico, it was only 4 percent, and as for Iran, it was accounted for about 1.3 percent.

Not all tourism receipts are retained within the economy. In fact, there is an outflow of foreign exchange for some of the goods and services consumed by visitors, as well as for capital goods invested in tourism and for payments abroad. The import needs depend on the level of development and the degree of diversification of substitutes for imported products and on the qualitative level of the tourism supply in each country (World Tourism Organization, 2000a).

### **2.7 Tourist Income Multiplier and Value-Added**

The tourist income multiplier (time) is a coefficient that expresses the amount of income

generated by a unit of tourism expenditure<sup>2</sup>. In Jamaica, a stopover visitor spending one dollar creates a ripple effect of US\$1.60 within the local economy, while a dollar spent by a cruise-ship visitor generates US\$1.20. In the Dominican Republic, the time has been estimated at US\$1.70.

The value-added concept is particularly important when considering the impact of tourism in the Caribbean region. Value is added when a product is developed, processed, refined, or remarked in a manner that allows it to be sold at a higher price than the prices of the raw materials, services and agricultural sectors supplying tourist consumption that are well positioned to achieve higher levels of value-added in the tourism sector.

When a country's natural resources are packaged by foreign tour operators and sold through sophisticated marketing techniques, a substantial portion of the value-added is created and captured by those tour operators, and therefore not returned to the country (Murphy, 2005). To increase the value-added of tourism, the host-country businesses and residents must offer travel services such as packaged tours ("land services"), offering locally owned accommodations and providing the necessary means for tourists to visit natural areas.

## **2.8 Income Distribution Effect (IDE) and Employment**

The IDE offers one of the strongest socioeconomic arguments in favour of tourism development. It describes how the income generated by the sector is distributed. The analysis can be undertaken at spatial and functional levels.

At the spatial level, tourists prefer to travel in regions with little industrial development. They also tend towards areas of little agricultural value. For these reasons, tourism can become a dynamic force in regional economies. Within a country, tourism demand originates in urban concentrations where the highest incomes are found. A percentage of such incomes is normally set aside for tourism in areas that are geographically different from the visitors' home base, thus, reinforcing the process of internal income redistribution. Internationally, a portion of the tourism consumption by developed countries occurs in the developing countries, favouring the process of international income redistribution (Williams & Shaw, 2009). On the other hand, at the functional

level, the income generated tends to favour employment, which is estimated to contribute more to the total value-added of the industry than other factors do, because so much of tourism involves personal services. In addition, it has been estimated that, worldwide, tourism directly or indirectly supports sixty-five million jobs, including hotel managers and staff, taxi drivers, tour operators and shop attendants, among others. Conversely, secondary employment is generated in agriculture, industry, handicrafts and services.

Tourism compares favourably with other economic activities as a generator of both employment and income, toothy directly and diffused through the economy. An OAS study on new hotel development in the Caribbean estimates that every investment of US\$80,000 in the tourism industry in the region generates forty-one jobs<sup>3</sup> (Organization of American States, 2005). The same investment would create only sixteen new jobs in the petroleum industry and fifteen in metallurgy. Moreover, according to the CTO, the 77,319 hotel rooms in fifteen Caribbean countries equal 88,697 jobs, or almost 1.15 per room<sup>4</sup> (Caribbean Tourism Organization, 2008).

Hotels account for about 75 percent of tourism employment, i.e. distribution, transport, finance, insurance and entertainment that make up the other 25 percent. Every room in a three- or four-star hotel in Venezuela generates one job. According to the IDB, for five-star hotels, each room creates 1.3 jobs. Moreover, based on the OAS study, one job generated by a hotel generates one more job elsewhere in the tourism trade and two in the rest of the economy; thus, one job generates an estimated three others. The tourism sector, particularly hotels, can play an important role in attracting foreign investment and providing training for employees. Many tourism ventures include foreign equity participation and technical knowledge about the construction and operation of hotels. The former represents a mobilization of international financial resources, which can be regarded as a desirable substitute for foreign borrowing. Outside management can be used to train large numbers of employees who would not otherwise have access to training. Furthermore, business provides a stimulus for the development of other ancillary businesses catering to tourists (WTO & IHRA, 2009).

<sup>2</sup> - The calculation is based on the familiar Keynesian multiplier  $K = 1/MPS + MPM$ , where MPS is the marginal propensity to save and MPM is the marginal propensity to import (or to spend on tourism abroad).

<sup>4</sup> - Caribbean Tourism Organization, Caribbean Tourism Statistical Report, 2008.

## 2.9 Tourism and Balance of Payments

Tourism can make an important contribution to a country's balance of payments. It offers the developing countries the possibility of diversifying their export earnings, particularly given that; (i) traditional exports are subject to price fluctuations, and (ii) there is a trend towards reducing the administrative, monetary and border formalities that affect international tourism mobility.

With only a few exceptions, the terms of trade for developing countries, i.e. the ratio between the prices that a country receives for its exports and the prices it pays for its imports have traditionally been unfavourable because of the fluctuations in the prices of raw material exports. But in the case of international tourism, if the index of average international tourist expenditure is taken as the expression of the price of the international product, the prices received have enjoyed greater stability than the prices of raw materials. In fact, prices have tended to increase in a stable manner due to several reasons, such as the demand for holidays, the growth of business travel and the rigidity of destination

supply in short and medium terms (Kottke, 2008). Conversely, the prices of other products are affected by the speculative or strategic offers; however, this is generally not the case with tourism. It is therefore a sector that tends to improve the terms of trade of an economy in the medium as well as the short terms.

## 2.10 Tourism the Most Important Economic Activity

For many third world countries, tourism has become the most important economic activity, especially as the major earner of foreign exchange. This is in part the result of the declining importance of sugar, bananas, bauxite and oil as the engines of growth. But it is also a reflection of the increasing importance given to recreation and leisure as a result of world's rising income levels. In addition, unlike many goods and services, tourism has no exact substitutes, meaning that the demand for holidays will grow rather than be raided for something else. Political boundaries that split regions, metropolitan areas or other natural market areas may also be an issue.

**Table (1): Tourist Destination Attributes**

CLIMATE	NATURAL RESOURCES	INFRASTRUCTURE	AMENITIES	CULTURAL	SOCIOECONOMIC POLITICAL
Temperature	Beaches	Water/energy Supply	Accommodations	Historic Features	Industrial Structure
Rainfall	Lakes	Drainage	Tourism Organizations	Theaters	Government Structure
Humidity	Rivers	Telecommunications	Restaurants	Concert Halls	Planning System
Sunshine	Forests	Roads	Shopping	Art galleries	Language
	Mountains	Railways	Sport facilities	Museums	Religion
	Flora	Ports	Recreational	Architecture	Gastronomy
	Fauna	Airports	Parks	Exhibitions	Hospitality

Hotel Amusements	0.13	0.27	22.08	0.19
Eating & Drinking	0.78	2.05	1.74	24.84
Services	2.13	5.73	6.26	2.72
Other	0.06	0.00	0.17	0.09
<b>Total Jobs Created</b>	<b>14.45</b>	<b>47.87</b>	<b>38.95</b>	<b>33.37=134.75</b>

Differences in local values and laws can have a dramatic effect on the apparent relative attractiveness of two otherwise comparable areas. The tourism effects appear most often when two adjacent jurisdictions have differing policies on such controversial recreational and entertainment activities as legalized gambling or the sale and consumption of alcoholic beverages. Often, however, in these cases, customers are drawn from the local or regional markets (Beckhuis, 2001). Thus, less of an "export" effect is created from spending, and therefore, little economic stimulus is added to the region. Nonetheless, in comparison with nearby jurisdictions which do not permit these activities, the counties or communities permitting such activities can be tremendously successful as measured by the revenues and jobs created at the local level.

The following table summarizes the economic impacts and demonstrates the multiplier effects of adding 100 tourists on job creation in a community.

**Table (3): Jobs Created from \$1 Million in New Demand for Final Output for Hotels and Amusements.**

Industry	County	Metro Area
Construction	0.3	0.4
Manufacturing	1.4	1.9
Transportation, Communication & Utilities	0.9	1.1
Wholesale Trade and Retail Trade	1.7	2.4
Finance Insurance & Real Estate	0.7	1.0
Hotel & Amusements	12.7	14.5
Services	4.6	5.9
Other	0.1	0.2
<b>Total Jobs Created</b>	<b>22.4</b>	<b>27.4</b>

### 3. Conclusion

Research found that an average of 22.4 direct and indirect jobs is created in non-metropolitan counties for each \$1 million of new demand for final output from the hotel and amusement industries. The impact on metropolitan areas is slightly higher at 27.4 new jobs created. The increase in demand for hotel and amusement services also affects almost all major sectors of the business community as shown in the following table. As may be expected, the greatest impact is on direct employment in the hotel and amusement industries, where 12.7 and 14.5 jobs are created in rural counties and metro areas, respectively

(World Tourism Organization, 2006).

There are other local revenues that are not easily quantified, as not all tourist expenditures are formally registered in the macro-economic statistics. Money is earned from tourism through informal employment, such as street vendors, informal guides, rickshaw drivers, etc. The positive side of informal or unreported employment is that, the money is returned to the local economy and has a great multiplier effect as it is spent over and over again. The World Travel and Tourism Council estimates that tourism generates an indirect contribution that is equivalent to 100% of direct tourism expenditure.

## Impact of Metformin on Immunity and Male Fertility in Rabbits with Alloxan- Induced Diabetes

Naglaa, Z.H. Eleiwa \* ; Hesham, A.M.; Hosny Abdel Fadil and Abdel Motal, S.M.

Dept. of Pharmacology, Faculty of Veterinary Medicine, Zagazig University, Egypt.  
\* [eleiwa02@yahoo.com](mailto:eleiwa02@yahoo.com)

**Abstract:** A study was designed to explore the possible side effects of metformin on immunity and fertility of male rabbits with alloxan- induced diabetes. Sixteen adult male rabbits were used in this study, they were classified into four equal groups as follows: the first group received neither alloxan nor metformin and remained as control group. Rabbits in the 2<sup>nd</sup> group were orally treated with metformin at a dose of 120 mg/kg b.wt once a day for 3 months .Rabbits in the 3<sup>rd</sup> group were administered alloxan, I/V, at a single dose of 100 mg/kg b.wt.Rabbits in the 4<sup>th</sup> group were administered alloxan ( 100 mg/kg b.wt, single I/Vdose ) then treated orally with metformin (120 mg/kg b.wt.) once daily for 3 months. Rabbits in all groups were subcutaneously injected with 2 ml polyvalent rabbit pasteurellosis vaccine after two months from the beginning of experiment for studying the immunological profile of the drug. Treatment of diabetic and non-diabetic rabbits with metformin evoked a significant decrease ( $P < 0.05$ ) in nitric oxide production on the 1<sup>st</sup> and the 2<sup>nd</sup> day post vaccination .In response to treatment with metformin, rabbits demonstrated a significant decrease ( $P < 0.05$ ) in serum lysozyme activity on the 1<sup>st</sup>, 2<sup>nd</sup> , 3<sup>rd</sup> day and in the 1<sup>st</sup> week post vaccination while diabetic rabbits treated with metformin showed a significant decrease ( $P < 0.05$ ) in serum lysozyme activity on the 3<sup>rd</sup> day and on the 1<sup>st</sup> , 3<sup>rd</sup> and 4<sup>th</sup> week post vaccination . In addition, treatment with metformin of diabetic and non-diabetic rabbits resulted in a significant decrease( $P < 0.05$ ) in testicular weight , sperm cell count, sperm motility and serum testosterone with a significant increase in sperm abnormalities and dead sperm %. Summing up our observations, the present study calls into question the justification for the use of metformin in a frame of a therapeutic strategy for diabetes due to its resulting negative impact on immunity and male fertility.

**Key words:** Metformin – alloxan – diabetes - rabbits

### 1. Introduction:

Diabetes mellitus is a syndrome characterized by disturbed metabolism and inappropriately high blood sugar (hyperglycaemia) resulting from either low levels of insulin or abnormal resistance to insulin's effects coupled with inadequate levels of insulin secretion to compensate (Tierney et al., 2002).

Treatment of type II diabetes has greatly improved due to the availability of new classes of oral antidiabetic drugs (OADs) and new insulin analogs (Rosak, 2002).

Metformin is one of antidiabetic drugs which belongs to the biguanide class of oral antihyperglycemic agents. It was first synthesized in 1929 and was shown to be a potent hypoglycemic agent, it was rediscovered in 1957 and widely used in Europe to treat type II obese patients. Metformin resurfaced in the 1980s and it was shown to increase insulin sensitivity; this encouraged its introduction to clinical practice in the United States for the first time (Bell and Hadden., 1997)

Metformin acts in the presence of insulin to increase glucose utilization and reduce glucose production, thereby countering insulin resistance. The effects of metformin include increased glucose uptake, oxidation and muscle glycogenesis, increased glucose metabolism to lactate by the intestine, reduced hepatic gluconeogenesis and possibly a reduced rate of intestinal glucose absorption (Clifford, 1993)..

On the other hand, many investigations reported some side effects of metformin therapy as lactic acidosis (Brassøe et al.,2005) ,vitamin B12-malabsorption that was recorded in about 1/3 of the diabetic cases (Ting et al.,2006) and high incidence of gastrointestinal side effects (Hoffman et al.,2003) as well as higher homocysteine levels(Wulffele et al., 2003).

It is extremely true and fitting to mention that the clinical effectiveness of a given drug would be in jeopardy if its adverse effects outweigh its efficacy. Therefore, the present work was designed to

explore the possible side effects of metformin on immunity and male fertility in rabbits with alloxan-induced diabetes.

## 2. Materials and methods

Materials:

1-Drug:

Metformin hydrochloride (Glucophage®), a product of Minapharm company, Egypt. Metformin is present in the form of tablet containing 1500mg of active drug.

Chemical name:

1,1-Dimethylbiguanide hydrochloride.

2-Alloxan:

Alloxan was purchased from El-Gomhoria Company, Egypt. It was given for induction of diabetes

3-Vaccine:

Formalized polyvalent rabbit pasteurellosis vaccine (VET. SER., VACC. RES. INST.-CAIRO-EGYPT) was used at a dose of 2ml s/c after two months from the beginning of experiment for immunological investigation

4- Experimental animals:

Sixteen adult male rabbits, weighing 2kg each, were obtained from Salsabil company, Fakous, Sharkeya, Egypt and allowed to acclimatize for a week at the animal house at the faculty of Veterinary Medicine . Animals were randomly assigned into four equal groups, four rabbits each and kept in a cage of four separate divisions , maintained at a 12-hour light dark cycle and a constant temperature of  $23 \pm 2^{\circ}\text{C}$  , received regular rabbit chow (Standard laboratory chow) and water was provided ad-libitum.

Methods:

Induction of diabetes:

Diabetes was induced in two groups of animals (The third and the fourth ones) by single intra-venous injection of alloxan with a concentration of 10% solution in 0.9% NaCl, at the dose of 100 mg/kg. b.wt. Diabetic status was confirmed when the fasting blood sugar value was above 200 mg/dl (Nammi et al.,2003).

Experimental design:

Sixteen adult male rabbits were used in this study, they were kept under hygienic conditions and fed on basic ration free from any medications or chemical additives and water was provided ad-lib.

Rrabbits were classified into four equal groups, as follows:

The first group (Control group ,Non diabetic non treated,):

Rabbits in the first group received neither alloxan nor metformin and remained as control group.

The second group (Non diabetic treated with metformin):

Rabbits in the second group were treated with metformin at a dose of 120 mg/kg b.wt per os through stomach tube after morning meal once a day for 3 months (Marquie, 1983).

The third group (Diabetic non treated, diabetic control):

Rabbits in the third group were injected I/V with alloxan at a single dose of 100 mg/kg b.wt.

The fourth group (Diabetic treated with metformin):

Rabbits in the fourth group were administered alloxan at a single dose of 100 mg/kg b.wt.(I/V), then treated with metformin at a dose of 120 mg/kg b.wt. Orally. The drug was given to rabbits early in the morning after meal once daily for 3 months

Rabbits in all groups were subcutaneously injected with 2 ml polyvalent rabbit pasteurellosis vaccine after two months from the beginning of experiment for immunological studies.

Laboratory assay:

A- Collection of samples:

5ml of venous blood samples were collected from the ear vein of all rabbits after 24, 48, 72hrs and 1<sup>st</sup> , 2<sup>nd</sup> , 3<sup>rd</sup> and 4<sup>th</sup> weeks of vaccine administration. The collected blood samples were allowed to clot. Clear serum samples were obtained by centrifugation of blood samples at 3000 rpm for 20 min. One part of serum samples was used immediately for blood glucose level estimation using spectrophotometer by glucose oxidase method (Barham and Trinder, 1972). The other part was stored at -20°C for immunological evaluation and measurement of serum nitric oxide production, lysozyme activity and testosterone level.

At the end of experimental period (3 months), rabbits were slaughtered, testes were dissected and weighed, tails of epididymis were collected for semen analysis.

B- Immunological evaluation:

1-Measurement of serum nitric oxide production:

Nitric oxide level in the serum was measured by spectrophotometer according to Rajaraman et al.,(1998) .

2-Measurement of lysozyme activity by agarose gel cell lysis assay:

The lysozyme activity in the serum was measured according to Schultz (1987).

The areas under the curve (AUCs) , representing lysozyme activity and nitric oxide release through the 30<sup>th</sup> days post vaccination , were evaluated as shown previously (Abdel Motal et al., 1987 ) . The areas for the control were expressed as 100%, the others relative to it.

#### C- Male fertility evaluation:

##### I-Testicular weight:

Was done by using digital electrical balance.

##### II- Semen analysis:

Was done according to method described by Williams et al., (1990) for examination of both sperm cell concentration, sperm motility, abnormalities and live/dead ratio.

##### III- Measurement of serum testosterone level:

Serum testosterone levels were estimated according to Burtis and Ashwood, (1994) using active testosterone enzyme immunoassay (EIA) DSL-10-4000 kit obtained from Diagnostic Systems Laboratories Inc.

#### D- Statistical analysis:

The data were analyzed using SPSS program. Results were reported as mean  $\pm$  S.E .The total variations were analyzed by performing the statistical design T-test. Probability levels of less than 0.05 were considered significant (SPSS, WIN.2003).

### 3. Results

#### I. Effect of metformin on blood glucose levels

As shown in table (1) ; treatment with metformin revealed a non significant decrease in blood glucose level on the 1<sup>st</sup>, 2<sup>nd</sup> and 3<sup>rd</sup> day post vaccination and a significant decrease ( $P<0.05$ ) in its level in the 1<sup>st</sup> , 2<sup>nd</sup> ,3<sup>rd</sup> and 4<sup>th</sup> week post vaccination compared with the control group.

All diabetic rabbits revealed a highly significant increase ( $P<0.01$ ) in blood glucose levels 24 hour post vaccination and then after compared with the control group while medication of diabetic rabbits with metformin evoked a highly significant decrease( $P<0.01$ ) in blood glucose level in all samples collected post vaccination compared with diabetic rabbits.

+  $P \leq 0.05$       ++  $P \leq 0.01$       + Compared with diabetic- non treated

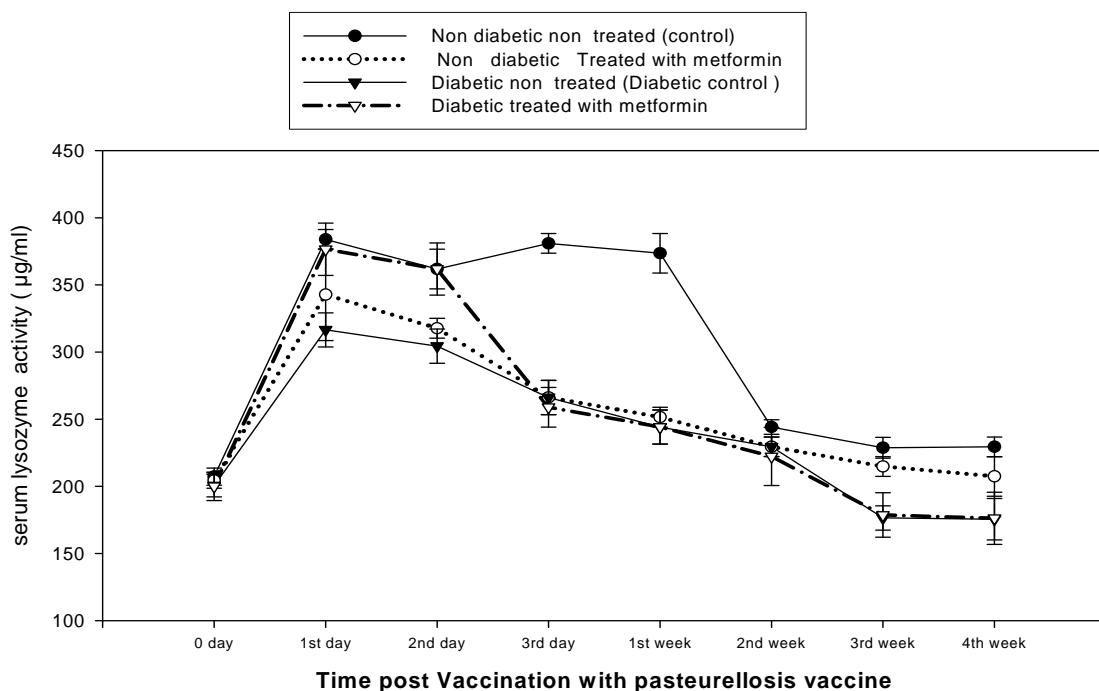

#### II. Effect of metformin on the immunological response:

##### A. Effect on nitric oxide production:

As shown in Fig. (1) and table (2) ; treatment with metformin exhibited a significant decrease ( $P<0.05$ ) in nitric oxide production on the 1<sup>st</sup> and 2<sup>nd</sup> day post vaccination and non significant decrease ( $P<0.05$ ) in nitric oxide production on the 3<sup>rd</sup> day, 1<sup>st</sup>, 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> weeks post vaccination compared with the control group.

Diabetic rabbits showed a highly significant decrease ( $P<0.01$ ) in nitric oxide production on the 1<sup>st</sup> and 2<sup>nd</sup> day post vaccination and non significant decrease in nitric oxide production on the 3<sup>rd</sup> day, 1<sup>st</sup>, 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> weeks post vaccination compared with the control group.

Diabetic rabbits showed a highly significant decrease ( $P<0.01$ ) in nitric oxide production on the 1<sup>st</sup> and 2<sup>nd</sup> day post vaccination and non significant decrease in nitric oxide production on the 3<sup>rd</sup> day, 1<sup>st</sup>, 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> weeks post vaccination compared with the control group.

**Fig. (1): Effect of metformin (120 mg/kg b.wt. per os) on nitric oxide production (ng/ml) in non diabetic and alloxan induced diabetic rabbits.**

Treatment of diabetic rabbits with metformin demonstrated a significant decrease in nitric oxide production on the 1<sup>st</sup> and the 2<sup>nd</sup> day post vaccination and non significant decrease in nitric oxide production on the 3<sup>rd</sup> day, 1<sup>st</sup> week, 2<sup>nd</sup> week, 3<sup>rd</sup> week and 4<sup>th</sup> week post vaccination compared with the control group.

Rabbits treated with metformin displayed 27.27% decrease in nitric oxide release allover the 30<sup>th</sup> days post vaccination. Diabetic rabbits demonstrated 45.45% decline, diabetic rabbits treated with metformin showed 27.27% decrement.

#### B. Effect of metformin on serum lysozyme activity.

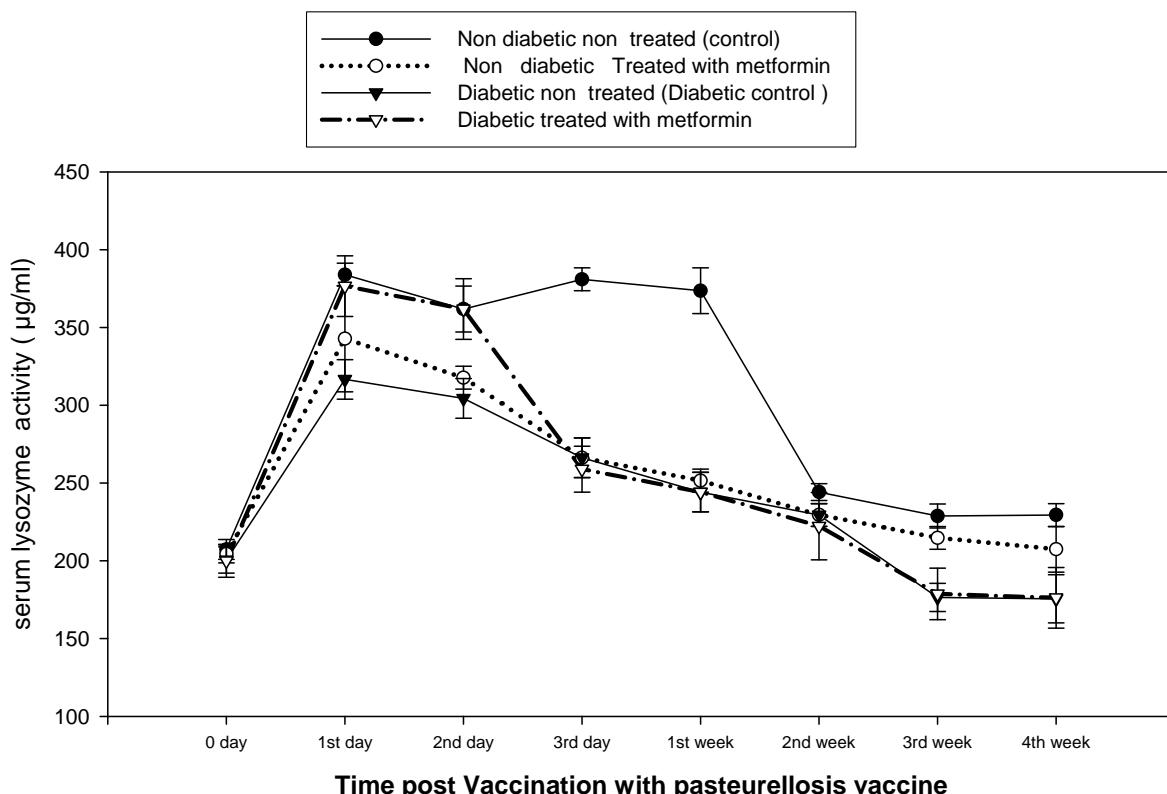

As shown in Fig. (2) and table (2); treatment with metformin demonstrated a significant decrease ( $P<0.05$ ) in serum lysozyme activity on the 1<sup>st</sup>, 2<sup>nd</sup> and a highly significant decrease ( $p<0.01$ ) on the 3<sup>rd</sup> day and in the 1<sup>st</sup> week post vaccination and non significant decrease in serum lysozyme activity in the 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> week post vaccination compared with the control group.

**Table (2): Effect of metformin (120 mg/kg b.wt. per os) given on nitric oxide production and lysozyme activity (represented by AUC and expressed as %) in rabbits with alloxan - induced diabetes.**

GROUPS	NITRIC OXIDE (%)	Lysozyme (%)
<b>Control</b>	100	100
<b>Treated with metformin</b>	72.73	80
<b>Diabetic control</b>	54.55	66.66
<b>Diabetic treated with metformin</b>	72.73	80

Diabetic rabbits revealed a significant decrease ( $P<0.05$ ) in serum lysozyme activity on the 1<sup>st</sup>, 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> week and a highly significant decrease ( $p<0.01$ ) on the 3<sup>rd</sup> day and in the 1<sup>st</sup> week post vaccination compared with the control group.

Diabetic rabbits treated with metformin showed non significant decrease ( $P<0.05$ ) in serum lysozyme activity on the 1<sup>st</sup> day, 2<sup>nd</sup> day and 2<sup>nd</sup> week post vaccination and a significant decrease in serum lysozyme activity on the 3<sup>rd</sup> day and on the 1<sup>st</sup>, 3<sup>rd</sup> and 4<sup>th</sup> week post vaccination compared with the control group.

**Fig. (2): Effect of metformin (120 mg/kg b.wt. per os) on serum lysozyme activity ( $\mu\text{g}/\text{ml}$ ) in non diabetic and alloxan induced diabetic rabbits.**

During the 30<sup>th</sup> days post challenge with polyvalent rabbit pasteurellosis vaccine, rabbits treated with metformin displayed 20% decrease in lysozyme activity. Diabetic rabbits showed 33.34% decline, diabetic rabbits treated with metformin displayed 20% decrease.

### III. Effect of metformin on male rabbit fertility:

#### 1) Effect on testicular weight

In response to treatment with metformin, rabbits demonstrated a significant decrease ( $P<0.05$ ) in testicular weight compared with the control group, while, diabetic rabbits exhibited non significant decrease in testicular weight compared with the control group (table 3).

Treatment of diabetic rabbits with metformin evoked a highly significant decrease ( $P<0.01$ ) in testicular weight compared with the diabetic rabbits.

#### 2) Semen analysis

##### a) Effect on sperm cell count

Treatment of rabbits with metformin showed a highly significant decrease ( $P<0.01$ ) in sperm cell count compared with the control group.

Diabetic rabbits demonstrated a significant decrease in sperm cell count compared with the control group.

Medication of diabetic rabbits with metformin elicited a highly significant decrease ( $P<0.01$ ) in sperm cell count compared with the diabetic rabbits.

##### b) Effect on sperm motility

Treatment of rabbits with metformin, displayed a significant decrease in sperm motility compared with the control group.

Diabetic rabbits displayed non significant decrease in sperm motility compared with the control group.

Treatment of diabetic rabbits with metformin induced a highly significant decrease ( $P<0.01$ ) in sperm motility compared with the diabetic rabbits.

**Table (3): Effect of metformin (120 mg/kg b.wt. per os) on male fertility in non diabetic and alloxan induced diabetic rabbits. (Mean  $\pm$  SE) (n = 4)**

Parameters Groups	Testicular weight (gm)	Sperm cell count (sp.c.c $\times 10^6$ /ml)	Sperm motility (%)	Dead (%)	Sperm abnormalities (%)	Serum testosterone Level (ng/ml)
control	20.33 $\pm$ 1.45	160.83 $\pm$ 5.83	91.66 $\pm$ 1.66	7.00 $\pm$ 0.28	9.56 $\pm$ 0.34	0.58 $\pm$ 0.30
Treated with metformin	15.33 $\pm$ 0.33*	110.00 $\pm$ 1.44**	80.00 $\pm$ 2.88*	13.26 $\pm$ 0.43**	13.50 $\pm$ 0.76**	0.11 $\pm$ 0.01*

+ P  $\leq$  0.05      ++ P  $\leq$  0.01

\* Compared with non diabetic- non treated

+ Compared with diabetic- non treated

#### c) Effect on dead sperm%

Rabbits treated with metformin exhibited a highly significant increase (P<0.01) in dead sperm % compared with the control group.

Diabetic rabbits demonstrated a highly significant increase (P<0.01) in dead % compared with the control group.

Medication of diabetic rabbits with metformin showed non significant increase in dead % compared with the diabetic rabbits.

#### d) Effect on sperm abnormalities

In response to treatment of normal rabbits with metformin, rabbits demonstrated a highly significant increase (P<0.01) in sperm abnormalities (coiled tail sperm and detached tail sperm) compared with the control group.

Diabetic rabbits displayed a highly significant increase (P<0.01) in sperm abnormalities (detached tail sperm and stunted growth sperm) compared with the control group.

Treatment of diabetic rabbits with metformin induced a highly significant increase (P<0.01) in sperm abnormalities (coiled tail sperm and detached head and tail sperm) compared with the diabetic rabbits.

#### 3) Effect on serum testosterone level

Rabbits treated with metformin displayed a significant decrease (P<0.05) in serum testosterone compared with the control group.

Diabetic rabbits demonstrated a significant decrease (P<0.05) in serum testosterone compared with the control group.

Medication of diabetic rabbits with metformin revealed a significant decrease (P<0.05) in serum testosterone compared with the diabetic rabbits.

#### 4. Discussion:

Metformin (dimethylbiguanide) is an antihyperglycaemic drug used to treat non-insulin dependent diabetes mellitus. It acts in the presence of insulin to increase glucose utilization and reduce glucose production, thereby countering insulin resistance. The effects of metformin include increased glucose uptake, oxidation and muscle glycogenesis, increased glucose metabolism to lactate by the intestine, reduced hepatic gluconeogenesis and possibly a reduced rate of intestinal glucose absorption. Metformin appears to facilitate steps in the post receptor pathways of insulin action, and may exert effects that are independent of insulin. In muscles, metformin increases translocation into the plasma membrane of certain isoforms of the glucose transporter (Clifford, 1993).

Nitric oxide (NO), has a wide variety of effects on cells. It has been found to affect different kinds of cells, with particularly striking effects in the control of blood pressure and the immune system (Rang et al., 1999).

In all sites, where NO is active, it is produced by the reaction of arginine with molecular oxygen to give citrulline as well as NO. The reaction is catalyzed by the enzyme nitric oxide synthase (NOS). NOS exist in several slightly different forms, depending on the kind of cell in which is found (Campbell, 1995).

Acknowledging the differences, it could be reasoned that a similar effect of NOS in the immune system might pertain.

In the current study, healthy rabbits treated with metformin demonstrated a significant decrease in nitric oxide production 24 and 48 hour post vaccination compared with the control.

Regrettably enough, our data are by no means sufficient to provide us with a ready clarification for the previous effect.

Nevertheless, going through literature could provide us with all right clue.

Convincing evidence is accumulating for the ability of vitamin B12 to modulate cellular immunity especially lymphocyte counts, CD8 cells and the natural killer (NK) cells. (Tamura et al., 1999).

Similarly, Erkurt et al., (2008) reported that vitamin B12 had important immunomodulatory effects on cellular immunity, and abnormalities in the immune system in pernicious anemia are restored by vitamin B(12) replacement therapy.

In vitamin B12-deficient patients, numbers of CD4 and CD8 lymphocytes decreased, CD4/CD8 ratio increased, and NK cell activity was depressed. After cyanocobalamin treatment, absolute numbers and percentage of lymphocyte subgroups were elevated. Increased CD4/CD8 ratio and depressed natural killer (NK) cell activity were restored and levels of C3, C4, and immunoglobulins were elevated (Erkurt et al., 2008).

The use of a multinutrient containing optimum amounts of essential trace elements and vitamins (as beta-carotene, Vitamins B6, B12, C, D and E, and folic acid) result in enhanced immune responses and reduction in the occurrence of common infections (Chandra , 2004).

Vitamins (A, B6, B12, C, D, E and folic acid) and the trace elements (iron, zinc, copper and selenium) work in synergy to support the protective activities of the immune cells. All these micronutrients are essential for antibody production. Overall, inadequate intake and status of these vitamins and trace elements may lead to suppressed immunity, which predisposes to infections and aggravates malnutrition. Thus, supplementation with these selected micronutrients can support the body's natural defense system by enhancing all three levels of immunity (physical barriers (skin/mucosa), cellular immunity and antibody production) (Maggini et al., 2007).

Kaplan and Basford (1976) noted that morphological and quantitative neutrophil abnormalities are common in the megaloblastic anemias of vitamin B12 and folic acid deficiency. The authors recorded that vitamin B12 has specific role in the production of intermediates necessary for normal cell function.

Patients receiving metformin have diminished vitamin B12(Bauman et al., 2000 and Ting et al., 2006) .

Sahin et al.,(2007) reported that patients with type 2 diabetes, metformin reduced levels of folate and vitamin B12 and increases homocysteine (Hcy). This deficiency was occurred through interfering with its absorption in the distal ileum (Quillen et al., 1999 and Rufenacht et al., 2008) .

Given the previous tapestry, it might be tenable to point out that vitamin B12 deficiency induced by metformin could account for the significant decrease in NO production.

In the current study, alloxan- induced diabetes elicited a significant decrease in serum lysozyme activity 24 and 48 hour and in the 3<sup>rd</sup> and 4<sup>th</sup> week post vaccination.

Lysozyme is bactericidal for almost all bacteria, hydrolyzing its cell wall resulting in its lysis. It activates the complement system and phagocytes (Jolles and Jolles, 1984).

The lysozyme protein (N-acetylmuramidase) is a major component of the specific granules of the polymorphonuclear leucocytes (PMN)and is found in high concentrations in the mucosal secretions in the eyes, oropharynx, respiratory tract and vagina. Several lines of evidence suggest that its localization at these sites is related to its role in the defense system. It is actively secreted by (PMN) cells during inflammatory response into the external environment as it has antimicrobial activity by degrading the glycosidic linkage of bacterial peptidoglycan (Richard and Theodore, 1991).

Hyperglycemic environment may enhance the virulence of various microorganisms. Candida albicans shows competitive binding and inhibition of complement mediated phagocytosis in a hyperglycemic environment (Hostetter, 1990).

Glucosuria enhances Escherichia coli growth and may be a reason for the increased incidence of urinary tract infections in diabetics (Geerlings et al., 1999).

Oxidative stress which is the metabolic response to hyperglycemia in patients with DM, may affect neutrophil lifespan, and phagocytic cell function resulting in a decrease in their ability to prevent or eliminate infection (Geerlings and Hoepelman, 1999 and Watson, 2002).

In general, patients with diabetes are at high risk of infections, which are more serious and prolonged. It is notable that the circulating levels of proinflammatory cytokines are elevated in diabetic patients and it has been suggested that the impaired functions of neutrophils contribute to the increased susceptibility to infections observed in these patients (Pickup et al., 2000).

The neutrophils of diabetic patients display increased necrosis and enhanced production of reactive oxygen species (Shurtz-Swirski et al., 2001). In the present experiment, healthy rabbits treated with metformin showed a significant decrease in serum lysozyme activity 24 and 48 hour post vaccination.

As pointed out previously with nitric oxide finding, the reduction in lysozyme activity, another

representative of cellular immunity could be further rationalized by vitamin B12 deficiency.

In the present study, alloxan induced diabetes in rabbits elicited a significant decline in sperm cell count and serum testosterone, and increase in dead % and sperm abnormalities.

In like manner, Naziroğlu, (2003) reported that streptozotocin (STZ) induced diabetes in rats was associated with impairment of testicular function leading to reduced fertility. Its etiology may involve oxidative damage by reactive oxygen species, and protection against this damage can be offered by antioxidant supplementation.

Similarly, Scarano et al. (2006) recorded that diabetes resulted in decreased body and reproductive organ weights, as well as diminished sperm counts in the testis and epididymis, associated with diminution of plasmatic testosterone levels, after natural mating, there was a decrease in the fertility in the diabetic adult male rats (25.5%) compared with control animals (81.5%).

Likewise, Shrilatha and Muralidhara, (2007) observed oxidative impairments in testis of STZ-induced diabetes in adult rats developed over time might at least in part contribute towards the development of testicular dysfunction through testicular degeneration leading to reduced fertility. Interestingly enough, diabetic rabbits medicated with metformin revealed a significant decrease in testicular weight, sperm cell count, sperm motility and serum testosterone, as well as an increase in dead % and sperm abnormalities.

Given the evidence, one is intrigued to surmise that the reproductive dysfunction seen in the shade of metformin treatment may be imputed to vitamin B12 deficiency.

The previous contention is commendable by the notion that vitamin B12 deficiency is induced by long-term use of metformin (Lin et al., 2007)

In this frame of reference, it is interesting to note that Vitamin B<sub>12</sub> deficiencies in men can lead to reduced sperm counts and lowered sperm motility. For this reason, B<sub>12</sub> supplements have been tried for improving fertility in men with abnormal sperm production (Kumamoto et al., 1988).

The concept is further boosted by the fact that mecabalamin (Me-B 12) enhances testicular function, resulting in an increased output of mature sperm. By oral administration of Me B 12 (1.0 mg/kg/day) to the oligozoospermic mice for 10 weeks, the sperm count, sperm motility, motile sperm count, diameter of seminiferous tubules and the percentage of good motile sperm were increased as compared with those of the control (Oshio et al., 1989).

On similar grounds, Sinclair, (2000) noted that number of nutritional therapies have been shown to improve sperm counts and sperm motility, including carnitine, arginine, zinc, selenium, and vitamin B12.

## 5. Conclusion:

Summing up our observations, the present study calls into question the justification for the use of metformin in a frame of a therapeutic strategy for diabetes due to its resulting negative impact on immunity and male fertility.

# Amniotic Membrane Extract for Acute Ocular Chemical Burns

Hosam Sheha, Hisham Hashem, Lingyi Liang, Mohamed Ramzy, Ahmed ZaKi,

**Abstract:** Background: Ocular chemical burns induce devastating and permanent damage to the ocular surface. Rapid intervention is required for maximal visual rehabilitation. Amniotic membrane transplantation (AMT) may save the ocular surface, however it introduces a potentially unnecessary surgical trauma in such compromised eyes. Amniotic membrane extracts (AME) could be a practical substitute of AMT in acute chemical burn. Aim: To evaluate the efficacy of topical AME in the management of acute ocular chemical burn. Methods: Non-comparative interventional case series. Six eyes of 4 consecutive patients with mild to moderate acute chemical burn, exhibiting persistent epithelial defect, inflammation and haze despite extensive conventional therapy were recruited. Topical AME was prepared and added to the conventional treatment within 2 days of the injury. Pain relief, inflammation, haze, and corneal epithelial healing were monitored. Results: Pain was significantly relieved, and inflammation was markedly reduced in all cases. The corneal epithelial defects rapidly healed while visual acuity improved within 11 (range 4-23) days. During an average follow-up period of 6 months (range, 3-8 months), all eyes retained stable surface with improved corneal clarity without neovascularization or symblepharon. Conclusions: Topical application of AME could be an effective adjunct in the treatment of mild to moderate cases of acute chemical burns. It allows non-traumatic and economic early intervention to promote epithelialization, reduce pain, haze and inflammation in acute phase, and prevent cicatricial complications in chronic phase. This result justifies additional large series controlled studies in the future.

[Hosam Sheha, Hisham Hashem, Lingyi Liang, Mohamed Ramzy, Ahmed ZaKi. Amniotic Membrane Extract for Acute Ocular Chemical Burns. Journal of American Science 2010;6(11):427-433]. (ISSN: 1545-1003).

**Key words:** Acute chemical burn, amniotic membrane extract, corneal epithelial defect

## 1. Introduction:

Ocular chemical burns injury is a serious ocular emergency in which rapid, devastating, and permanent damage can occur. The severity of the injury correlates directly to exposure duration and the causative agent. Treatment of such injuries requires medical and surgical intervention, both acutely and in the long term. Regardless of the underlying chemical involved, the common goals of management include removing the offending agent, controlling inflammation and promoting ocular surface healing with maximal visual rehabilitation. [1]

Various medical therapies have been used to achieve these objectives, including topical and systemic ascorbate, citrate, tetracycline, progesterone and steroids.[2-7] Previous studies revealed that early intervention with amniotic membrane transplantation (AMT) in mild and moderate chemical burns results in a marked reduction of symptoms, rapid restoration of the ocular surface, and improved visual acuities while preventing cicatricial complications in the chronic stage. [8-17]. However, surgically performed AMT renders a relatively high cost and potentially unnecessary surgical trauma in such compromised eyes. Furthermore, the membrane patch usually dissolves within several days so that multiple sessions of AMT may be required. [8; 16; 17] Recent studies have shown that topical amniotic membrane extracts (AME) has a comparable effect to AMT in promoting epithelialization, decreasing inflammation,

and suppressing corneal neovascularization.[18-21] Therefore, we hypothesized that AME could be a practical substitute for AMT in acute chemical burns. Herein we reported our experience in preparing and using AME as a rapid, economic, non-traumatic alternative modality in the treatment of acute chemical burns.

## 2. Methods

Patients:

This study was conducted, according to the tenets of the Declaration of Helsinki, to evaluate the effect of AME as an adjunct in the treatment of mild to moderate acute ocular chemical burns. This small series included 6 eyes of 4 patients, all males, with a mean age of  $34.5 \pm 15.8$  (range, 19-56 years). Their demographic data and clinical characteristics are summarized in Table 1. After obtaining a written informed consent, all patients received topical AME in combination with conventional treatment within 2 days following the onset of chemical burn. The injury was bilateral in 2 patients (Cases 1 and 2) and unilateral in the other two (Cases 3 and 4). The causative agents were alkali in 3 patients and acidic substance in one (Case 4).

Upon presentation, all patients complained of significant ocular pain, light sensitivity and blurred vision. Corneal epithelial defects were partial [Cases 1, 2 and 4 (Fig 1A, 1B)] or total [Cases 2 and 3 (Fig 2A, 2B)] and with various degrees of limbal and

conjunctival involvement. In addition, 4 eyes had limbal ischemia ranging from 2 to 6 clock hours. The severity was classified as Grade, I (2 eye), Grade II (2 eyes) and Grade III (2 eyes) based on the criteria defined by Roper-Hall.[22] Microorganism culture of all ulcer smears was negative and intraocular pressure (IOP) was normal in all cases.

All patients were initially treated with conventional medical therapies including saline/water irrigation to normalize the ocular surface pH, removal of remaining particulate materials, topical antibiotics, lubricants, 10% ascorbic acid and 6% citrate, antibiotic-steroids and cycloplegics, oral vitamin C or a combination thereof for the first 2 days after injury. When improvement was not apparent, all patients were detailed with information about the clinical course of chemical burns of the eye, alternative treatments, and advantages and disadvantages of AME and AMT. After a written consent was obtained, AME eye drops were added to the regimen.

Preparation of AM and extraction was carried out under sterile conditions. Each placenta was rinsed with sterile saline solution containing 1% penicillin-streptomycin-neomycin (PSN) antibiotic mixture (Invitrogen/Gibco, Grand Island, NY). After peeling off from the attached chorion, AM was submerged in liquid nitrogen. Under cold conditions, the membrane was cut into small pieces, manually ground into fine powder, and homogenized with normal saline. The homogenate was then centrifuged twice at 15,000 rpm for 30 minutes at 4°C. The supernatant was collected and the protein concentration was measured by DC protein assay (Bio-Rad, Hercules, CA). Non preserved 100 µg/ml eye drops were prepared and kept frozen at -20°C.

AME was instilled hourly for the first week, once every two hours until complete re-epithelialization were achieved, then 4 times daily for 2 weeks and was tapered off thereafter.

Subjective symptoms were scaled at each visit as 0 (No discomfort, No haze), 1 (Mild

discomfort and/or Mild haze), 2 (Moderate discomfort and/or Moderate haze) and 3 (Severe discomfort and/or Dense haze). Ocular surface inflammation was graded as 0 (absent), 1 (mild), 2 (moderate), 3 (severe). Fluorescein staining was conducted to evaluate epithelialization.

### 3. Results:

The average follow-up period was 6±2.3 months (range, 3-8 months). The results were summarized in Table 1. All patients reported a significant relief of pain and light sensitivity within the first week after AME treatment with overall symptomatic scores reduced from 2-3 to 0-1. Inflammation scores significantly decreased from 2-3 at first visit to 0-1 at the second week.

Rapid and progressive epithelialization was also observed in all eyes depending on the severity; for Grade I injury (Case 4, Fig 1) with less limbal involvement the epithelialization was completed in a centripetal manner. However, for Grade III injuries (Cases 3, Fig 2) with extensive limbal involvement the epithelialization started circumferentially to close the limbal defect before moving centripetally to close the corneal defect. After AME treatment, complete epithelialization was obtained in all eyes within a mean period of 11 days (range, 4-23 days, Table 1).

Accompanied with re-epithelialization, corneas, which were initially presented with edema and haze became clear (Fig 1E), or left with mild haze without edema (Fig 2E).

Impression cytology analysis was then performed after the ocular surface had been stable for more than three months, where no limbal stem cell deficiency was noted. There were no cicatricial complications such as symblepharon at the final visit (Fig 1F, 2F). Best corrected visual acuities (BCVA) improved to 20/20 in 5 eyes (83%) while Case 3 had BCVA of 20/60 due to residual corneal haze (Table 1). The ocular surface remained stable in all eyes during the follow up period.

**Table 1. Results of AME in treating acute chemical burns.**

Case No.	Eye No.	Agent	Grade	Limbal Ischemia (CH)	Symptoms Score		BCVA		Inflammation Score		Epithelialization (Days)
					Before	After	Before	After	Before	After	
1	1	Alkali	I	0	2	0	20/40	20/20	2	0	6
	2		II	2	3	0	20/50	20/20	3	0	8
2	3	Alkali	III	6	3	1	20/60	20/20	3	0	21
	4		II	4	2	0	20/400	20/20	3	1	12
3	5	Alkali	III	6	3	1	20/400	20/60	3	1	15
4	6	Acid	I	0	2	0	20/200	20/20	2	0	4

Note: CH: Clock Hours, BCVA: best corrected visual acuity

#### 4. Discussion:

Inflammatory mediators released from the ocular surface at the time of chemical burns induce tissue necrosis and attract further inflammatory reaction. This vigorous inflammatory response not only inhibits re-epithelialization but also increases the risk of corneal ulceration and perforation. In this non-comparative case series, AME was prepared and applied simultaneously with the conventional treatment to help break this inflammatory cycle and promote healing in patients with acute chemical burn with and without limbal involvement. The results of the present study revealed that early application of AME could be effective in rapidly relieving symptoms, reducing inflammation, and promoting epithelialization in mild to moderate acute chemical burn and consequently. It may also thwart limbal stem cell deficiency (LSCD) and symblepharon at the chronic stage.

Human amniotic membrane transplantation has been widely performed as a therapy for a variety of ocular surface disorders, and has been known to be highly effective not only in promoting re-epithelialization but also in suppression of inflammation. The mechanisms of action of the amniotic membrane transplantation are considered to include prolongation and clonogenic maintenance of epithelial progenitor cells, promotion of goblet and non-goblet cell differentiation, suppression of Transforming Growth Factor beta signaling, myoblastic differentiation of normal fibroblasts, and exclusion of inflammatory cells.[23] Based on the inherent biological actions known to amniotic membrane,[24-26] several investigators have explored the clinical efficacy of deploying AMT as a temporary graft to reduce inflammation and to promote healing in acute chemical burns.[9;12-14;17] Application of AME as eye drops is a different approach for the treatment of alkali injuries; Bonci et al [21] prepared a suspension containing homogenized amniotic membrane to investigate its beneficial effect on ocular surface diseases. They used this suspension to treat 21 patients with different ocular diseases exhibiting inflammation and epithelial defects; re-epithelialization was completed after 15–30 days with no side effects. However, they focused on the beneficial effects of the amniotic stromal matrix, rather than on the function of viable amniotic cells. It has been reported that amniotic cells have multiple functions, such as the synthesis and release of neurotransmitters [27-32] and neurotrophic factors [33; 34] and are a source of soluble anti-inflammatory factors. [20] In our study we modified the technique described by Jiang et al, [18] to ensure keeping all the active ingredients of AM by avoiding heat and filtration.

Despite variable extents of ocular surface epithelial defects, all patients reported significant relief of pain and light sensitivity within the first week after AME treatment.

Although one may attribute AME's effect in relieving pain to its anti-inflammatory action, we suspect that such a rapid action in pain relief might be mediated by a yet unknown anti-pain action that deserves further investigation.

Ocular surface inflammation was markedly reduced in all cases after treatment. Although the exact action mechanism remains to be determined, the aforementioned effect may be associated with early delivery of AM's anti-inflammatory active ingredients, which are retained in AME.[18-21] This anti-inflammatory effect is crucial in the treatment of chemical burns, as inflammation severely threatens stem cell survival[35], aggravates neovascularization, and induces apoptosis of keratocytes and stromal melting[36]. While topical corticosteroids in chemical burn are debatable, AME can function as an inflammation inhibitor without side effects.

When AM was used as a temporary patch, polymorphonuclear cells rapidly adhere to its stromal side in rabbit models of alkali burns [10] and in human patients with chemical burns, [37; 38] where these adherent cells underwent rapid apoptosis. [38, 39] Similarly, mononuclear cells, including lymphocytes and macrophages also underwent rapid apoptosis when adherent onto AM stroma in a murine model of HSV-induced necrotizing stromal keratitis. [40; 41] Such a unique anti-inflammatory action of the AM by promoting cellular apoptosis has been recapitulated in an in vitro culturing system using murine macrophages, [42] and recently He et al, reported that such an activity could be retained in AME. [43]

Although AME lacked the bandage effect of AMT, epithelialization started as early as four days in cases with nearly intact limbus; however, it took longer when there was nearly total limbal involvement with/without regional ischemia. It has to be noted that no impression cytology was performed at the initial visits, and limbal stem cell dysfunction was assumed clinically in cases with limbal ischemia. All eyes maintained corneal integrity without stromal melting. We speculate AME might be responsible for inhibiting such a stromal melting through multiple mechanisms: *first*, by maintaining the balance between the matrix metalloproteinase (MMP) and tissue inhibitor of matrix metalloproteinase (TIMP),[44] as TIMPs were found in epithelial and mesenchymal cells as well as in the compact layer of the amniotic membrane stroma, [45] and *second*, through reducing keratocyte apoptosis or modifying

the proliferation and migration of stromal fibroblasts.[39;46]

Interestingly, there was no abnormal limbal or peripheral corneal vascularization during the follow-up period. We further observed that the healed surface did not show any evidence of conjunctivalization, clinically or by impression cytology. We believe that limbal healing resulted from rapid recovery of limbal epithelial stem cells after the acute insult. Further investigation is needed to confirm the ability of AME to resurrect and promote *in vivo* expansion of limbal stem cells.

Collectively, our results showed that AME could be an effective adjunct in the treatment of mild and moderate cases of acute chemical burn by promoting healing, reducing inflammation, and restoring vision. Although we noted that instillation of AME in combination with the conventional therapy could successfully deliver AM's desirable actions, our series was still too small to determine its efficacy in managing different types of chemical burns. Additional controlled studies are needed to confirm that AME is a safe, non-traumatic, convenient, and economical alternative therapy to enhance corneal wound healing in acute chemical burn as well as other inflammatory ocular surface diseases.

\*[elhamabdelhady@hotmail.com](mailto:elhamabdelhady@hotmail.com)

**Abstract:** Biochemical and molecular characterization of eight tomato varieties were carried out based on seed storage proteins electrophoresis and RAPD markers. The electrophoretic pattern of water soluble protein produced 4 monomorphic bands, 6 polymorphic band and 3 unique bands .The pattern of non soluble protein produced 9 bands, one band is unique and considered a positive specific band of tomaten cartago variety and the others are polymorphic bands. RAPD results revealed a high level of polymorphism among the studied genotypes. All of the seven random primers screened gave reproducible polymorphic DNA bands. A total number of 81 amplified DNA bands were generated across the studied genotypes with average of 11.57 bands /primer. 37 bands out of the total number were polymorphic and 19 were unique. Combination of the all data derived from the SDS-protein markers of both water soluble and non soluble proteins produced a dendrogram almost similar to that obtained by the RAPD analysis. It could be concluded that, both of SDS-Protein and RAPD markers are equally important for genetic analysis and indicate a considerable amount of genetic diversity between the different studied varieties of *Lycopersicon esculentum* L.

[Elham A. A. Abd El-Hady\*, Atef A. A. Haiba , Nagwa R. Abd El-Hamid, and Aida A. Rizkalla. Phylogenetic Diversity and Relationships of Some Tomato Varieties by Electrophoretic Protein and RAPD analysis. Journal of American Science 2010;6(11):434-441]. (ISSN: 1545-1003).

**Keywords:** Tomato, Genetic diversity, SDS-protein, RAPD-PCR.

### 1. Introduction:

Tomato (*Lycopersicon esculentum* L.) is a member of the family Solanaceae and significant vegetable crop of special economic importance in the horticultural industry worldwide (He *et al.*, 2003 and Wang *et. al.*, 2005). Although the genus *Lycopersicon* includes a few species, its taxonomy is still questionable and phylogeny has not been completely established (Warnock, 1988)

The classification between various subgenera, species and subspecies is based primarily on morphological attributes. However, these morphological characters may be unstable and influenced by environmental conditions (Goodrich *et al.*, 1985). Over the years, the methods for detecting and assessing genetic diversity have extended from analysis of discrete morphological traits to biochemical and molecular trait. Therefore, the advent of the electrophoresis as an analytical tool provides indirect methods for genome probing by exposing structural variations of enzymes or other protein genome (Cook, 1984 and Gilliland, 1989).

The electrophoresis of proteins is a method to investigate genetic variation and to classify plant varieties (Isemura *et al.*, 2001). Its banding pattern is very stable which advocated for cultivars identification purpose in crops. It has been widely suggested that such banding patterns could be

important supplemental method for cultivars identification (Tanksley and Jones, 1981; and Thanh and Hirata, 2002). Analyses of SDS-PAGE are simple and inexpensive, which are added advantages for use in practical plant breeding.

DNA molecular markers technology, which are based on sequence variation of specific genomic regions, provide powerful tools for cultivar identification and seed quality control in various crops with the advantages of time-saving, less labor-consumption and more efficiency (Hu and Quiros, 1991; Mongkolporn *et al.*, 2004; Dongre and Parkhi, 2005; Garg *et al.*, 2006 and Liu *et al.*, 2007).

Random Amplified Polymorphic DNA (RAPD) is based on *in vitro* amplification of randomly selected oligonucleotide sequences. Amplification takes place by simultaneous primer extension of complementary strands of DNA; the primers use the plant DNA as a template for PCR amplification. RAPD is very useful in the study of biodiversity, hybridization, gene mapping and genetic map construction (Sharma and Sharma, 1999).

Generally, molecular markers have proven to be useful tools for characterizing genetic diversity in agricultural crops. Researchers have studied genetic variation in tomato landrace and cultivar collections using various molecular techniques, including restricted fragment length polymorphism

(RFLP), amplified fragment length polymorphism (AFLP), random amplified polymorphic DNA (RAPD) and simple sequence repeats (SSR) (Miller and Tanksley, 1990, Rus- Kortekaas *et al.*, 1994, Bredemeijer *et al.*, 1998, Villand *et al.*, 1998, Mazzucato *et al.*, 2003, Park *et al.*, 2004, Carelli *et al.*, 2006 Garcia-Martinez *et al.*, 2006). The aim of the present study was to find out the phylogenetic relationships of eight tomato varieties using protein profiles and random amplified polymorphic DNA (RAPD) analysis.

## 2. Materials and methods

Seeds of eight tomato cultivars of diverse origins grown in Egypt (Tomaten cartago GC781, Karnak, Fac-68, Floradid, Jack pot, Casel rock, Packmor and Petto 86) were used for the present Study and kindly supplied by Horticulture Research Institute, Agricultural Research Center, Giza, Egypt.

### SDS-protein electrophoresis:

Sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) for water soluble and non soluble proteins was performed according to the method of Laemmli (1970), as modified by Studier (1973). Molecular weights of different bands were calibrated with a mixture of standard protein markers include myosin (212 KDa), B-galactosidase (120KDa), phosphorylase b (97KDa), bovinserumalbumin (66.2KDa), ovalbumin (45KDa), carbonic anhydrase (31KDa), soybean trypsin inhibitor (20KDa), lysozyme (14.4KDa) and aprotinin (6.5KDa) from Bio Basic Inc. The banding profile was photographed and scored.

### DNA isolation:

Genomic DNA was isolated from the young leaves by using Bio Basic Kits. The quality of isolated genome DNA was checked by agarose gel electrophoresis.

### DNA amplification:

Seven decamer oligonucleotide primers obtained from (metabion international AG) were used for the polymorphism survey. Amplification reactions were carried out in 25 $\mu$ L volumes, containing (5  $\mu$ L of 5x buffer, 3.0  $\mu$ L of dNTPs (2.5mM) 3  $\mu$ L of Mg cl2 (25 m M), 3.0  $\mu$ L primer (2.5  $\mu$  L) ,0.3  $\mu$  L of Taq polymerase( 5U/  $\mu$ L) and 2.0  $\mu$ L of genomic DNA (50 ng/  $\mu$ L). Amplification was performed in PTC-100 PCR version 9.0 from M J Research-USA. Programmed for an initial denaturation at 94 °C 5 min, 40 cycles of 1 min denaturation at 94 °C, 1 min annealing at 40°C and 2 min extension at 72°C followed by final extension for 5 min at 72°C.

Amplified products from the RAPD reactions were separated by horizontal gel electrophoresis unit using 1.5% agarose gel in TAE buffer and stained with ethidium bromide .The run was performed at 95 volt for 55 min. DNA ladder 1Kb was used from fermentas with lengths ranged from 264 to 11507 bp and then the gel was visualized by UV-transilluminator to examine the reproducibility of banding patterns, then photographed by gel documentation system, Biometra – Bio Doc Analyze. Each PCR reaction was repeated twice in order to ensure that RAPD banding patterns were consistent and reproducible and only stable products were scored.

### Statistical analysis:

The electrophoretic patterns of water soluble and non soluble proteins, and the reproducible banding patterns of each primer which produced by RAPD were chosen for analysis. Each gel was scored as present (1) or absent (0), and pair wise comparisons between individuals were made to calculate the Jaccard's coefficient of genetic similarity matrix using SPSS program (statistical Package for Social Scientists) version-10 (Norman *et al.*, 1975). Cluster analysis was performed to produce a dendrogram using unweighted pair-group method with arithmetical average (UPGMA).

## 3. Results and Discussion:

### 1. SDS protein analysis

#### 1-1. Water soluble protein:

SDS-electrophoretic patterns of water soluble and water non soluble protein fractions were used to find out the phylogenetic relationships among some varieties of tomato. Figure (1) demonstrates the water soluble protein banding patterns of the eight tomato varieties belonging to (*Lycopersicon esculentum* L.).

The SDS banding pattern of water soluble protein produced 13 bands distributed in all varieties with molecular weights ranging from 6.50 KDa to 130.24 KDa. with polymorphism percentage reached to 86.231% between the eight tomato varieties. The pattern of these bands is as follows, 4 bands are monomorphic with molecular weights of 42.55, 18.14, 11.08 and 9.63 KDa., while 6 bands are Polymorphic with molecular weights of 103.09, 46.89, 26.67, 12.62, 8.31 and 7.15 KDa., in addition to three unique bands which have been observed in three varieties, Jack Pot had one of these positive specific band with molecular weight of 130.24 KDa. Also, Casel Rock had one positive specific band with molecular weight of 16.33 KDa, and tomaten Cartago had the third positive specific bands at molecular weight of 6.50 KDa. These bands could be

considered as specific markers for distinguishing these varieties from each others.

#### 1-2. Water non soluble protein:

The SDS banding pattern of water non soluble protein produced 9 bands distributed in all varieties with molecular weights ranging from 6.50 to 69.02 KDa. The polymorphism percentage reached to 100% between the studied tomato varieties. Figure (1) shows that water non soluble protein bands distributed as follows, only one band is unique with molecular weight of 14.37KDa. and considered a positive specific band of tomaten cartago variety, while the others are polymorphic bands.

The UPGMA method was used to calculate the similarity coefficient among the studied tomato varieties of both water soluble and water non soluble proteins individually, based on existence of the bands (presence or absence) and their average was used as an approximate value for recognizing groups of varieties in dendrogram (Fig.2 a&b), which showed the same relationship between tomato varieties, when the data of water soluble proteins and water non soluble proteins were combined for UPGMA cluster analysis, the obtained dendrogram (Fig.2c) revealed almost the same cluster pattern of the eight studied tomato varieties.

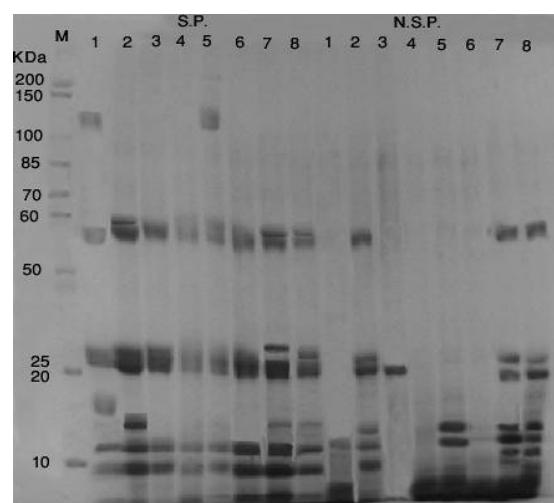

The similarity coefficient based on water soluble and non soluble proteins markers ranged from 0.771 to 0.135. Table (1) showed that the highest similarity value (0.771) was between Cartago and Jac-pot. While the lowest value of (0.135) was between Cartago and Betto. The relationship between Casel rock and Floradid was 0.574, and between Casel rock and Fac-68 was 0.646. Betto is equally closely related to both Karnak and Pack-mor (0.733).

The clusters obtained from the dendrogram Fig. (2c). showed that the studied tomato varieties are grouped in three main groups. The first one consists of tomaten cartago and jack-pot which were the most related varieties to each other. The second group includes Casel rock, Floradid and Fac-68 .while, the third group consists of karnak , Betto and Pack-more ,therefore , it could be concluded that the results of water soluble and non soluble protein could differentiate between the studied tomato varieties producing some specific bands that can be used to distinguish such variety from each others. These specific variations were analyzed to assess the protein polymorphisms between different varieties of tomato and clarify the genetic nature of polymorphic bands. Similary, different cultivars of cultivated chickpea were examined by Ahmad and Slinkard (1992), they concluded that seed protein was a very conservative trait in chickpea. Also, Raymond *et al.* (1991), and De vries (1996), reported similar electrophoretic

patterns of protein among the cultivars of sunflower and lettuce. Munazza *et al.* (2009) studied the electrophoretic characterization in different genotypes of oilseed Brassica based on analysis of seed storage proteins to assess the protein polymorphisms within and different cultivated species and clarify the genetic nature of polymorphic bands to differentiate the yellow and brown seeded varieties of Brassica.

Furthermore, This electrophoretical proteins can detect genetic purity test in case of vegetables such as tomato by several studies using isozyme and protein polymorphism (Thanh *et al.*, 2006, Tanksley and Jones, 1981; Wang *et al.*, 2005).The reduction of genetic variation in tomato (*Solanum lycopersicum L.*) through domestication and breeding (Tanksley and McCouch,1997; Barrero and Tanksley,2004) has resulted in the need for conservation, characterization, and utilization of genetic resources.

The high stability of protein profile makes protein electrophoresis a powerful tool in elucidating the origin and the evolution of cultivated plants (Ladizinsky and Hymowitz,1979), so it seems to say that SDS-PAGE technique has proven to be a useful in supporting classical taxonomy studies (Thanh *et al.*, 2003).

## 2- Molecular studies:

Seven RAPD primers were tested against the eight tomato varieties. The sequences of these primers are listed in Table (2). The RAPD profiles of the amplified products are shown in Fig. (3). The number of bands and the degree of polymorphism revealed by each primer are given in Table (2). Generally, the levels of polymorphism were varied with different primers among the different tomato varieties. The percentage of polymorphism produced by each primer differed from one primer to the other, the maximum value of polymorphism was 85.714% produced by primer OPD-13. While, the minimum value of polymorphism was 45.455% by primer OPX-17, with an average polymorphism of 66.479 % across all the genotypes.

A total number of 81 amplified DNA bands were generated across the studied genotypes with average of 11.57 bands/ primer. Out of the total band, 37 polymorphic and 19 unique ones were detected. The RAPD profiles of the amplified products of each primer are shown in Fig.3 (a, b, c, d, e, f and g). A maximum number of 17 bands were amplified with primer opc-19 and a minimum of 7 bands with primer OPD-13. The number of monomorphic bands was primer dependent and ranged from 1 band by primer D-13 to 6 bands by primer OPN-06 and primer OPX-17.

The genetic similarity coefficient, recognized the eight studied tomato variety, the highest similarity value was 0.891 which recorded between Cartago and Jac-Pot, while the lowest similarity value was 0.401 between cartago and Karnak Table (3).

Similarity coefficient matrices were used to generate a dendrogram of tomato genotypes based on UPGMA analysis Fig (4), the analysis divided the eight genotypes into three distinct clusters .The first cluster includes Cartago and Jac-Pot with the highest similarity value (0.891), while the second cluster contains three genotypes, Floradid and Casel Rock which are moderately related (0.673) then come Fac-

68 which is highly related to Casel Rock (0.810). The third cluster comprises of Betto, Pack-more and Karnak. In which Pack-mor and Karnak are highly related to each other (0.864) and Betto was closer to Pack-more (0.795) than Karnak (0.699).

From the previous results it could be concluded that, the dendrogram on the basis of RAPD revealed almost the same phylogenetic relationships between the eight studied tomato varieties that obtained by combining the data from the markers of water soluble and non soluble proteins.

Some earlier researchers stated that the application of both biochemical and molecular genetics techniques have an important potential to provide a new tool for the study of both wild and domesticated species in respect to investigation of evolution and migration of species from their gene pool centers (Badr *et al.*, 2000 and Fregonezi *et al.*, 2006 ).

The identification and characterization of species become possible through fingerprinting for each species since DNA is a source of informative polymorphism (El-Rabey, 2008), consequently, techniques of molecular genetic markers have an important potential for the detection of genetic differences among species (Benmoussa and Achouch, 2005). Many investigations reported that, RAPD analysis is revealed high genetic polymorphism of the tomato genome and established the phylogenetic relationships among members of the genus *Lycopersicon* Mill. The resulting dendrogram was consistent with *Lycopersicon* phylogeny based on the molecular data of RFLP, ISSR, microsatellite analysis and with the classification based on morphological characters (Ruck, 1979; Palmer and Zamir, 1982; Miller and Tanksley 1990; Khrapalova, 1999 and Lingxia *et al.*, 2009). Therefore, the use of molecular markers in the applied breeding programs can facilitate appropriate choice of parents involved

for crosses. Munazza *et al.*, (2009) reported that the assessment of genetic diversity within and between landraces should have priority for varieties improvement. At the same time it is necessary to develop better methods of characterization and evaluation of germplasm collections, to improve strategies for conservation and collection of germplasm and to increase the utilization of plant genetic resources.

#### 4. Conclusion:

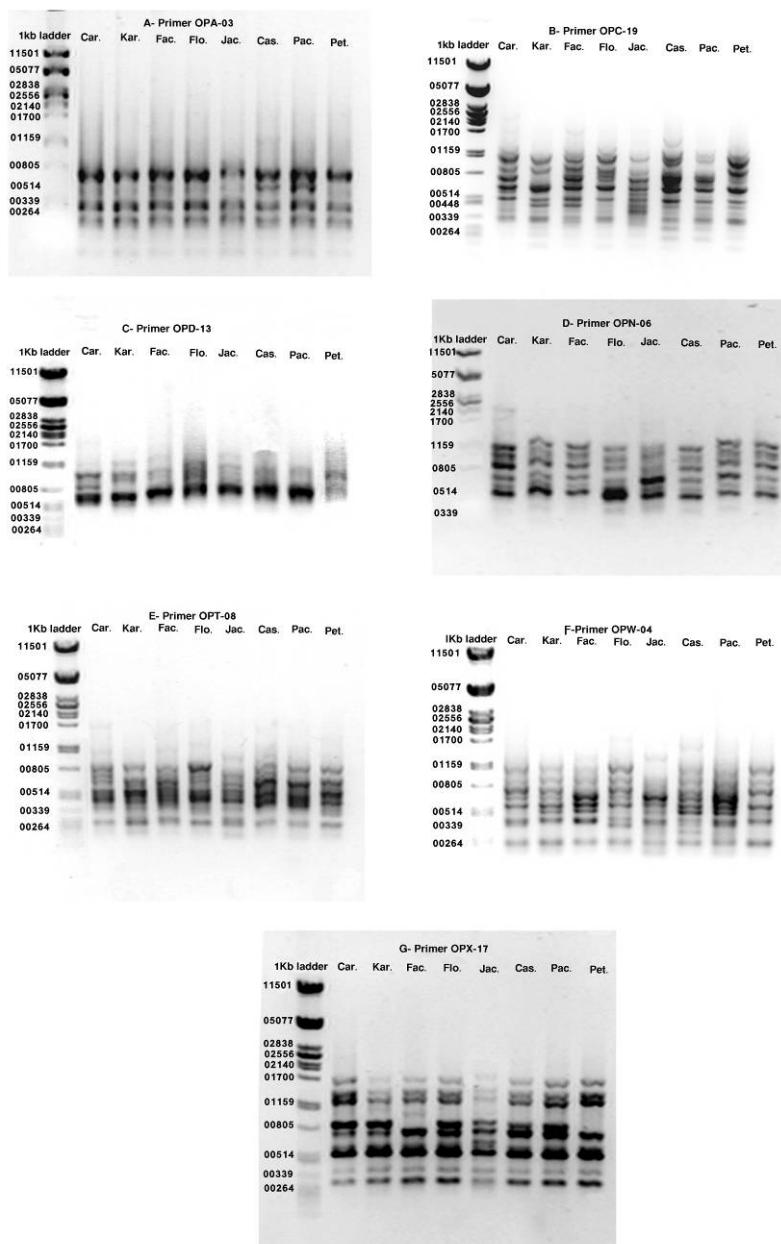

Eight tomato varieties were used in order to elucidate their genetic diversity by using SDS-proteins and RAPD-PCR analysis. It could be concluded that the present biochemical results, water soluble and non soluble protein, can differentiate between the studied tomato varieties by producing some specific bands that could be used to distinguish any variety from each others. These specific variations were analyzed to assess the protein polymorphisms between different varieties of tomato and clarify the genetic nature of polymorphic bands. On the molecular level, seven primers were used to differentiate between these varieties and gave reproducible results with wide variations in their band numbers. The molecular markers obtained by the RAPD technique revealed a remarkable molecular discrimination between the eight tomato varieties under the study. The phylogenetic analysis on the basis of RAPD derived a dendrogram revealed almost the same cluster pattern that obtained from the combined markers of water soluble and non soluble proteins and confirm the phylogenetic relationship between the eight studied tomato varieties. It could be concluded that, both of SDS-Protein and RAPD markers are equally important for genetic analysis and indicate a considerable amount of genetic diversity between the different studied varieties of *Lycopersicon esculentum* L.

**Abstract:** **Objective:** To assess the effect of acidulated phosphate fluoride gel (APF), sodium fluoride varnish (NaF) and casein phosphopeptide-amorphous calcium phosphate fluoride paste (CPP-ACPF) on the dental erosion produced by coca cola in primary and permanent teeth. **Design:** Sixty extracted human primary molars ( $n = 30$ ) and young permanent premolars ( $n = 30$ ) were used in this study. The coronal portion of each tooth was sectioned mesio-distally. Specimens were prepared by embedding the crown sections in acrylic resin blocks leaving the enamel surfaces exposed. Specimens were ground, polished and randomly assigned to one of three groups each of 10 according to the protective agent used: APF gel (1.23% F), NaF varnish (0.1%F), and CPP-ACPF paste (0.2%F). Half of the exposed enamel surface was protected with adhesive tape during the treatment of the remaining surface according to their group. Six daily demineralization–remineralization cycles of 5 minutes of immersion in a cola drink (pH 2.3) and 30 minutes in artificial saliva were conducted for 14 days. Surface Vickers Micro-hardness readings were recorded at baseline and 14 days later for both halves. Percentage surface microhardness reduction (%SMHR) was then calculated. Data were analyzed using ANOVA and Duncan's post-hoc test ( $p < 0.05$ ). **Results:** All of the tested fluoride treatments were able to reduce erosive enamel loss in both primary and permanent groups. In primary teeth only APF gel showed significantly higher anti-erosive effect than both fluoride varnish and CPP-ACPF paste. In permanent teeth both CPP-ACPF paste and APF gel showed significantly higher protective anti-erosive effect than fluoride varnish. **Conclusions:** under the conditions of this study, all of the tested fluoride treatments were able to reduce erosive enamel loss in both primary and permanent teeth. Primary and permanent enamel substrates reacted differently to different fluoridated compounds. CPP-ACPF paste is a promising remineralizing material.

**Keywords:** dental erosion, fluoride varnish, fluoride gel, CPP-ACPF paste, microhardness, primary, permanent.

## 1. Introduction

Erosive tooth wear or dental erosion has gained more attention from the dental profession since the decline in dental caries in many industrialized countries. Dental erosion is a localized loss of the tooth surface by a chemical process of acidic dissolution of nonbacterial origin.<sup>1</sup> This process may be caused by extrinsic or intrinsic agents. Extrinsic agents include acidic foodstuffs, beverages, snacks and may also occur following environmental exposure to acidic agents.<sup>2,3</sup> One of the most common extrinsic factors that cause dental erosion is the excessive consumption of acidic food and beverages.<sup>4,5</sup> Intrinsic erosion is associated with gastric acid which may be present intra-orally

following vomiting, regurgitation, gastro-oesophageal reflux.<sup>6</sup>

Lifestyle changes and a rise in the consumption of acidic foods and beverages have led to an increase in the prevalence of dental erosion around the world in recent years. High prevalence numbers ranging from 30%<sup>7</sup> to 68%<sup>8</sup> have been reported, especially among children and adolescents,<sup>9</sup> while the prevalence and etiology of dental erosion have been the focus of innumerable papers in the last two decades, studies regarding the prevention of this disease by chemical substances are still needed.

Several studies have reported the effectiveness of topical fluoride as a cariostatic agent in enhancing enamel remineralization.<sup>10-14</sup> A similar

anti-erosive capability of different topical fluorides was tested.<sup>15-17</sup>

In recent years casein phosphopeptide-amorphous calcium phosphate (CPP-ACP) nanocomplexes have also been demonstrated to have anticariogenic<sup>16-21</sup> as well as anti- erosive properties.<sup>22-24</sup>

Current recommendations in many recent studies for management of demineralized lesions include the use of oral products containing CPP-ACP (e.g., Tooth Mousse and Recaldent) and fluoride,<sup>18,19,22,24</sup> thus MI paste plus was recently introduced in the market combining both. MI paste plus is water based, lactose free cream containing casein phosphopeptide and amorphous calcium phosphate fluoride (CPP-ACPF). The level of fluoride is 0.2% w/w (900 ppm) which approximates that of adult toothpastes. When CPP-ACPF is applied in the oral environment, it will bind to biofilms, plaque, bacteria, hydroxyapatite and soft tissue localizing bio-available calcium, phosphate and fluoride.

A controversial issue in dental erosion literature involves differences in erosion progression rates between primary and permanent teeth. Some authors stated that primary enamel is more susceptible to erosion than permanent enamel<sup>25-27</sup> while others found no differences between these two types of substrates.<sup>28-30</sup> However, the protective effect of different remineralizing agents especially CPP-ACPF on both primary and permanent enamel did not receive much attention.

Softening of the enamel surface is an early manifestation of the erosion process. Reduced surface hardness which accompanies erosion of the enamel surface by acidic beverages can be assessed using a physical measurement such as the hardness test.<sup>17, 23, 31</sup>

In view of the above considerations, the present paper aimed to investigate the protective effect of single application of 0.1% NaF varnish, 1.23% APF gel and CPP-ACPF on artificially induced dental erosion in human primary and permanent enamel. Thus the null hypothesis tested was that the different fluoride treatments will not exhibit different protective potential on enamel erosion.

## 2. Material and Methods

### Sample preparation

Sixty human primary molars ( $n = 30$ ) extracted from children 10- 12 years old and young permanent premolars ( $n = 30$ ) extracted for orthodontic purpose from children 12-14 years old were used in this study. Enamel specimens were prepared by sectioning the coronal portion from the

radicular portion of each tooth using a diamond bur in a high-speed handpiece with an airwater spray. The crowns were then transversely sectioned from the mesial to distal surface through the center of the crown using a high-speed saw (Buehler Int., Evanston, IL) cooled with water. The enamel sections that were free of any caries or any enamel defects were embedded in acrylic resin with the outer buccal or lingual enamel surface exposed. The enamel surfaces were ground wet using 600-2000 grit silicon carbide abrasive paper (Buehler, Lake Bluff, IL) and polished with 1.0 and 0.05 mm alumina suspension (Buehler) to expose flat enamel for microhardness measurements. Test specimens were randomly assigned to one of three groups each of 10 according to the protective agent used: 1.23% APF gel (dentsply professional 1301 Smile Way, York PA 17404), 0.1 % NaF varnish (flour protector, Ivoclar Vivadent AG, FL - 9494 Schaan Liechtenstein), and 0.2% CPP-ACPF paste (Prospec™ MI Paste, GC Corporation, Tokyo, Japan).

### Fluoride treatment

Before topical fluoride application, the specimens were thoroughly rinsed with deionized water and delicately dried using a paper towel. Half of the exposed enamel surface of each specimen was protected with adhesive tape while the remaining surface was treated according to their group. APF gel and CPP-ACPF paste were applied for 4 minutes with the aid of a cotton tip and were later removed by squirting deionized water to rinse thoroughly. The NaF varnish was applied using a microbrush, left to act at the enamel surface for 12 hours to simulate clinical topical fluoride application<sup>10</sup>, and then delicately removed using cotton tips immersed in deionized water. No chemical substances were used for the removal of the varnish in order not to alter the enamel surface. All specimens were then stored in artificial saliva overnight.

### pH cycling

Six daily demineralization-remineralization cycles of 5 minutes of immersion in a cola drink (pH 2.3) and 30 minutes in artificial saliva were conducted for 14 days. All specimens were stored in artificial saliva between and after cycles. During demineralization cycles, the specimens were immersed in cola drink (Coca-Cola) of pH 2.3; at room temperature for 5 minutes in separate containers (15 ml/specimen) hermetically sealed.<sup>32</sup> The cola drink was changed every cycle. After thorough rinsing with deionized water and careful drying, the specimens were stored in artificial saliva solution during the 30 minutes resting intervals and

overnight. The artificial saliva solution was changed every 2 days.

### **Hardness assessment**

Enamel demineralization was measured as surface softening. The surface Micro-hardness (SMH) of the specimens was determined using Digital Display Vickers Micro-hardness Tester (Model HVS-50, Laizhou Huayin Testing Instrument Co., Ltd. China) with a Vickers diamond indenter and a 20X objective lens. A load of 200 g was applied to the surface of the specimens for 15 seconds. Five indentations were equally placed over a circle of 1-mm diameter at the middle third of the specimens. The diagonal length of the indentations was measured by built in scaled microscope and Vickers values were converted into micro-hardness values. SMH was obtained using the following equation:  
 $HV=1.854 P/d^2$  where, HV is Vickers hardness in Kgf/mm<sup>2</sup>, P is the load in Kgf and d is the length of the diagonals in mm. The surface Micro-hardness of the specimens was measured once at baseline, and after 14 days of the six daily demineralization-remineralization cycles for both treated and untreated teeth halves. Additionally, the percentage reduction in surface microhardness (% SMHR) was calculated as:

$$\frac{\text{Microhardness (at base line)} - \text{Microhardness (After)}}{\text{Microhardness (at base line)}} \times 100$$

### **Statistical analysis**

Data were presented as means and standard deviation values. Analysis of Variance (ANOVA) was used to compare between means of the three groups. Duncan's post-hoc test was used to determine significant differences between the means when ANOVA test result is significant. Paired t-test was used to compare between mean microhardness values before and after treatment within each group.

The significance level was set at  $P \leq 0.05$ . Statistical analysis was performed with Statistical Package for Scientific Studies (SPSS 16.0, SPSS, Inc., Chicago, IL, USA.) for Windows.

## **3. Results**

### **Primary teeth:**

The mean ( $\pm SD$ ) values of SMH in the different groups at base line and after 14 days of demineralization-remineralization cycles for treated and untreated teeth halves were respectively (263.4 $\pm$  2.6, 213.5 $\pm$ 6.6 and 184.8 $\pm$  19.5), (277.7 $\pm$ 73, 191.3 $\pm$ 23.4 and 176.9 $\pm$ 11.5) and

(285.5 $\pm$ 37.9, 196.9 $\pm$ 28 and 184.9 $\pm$ 32.5) for the gel, varnish and paste groups respectively, table (1). As regards the mean ( $\pm SD$ ) %SMHR of treated and untreated teeth halves, were (18.6  $\pm$ 3.3 and 29.6 $\pm$ 6.7), (29.3  $\pm$ 9.6 and 33.9 $\pm$ 12.2), and (29.8  $\pm$  15.4 and 34.8 $\pm$ 12.2) for the gel, varnish and paste respectively, table (2) and fig. (1).

Statistical analysis showed that all of the three treatments were able to diminish the amount of enamel hardness loss and provide a significant protective effect against erosive enamel loss than the untreated teeth halves with no statistically significant difference between untreated halves. Moreover, APF gel group showed the statistically significantly lowest mean % SMHR (i.e. APF gel showed the highest protective effect against erosive enamel loss) compared to fluoride varnish and CPP-ACPF paste with no statistical significant difference between them.

### **Permanent teeth:**

The mean ( $\pm SD$ ) values of SMH in the different groups at base line and after 14 days of demineralization-remineralization cycles for treated and untreated teeth halves were respectively (268.4 $\pm$ 41.4, 187.4 $\pm$ 18.7 and 170.8 $\pm$ 22.62), (336.5 $\pm$ 25.7, 191.9 $\pm$ 9 and 169.8 $\pm$ 15.9), and (297.5 $\pm$  32.3, 225.9 $\pm$ 1.6 and 185.7 $\pm$ 28.1) for the gel, varnish and paste group respectively, table (1). As regards the mean ( $\pm SD$ ) %SMHR of treated and untreated teeth halves, were (28.7  $\pm$ 16.3 and 35 $\pm$ 16), (42.9 $\pm$ 2 and 49.6 $\pm$ 1.6) and (23.6  $\pm$ 8.8 and 36.7 $\pm$ 16.3) for the gel, varnish and paste respectively, table (2) and fig. (1).

Similar to primary teeth statistical analysis showed that all of the three treatments were able to diminish the amount of enamel hardness loss and provide a significant protective effect against erosive enamel loss than the untreated teeth halves with no statistically significant difference between untreated halves. Moreover, there was no statistically significant difference between APF gel and CPP-ACPF paste groups which showed lower means % SMHR (i.e. highest anti-erosive protective effect) than the fluoride varnish group.

Comparing primary and permanent teeth, in primary teeth only APF gel showed statistically significantly the lowest mean % SMHR compared to the CPP-ACPF paste and varnish groups. However, in the permanent teeth both APF gel and CPP-ACPF paste showed statistically significantly the lowest mean % SMHR compared to the fluoride varnish group.

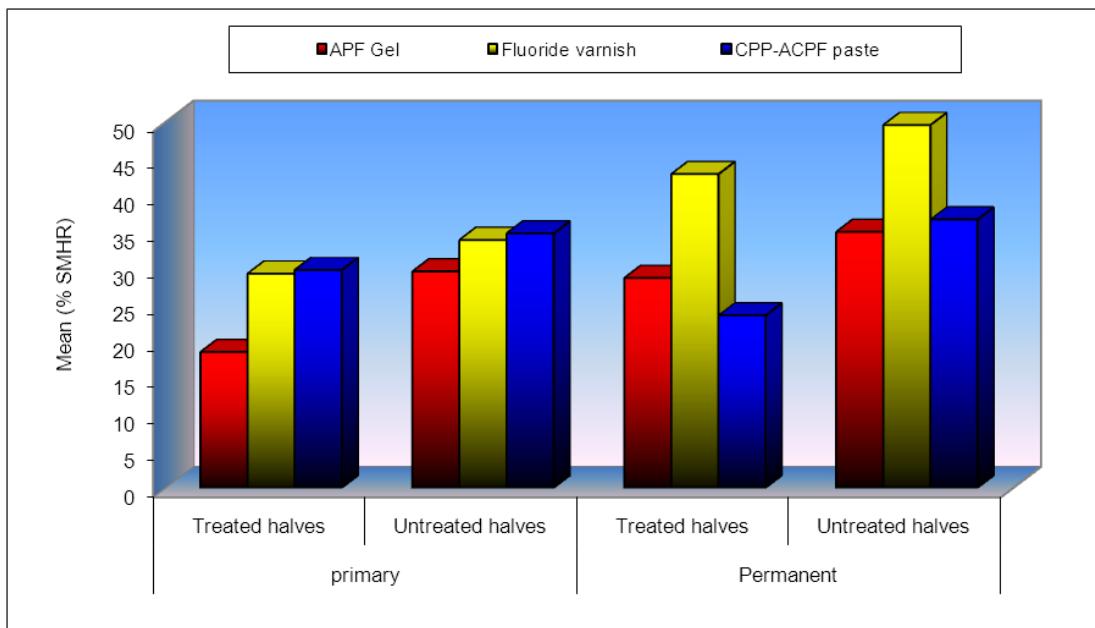

**Table (1):** Means and standard deviation (SD) values of surface microhardness (SMH) in the different groups at base line and after 14 days of demineralization-remineralization cycles for both treated and untreated teeth halves in primary and permanent teeth.

Teeth	Treatment	Group		APF gel		fluoride varnish		CPP-ACPF paste	
		Mean	SD	Mean	SD	Mean	SD	Mean	SD
primary	Before (at base line)	262.4	2.6	277.7	73	285.5	37.9		
	After (Treated half)	213.5	6.6	191.3	23.4	196.9	28		
	After (Untreated half)	184.8	19.5	176.9	11.5	184.9	32.5		
Permanent	Before (at base line)	268.4	41.4	336.5	25.7	297.5	32.3		
	After (Treated half)	187.4	18.7	191.9	9	225.9	1.6		
	After (Untreated half)	170.8	22.6	169.8	15.9	185.7	28.1		

**Table (2):** Means (+SD) values and results of ANOVA test for the comparison between (% SMHR) of the treated and untreated teeth halves in primary and permanent teeth.

Teeth	Teeth halves	Group		APF gel		fluoride varnish		CPP-ACPF paste		P-value
		Mean	SD	Mean	SD	Mean	SD	Mean	SD	
primary	Treated halves	18.6 <sup>b</sup>	3.3	29.3 <sup>a</sup>	9.6	29.8 <sup>a</sup>	15.4			<b>0.034*</b>
	Untreated halves	29.6	6.7	33.9	12.2	34.8	12.2			<b>0.872</b>
Permanent	Treated halves	28.7 <sup>b</sup>	16.3	42.9 <sup>a</sup>	2	23.6 <sup>b</sup>	8.8			<b>0.045*</b>
	Untreated halves	35	16	49.6	1.6	36.7	16.3			<b>0.386</b>

\*: Significant at  $P \leq 0.05$ , Means with different letters are statistically significantly different according to Duncan's test

**Fig. (1):** Means (% SMHR) of both treated and untreated teeth halves in primary and permanent teeth

#### 4. Discussion:

Epidemiological studies have reported that dental erosion is common in adolescents, 37% in the UK and 41% in the US,<sup>33</sup> and that its incidence is increasing with time.<sup>34</sup> Erosion may not only cause direct loss of surface enamel or dentin, but also renders tooth structures more susceptible to caries.<sup>35</sup> The 1993 UK Child Dental Health survey<sup>36</sup> reported that over half of five and six years-old children had eroded surfaces on one or more primary incisors. Among children aged 11 years or older, a quarter or more were found to have some erosion of the palatal surfaces of the upper permanent incisors. Erosion appears to have increased in children particularly from the higher socioeconomic groups.<sup>37, 38</sup>

Recently a new material CPP-ACPF paste was introduced to the market combining both CPP-ACP and fluoride. None of the studies up to our knowledge studied the protective anti-erosive effect of this material on both primary and permanent teeth. Moreover, in this study this effect was compared to two of the most commonly used fluoride products in dental practice nowadays as 2.26% NaF varnish and 1.23% APF gel.

Cola was used in this study to induce artificial erosive effect as in other studies<sup>23, 31</sup> since; it is one of the most commonly consumed acidic beverages. The cola drink was changed every cycle to ensure that it was carbonated and to reduce the buffering effect from ions dissolved from the enamel surface. Cola containers were hermetically sealed because removal of gas from the drink may increase its pH and decrease its potential of dissolving hydroxyapatite

Indentation hardness testing with either Knoop or Vickers indenter has been used for the measurement of initial enamel hardness, enamel softening as an early manifestation of the erosion process, as well as enamel hardening after remineralization. Both indenters are suitable for hardness testing of non-metallic materials.<sup>10, 17, 23, 39, 40, 41</sup> Vickers hardness test was chosen in this study with the 200 g load because it provided the appropriate size of indentations for accurate measurement with the available equipment and the present experimental design. SMH readings were recorded at baseline, and after 14 days of the six daily demineralization–remineralization cycles for both treated and untreated teeth halves to determine minor changes due to erosive enamel loss. Additionally, the % SMHR was then calculated to refer this minor reduction in SMH to the initial readings at base line of the same teeth.

The results of our study showed that all of the three fluoride treatments were able to diminish the amount of enamel hardness loss and provide protective effect against erosive enamel loss in the treated teeth halves than the untreated halves in both primary and permanent teeth. These results are in accordance with those of previous studies that investigated the effect of APF gel<sup>17, 42</sup> and NaF varnish<sup>17, 43, 44</sup> on dental erosion. Moreover similar to our study, these studies showed a reduction of hardness in all treated groups indicating that, although fluoride products can inhibit dental erosion, they do not completely prevent it. Contradictory results ranging from no or limited protection of topical fluoride against dental erosion<sup>38, 45, 46</sup> up to

almost complete protection<sup>47</sup> are found in literature. This may be due to differences in study design, particularly regarding the type of dental substrate, the frequency of application, the pH and concentration of the different fluoridated substances used.<sup>17,48</sup>

In primary teeth our results showed that APF gel provided the highest protective effect against erosive enamel loss compared to fluoride varnish and CPP-ACPF. This can be explained on bases that the acidic pH of APF gel may have etched the enamel surface and helped to increase the incorporation of fluoride into enamel. Another explanation may be that the free negative fluoride ions become more reactive in acidic media, thus enhance the formation of CaF<sub>2</sub>. Several studies agreed with the enhancement of the formation of the CaF<sub>2</sub> layer under acidic conditions when comparing neutral to acidic fluoride solutions<sup>49</sup> and when comparing neutral to acidic fluoride gels.<sup>50-51</sup> limited studies compared the APF gel to the varnish due to difference in application techniques.<sup>10,17</sup> However, our result that the APF gel offer higher protective anti-erosive effect than the fluoride varnish comes in agreement with Lee et al., 2010<sup>10</sup> who found that APF gel showed the better effect in terms of fluoride uptake. Moreover, Murakami et al., 2009<sup>17</sup> stated that although the fluoride varnish used in his study had a greater concentration of fluoride (2.26%F) and was left to act in contact with the teeth for a longer period of time, the APF gel showed similar protective anti-erosive effect. However, in our study the significantly higher anti-erosive effect of the APF gel over the varnish can be attributed to the lower concentration of fluoride in the varnish used in our study (0.1%F).

In the permanent teeth, although all of the three treatments were able to diminish the amount of enamel hardness loss and provide protective effect against erosive enamel loss than the untreated teeth halves similar to primary teeth. Yet, the protective effect offered not only by APF gel but also by the CPP-ACPF paste was significantly higher than that of the fluoride varnish. Thus CPP-ACPF paste showed significantly high erosive protection potential in permanent teeth. This can be attributed to the formation of a stabilized amorphous calcium fluoride phosphate phase. These results come in agreement with several studies that proved that the combined effect of CPP-ACP and fluoride as two separate products was beneficial in enhancing remineralization and anticariogenic effect,<sup>19, 52</sup> as well as improving acid-resisting effect.<sup>52, 53</sup>

Our results can be justified on bases that this recently introduced material combines both fluoride and CPP-ACP in one product thus offering the protective effect of both of them.

The protective effect of fluoride is mainly attributed to the formation of a CaF<sub>2</sub> like layer on the tooth surface, which acts as a fluoride reservoir. During an acidic attack, fluoride released from the CaF<sub>2</sub> deposit can be incorporated into the mineral by forming fluoroapatite or fluorohydroxyapatite resulting in a decreased susceptibility to further dissolution. A similar mode of action is assumed for the anti-erosive capability of fluorides. Additionally, the CaF<sub>2</sub> layer might act as a mechanical barrier hampering the contact of the acid with the underlying enamel or as a mineral reservoir, which is attacked by the erosive challenge, thus leading to a buffering or depletion of hydrogen ions from the acid. The formation of the CaF<sub>2</sub> layer depends on the pH and the concentration of the fluoride agent and the duration of application.<sup>54</sup> As high concentrated fluoride agents or a prolonged application time might lead to a thicker and more stable CaF<sub>2</sub> precipitate, an intensive fluoridation is considered as most effective for prevention of erosive enamel loss.<sup>55, 56</sup>

The protective effect of CPP-ACP lies in the fact that it provides a reservoir of neutral ion pair that inhibits enamel demineralization and promotes remineralization.<sup>18, 57</sup> Calcium and phosphate ions are building blocks for the remineralization process, and are found in saliva. Casein phosphopeptide amorphous calcium phosphate complex (CPP-ACP) has been introduced as a supplemental source of calcium and phosphate ions in the oral environment. The amorphous calcium phosphate is biologically active, and is able to release calcium and phosphate ions to maintain saturation levels of calcium and phosphate at the tooth surface. It is hypothesized that, in addition to the prevention of erosive demineralization, CPP-ACP also remineralizes (repairs) eroded enamel and dentine crystals. This hypothesis is supported by an observation that superficial granular structures, probably representing remineralized enamel crystals were formed on the enamel surface after exposure to a sports drink containing CPP-ACP.<sup>58</sup>

Comparing primary and permanent teeth, in primary teeth only APF gel showed statistically significantly the lowest mean % SMHR compared to the CPP-ACPF paste and varnish groups. However, in the permanent teeth both APF gel and CPP-ACPF paste showed statistically significantly the lowest mean % SMHR compared to the fluoride varnish group. This can be attributed to two factors, first to the structural difference between both primary and permanent enamel. Deciduous teeth demonstrate a higher degree of enamel porosity<sup>59</sup> and a lower degree of mineralization<sup>60</sup> than permanent teeth. This was attributed to greater density of the interprismatic fraction and the prism-junction in deciduous enamel

than its permanent analogue.<sup>61</sup> This difference in porosity might contribute, at least in part, to the observed variation to the response to various protective agents. Other differences between deciduous and permanent tissues may also be of importance. For example deciduous enamel has a higher content of carbon dioxide and carbonate, as well as a lower content of phosphorous and calcium phosphate than the permanent tissue in its composition.<sup>29,62,63</sup> Primary enamel has less organized microcrystals<sup>64</sup> and a greater diffusion coefficient.<sup>28</sup> Furthermore, primary teeth possesses an aprismatic layer on its outer surface, which erodes in a highly irregular manner and is probably not as liable to erosive destruction when compared to prismatic enamel.<sup>24, 65</sup>

A second explanation to the significantly high anti-erosive effect of CPP-ACPF paste on permanent enamel and not on primary one may be the increased reactivity of the permanent teeth. In this study different primary and permanent substrates, at different developmental stages and with different post-eruptive ages were used. Thus, an "older" tooth that has been exposed to the oral environment and in contact with the acids and fluoride for longer periods of time during its life cycle than a newly erupted "young" tooth is expected to be more mineralized and more acid resistant.<sup>66, 67</sup> In the present study, exfoliated human primary molars and young premolars extracted for orthodontic purpose from children aged 12-14 years old were used. The exfoliated primary molar specimens had been exposed to the oral environment for a much longer period of time, adding more acid-resistant fluoridated crystals to its enamel's composition when compared to young permanent premolars. Thus it can be anticipated that it may differ than permanent teeth in its response to different remineralizing agents.

Our results that CPP-ACPF paste showed statistical significant low mean % SMHR as APF gel in the permanent teeth has shown that CPP-ACPF is a very promising remineralizing material. In study by Schupbach et al., 1996<sup>68</sup> it was demonstrated that CPP-ACPF could be incorporated into the pellicle in exchange for albumin and that it inhibits the adherence of *S. mutans* and *S. sobrinus*. Therefore, CPP-ACPF can be expected to be effective intraorally on both permanent and primary teeth in high-risk patients. The fact that this paste can be self-applied as recommended by the manufacturer renders it available in the oral cavity for longer periods, thus saliva will enhance the effectiveness of CPP-ACPF and the flavor will stimulate the saliva flow. The longer CPP-ACPF and saliva are maintained in the mouth, the more effective the expected results. Although our study could not simulate the complex

oral environment, it showed the potential of CPP-ACPF paste for reversing the harmful effect of a cola drink on tooth surfaces especially in permanent teeth. It is speculated that the effect of CPP-ACPF paste will be enhanced under oral conditions in the presence of biofilm which can bind to casein phosphopeptide and act as a reservoir for calcium and phosphate ions, thus enhance remineralization. It also neutralizes the acid challenges from acidogenic bacteria in plaque and from other external and internal acid source.<sup>23</sup>

### 5. Conclusion:

Under the conditions of this study, these conclusions can be derived:

1. All of the tested fluoride treatments positively reduced erosive enamel loss in both primary and permanent teeth.
2. In primary teeth only APF gel showed effective anti-erosive effect.
3. In permanent teeth both CPP-ACPF paste and APF gel showed effective protective effect against dental erosion.
4. Primary and permanent enamel substrates reacted differently to different fluoridated compounds.
5. CPP-ACPF paste is a promising remineralizing material.

### Recommendations:

Future studies are needed to determine which topical fluoride agent exerts the most protective anti-erosive effect intraorally.

[hydro\\_vision@yahoo.com](mailto:hydro_vision@yahoo.com)

**Abstract:** The diatoms of Oloe lagoon for the first time were studied at monthly intervals for two years (February 2002-January 2004). A total of forty-eight species belonging to eighteen genera was found in diatoms, with pennate forms being more diverse and less abundance than the centric forms. *Aulacoseira granulata*, *A. granulata var. angustissima*, *A. granulata var. angustissima f. spiralis*, *A. granulata var. angustissima f. curvata*, *A. granulata var. muzzaensis*, *A. islandica* and *Cyclotella meneghiniana* were the more abundant and frequently occurring centric species throughout the study period. More frequently occurring pennate diatoms include: *Synedra ulna*, *Nitzschia closterium*, *Pinnularia major*, *Navicula oblonga*, *Cymbella minuta*, *Nitzschia palea*, *Surirella elegans* and *Gomphonema parvulum*. Rarely occurring diatoms at this station included *Biddulphia laevis*, *Melosira varians*, *Nitzschia accicularis*, *Pinnularia laevis*, *Cocconeis placentula* and *Eunotia gracilis*. In this study, six new diatoms species were recorded for Lagos lagoon complex. Community structure analysis shows a highly diverse environment.

**Keywords:** diatom; Oloe lagoon; genera; Lagos lagoon complex; diverse environment

### INTRODUCTION

Diatoms are valuable indicators of environmental conditions, since they respond directly and sensitively to many physical, chemical and biological changes that occur in the aquatic environment. Among unicellular microalgae, diatoms probably represent one of the most diverse groups, with a number of species estimated to be between 10000 and 100000 (Battarbee et al, 1999) hence, they constitute an ideal group to study its biodiversity. The diversity, abundance and distribution of phytoplankton within any lagoon have a direct correlation with the water quality and consequently the whole community structure. This is due to the fact that phytoplankton forms the base of any aquatic food chain and organic production in the lagoon and coastal ecosystem (Carson and Pan 1999). According to Van Den et al 1998, the composition of diatom communities reflects an entire complex of ecological parameters at a particular site. Lagoon and coastal ecosystems are the most productive zone of any marine environment due to the high anthropogenic inputs and shallowness of this zone which allows effective light penetration for photosynthesis by phytoplankton. The bulk of local fish production comes from the artisanal sector operating within this zone in Nigeria. Yet, the lagoonal environments are being highly influenced by ecological factors and human actions mainly from refuse and sewage dump,

as well as agricultural wastes coming from river discharges and industrial effluents. The Nigerian coastal zone experiences a tropical climate consisting of rainy season (April to October) and dry season (November to March), it is low lying with heights of not more than 3.0 m above sea level and is generally covered by fresh water swamp, mangrove swamp, lagoonal marshes, tidal channels, beach ridges and sand bars. Lorhurst (1964) reported that the Nigerian coastal surface water is uniformly warm (about 28°C) and of low salinity (<32%). The vegetation is also characterized by Mangrove forests, brackish swamp forests and Rain forests. At present, there is no such checklist for Oloe lagoon diatoms hence this study lists diatoms species of this lagoon and also mentioned the species that is first record to Nigeria coastal waters.

### DESCRIPTION OF STUDY AREA

Oloe lagoon (Fig. 1) is an expanse of shallow freshwater which extends between Lagos and Ogun States. It is presumably the smallest of the lagoons in South Western Nigeria with a surface area of 9.4km<sup>2</sup>, and lies at the distal end of Badagry creek between longitudes 6° 26'N to 6° 30'N and latitudes 3° 01'E to 3° 07'E. The main body of the lagoon lies within Badagry Local Government Area and it opens up to the Atlantic ocean via the Lagos Harbour and Dahomey in the Republic of Benin. The major

source of water are River Owo with a source in a town called Toto Owo where River Ore and Illo form a confluent with River Oponu in Ogun State (Akanni, 1992). Seventeen stations were chosen for sampling within the lagoon. The lagoon is shallow at most points and is open all year round via the Lagos harbour to the sea (Hill and Webb, 1958; Sandison, 1966; Sandison and Hill, 1966). Like all parts of South-western Nigeria, the Ologe lagoon is exposed to two distinct seasons namely the wet (May – October) and the dry (November – April) (Nwankwo, 2004b). Like all parts of South-western Nigeria, the Ologe lagoon is exposed to two distinct seasons namely the wet (May – October) and the dry season (November – April) (Nwankwo, 2004b; Sandison and Hill, 1966). The harmattan, a short season of dry, dusty North-East Trade winds experienced sometimes between November and January in the

region reducing visibility and lowering assemblages is the common macrofloral assemblages especially in areas with reduced anthropogenic influence. The lagoon deposits are varied, and are reflected in the pattern and type of vegetation in the region. Most parts of the Ologe lagoon are colonized by recognizable riparian dense swamp rainforest community dominated by raphia palms especially *Raphia hookeri*, *Elaeis guineensis*, *Acrotiscum aureum* and *Cocos nucifera* (Nwankwo, et al 1999). Very few mangrove communities are recognizable around the Badagry creek end. Notable fauna of the area includes amphipods, Oligochaetes, few polychaetes, isopods, barnacles, oysters, periwinkle, nematodes, fiddler crabs, crabs, among others (Sandison and Hill, 1966; Onyema, et al 2007). The mainstay of communities that live around this environment is artisanal fishing.

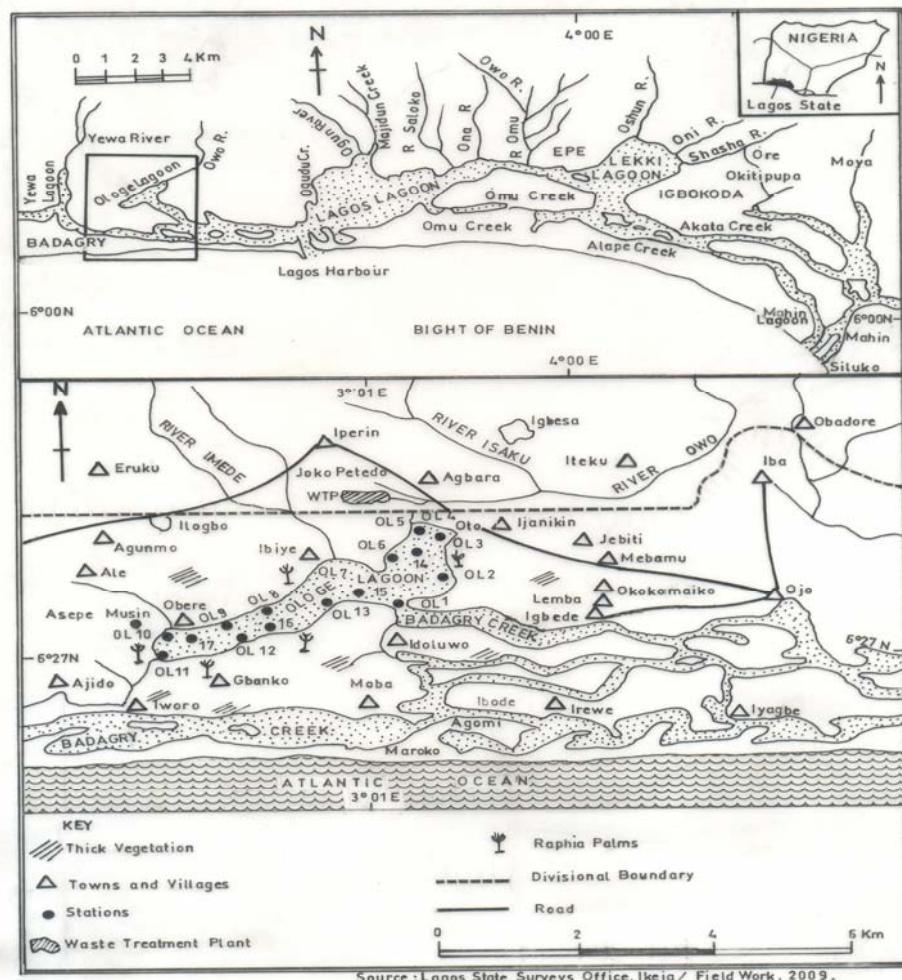

Fig 1: Ologe lagoon showing sampling stations

## MATERIALS AND METHODS

A motorized boat and a Global Positioning System (GPS) were used in seventeen sampling stations during the 24 months sampling period (February 2002-January 2004). These stations were chosen to reflect differences in environmental gradients which exist in the same body of water. All samples were taken using standard plankton net of 55 µm mesh size towed steadily for 10 min at low speed and preserved in 4% unbuffered formalin in appropriately labeled plastic container.

All samples were collected during the hours of daylight to minimize variations due to diurnal migration. To enhance diatom identification sub samples of the original samples were acid-cleaned using nitric acid and investigation was made using Olympus BX51 photomicroscope at the Protistology and Aquatic Ecology Research Laboratory, University of Ghent, Belgium. Taxonomic keys employed in the identification included Hustedt (1930, 1937, 1942, 1971), Patrick and Reimer (1966, 1975), Prescott (1973, 1982), Round (1991), and Van-Den et al (1998).

## RESULTS

As shown in table 1, out of a total of forty-five diatom taxa belonging to eighteen genera were observed in this study, twenty-nine were pennates while sixteen are centric forms. Species indicated in asterisk are first reports for Lagos lagoon complex.

## DISCUSSION

The number of diatoms taxa (45) observed in Ologe lagoon is very low compared to other published study from other lagoons and rivers so far. This checklist is the first that will record such low number of diatoms possibly due to high eutrophication in the lagoon. The pennales recorded higher number of taxa followed by centrals. This is in conformity with the species composition and phytoplankton abundance density found for some diatom species of Lagos lagoon (Nwankwo, 1990), some coastal waters of Nigeria (Kadiri, 1999) and Bonny River during complex research study concerning ecosystem of Niger Delta (RPI Report, 1985). The pennales were more prevalent and could be as a result of rainfall which introduces flooding thereby mixing up the water, boat navigation since artisanal fishing is the mainstay of the people living around the area or may be due to their possession of raphe with which they adhere to suitable substrate. From the checklist it can be stated that Ologe lagoon was dominated by single floristic grouping with *Aulacoseira granulata* and its varieties being more abundant species all through the stations.

**Abstract:** Background/aim: Rheumatoid arthritis (RA) is supposed to be influenced by genetic and environmental factors and so also dermatoglyphics. Therefore, the present study was undertaken to find out a possible correlation of some quantitative and qualitative dermatoglyphic variables with rheumatoid arthritis (RA) and its radiological grading. Materials and methods: This study was conducted on 60 clinically confirmed RA patients and an equal number of controls. Different qualitative dermatoglyphic patterns (ulnar& radial loops, whorls and arches) and quantitative dermatoglyphic measures (total finger ridge count, pattern intensity and a-b ridge count) in addition to palmar creases were studied on rheumatoid arthritis patients and controls. Comparison between patients and controls in both sexes was done and recorded. Also, correlation between significant dermatoglyphic changes in RA patients and radiological changes were studied. Results: Loops were the most common type of the qualitative dermatoglyphic patterns of the fingers, followed by whorls then arches. In both male and female patients, there was significant marked decrease in ulnar loops and significant increase in arches. Total ridge count and pattern intensity of patients were decreased in both hands of both sexes; however, this decrease was significant in the left hand of males and right hand of females. Moreover, the a-b ridge count was significantly decreased in both hands of female and left hand of male patients. Regarding the unusual palmer flexion creases, there was significant increase only in the Sydney line in female right hands. Significant inverse correlation was noted between total ridge count of the fingers and the radiological erosion in both males and females. Conclusion: The findings of the present work demonstrate the association between some dermatoglyphic patterns and RA suggesting that dermatoglyphics can represent an anatomical, non-invasive, inexpensive tool for screening high-risk population, and thus facilitate early detection and management. Also the relationship between total ridge count and the aggressive type of RA indicate that this dermatoglyphic variable might play a significant role not only for screening but also for studying the behavior of the disease.

**Keywords:** dermatoglyphics, fingerprints, rheumatoid arthritis.

## 1. Introduction:

Rheumatoid arthritis is a chronic inflammatory disease that predominantly manifests as persistent synovial inflammation of peripheral joints. Severity and prognosis of RA are influenced by a variety of demographic factors, such as race, gender, age, profession and educational level (Landewe, 2007).

The clinical course of Rheumatoid arthritis (RA) fluctuates and its prognosis is difficult to predict. In many patients the disease was severe resulting in progressive joint erosion, destruction and severe disability which are not capable of recovery (Dubucquoi et al., 2004). Early treatment with the currently available anti-rheumatic drugs may stop or delay such erosions. To avoid the potentially serious side effects, diagnostic tests of high specificity for RA are desirable (De Vries Bouwstra et al., 2005).

The prognostic markers that could identify patients with the aggressive rapidly progressing type of the disease would help in early diagnosis and treatment. They would also protect patients with less aggressive disease from possible over treatment and toxicities (Landewe, 2007).

Dermatoglyphics came from ancient Greek derma (skin) and glyph (Carving). It is the scientific study of the pattern configurations of finger and palm prints. They have a significant genetic component and its development begins during the second month of intrauterine life. They also reflect the non genetic environment of early pregnancy, an important time window for tissue differentiation and organogenesis. Fingerprints and the number of epidermal ridges observed in postnatal life provide a measure of fingertip growth activity during the early fetal period and may be useful in the study of metabolic or

anatomic programming related to the early prenatal environment. Also, the presence of abnormalities in dermatoglyphics constitutes an evidence of a prenatal insult that has occurred in early prenatal life (Zhou et al., 2002 & Kahn et al., 2008).

The finger and palmar print patterns have already been studied with respect to various genetic diseases like Down, Turner and Klinefelter syndromes (Richards and Mandasescu, 1997 & Kobyliansky et al., 1999). In one study, dermatoglyphics were used as markers of early prenatal stress in children with idiopathic intellectual disability (Rosa et al., 2001). Also, several studies have reported its alterations in gastric cancer (Zivanović et al., 2003), bronchial asthma (Gupta and Prakash, 2003), schizophrenia (Chok et al., 2005), open angle glaucoma (Novak-Laus et al., 2005) and breast cancer (Chintamani et al., 2007).

Few studies are available on the association between dermatoglyphics and RA. Both genetic and environmental factors can contribute to the susceptibility and severity of RA disease (Reveille, 1998). Since ridge patterns are formed early in fetal development and remain unchanged throughout life, unusual dermatoglyphics may indicate gene or chromosomal abnormalities consistent with a disease such as RA (Rajangam et al., 2008).

Therefore, the present study was undertaken to find out a possible correlation of some quantitative and qualitative dermatoglyphic variables with rheumatoid arthritis (RA) and its radiological grading.

## 2. Materials and methods

This study was carried out on 60 RA patients diagnosed according to the American College of Rheumatology (ACR) revised criteria for the classification of RA (Arnet et al., 1988). They were 12 males and 48 females and their ages ranged from 23-63 years with a mean of  $41.3 \pm 8.2$ . The duration of the disease ranged from 5 months to 10 years with a mean of  $4.2 \pm 2.3$  years. These patients were recruited from the attending outpatient clinic of the Physical Medicine and Rheumatology of Tanta University Hospital in addition to 60 apparently healthy persons (12 males and 48 females) that had no self or familial history of RA and served as a control group. It may be noted that, for any study on dermatoglyphics, age similarity may not be required because the dermatoglyphics, once formed usually do not change, unless affected by occupational hazards. Consent was taken from all participants and detailed clinical examination was done to exclude patients with congenital diseases, hand burn, deformity or injury.

The following parameters were obtained: different patterns of finger tips (finger prints), total finger ridge count (number of epidermal ridges), pattern intensity (total number of tri-radial of the fingers), types of palmar creases and the a-b ridge count of the palm (number of ridges between the bases of index and middle fingers). The prints of all participants were taken by the ink and paper method. The ends of the fingers were inked and then pressed or rolled one by one on a glossy paper. Also, the palm of clean dried hands were smeared with the ink and pressed against the paper to show palmar creases and the interdigital areas. The prints were then scanned and analyzed. Counting of palmar and finger ridges were done by magnification of the prints by computer or a magnifying hand lens. All parameters were studied on both hands together and separately. Comparison between patients and controls in both males and females was also done.

### Dermatoglyphic Patterns:

Fingerprint patterns in the present study included three main types: whorls, loops, and arches. Under these major types, other subtypes were also noticed in the present study and considered normal anatomical variations (Figs. 1, 2, 3). The whorl is distinguished by its concentric design. The majority of the ridges make circuits around the core (Fig. 1). In arches, the dermal ridges pass from one margin of the digit to the other with a gentle, distally bowed sweep (Fig. 2). In loops, the ridges curve around only one extremity of the pattern forming the head of the loop. Loops can be further divided into ulnar and radial types: ulnar loop when the loop opens to the ulnar margin of the hand and radial loop when the loop opens to the radial margin (Fig. 3).

A triradius is located at the meeting point of three opposing ridge system (Fig 4). This marks the edge of the loop pattern as it possesses only one triradius. In arch pattern, there is no triradius while whorls usually have two triradii.

**Ridge Count of the fingers:** After locating the triradii and the core, as the outer and inner points of the count, a line is set in position to connect them (Fig. 3). Ridge counts for each fingertip were calculated from the number of primary epidermal ridges that intersected or touched the straight line drawn from the central core of the fingerprint pattern to the bifurcation of the triradius. The count on the ten fingers of each individual is then summed up to give a single value, the total ridge count. Consistent with standard methods, fingertips with an arch pattern were assigned a ridge count of zero. Fingertips with a loop pattern have a ridge count equal to the number of ridges crossing the single straight line (Fig. 3). For fingertip patterns with two triradial points e.g.,

whorls, the following ridge-counting protocol was used according to Kahn et al., (2001) ridge count = ridges crossing the longer line + half of ridges crossing the shorter line (Fig. 3).

The a-b ridge count is a measure of the size of the second interdigital area of the palm of the hand, between the bases of the index and middle fingers. It is made by the count of the number of ridges between the triradius a, at the base of the index finger, and the triradius b, at the base of the middle finger (Fig. 4).

**Pattern Intensity:** Pattern intensity refers to the complexity of ridge configurations. It can be expressed by counting the number of triradii present. According to the number of triradii, a digit can have a pattern intensity that ranges from zero to two. Considering the two hands together, the number of triradii in all ten fingers of an individual ranges from zero to twenty. The simple arch, which lacks a triradius, is assigned the number 0, the tented arch and the loop are both assigned 1, as each has one triradius and the whorls typically possess two triradii (Figs.1,2,3).

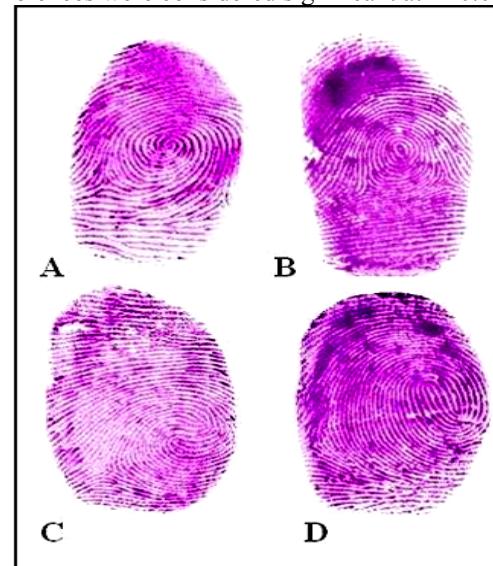

**Flexion creases:** Normally there are three main flexion creases in the palm of the hand, distal transverse, proximal transverse and longitudinal. The abnormal palmer flexion creases considered in the present study were the Simian line, partial Simian line and the Sydney line (Figs. 5,6). In Simian Line, the two distal horizontal creases are fused to form a single horizontal crease. Sometimes there will be traces of the original lines which attempt to fuse as they move across the palm but instead of creating a fully formed Simian, they form what is called partial simian line. Sydney line means the continuation of the proximal transverse crease until the ulnar border of the palm. Interpretation of all parameters was done according to the previous dermatoglyphic studies of Rosa et al., (2001); Zhou et al., (2002); Ravindranath et al., (2003); Corona Rivera et al., (2005) and Karmakara et al., (2008).

**Radiological assessment:** Postero-anterior radiographs of the hands of the patients were obtained and the degree of RA progression was assessed according to Larsen scoring (Larsen, 1995).

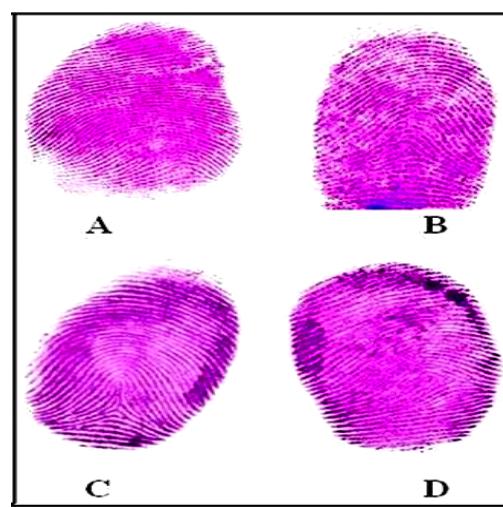

#### Statistical Analysis:

The collected data were organized, tabulated and statistically analyzed using SPSS software statistical computer package, version 12. The differences of qualitative data of finger tips (whorls, loops and arches) and that of the quantitative data (total finger ridge count, pattern intensity and a-b ridge count) as well as palmar creases were recorded. As regards to the qualitative data, the number and percentage of distribution were calculated. For quantitative data, the range, mean and standard

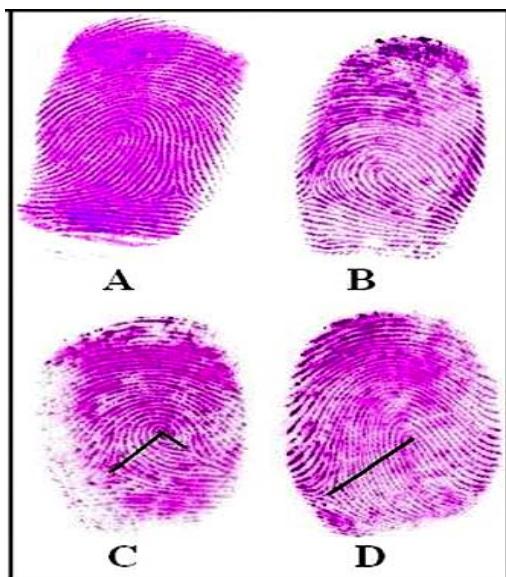

deviation (SD) were measured. In addition, the correlation between radiographic erosion and the significant dermatoglyphic variables detected in this study was evaluated by Pearson's correlation coefficient. The difference between two means was statistically analyzed using the student t-test and the differences were considered significant at  $P<0.05$ .

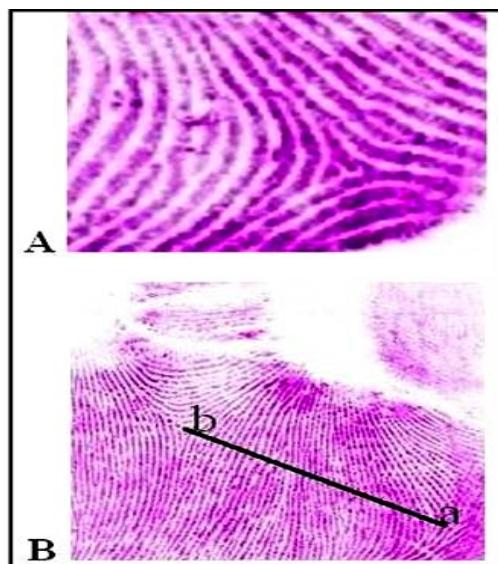

**Fig. (1):** A photograph showing the different types of whorls observed in the present study.

### 3. Results

In the present study, loops were the most common type of finger ridge patterns, accounting for 48.5% of finger prints of normal individuals, followed by whorls (40.83%), and lastly the arches (10.67%).

The distribution of finger ridge patterns in patients and controls are shown in tables (1, 2). It was found that ulnar loops were significantly decreased in both hands of male and female patients. In males, the P value was 0.021 in right hand and 0.004 in left hand, while in females P value was 0.011 in right hand and 0.001 in left hand. The radial loops showed non significant increase in male left hand ( $P= 0.863$ ) and non significant decrease in female right and left hands ( $P= 0.0352, 0.896$ ) respectively. Arches were significantly increased in both right and left hands of males ( $P=0.009, 0.007$ ) respectively and of females ( $P= 0.003, 0.028$ ) respectively. As regards to whorls, non significant decrease was noticed in male right and left hands ( $P= 0.078, 0.089$ ) respectively, while in females there was non significant decrease in right hand ( $P= 0.0236$ ) and non significant increase in the left hand ( $P= 0.058$ ). (Tables 1, 2).

The total ridge count of fingers is presented in table 3. The mean ridge count of the RA patients was decreased in both hands of males and females when compared to the controls. This decrease was statistically significant in the left hand of males ( $P= 0.002$ ) and right hand of females ( $P= 0.001$ ).

The main pattern intensity (number of triradii in finger tips) included in the present study is shown in table 4. It was decreased in RA patients in both males and females. It was statistically significant in left hand of males ( $P= 0.019$ ) and in right hand of females ( $P= 0.012$ ).

The a-b ridge count (number of ridges between the triradii a&b at the bases of index and middle fingers) is considered in table 5. The mean a-b ridge count of RA patients was decreased in both hands of males and females in comparison to the control. This decrease was statistically significant in left hand of males ( $P= 0.002$ ) and both hands of females ( $P= 0.001, 0.001$ ).

The distribution of unusual palmar flexion creases in the RA patients and controls is shown in tables 6,7. The most frequent unusual creases were

Sydney line, Simian and partial Simian creases. The only significant increase was in the Sydney line in female right hands ( $P=0.050$ ).

Comparison between patients with radiological erosion detected by x-ray and the significant dermatoglyphic variables observed in this study was done. Considering both hands together, significant inverse correlation was noted between total ridge count of the fingers and radiological erosion in both males and females ( $P=0.023, 0.039$ ) respectively (Tables 8, 9 and figures 7,8).

#### 4. DISCUSSION

Different qualitative dermatoglyphic patterns were studied in this work. It was noticed that loops were the most common type observed in normal individuals followed by whorls, and lastly arches. Similarly, *Igbigbi and Msamati (2002)* demonstrated that ulnar loops were the most predominant digital pattern type in both sexes followed by whorls in males and arches in females. Their study documented similarities in digital ridge patterns between some African countries indicating their close historical and anthropological relationship. However, significant differences were demonstrated between them and Europeans. These results emphasize that digital patterns are specific in differentiating ethnic and population groups.

In the present work, ulnar loops were significantly decreased in both hands of both sexes of RA patients compared with controls, however, radial loops showed non significant changes. Going in line with these results, *Taneja et al., (1993)* reported a significant decrease in ulnar loops in the right hand of females and both hands of male patients with RA.

Radial loops showed also significant decrease in both hands of male patients. In another study conducted on finger print patterns on individual fingers of RA patients, loops were especially decreased in the 3rd finger of males and in the 1st and 4th fingers of females (*Ravindranath et al., 2003*).

In the present work, arches were significantly increased in both hands of male and female patients. This finding was partially coincided with *Taneja et al., (1993)* who reported an increase in arches on both hands of females and left hand only of males. Also, *Ravindranath et al., (2003)* noted that with both hands together, arches were significantly increased in male patients but female patients showed significant increase only in some individual fingers (3<sup>rd</sup> and 4<sup>th</sup> fingers). *Todd et al., (2006)* mentioned that the embryologic timing of the ridge pattern formation was associated with the type of dermatoglyphic pattern development. Early ridge formation was associated with whorls, late formation with arches, and intermediate formation with loops. They suggested that clinical syndromes which arrested embryologic development and decreased developmental maturation tend to have more arches and fewer whorls.

Regarding whorls, non significant change was noticed in the present work, not only in females but also in male patients. In a previous study,

frequency of whorls was reported to be increased on the right hand of male, and both hands of female RA patients (*Taneja et al.*, 1993). This was in contrast to the study conducted by *Ravindranath et al.*, (2003) on RA who found significant decrease in whorls in both hands of males and non significant change in females.

The main pattern intensity (number of triradii in all fingers) was also considered for correlation in the present study. It was decreased in RA patients than controls in both sexes. However, it was significant in left hand of males and right hand of females. Reviewing the available literature, the relation between pattern intensity and RA disease was not reported. The decreased number of triradii (pattern intensity) observed in this study can be explained by the decreased whorls (each whorl has two triradius) and significant increase in arches (the arch has no triradius) noticed in RA patients.

Although *Taneja et al.*, (1993) did not observe any difference between RA patients and controls regarding the total finger ridge count, the results of *Rajangam et al.*, (2008) showed a significant increase of the total ridge count only in the right hand of male patients. In the present study total finger ridge count was decreased in patients as compared to controls and this decrease was statistically significant in left hand of males and right hand of females.

The mean a-b ridge count of the palm of RA patients was also decreased in both hands of males and females when compared to the controls. This finding don't coincides neither with *Taneja et al.*, (1993) who did not observe any significant difference between patients of rheumatoid arthritis and controls for the a-b ridge count, nor with *Rajangam et al.*, (2008) who noted a significant increase in the a-b ridge count in both male and female patients.

It was suggested that the a-b ridge count is more environmentally determined and less heritable than other dermatoglyphic traits such as finger tips patterns. The a-b ridge count is sensitive to environmental stress because the area of the palm in which a-b ridge count is situated, the second interdigital region, begins to develop earlier than the fingers and its progression is more slowly. Thus the ridges in this region may develop over a longer period of time, exposing the area to potential environmental insult. On the other hand, total ridge count appears to be under relatively strong genetic control and little influenced by environmental factors (*Fearon et al.*, 2001). In the present work, the significant decrease in both a-b ridge count and total finger ridge count in RA patients confirm that RA disease is influenced by both genetic and environmental factors.

The distribution of unusual palmer flexion creases in patients and controls was also studied in this work. Sydney line, Simian and partial Simian creases were the most frequent creases observed, however, significant increase was noticed only in Sydney line of female patients right hand. In the study conducted by *Ravindranath et al.*, (2003), partial Simian crease was the only significantly increased unusual pattern in male patients, while Sydney line was absent in both males and females.

In the field of anthropology, researchers found that there are divergences of different degrees between races, nationalities, and even populations. Diagnosis on individuals of different nationalities cannot use the same standards (*Hui et al.*, 2003). Significant correlation between dermatoglyphics and geographic distances was also noticed by *Natekar et al.*, (2006). This may explain the presence of variations between different results in this field. Dermatoglyphics by themself are not enough to diagnose RA disease but the results of this work suggest that dermatoglyphics can at least serve to strengthen the diagnostic impression about RA disease especially in unidentified patients or those with early signs of joint inflammation.

Dermatoglyphic deviations observed in the present work were tested for correlation with radiologic diagnosis. The mean total finger ridge count showed significant inverse correlation with radiographic erosion. This finding indicates that this specific dermatoglyphic variable may help to predict the aggressive type of RA disease. Moreover, the significant correlation between radiographic erosion and total ridge count observed in this work together with the suggestion of *Fearon et al.*, (2001) that total ridge count appears to be under relatively strong genetic control and little influenced by environmental factors lead us to the suggestion that erosive changes in RA was more likely to be due to genetic causes. So, it is possible to estimate the individual predisposition to this aggressive type of the disease and thus to guide therapy decisions early to attenuate cumulative inflammation as soon as symptoms appear.

## 5. Conclusion:

The findings of the present work demonstrate the association between some dermatoglyphic patterns and RA disease suggesting that dermatoglyphics can represent an anatomical, non-invasive, inexpensive tool for screening high-risk population, and thus facilitate early detection and management. Also the relationship between total ridge count and the aggressive type of RA indicate that this dermatoglyphic variable might play a significant role not only for screening but also for

studying the behavior of the disease. Further studies are recommended to support our findings regarding the importance of dermatoglyphics as an anatomical marker in rheumatoid arthritis.

# High Efficiency Production of Mosquitocidal Toxin by a novel *Bacillus sphaericus* isolate from Egyptian Soils on Local Agroindustrial Byproducts

**M.S.Foda,<sup>1\*</sup> Fawkia M. El-Beih,<sup>2</sup> Maysa E. Moharam,<sup>1</sup> Nora N.A.El-Gamal<sup>1</sup>**

<sup>1\*</sup> Microbial Chemistry Department, National Research Center, Dokki, Giza, Egypt.

<sup>2</sup> Faculty of Science, Ain Shams University, Cairo, Egypt.

<sup>\*</sup>[foda302002@yahoo.com](mailto:foda302002@yahoo.com)

**Abstract:** Eighty six cultures were isolated from soil of different Egyptian Governorates including Quina, El-Menofeya, El-Gharbia, El-Sharkia, El-Behera and Kafr EL-Sheikh Governorates. Investigations on the mosquitocidal Egyptian isolates have revealed that isolate No.1 have the ability to form more toxin than the international reference strain *Bacillus sphaericus* 2362(Bs 2362).The selected isolate No.1 exhibited a lower LC<sub>50</sub> and LC<sub>90</sub>values than the International strain B.s 2362 upon bioassay against second instars' larvae of *Culex pipiens*. The Egyptian isolate No.1was identified morphologically and biochemically as *Bacillus sphaericus*. Physiological factors affecting growth and toxin formation in *B. sphaericus* No 1 in comparison to B.s 2362 were carried out. THE organism grown on modified Nutrient broth medium yielded the highest larval toxicity against the second instars' of *Culex pipiens* for both *Bacillus sphaericus* isolate No 1 and the international strain *Bacillus sphaericus*. The Optimum air : medium ratio were 9:1 and 4:1 of the flask volume for 4 and 3 days incubation periods using 2%and 3% sizes of inocula for *B. sphaericus* 2362 and the Egyptian isolate *B. sphaericus*No.1, respectively. Sodium acetate was the suitable carbon source for the isolate *B. sphaericus* No.1, while *B.s* 2362 was capable to utilize both sodium acetate and sodium succinate as carbon sources.The Egyptian isolate *B. sphaericus* No.1exhibited the highest mosquitocidal activity upon growth on kidney beans seeds and sesame meal as nutrient substrates at 3% final concentration, while *B.s* 2362 exhibited the highest mosquitocidal activity by utilizing soy beans, lentils and sesame meal as complete media for growth and mosquitocidal toxin production.

**Key words:** *Bacillus sphaericus*, isolation, characterization, mosquitocidal toxin, physiology, agroindustrial byproducts.

## 1. Introduction:

The mosquito acts as a vector for many of the world's most serious diseases, both parasitic e.g. malaria (*Anopheles*), lymphatic filariasis (*Anopheles*, *Aedes*, *Culex* and *Mansonia*) and viral e.g. yellow fever, dengue (both *Aedes*) and encephalitis (*Culex*). (Baumann *et al.*, 1991).

*Bacillus sphaericus* has been successfully used for the biological control of numerous of disease -transmitting mosquitoes and black fly species (Lacey and Undeen, 1986). The prime advantage of the *B. sphaericus* strain lies in their ability to persist for longer periods in the environment than *Bacillus thuringiensis* var. *israelensis*. This may be due to recycling and amplification of spores in larval cadavers under certain aquatic situations or may be simply due to the long-term persistence of sufficient and accessible toxin in the environment or a combination of both of

the above (Singer, 1990; Correa & Yousten, 1995). Major advantage of these bacterial insecticides are their safety, biodegradability, and low environmental impact (Maramorosch, 1987)

Opota *et al.* (2008) reported that the binary toxin (Bin) from *Bacillus sphaericus* exhibits a high insecticidal activity against *Culex* and *Anopheles* mosquitoes. The cytotoxicity of Bin requires an interaction with a specific receptor present on the membrane of midgut epithelial cells in larvae, a direct correlation exists between binding affinity and toxicity. The toxin binds with high affinity to its receptor in its primary target namely, *Culex pipiens* (Baumann, *et al* 1991).

The present work paper aims for isolation of new *Bacillus sphaericus* strain with mosquitocidal activity that exceeds the existing international strains e.g. *B. sphaericus*2362. In the hope to reduce Production costs of mosquitocidal toxin used for

biological control of disease-transmitting mosquitoes in the developing countries production physiology of the bacterial toxin was studied on synthetic and agroindustrial byproducts.

## 2. Materials and methods

### Microorganisms

The International strain *Bacillus sphaericus* 2362 was kindly obtained from prof. F.G. Priest, school of life sciences, Heriot watt university, UK

A new *Bacillus sphaericus* isolate namely No.1 was isolated from soils of Quina Governorate, Egypt.

### Media

Synthetic media used for cultivation of the pure organisms and their activation prior to physiological studies.

- Nutrient Broth medium: (g/l) peptone 5, beef extract 3, for solidification 25 g agar were added.
- Luria- Burtani(LB) medium: (g/l) peptone 10, yeast extract 5, sodium chloride 10.
- NYSM broth medium: nutrient broth, yeast extract 0.5 g/l

Trace elements, (g/100ml): Manganese chloride 0.09, Calcium chloride 1.03, Magnesium chloride 2.03.

1 ml of the filter sterilized trace elements solution was added to 100 ml of the medium.

2. Media used for growth, sporulation and mosquitocidal toxin production in shake cultures.

#### a- Media based on Agroindustrial by-products:

These media included offal's meal, feather meal and cotton seed meal (Ministry of Agriculture). Most of these agroindustrial by-products are currently used in animals feed and available in Egyptian market.

#### b-Media based on cheap, locally available plant proteins:

Certain legume seeds that are locally available in Egypt were examined as protein sources for growth, sporogenesis and mosquitocidal toxin production. These legumes seeds such as soy beans, kidney bean, black eyed bean, yellow split pea, and lentils were finely grinded and used in conjunction with the standard mineral salt solution ( $\text{KH}_2\text{PO}_4$ , 0.5g/L,  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ , 0.25g/L,  $\text{CaCl}_2$ , 0.1g/L,  $\text{FeSO}_4 \cdot 5\text{H}_2\text{O}$ , 0.01 g/L) at appropriate concentration.

### Bioassay of bacterial toxins against Mosquitoes larvae.

Bioassay of locally isolated *Bacillus* cultures including *B. thuringiensis* and *B. sphaericus* were carried out as described by Priest and Yousten (1991). Toxicity was determined with laboratory

reared *Culex pipiens*. Serial dilutions in distilled water were tested in a preliminary toxicity screen. The range of concentration of full grown whole culture (FWC) which killed 50% and 90% of the larvae were identified. Then further toxicity tests were done in the range recorded to evaluate precisely the  $\text{LC}_{50}$  and  $\text{LC}_{90}$  values for each highly promising bacterial culture.

The corrected mortality was then plotted against culture dilution of cells/ml on log paper to determine  $\text{LC}_{50}$  and  $\text{LC}_{90}$  values for each highly promising bacterial cultures.

The bacterial dilutions were placed in small cups in duplicates along with 10 second instar larvae. Appropriate controls were run simultaneously using distilled water instead of cultures. The cups kept at room temperature at  $27 \pm 2^\circ\text{C}$ . The mortality percentage was recorded by counting the number of live larvae and corrected by using appropriate control and applying Abbott's formula (Abbott, 1925). The medium lethal concentrations  $\text{LC}_{50}$  of potent isolates was computed through probit analysis within 95% confidence limits using propan program.

Abbott's formula:

$$\text{Corrected mortality \%} = \frac{\text{Observed mortality \%} - \text{Control mortality \%}}{100 - \text{Control mortality \%}} \times 100$$

## 3. Results

### 1. Isolation, Identification and Mosquitocidal Toxin Production by *Bacilli* isolated from the Egyptian environments

Eighty six isolates were obtained from soils and mud samples of six different Egyptian Governorates including Quina, El-Menofeya, El-Gharbia, El-Sharkia, El-Behera and Kafr EL-Sheikh. Among these isolates, isolate No.1 obtained from Quina Governorate was the only isolate giving 100% mortality up to culture dilution  $10^{-5}$ . Accordingly this isolate obtained from Quina Governorate was selected for further investigation.

### 2. Determination of $\text{LC}_{50}$ and $\text{LC}_{90}$ values of the Egyptian isolate No.1 obtained from Quina Governorate soils.

$\text{LC}_{50}$  and  $\text{LC}_{90}$  of isolate No.1 and *B. sphaericus* 2362 bioassayed against second instar larvae of *Culex pipiens* revealed that the Egyptian isolate No.1 is more toxic than the reference strain 2362. (Table 1).

### 3. Identification of the Egyptian isolate No.1 isolated from Quina Governorate.

The colonies exhibited beige color with medium size colonies, the texture is smooth semi-

glistening with round margin; the appearance of colonies is shiny with little elevation and flat.

Examination of the cells with the electron microscope revealed the rod-shaped of the vegetative cells as shown in Fig (1); sporulated cells (sporangia) with subterminal spores that are round in shape giving the sporangia club shaped appearance as shown in Fig (2). Also it was observed that isolate No.1 produced a spherical spore and round crystals when examined under the electron microscope as shown in Fig (3).

Some biochemical tests were carried out for the identification of the Egyptian isolate No.1 obtained from Quina Governorate (Table 2).

#### 4. Comparative Physiological studies on factors affecting growth, sporulation, and toxin production of the Egyptian isolate *B. Sphaericus* No.1 and the International *B. sphaericus* 2362 strain under submerged fermentation conditions

##### 4.1. Effect of types of media on growth parameters, sporulation titer and mosquitocidal toxicity under submerged conditions.

Four types of media were used in this study namely Nutrient yeast salt medium, Luria –Bertani medium, Nutrient broth (NB), and modified Nutrient broth (NB+ 0.5% yeast extract) The obtained results showed that modified Nutrient broth medium yielded the highest larval toxicity against the second instars' larvae of *Culex pipiens* for both *B.s* isolate No1 and the international strain *B.s* 2362, (Tables 3, 4)

##### 4.2 Effect of aeration level on growth and toxicity of *B. sphaericus*

In this experiment the extent of aeration was altered by varying the air : medium ratio (amount of medium in the culture flask). The effect of aeration extent on growth parameters and toxicity of the mosquitocidal agent produced by the organisms under study are shown in Figure (4). It was noted that the viable count and toxicity increased with increasing the air: medium ratio. Furthermore, The sporulation and toxin production gave the highest titers when the medium volume occupied 10% and 20%, i.e. corresponding to air: medium ratio 9:1 and 4:1 of the flask volume for *B. sphaericus* 2362 and the Egyptian isolate *B. sphaericus* No.1, respectively.

##### 4.3. Effect of different carbon sources utilized by *B.sphaericus* on growth parameters and mosquitocidal toxin formation.

It is known that *B. sphaericus* can not utilize carbohydrates for growth due to the lack of many of the enzymes of Embden Meyerhof and hexose monophosphate path ways (Russel *et al.*, 1989). In this experiment different carbon sources were used

for testing the ability of the tested organisms *B. sphaericus* No.1 and *B. sphaericus* 2362 to utilize this carbon sources. The results revealed that sod. acetate was utilized by the isolate *B. sphaericus* No.1, at which the sporulation and toxin production yielded the highest titers. On the other hand, *B. sphaericus* 2362 was capable to utilize sod. acetate and sod. succinate, as shown in Figure (5).

##### 4.5. Effect of inoculum size on growth parameters and mosquitocidal toxin formation of *B. sphaericus*.

Different volumes of overnight growing culture were used as inocula for a set of 250 ml conical flasks each containing 25ml of modified nutrient liquid medium . The results of growth parameters and toxin production of tested organisms are illustrated by Figure (6).

The increase of inoculum size has led to the increase of sporulation titer and toxin production up to 3% inoculum size, and then decreased with the increasing of inoculums size in case of the Egyptian *B. sphaericus* No.1. However the sporulation and toxin production of *B. sphaericus* 2362 showed a little effect by changing the inoculum size. The highest toxicity were achieved using 3% inoculums size and 2% by isolate *B. sphaericus* No.1 and *B. sphaericus* 2362, respectively.

##### 4.6. Effect of incubation period on growth parameters and mosquitocidal toxin formation of *B. sphaericus*.

This experiment was carried out under standard conditions by using a set of 250 ml conical flasks containing 25ml of modified nutrient liquid medium, then the extent of growth, sporulation titer and toxin production were followed and determined by harvesting after 2, 3, 4 and 7 days of incubation at  $28 \pm 2^{\circ}\text{C}$  on a rotary shaker.

The results are shown in Figure (7). The mortality increased with increasing the incubation period until 3 days incubation period in case of *B. sphaericus* No.1 and 4 days for *B. sphaericus* 2362

##### 4.7. Effect of different by-products and grinded legumes seeds used as complete media on growth, sporulation and toxin production of *Bacillus sphaericus*.

Ten agro industrial byproducts that are available in Egypt were examined as a complete cost effective media for toxin production. The data in Figure(8) illustrated that the Egyptian isolate *B. sphaericus* No.1 exhibited the highest mosquitocidal activity by utilizing kidney beans and sesame meal as nutrient substrate at 3% final concentration, while *B. sphaericus*2362 exhibited the highest mosquitocidal activity by utilizing soy beans, lentils and sesame meal as growth media for growth and mosquitocidal toxin production.

**Table(1): Values of LC<sub>50</sub> and LC<sub>90</sub> for mosquitocidal toxins of the Egyptian isolate No.1 in comparison with those of the International strain of *Bacillus sphaericus* 2362 at confidence limits(95%). The bioassay was carried out against second instar larvae of *Culex pipiens*.**

#### 4. Discussion:

The mosquito acts as a vector for many of the world's most serious diseases, both parasitic e.g. malaria (*Anopheles*), lymphatic filariasis (*Anopheles*, *Aedes*, *Culex* and *Mansonia*) and viral e.g. yellow fever, dengue (*Aedes*) and encephalitis (*Culex*). The present work aims to isolate some local isolates of *B. sphaericus* pathogenic to mosquito larvae from the Egyptian environment. It was also devoted to investigate the growth physiology and various factors that are affecting growth, sporulation and toxins formation. On the other hand, special attention was given to search for suitable media that are low-priced and locally available in Egypt for *B. sphaericus* production on a large scale. The goal stemmed from the fact that the feasibility of economic production of spores and toxin crystals of *B. sphaericus* is dependant to a large extent on production costs and availability of raw materials under the local conditions. Physiological factors affecting growth and toxin formation in *B. sphaericus* revealed that modified Nutrient broth medium yielded the highest larval toxicity against the second instars' of *Culex pipiens* for both *Bacillus sphaericus* isolate No 1 and the international strain *Bacillus sphaericus* 2362. The requirements of individual bacterial strain for nutrients may vary for different strains and also of different isolates within the same strain within the same species. Thus optimal concentration of nutrients for one isolate may not necessarily be suitable for another. Therefore, it is impossible to recommend a fermentation medium that will be best for all isolates of the same species (Foda *et al.* 2000).

It is established that *B. sphaericus* is an obligate aerobe and adequate air supply is needed for

growth, initiation of sporulation and toxin synthesis (Yousen and Wallis, 1987). In our studies, it was found that the maximum sporulation and toxicity were achieved when the medium volume to air ratio was 1:4 for the Egyptian isolate *B. sphaericus* No.1 and 1:9 for the International strain *B. sphaericus* 2362 that was used for comparative purposes. The increase in medium volume to air ratio has lead to the decrease in sporulation and toxicity. This result agrees with what reported by Yousen and Wallis (1987). They found that oxygen was required for toxin production by *B. sphaericus* strain 2362. However, they reported that increasing the level of dissolved oxygen (DO) in the medium by use of pure oxygen in the gas stream lowered toxin production, while in case of strain 1593, (another *B. sphaericus* International strain), increased (DO) produced a block in sporulation, but toxin synthesis was normal (Yousen *et al.*, 1984).

The result of growth parameters of tested organisms indicated that *B. sphaericus* isolate No.1 gave high sporulation titer and toxicity at inoculum size 3% and a decrease in toxicity was recorded by increasing the inoculum size. However the highest sporulation and toxin production levels of strain 2362 were achieved by inoculum size 2%. This result agrees with that reported by Foda *et al.* (2000), they reported that the sporulation of the Egyptian isolate No. 69 increased by decrease in the inoculum size to reach  $7.5 \times 10^6$ /ml viable count whereas the sporulation of strain *B. sphaericus* 2362 exhibited a little effect by changing the inoculum size.

*B. sphaericus* can not use carbohydrates for growth due to the lack of many of the enzymes of Embden Meyerhof and hexose monophosphate pathways (Russel *et al.*, 1989).

In the present study, it has been found that the Egyptian isolate *B. sphaericus* No.1 grew well using acetate as sole carbon source. On the other hand the International strain *B. sphaericus* 2362 grew with acetate or succinate as sole carbon source. This result agrees with what reported by (Gordon *et al.*, 1973; De BarJac *et al.*, 1980; Klein *et al.*, 1989; Widjaya *et al.*, 1992 and Ahmed *et al.*, 1993 and 1996). They reported that numerous strains of *B. sphaericus* grew with acetate, Pyruvate, lactose, glutamate, succinate, histidine and arginine, as sole major carbon and energy sources.

In the present study, ten leguminous seeds and agroindustrial by-products were used as nutrient substances at 3% concentration and the result indicated that soy beans, kidney beans and sesame seed meal could be used efficiently as nutrients sources to support growth, sporulation and toxin production of the Egyptian isolate *B. sphaericus* No.1. High levels of toxicity were obtained even at low concentration of diluted culture ( $3 \times 10^6$ ), as inocula. On the other hand, *B. sphaericus* 2362 grew well on a medium contained soy beans, lentils and sesame seed meal and the growth, sporulation and high levels of toxin production were achieved at the same culture dilution. Uses of such various by-products as well as legume seeds have shown that local production from inexpensive ingredients available in different regions is possible. Such studies may pave the way for mass production on industrial scales. Dulmage *et al.* (1970) cultured *B. sphaericus* 1593 and 2362 separately in a fermentor on peptonized milk medium with yeast extract and mineral supplements. The fermentor beer was centrifuged and then resuspended in lactose solution and precipitated with acetone. These powders were highly insecticidal to *Culex quinquefasciatus* larvae producing LC<sub>50</sub> values in the range of  $10^2 \mu\text{g}/\text{ml}$ . Obeta and Okafor (1983) formulated five media from dried cow blood, mineral salts and seeds from four species of legumes (ground nut cake, cowpea, mambara beans and soy beans) for production of *B. sphaericus* 1593. Good growth, sporulation and toxin activity of *B. sphaericus* 1593 were obtained with all tested media. Dharmsthiti *et al.* (1985) grew *B. sphaericus* on a medium containing 7% hydrolyzed liquor by-product from a monosodium glutamate factory. Klein *et al.* (1989) used hydrolyzed industrial peptones (waste product of industry) for constructing seven media for production of *B. sphaericus* larvicides. These media contained 5 g/l industrial peptone in 50 mM phosphate buffer (pH 7.0) in combination with other carbon and nitrogen sources. Industrial peptone medium supplemented with glycerol was the most efficient medium for growth and larvicides production by *B. sphaericus* 2362. The local availability of proteinaceous materials is vitally important for *B. sphaericus* fermentation. For example, one of the most useful nitrogen sources is cotton seed flour (Dulmage *et al.* 1990). They reported that several nitrogen sources are used in *Bt* fermentation, including soybean flour, cotton seed flour and fish meal. The soy

flour and cotton seed flour were both very good sources of nutrients for both *Bt* and *B. sphaericus* production. Gangurde and Shethna (1995) concluded that mustard seed meal (MSM) contains 40% protein, with glutamic acid and arginine as a major amino acids. Therefore, growth and larvicidal activity of *B. sphaericus* 2362 and 1593 produced in MSM can be attributed in part to the presence of these amino acids. Ampofo (1995) used some local raw-materials for production of *Bs* insecticides in Ghana. He tested anchovy, spent grain form breweries, bambara beans and sprout maize as media for production of *B. sphaericus* IAB 881. He reported that larvicidal activity of *Bs* IAB 881 grown in anchovy, spent grain, bambara beans and sprout maize, was similar to that obtained in synthetic medium with LC<sub>50</sub> ranging from  $0.3 \times 10^{-5}$  to  $0.68 \times 10^{-6}$  (dilution). Cell counts were in the range of  $11 \times 10^8$  –  $36 \times 10^8$  CFU/ml and spore counts were between  $29 \times 10^7$  and  $61 \times 10^7$  CFU/ml. El-Bendary (1999) used ground agroindustrial by-products and leguminous seeds at 2% final concentration as media for production of *B. sphaericus* in distilled water with or without addition of NYSM salts. The obtained results indicated that most of the tested substances supported formation of highly efficient media for *Bs* toxin production of appreciably high sporulation yield and toxicity. She also reported that the most efficient media for *B. sphaericus* toxin production were soy flour, cotton seed flour, corn steep solids and offals meal. Furthermore, it was observed that addition of NYSM salts to these substances increased the *B. sphaericus* toxicity. Moreover, the toxicity of *B. sphaericus* increased about 1.5-4.5 times when these agroindustrial by-products were partially hydrolyzed by nuclease or alkalase enzymes before using as media. El-Bendary *et al.* (2008), used whey permeate (WP) for production of mosquitocidal toxin by *B. sphaericus* 2362 and the Egyptian isolate, *B. sphaericus* 14N1 under both submerged and solid state fermentation conditions. Under submerged fermentation, high mosquitocidal activity was produced by *B. sphaericus* 2362 and *B. sphaericus* 14N1 at 50% -100% and 25% -70% whey permeate, respectively.

[<sup>\\*</sup>hemmdan@yahoo.com](mailto:hemmdan@yahoo.com)

**Abstract:** Accurate, precise and reproducible isocratic RP-HPLC method was developed and subsequent validated for the analysis of Torasemide (I), Irbesartan (II) and Olmesartan medoxomil (III) at ambient temperature, using Atlantis 4.6 mm x 250 mm RP-C18 Column, with a flow rate of 1.5 ml.min<sup>-1</sup>, and UV. detector at 288 nm and 260 nm for (I) and (II and III), respectively. By adopting the mentioned chromatographic technique, (I) and (III) were determined in the presence of their acidic and alkaline-degradates separately as stability-indicating methods utilizing phosphate buffer pH = 3:acetonitrile (60:40, v/v), phosphate buffer pH = 3.2:acetonitrile (60:40, v/v) as a mobile phase, respectively, while (II) was determined in presence of Hydrochlorothiazide (HCTZ), using phosphate buffer pH = 4:acetonitrile (70 :30, v/v). All the proposed methods were validated according to the International Conference on Harmonization (ICH) guidelines and successfully applied to determine the mentioned studied drugs in pure form, in laboratory prepared mixtures and in pharmaceutical preparations. The obtained results were statistically compared to the reference methods of analysis [for I and "II and III", respectively] and no significant differences were found. [M. Farouk, O. Abd ELAziz, A. Hemdan, M. Shehata. Novel Validated Chromatographic Method for Determination of Some Anti-hypertensive Drugs. Journal of American Science 2010;6(11):476-486]. (ISSN: 1545-1003).

**Keywords:** Torasemide, Irbesartan, Olmesartan medoxomil, High Performance Liquid Chromatography, Stability Indicating method

## 1. Introduction:

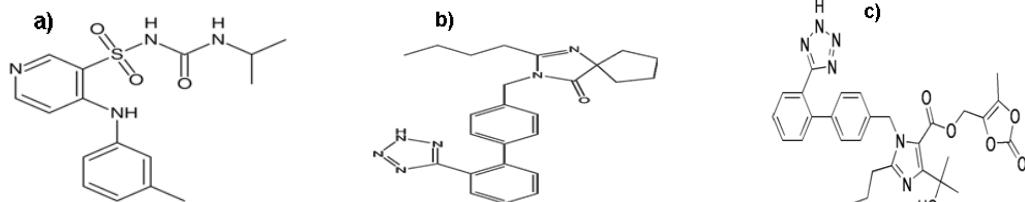

Figure (1): Chemical structure of: a) Torasemide, b) Irbesartan, c) Olmesartan medoxomil

Torasemide (I) is (1-isopropyl-3-[[4-(3-methylphenylamino) pyridine]-3-sulfonyl] urea) a loop diuretic, mainly used at low doses for the management of hypertension, where in large doses used for management of oedema associated with congestive heart failure<sup>(1)</sup>. Irbesartan (II) is 2-butyl-3-[[2-(tetrazol-5-yl)biphenyl-4-yl]-methyl]-1,3-diazaspiro[4.4]non-1-en-4-one, acts as an angiotensin-II receptor antagonist, used mainly for the treatment of hypertension<sup>(2)</sup>, while, Olmesartan medoxomil (III) is 5-methyl-2-oxo-1,3-dioxolen-4yl methyl-4-(1-hydroxy-1-methylethyl)-2-propyl-1-[4-(2-tetrazole-5-yl)phenyl] methylimidazole 5 carboxylate, used for the treatment of hypertension by the same mechanism as (II)<sup>(3)</sup>. The ICH-guidelines<sup>(4)</sup> recommends performing stress-testing of the drug substance that can help in identifying the

likely degradation-products, also can be useful in establishing the degradation-pathways and validating the stability-indicating power of the analytical procedures used<sup>(5)</sup>. Stability-indicating methods can be used for evaluating the drug in the presence of its-degradation products, excipients and additives<sup>(6)</sup>. Several methods have been reported for the determination of (I), including colorimetry<sup>(7)</sup>, differential-pulse adsorptive stripping voltammetry<sup>(8)</sup>, capillary zone electrophoresis (CZE)<sup>(9,10)</sup>, gas chromatography<sup>(11)</sup>, micellar liquid chromatography<sup>(12)</sup>, and high-performance liquid chromatography<sup>(13-22)</sup>. Alone or in combination with HCTZ, Irbesartan has been determined by derivative spectrophotometry<sup>(23-27)</sup>, kinetic Spectrophotometry<sup>(28)</sup>, spectrofluorimetry<sup>(29)</sup>, colorimetry<sup>(30)</sup>, adsorptive stripping voltammetric<sup>(31)</sup>,

A differential pulse (DP) and square wave (SW) voltammetry<sup>(32)</sup>, capillary zone electrophoresis<sup>(33-35)</sup>, micellar electrokinetic chromatography<sup>(36)</sup>, and high-performance liquid chromatography<sup>(37-43)</sup>. While for Olmesartan medoxomil (III), several methods have been reported for its determination, either alone or in combination with HCTZ, these methods were based on absorption ratio spectrophotometry<sup>(44)</sup>, ratio spectra derivative and zero-crossing difference spectrophotometry<sup>(45,46)</sup>, derivative spectrophotometry<sup>(47)</sup>, direct spectrophotometry<sup>(48,49)</sup>, capillary zone electrophoresis<sup>(50)</sup>, high performance thin layer chromatographic method<sup>(51,52)</sup>, and high-performance liquid chromatography<sup>(52-59)</sup>.

The main goal of this work is to establish accurate, precise, rapid and reproducible isocratic chromatographic methods for determination '(I), and (III) in presence of their-degradates and simultaneous determination of (II) in binary mixture with HCTZ that can be adopted as a technique for the routine quality control analysis of these drugs in raw material and pharmaceutical preparations as well as for stability studies.

## 2. Experimental:

### 2.1. Chemicals and reagents

Torasemide was kindly provided by Apex Pharma-Egypt and certified to contain 99.70%. Examide® tablets: batch number: MT1120410, manufactured by Apex Pharma-Egypt Company. Each tablet was labeled to contain 20 mg of Torasemide. Irbesartan was kindly obtained by Sanofi-Aventis Egypt and certified to contain 99.90%. Co-Approval® tablets: batch number: 1145, manufactured by Sanofi-Aventis Egypt. Each tablet was labeled to contain 300 mg of Irbesartan and 12.5 mg Hydrochlorothiazide. Hydrochlorothiazide (HCTZ) was kindly provided by Multi-Pharma Egypt and certified to contain 99.50%. Olmesartan medoxomil was kindly provided by Apex Pharma-Egypt and certified to contain 99.70%. Erastapex® tablets: batch number: MT3241009, manufactured by Apex Pharma-Egypt Company. Each tablet was labeled to contain 40 mg of Olmesartan medoxomil.

Acetonitrile, ethyl acetate, methanol and bi-distilled water (Riedel-dehaen, Sigma-Aldrich, Germany), hydrochloric acid, sodium hydroxide and sulfuric acid (BDH), each 'aqueous 0.1, '0.1 and 6.6' and 5M. 'Monobasic potassium phosphate and O-phosphoric acid (Adwic)' and triethylamine (Fluka).

All chemical and reagents used through this work are of chromatographic analytical grade. Bi-distilled water is used throughout the whole work and is indicated by the word "water".

### 2.2. Instruments

The HPLC Schimadzu LC-Lab Solution instrument comprised an isocratic pump model Schimadzu LC-20AD, connected to PC and software (LC-Solution), SIL 20A auto-sampler - Schimadzu injector and a Schimadzu SPD20A UV detector. The chromatographic separation was performed using Atlantis C18 column (5μm, 250 x 4.6 mm i.d.) at ambient temperature.

Ultrasonic vibrator, Crest Ultrasonic-Tru / Sweep; Model 575TAE, N. Y, U.S.A.

A (Jenway 3510, UK) pH-meter, equipped with combined glass electrode for pH adjustment.

### 2.3. Standard Solutions

#### 2.3.1. Standard solutions of the investigated drugs

Stock standard solutions of (I, II and III), each having concentration of (0.5 mg.ml<sup>-1</sup>), were prepared in methanol, respectively, where all the prepared solutions were used as a working standard solutions.

#### 2.3.2. Standard solution of Hydrochlorothiazide

Stock standard solution of HCTZ having concentration of (0.5 mg.ml<sup>-1</sup>), was prepared in methanol, where it was used as a working standard solution.

#### 2.3.3. Standard solution of degradates

##### 2.3.3.1. Standard solution of Torasemide degradates

Standard stock solution of acid-degrade, was prepared, by mixing 50.0 mg of (I) with 20 ml of 5.0 M sulfuric acid, refluxing for 12 hours, cooling, then neutralizing the media with 6.6 M NaOH, and making the volumes to 100 ml with methanol to obtain a concentration of 500 μg.ml<sup>-1</sup>.

##### 2.3.3.2. Standard solution of Olmesartan degradates

Standard stock solution of alkaline-degrade, was prepared, by mixing 50.0 mg of (III) with 10 ml of 0.1M NaOH, refluxing for 20 minutes, cooling, then neutralizing the media with 0.1M HCl and making the volumes to 100 ml with methanol to obtain a concentration of 500 μg.ml<sup>-1</sup>.

Complete degradation was checked by TLC using silica gel 60 F254 plates and chloroform: ethyl acetate: methanol [8 : 8 : 4 ] as a mobile phase.

### 2.4. Procedures:

Stationary phase, Atlantis C18 column (5μm, 250 x 4.6 mm i.d.), acetonitrile: phosphate buffer 'pH 3' in a ratio (40:60, v/v), acetonitrile: phosphate buffer 'pH 4' in a ratio (30:70, v/v) and acetonitrile: phosphate buffer 'pH 3.2' in a ratio (40:60, v/v) as 'degassed and filtered' mobile phases with a flow rate of 1.5 ml.min<sup>-1</sup> were the chromatographic conditions

adopted for determination of Torasemide, and 'Irbesartan and Olmesartan medoxomil' using UV detection at 288 and 260 nm, respectively. Construction the calibration curves were performed by transferring aliquots of each working standard solution separately into a series of 25 ml volumetric flasks and diluting with the mobile phase to the volume, having a concentration range of 0.2 – 25, 0.1-20, 0.5-30  $\mu\text{g mL}^{-1}$  for the investigated drugs, respectively. Under the previously mentioned chromatographic conditions, 100 $\mu\text{l}$ -volume from each solution was injected in triplicate, using HCTZ and Torasemide as an internal standards in a concentration of 50 and 4  $\mu\text{g mL}^{-1}$  for determination of I and (II and III), respectively. The obtained average peak area for each concentration of each drug was plotted versus concentration and the regression equation was then computed.

#### 2.5. Assay of the pharmaceutical formulations:

Five tablets of Examide®, Co-Approval® and Erastapex® were accurately weighed and finely powdered separately. Portion of each powder equivalent to 10 mg (I, II and III) were accurately weighed, transferred to 100 ml volumetric flask, shaked for 15-minutes with 50 ml methanol, filtered completed to the volume with methanol, to obtain a concentration of 100  $\mu\text{g mL}^{-1}$  and then the mentioned procedure under 2.4. was adopted.

### 3. Results and Discussion:

#### 3.1. Method development:

##### Torasemide and Olmesartan

Separation of I and III from their degradation-products has been performed on Atlantis C18 column (5 $\mu\text{m}$ , 250 x 4.6 mm i.d.). The proportion of the mobile phase components was optimized to reduce each of 'retention time and tailing' and to enable good resolution from its-degradates. At high acetonitrile ratio, retention time of different components decrease but with excessive tailing of its peak. High resolution was obtained by using acetonitrile: phosphate buffer 'pH 3' in a ratio (40:60, v/v) and acetonitrile: phosphate buffer 'pH 3.2' in a ratio (40:60, v/v) as a mobile phase, with a flow rate 1.5  $\text{ml min}^{-1}$ , and detection at 288 and 260 nm, respectively, where the maximum sensitivity was observed. The average retention time was 3.56 ± 0.03 and 3.85 ± 0.03 min, respectively, as shown in (Figures 2, 3, 6 and 7).

##### Irbesartan

Separation of ibesartan from HCTZ in binary-mixture has been performed on Atlantis C18 column (5 $\mu\text{m}$ , 250 x 4.6 mm i.d.). The proportion of the mobile phase components was optimized to

reduce each of 'retention time and tailing' and to enable good resolution of II from HCTZ. At high acetonitrile ratio, retention time of different components decrease but with excessive tailing of its peak. High resolution was obtained by using acetonitrile: phosphate buffer 'pH 4' in a ratio (30:70, v/v) as a mobile phase, with a flow rate 1.5  $\text{ml min}^{-1}$  and detection at 260 nm, where the maximum sensitivity was observed. The average retention time was 9.89 ± 0.03 min as shown in (Figures 4-5).

#### 3.2. Methods validation.

ICH-guidelines<sup>4)</sup> for method validation were followed. All validation parameters are shown in (Table 1).

##### 3.2.1. Linearity:

A linear correlation was obtained between peak area and concentration of (I, II and III) in a range of 0.2 – 25, 0.1-20, 0.5-30  $\mu\text{g mL}^{-1}$  with correlation coefficient [r] = 0.9998, 0.9999 and 0.9999, respectively.

##### 3.2.2. Accuracy:

Accuracy of the proposed methods was tested by analyzing freshly prepared solutions of the studied drugs in triplicate. The recovery percent and standard deviations (S.D.) revealed excellent accuracy. The results obtained by applying the proposed chromatographic methods were statistically compared with those results obtained by the reference methods<sup>(60-62)</sup>. It was concluded that with 95% confidence, there is no significant difference between them since the calculated t and F values are less than the theoretical values<sup>(63)</sup> (Tables 2a-2c).

##### 3.2.3. Repeatability and reproducibility:

The intra- and inter-day precision was evaluated by assaying freshly prepared solutions in triplicate, as shown in (Table 1).

##### 3.2.4. Specificity:

The specificity of the adopted HPLC method was illustrated by the complete separation of the studied drugs, as shown in (Figures 2-7). The Rs-values from main (acid alkaline-degradates) and from HCTZ were always above 2, which ensured complete separation. Furthermore, I and III were determined in solutions of laboratory prepared mixtures containing their acid and alkaline-degradates and III from HCTZ by the proposed method. The Recovery % and R.S.D. % proved the high specificity of these methods (Table 3).

### 3.2.5. Robustness and system suitability of the HPLC method:

The robustness of an analytical procedure is a measure of its capacity to remain unaffected after slight but deliberate changes in the analytical conditions. Separation of the studied drugs from their different-degradates or from other drug in-combination was performed under these conditions. There was slight decrease or increase in the Rs-values of all peaks. However, the calculated Rs-values were always above 2, ensuring complete separation. The system suitability parameters of HPLC method were evaluated<sup>(64)</sup> (Tables 4a-4c).

### 3.3. Standard addition technique:

The proposed methods were applied for the determination of the studied drugs in the commercial tablets. The results shown in (Tables 5a-5c), were satisfactory and with good agreement with the labeled amount. Moreover, to check the validity of the adopted proposed methods, the standard addition method was applied by adding known amounts of the studied drugs to the previously analyzed tablets. The recoveries were calculated by comparing the concentration obtained from the spiked samples with that of the pure drug. The results of the commercial tablets analysis and the standard addition method (recovery study) (Tables 5a-5c) suggested that there is no interference from any excipients, which are normally present in tablets.

### 3.4. Identification of Torasemide acid-degrade and Olmesartan medoxomil alkaline-degrade:

#### 3.4.1. Identification of Torasemide acid-degrade

Structure elucidation of Torasemide acid-degrade exhibiting terminal amide bond cleavage, resulting in formation of hydroxyl and carbonyl groups, which was explained by utilizing FT-IR

"Fourier transform spectroscopy" and M.S., techniques. In the FT-IR technique, the acid-degrade showed a similar absorption pattern to (I) except the appearance of the acid-degrade bands at 3463.4 and 1735.7 cm<sup>-1</sup>, respectively, while in M.S., two peaks were delivered at m/z 59 and 307, respectively, (figures 8a-8c).

#### 3.4.2. Identification of Olmesartan alkaline-degrade

By the same manner, the structure elucidation of Olmesartan alkaline-degrade exhibiting ester bond cleavage, resulting in formation of hydroxyl and carbonyl groups, which was explained by utilizing FT-IR "Fourier transform spectroscopy" and M.S., techniques. In the FT-IR technique, the alkaline-degrade showed a similar absorption pattern to (III) except the disappearance of the ester carbonyl band at 1737.2 cm<sup>-1</sup> and the appearance of the corresponding Hydroxyl and carbonyl bands of the carboxylic group of the degradation product at 3423.5 and 1712.7 cm<sup>-1</sup>, respectively, on the other hand, mass spectrum of the alkaline degradation product exhibited two new peaks at m/z 130 and 446, respectively, (figures 9a-9c).

## 4- Conclusion:

The proposed HPLC methods were precise, specific, accurate and reproducible , where Torasemide, Irbesartan and Olmesartan can be determined in bulk powder and in pharmaceutical formulations without interference from excipients present, as well as in the presence of their different-degradates or other drug in-combination by the d. ICH-guidelines were followed throughout method validation and the suggested methods can be applied for routine quality control analysis and stability studies.

<sup>1</sup> Department of Microbiology Faculty of Veterinary Medicine

<sup>2</sup> Department of Microbiology & Immunology National Research Center, Cairo Egypt

**Abstract:** The present investigation studied the diversity of 19 *S. aureus* isolates (9 from bovine and 10 from human sources) in comparison with the standard Cowan I strain by conventional methods and by PCR technology. The latter uses primers targeted to species-specific parts of genes encoding coagulase (*coa*), enterotoxin A (*sea*) and B (*seb*), *mec A* gene encoding methicillin resistant *S. aureus* (MRSA) and *Staphylococcus* protein A (*spa*) gene. *S. aureus* isolates (19) as well as the Cowan 1 strain were tested for antimicrobial sensitivity with 15 antibiotics by disk diffusion method and classified as susceptible, intermediate and resistant. 57.9% of isolates had a relatively high molecular weight plasmid. The *mec A* gene among the chosen MRSA *S. aureus* isolates recovered from human and bovine sources was discussed. Polymorphisms of *coa* and *spa* genes were detected among *S. aureus* isolates. The examined isolates had coagulase gene ranging from 423 bp to 658 bp and the Cowan -1 strain had amplified fragment at 642 bp. All examined *S. aureus* isolates gave an amplified *spa* gene product at approximately from 396-464 bp. The prevalence of enterotoxin genes *sea* and *seb* were determined and the diversity among the chosen isolates was recorded.

[J.El-Jakee, Ata S. Nagwa, Gad El-Said, W.A., Bakry,M.A., Samy, A.A., Khairy E.A., Elgabry, E.A. Diversity of *Staphylococcus aureus* Isolated from Human and Bovine Estimated by PCR - Gene Analysis. Journal of American Science 2010;6(11):487-498]. (ISSN: 1545-1003).

**Keywords:** *S. aureus*, antibiogram sensitivity, MRSA, Enterotoxins, coagulase gene, *spa* gene.

### 1. Introduction

*Staphylococcus aureus* is recognized as causing health care associated and community-acquired infections in every region of the world. Enterotoxigenic *S. aureus* in milk posses a potential health hazard to consumers, the identification of such strains should be used as apart of a risk analysis of milk and milk products (Zouharova and Rysanek, 2008). *S. aureus* is among the most important nosocomial pathogens because of both the diversity and the severity of the infections it causes, including superficial, deep skin and soft-tissue infections, endocarditis, and bacteremia, as well as a variety of toxin-mediated diseases such as gastroenteritis, staphylococcal scalded-skin syndrome, and toxic shock syndrome (Waldvogel, 1995 and Lowy, 1998).

Staphylococcal enterotoxins (SEs) are serologically grouped into five major classical types which are SEA, SEB, SEC, SED and SEE in addition to toxic shock syndrome toxin (TSST-1) which causes toxic shock syndrome in human, SEA and SEB are usually more common in milk and milk products (Chiang *et al.*, 2006). The resistance to antimicrobial agents among staphylococci is an increasing problem; these strains often reveal resistance to various drug classes in addition to beta-lactam resistance (Dizbay *et al.*, 2008).

Results obtained from analysis of enterotoxigenic *S. aureus* biochemically and

genotypically by using PCR for encoding genes revealed a strong correlation between each other (Lawrynowicz-Paciorek *et al.*, 2007). A reliable and rapid identification of *S. aureus* colonies from samples is a cornerstone in the control of *S. aureus* infection. Identification of bacterial pathogens still relies mainly on phenotypic criteria. Based on the above it is important to study *S. aureus* using modern differentiating diagnostic techniques like PCR and gene analysis. The goal of the present investigation is to study phenotypic and genotypic characterizes of *S. aureus* recovered from human and bovine sources.

### 2. Materials and Methods

#### Samples:

A total of 830 samples were collected from cattle, buffaloes and human for isolation of *Staphylococcus* species. They were collected from milk samples and septic wounds from bovine's dairy farms in Giza, Fayoum and Animal Health Research Institute (AHRI) Dokki. Giza. Egypt. Urine, septic wounds and nasal swabs from cases with respiratory symptoms were obtained from workers in the farms, out patient clinics of Cairo University Hospitals (CUH) and human laboratories (Cairolab, Elborg and Alfa Lab.) were also collected in nine months period from April 2007 to January 2008 as shown in Table (1).

**Table (1): Types and numbers of the samples collected.**

Source of the isolates	Type of samples	No. of The examined samples
Bovine	- Milk from mastitic cows	200
	- Milk from mastitic Buffaloes	150
	- Swabs from cow septic wounds	50
Human	- Urine from infected urinary tract	150
	- Swabs from septic wounds	150
	- Nasal swabs from cases with respiratory symptoms	130
Total		830

**Identification of staphylococci:**

The collected samples were cultured onto nutrient agar "Difco", sheep blood agar and Bacto-Mannitol salt agar "Difco". The inoculated plates were incubated for 24-48 hours at 37°C. The suspected colonies were picked up and propagated in nutrient agar slope for further examinations. Staphylococci were identified according to Quinn *et al.* (2002).

**Characterization of *S.aureus* isolates (Cruickshank *et al.*, 1975):**

The *S. aureus* isolates were identified by using the following tests: Catalase, coagulase, maltose fermentation, urease activity, mannitol fermentation, pigment production onto nutrient agar "Difco", hemolytic activity on sheep and human blood agar, DNase activity on DNase medium "Oxoid", lysozyme activity, gelatinase activity, growth on Baird-Parker Medium "Biomerieux" containing 1% potassium tullerite, lipase activity on egg yolk agar medium, protease activity of *S. aureus* on milk agar medium, fibrinolysin activity on plasma agar medium, Vogues Proskauer test for detection of acetone production, detection of SpA by agglutination using SpA agglutination kits (Wellcome Diagnostics). As well as Crystal violet agar growth type according to Rodgers *et al.* (1999). Crystal violet agar plates were prepared by adding 6 or 8 ug/ml of crystal violet to tryptose agar (Oxoid). Few colonies of the isolates were spot inoculated on plates of both concentrations, incubated at 37°C, and examined after 24 hours. The 6 ug/ml plate was examined if growth was inhibited on the 8 ug/ml plate. Growth of a cream to yellow color with or without violet margins was recorded as growth type A. Growth mainly of blue or violet color

was recorded as growth type C and white color was recorded as growth type E.

**Susceptibility of *S. aureus* isolates to antibacterial agents:**

15 antibacterial disks "Oxoid" were used and the disk diffusion technique was adapted according to Finegold and Martin (1982). After incubation, the degree of sensitivity was determined according to NCCLS (2002) Cheesbrough (2006) and Bannerman and Peacock (2007).

**Detection of plasmid.**

Plasmid DNA extraction was performed in Biotechnology Centre for Services and Research (BCSR) in Faculty of Veterinary Medicine, Cairo University. Extraction of miniprep performed according to Sambrook and Russel (2001). The extracted plasmid was evaluated as visible bands being sized by DNA molecular marker (Hind III digest), that measures molecular weight 81-23000 bp ( Gibbco).

**PCR procedure (Sambrook and Russel, 2001)**

Polymerase chain reaction was performed in Biotechnology Centre for Services and Research (BCSR) in Faculty of Veterinary Medicine, Cairo University. Qiagen extraction kit for DNA extraction from *S. aureus* isolates staphylococcal species was used as described by manufacturer manual of Qiagen, Germany. Primers were synthesized by Metabion Company, Germany as mentioned in Table (2). The presence of specific amplified DNA bands was detected by visualization with UV light at wave length 421 nm and compared with molecular size marker (Ladder) with MW 100 bp and measures MW 100-1500 bp obtained from Amersco Cleveland Ohio, USA. Cowan I strain of *S.aureus* obtained from the Namru 3 in Egypt was used as positive control.

### 3. Results and Discussion

Analyses of the genotype distributions of *S. aureus* strains of diverse origin demonstrated a certain host specificity. It seems that the occurrence of some staphylococcal lineages is restricted to animals (Sung *et al.*, 2008 and Smyth *et al.*, 2009). Livestock-associated *S. aureus* seems to be an underappreciated source of pathogenic strains (Bystron *et al.*, 2010). Several methicillin resistant *S. aureus* (MRSA) clones have disseminated worldwide (Deurenberg *et al.*, 2007). Although bacterial interaction is a well recognized phenomenon, there has been surprisingly little research with respect to MRSA and MSSA. The mechanism/s responsible for this phenomenon is not readily apparent (Al-Kulaifi *et al.*, 2009).

In this study a total of 830 samples were investigated bacteriologically to detect the occurrence of staphylococci among bovine and humans samples. The isolation rate among human samples was 33% while it was 28.3% in bovine samples. 209 *S. aureus*, 21 *S. intermedius* and 25 *S. hyicus* isolates secured from bovine and humans' origins were identified using the most important conventional biochemical tests as catalase, coagulase and acetone production as shown in Table (3).

A number of different phenotypic and genotypic techniques are available to classified strains for epidemiological investigation in the detection and tracking of outbreaks (Wildemauwe *et al.*, 2010). In veterinary microbiology, many phenotypic methods include (pigment production, hemolytic activities, DNase, etc have been applied for characterization of *S. aureus* strains. As shown in

Table (4) it is clear that all isolates were positive for coagulase test, mannitol fermentation, acetone production and show a characteristic growth on Baird parker and crystal violet media which considered being selective media for *S. aureus*. In this concern, Brown and Ngeno (2007) recorded that all positive isolates gave positive reactions in mannitol salt fermentation, in catalase and tube coagulase and latex agglutination tests also, sixteen isolates demonstrated beta hemolysis on horse blood agar while four were not beta hemolytic.

In the present investigation characterization of 19 *S. aureus* isolates (9 from bovine and 10 from human sources) in comparison with the standard Cowan I strain was performed by conventional methods and by PCR technology. Worldwide, the prevalence of multi-resistant *S. aureus* strains has been increased problematically. Increased attention has been focused on plasmid-encoded resistance to antiseptics and disinfectants in antibiotic resistant staphylococci (Bjorland *et al.*, 2003). 57.9% of isolates had a high molecular weight plasmid (more than 18000kbp) as well as Cowan 1 strain as shown in photo (1). Lindsay (2010) recorded that plasmids in *S. aureus* are predominantly of two types, small rolling circle plasmids often encode only one or two resistance genes, such as pT181 (Khan, 2005). The larger plasmids replicate by the theta mechanism and can carry a combination of resistance genes including penicillinase, heavy metals, detergents, trimethoprim and aminoglycosides, some of which are due to integrated small plasmids or transposons (Berg *et al.*,

1998). Some larger plasmids also encode the *tra* genes for conjugative transfer and many strains of *S. aureus* carry one or more plasmids (Lindsay, 2010).

Methicillin (oxacillin) -resistant *S. aureus* (MRSA) was first described in 1961 (Jevons, 1961) and since then has become a significant pathogen in nosocomial infections (Hartman and Tomasz, 1986). For clinicians, the spread of these methicillin-resistant strains has been critical as the therapeutic outcome of infections that result from MRSA is worse than those from methicillin-sensitive strains (MSSA) (Cosgrove *et al.*, 2003). This study aimed to assess the antimicrobial susceptibility patterns and prevalence of methicillin resistance among the chosen *S. aureus* isolated (19 isolates) from human and bovine sources, as well as the Cowan 1 strain as shown in Tables (5-7). High resistance was recorded to methicillin (60%) among the examined *S. aureus* isolates, followed by oxytetracycline (55%) ampicillin & sulphamethoxazole-timethoprim (45% each). Then amoxicillin (40%), ofloxacin (30%), clindamycin & erythromycin (25% each) and amoxicillin clavulanic acid, cefoperazone & cefotaxime (15% each) as shown in Table (5). Meanwhile 95% of the examined *S. aureus* isolates were sensitive to vancomycin, 85% to cefotaxime and 80% to amoxicillin clavulanic acid and cefoperazone. The human isolates were often multidrug resistant, unlike the animal isolates (Lindsay, 2010). 7 out of 10 isolates from human origin were MRSA (70%) and 5 out of 9 *S. aureus* isolates (55.6%) of bovine origin were MRSA, in addition to the Cowan 1 strain as shown in Tables (6 &7).

Interestingly, VRSA are less fit than MRSA in the presence of low concentrations of vancomycin which may be prevalent in hospitals (Foucault *et al.*, 2009). However, in the absence of vancomycin they are fit, yet, no spread of VRSA in hospitals has been reported (Lindsay, 2010). Only one isolate showed an intermediate resistance to vancomycin as shown as in Table (5). Outbreaks of VISA are not reported, and their endemic potential is probably low. Of more concern are fully VRSA strains, first reported in the USA in 2002 (Zhu *et al.*, 2008).

Methicillin-resistant staphylococci carry the *mecA* gene, which encodes a specific low-affinity penicillin-binding protein 2a (PBP<sub>2a</sub>), this protein is responsible for the methicillin resistance in staphylococci (Hackbart and Chambers, 1989). As shown in Photo (2) all methicillin-resistant *S. aureus* isolates were *mecA* gene positive by PCR among the examined isolates and the standard strain. Polymerase chain reaction and DNA hybridization detection of the *mecA* gene in staphylococci is unaffected by the level of its expression (Mo and Wang, 1997).

Comparable PCR-based systems for identification of *S. aureus* isolates under investigation have been used. The coagulase gene (*coa*) typing (Reinoso *et al.*, 2008) have been used to identify and compare *S. aureus* genotypes. As shown in Photo (3), all isolates examined had coagulase gene. Two different PCR products were detected, one in size ranging from approximately 423 bp to 484 bp and another at 608 to 658bp. The standard Cowan I strain had an amplified PCR fragment at 642bp (Photo, 3). Length and sequence polymorphisms of the coagulase gene and its use for genotypic characterization of *S. aureus* had been already shown (Stephan *et al.*, 2000 and Su *et al.*, 2000). Studies carried out by other researchers (Kalorey *et al.*, 2007; Reinoso *et al.*, 2008) showed different coagulase gene types. The reason for this polymorphism among *S. aureus* isolates is unclear, but it seems to be because of deletion or insertion mutations by which a portion of the 3' end region of the *coa* gene is deleted or several nucleotides are inserted and as a consequence change the *coa* gene size and probably antigenic properties of the coagulase enzyme (Saei *et al.*, 2009). Mobile genetic elements (MGE) are discrete pieces of DNA that encode factors allowing them to mobilise within or between genomes (Lindsay, 2008). In *S. aureus*, the major MGE are bacteriophage, pathogenicity islands (SaPI), plasmids, transposons and staphylococcal cassette chromosomes (SCC). Most MGE show evidence of frequent horizontal transfer and recombination (Lindsay, 2010). The evolution of new human and animal pathogenic strains of *S. aureus* has been due to the accumulation of mobile genetic elements (MGE) encoding methicillin resistance and virulence factors into successful lineages (Lindsay, 2010).

*S. aureus* is able to produce a number of virulence factors such as protein A or leukocidins (Kerro Dego *et al.*, 2002). Protein A is located in the cell wall and captures antibodies (Foster and McDevitt, 1994). Photo (4) showed agarose gel electrophoresis of *spa* gene amplification products. It is clear that all examined *S. aureus* isolates gave an amplified *spa* gene product at approximately from 396-464 bp. Tang *et al.* (2000) had shown that detection of genetic polymorphisms in the X region of the *spa* gene can be used as a typing method to determine the epidemiologic relatedness of MRSA isolates. Protein A is a component of the *S. aureus* cell wall and is covalently bound to the peptidoglycan. The *spa* gene is approximately 2,150 bp and contains three distinct regions: the Fc portion, the X region, and the C terminus, the polymorphic X region contains various numbers of 24 bp repeats with various sequences had been described by Frénay *et al.* (1996). With the *spa* typing, a great number of

different types were obtained (Wildemauwe *et al.*, 2010). The variability of this gene indicate that sequence analysis of the *spa* gene could be used as an alternative system for the molecular typing of *S. aureus* isolates.

*Staphylococcus aureus* is one of the most common agents in bacterial food poisoning outbreaks. Its strains produce a spectrum of protein toxins and virulence factors thought to contribute to the pathogenicity of this organism (Adwan *et al.*, 2005). The staphylococcal enterotoxins (SEs) have been classified into many different types. The most common types of these enterotoxins are SEA to SEE. Isolates carrying toxin genes *sea* to *see* are responsible for 95% of staphylococcal food poisoning outbreaks (Bergdoll, 1983). The remaining staphylococcal food-borne disease outbreaks may therefore be associated with other newly identified SEs (MacLauchlin *et al.*, 2000; Omoe *et al.*, 2002 and Rosec & Gigaud, 2002). This study was conducted to determine the prevalence of enterotoxin genes A (*sea*) & B (*seb*) among the chosen *S. aureus* isolates recovered from human and bovine sources. The results in Photo (5) show that bovine strains (33%) were positive for both *sea* and *seb* genes, while 11.1% were positive for *seb* gene only. Among human strains, 20% were positive for *sea* gene and *seb* gene each. The Cowan 1 strain was positive for both *sea* and *seb* genes. Out of the 100 *S. aureus* isolates (milk sheep origin =52: milk cows origin =

48) tested by Adwan *et al.* (2005) for SE-genes, 37 (37%) were positive and the majority of these positive toxin gene isolates, 20 (54.1 %), were *seb*-positive. This result was consistent with previous reports from Japan, Poland and Slovakia, where 64% to 85% of the enterotoxigenic *S. aureus* isolates recovered from raw poultry meat or different food samples and food manufacturers harbored the toxin gene *seb* (Holeckova *et al.*, 2002 and Kitai *et al.*, 2005). In this study 10 out of 20 strains were negative for enterotoxins genes. Also 15 *S. aureus* poultry isolates were found to be non enterotoxigenic by Bystron *et al.* (2010).

It could be concluded that antibiogram clarifying the developed resistance of *S. aureus* strains to commonly used antibiotics ensuring that the right use of antibiotic of choice is very important in line of treatment and control of the infections caused by *S. aureus* especially MRSA strains. Genotyping by PCR is highly effective in detection of *S. aureus* with high sensitivity and specificity especially with polymerization of *coa* and *spa* genes which considered the cornerstone markers for detection and study of *S. aureus*. PCR results of *mecA* gene gave sharp differentiation between many strains which help in determination of the suspected source of infection especially in nosocomial infection cases also in case of repeated infections with the same strain in case of treatment failure or insufficient disinfection.

# Implementation of a rapid procedure for distinguishing enterotoxigenic Clostridium perfringens

<sup>1</sup>J. El-Jakee, <sup>2</sup>Ata S. Nagwa, <sup>2</sup>Bakry, M.A., <sup>2</sup>Sohier, M. Syame, <sup>2</sup>Samy A.A., <sup>2</sup>Khairy E.A.

1Department of Microbiology, Faculty of Veterinary Medicine, Cairo University, Cairo, Egypt

2Department of Microbiology and Immunology National Research Center, Cairo, Egypt

**Abstract:** The objective of the present study is to develop an easy method for detection of toxigenic *C. perfringens* isolates .4 *C. perfringens* isolates (type A, B, C & D) were collected from chickens and reconfirmed on the basis of conventional tests and multiplex PCR. Antisera were prepared from *C. perfringens* types A, B, C & D separately in different groups of rabbits. The titres of the prepared hyperimmune sera were estimated by ELISA & staphylococci protein A (SpA) agglutination test. An attempt was carried out to detect *C. perfringens* toxins in infected fecal samples. The fecal samples were infected by 20 & 40 µg /ml *C. perfringens* toxins (A, B, C & D) and examined by double sandwich ELISA & SpA agglutination methods. In addition the sensitivity of PCR for detection of *C. perfringens* types were compared with conventional culture technique among fecal samples contaminated with *C. perfringens* types and the results were discussed.

[J. El-Jakee, Ata S. Nagwa, Bakry, M.A., Sohier, M. Syame, Samy A.A., Khairy E.A. Implementation of a rapid procedure for distinguishing enterotoxigenic Clostridium perfringens. Journal of American Science 2010;6(11):499-508]. (ISSN: 1545-1003).

**Keywords:** *C. perfringens*, ELISA, SpA agglutination, PCR.

## 1. Introduction

Clostridia are commonly found in the environment, occurring in soil, sewage, and waters, as well as in the intestines of both man and animals. Members of the genus *Clostridium* are widely recognized as enteric pathogens for man, domestic animals and wildlife (Songer, 1996). *Clostridium perfringens*, a part of normal gut flora, is commonly involved in diseases in most domestic animals and some wildlife, including horses, poultry, birds, rabbits, sheep, goats, cattle, mink, ostrich, dogs and cats (Nillo ,1993). Smyth and Martin (2010) recorded that necrotic enteritis is a serious disease of chickens and turkeys caused by *Clostridium perfringens* and demonstrated that *C. perfringens* strains from a mammalian species and from normal chickens, can cause necrotic enteritis in chickens. *Clostridium perfringens* is an important cause of both histotoxic and enteric diseases (Fernandez-Miyakawa *et al.*, 2008). *C. perfringens* type D is the etiological agent of enterotoxaemia (pulpy kidney disease) of several animal species (Blood *et al.*, 1983). According to current knowledge, the disease is caused by epsilon toxin, a major exotoxin produced by this microorganism (Uzal and Kelly, 1996).

Substantial interest and effort have been expended in establishing new methods as well as improving classical methods for the detection and isolation of *C. perfringens*. The objective of the present study is to develop an easy method for typing of *C. perfringens* isolates in the veterinary routine diagnostic laboratory.

## 2. Materials and Methods

### Diagnostic antisera:

Diagnostic *C. perfringens* antisera type A, B, C and D were obtained from Welcome, Diagnostics Dartford, England from Microbiology department, Anaerobic Unit, Abbassia. They were used as control positive among the used serological test.

### Identification of *C. perfringens* isolates:

Four isolates of *C. perfringens* type A, B, C and D were collected from chickens. Each isolate was inoculated into freshly prepared Robertson's cooked meat medium (Smith and Holdman, 1968), and incubated anaerobically at 37°C for 24 hrs. Then a loopful from this culture was streaked onto neomycin sulphate sheep blood agar (Carter and Cole, 1990). The streaked inoculated plates were incubated anaerobically at 37°C for 24-48 hrs. The catalase negative colonies were picked up and examined for their morphological, cultural and biochemical characters according to Koneman *et al.* (1992). Biotyping of *C. perfringens* isolates by dermonecrotic reaction in Albino Guinea pigs was carried out according to Stern and Batty (1975).

### Multiplex PCR:

Template DNAs for PCR were prepared according to Osek and Winiarczyk (2001). Specific oligonucleotide primers for the toxin genes (alpha ( $\alpha$ ), beta ( $\beta$ ) and epsilon ( $\epsilon$ ) of *C. perfringens* toxins

were selected on the base of published sequences (Effat *et al.*, 2007) as shown in Table (1). The PCR product using 1.5% agarose gel electrophoresis and

DNA molecular weight marker of 100 base pair ladder (Bioron GmbH) (Jena Bioscience - Germany) was analyzed according to Sambrook *et al.* (1989)

**Table (1): Oligonucleotide primers for the toxin genes  $\alpha$ ,  $\beta$  and  $\epsilon$  of *C. perfringens***

Primer Designation	5'-----3' sequence	Amplified product size (bp)
CP ALPHA toxin F	GTTGATAGCGCAGGACATGTTAAG	402 bp
CP ALPHA toxin R	CATGTAGTCATCTGTTCCAGCATC	
CP BETA toxin F	ACTATACAGACAGATCATTCAACC	236 bp
CP BETA toxin R	TTAGGAGCAGTTAGAACTACAGAC	
CP EPSILON toxin F	ACTGCAACTACTACTCATACTGTG	
CP EPSILON toxin R	CTGGTGCCTTAATAGAAAGACTCC	541 bp

#### **Preparation of hyperimmune sera against *C. perfringens* isolates:**

Sixteen healthy rabbits of New Zealand breed, each of 1.5-2 kg body weight were obtained from the farm of "Animal Health Research Institute, Dokki, Giza". They were rest under strict good hygienic conditions during the whole period of experiment and provided with a balanced diet. They proved to be free from clostridial infections. Before beginning of the experiment, 3 ml blood sample from the ear vein of each rabbit was taken and the serum was separated and kept as non-infected control negative sample and kept at -20°C. The rabbits were classified into 4 groups, each group contains 4 rabbits. The first group was injected with *C. perfringens* type A, the second group was injected with *C. perfringens* type B, the third group was injected with *C. perfringens* type C and the fourth group was injected with *C. perfringens* type D. Each animal of each group was inoculated with 18 hrs culture of *C. perfringens* grow in medium containing 2% (w/v) polypeptone (Daigo, Osaka, Japan), 1% (w/v) glucose, 0.5% NaCl (pH 7.2) and heated at 100°C for 60 min. The immunization was carried out by injection of 0.5, 1.0, 1.0, 1.0, 1.5, 2.0, 2.0, 3.0, 3.0 and 3.0 ml of the suspension, respectively into ear vein of a rabbit at 3 day intervals (Yamagishi *et al.*, 1971). The sera of inoculated rabbits were collected and kept at 20°C till use.

#### **Preparation of toxin:**

*C. perfringens* types A, B, C and D were cultivated in cooked meat broth anaerobically at 37°C for 24 hrs. Each one of *C. perfringens* type A, B, C and D was inoculated into toxin production medium (Roberts *et al.*, 1970) and incubated for 5 hrs except type D incubated for 48 hrs. Centrifugation for type

A, B, C and D and the supernatant was taken. Trypsin was added to supernatant of type D and incubated for 1 hour. Dialysis was used for each toxin to remove small molecular contaminants according to Judson *et al.* (1987). The dialyzed toxin inside the dialysis bags were covered with polyethylene glycogen and left at 4°C to avoid protein denaturation until the solutions were concentrated to 5 ml (volume) in each bag. The bags were washed with distilled water and the solutions were collected in tubes and then deposited in a lyophilizer to concentrate the volume to 0.5 ml in each sample. The concentrated toxins were stored at -20°C till use. The protein content of 4 toxins of *C. perfringens* type A, B, C and D were measured using the modified Lowry's assay according to Lowry *et al.* (1951).

#### **Antibody assay (titration):**

Titration of the prepared hyperimmune sera was estimated by ELISA and SpA agglutination test.

#### **Enzyme linked immunosorbent assay (ELISA):**

Indirect ELISA was used to detect the antibodies against toxins of *C. perfringens* type A, B, C and D according to Harlow and Lane (1988). The sera were considered to be positive when the absorbency values were as or more than the cut-off value (the cut-off = double fold of the mean negative sera) according to Timmerck (1994).

#### **SpA agglutination test (Subramanayam *et al.*, 2000):**

A Cowan 1 strain of *S. aureus* (It was obtained in freeze lyophilized dried ampoules from the Namru 3 in Egypt) was spread over on brain heart infusion agar medium (Oxoid). Incubation was carried out at 37°C for 48 hrs, bacterial growth was scooped by a bent glass rod with PBS pH 7.2 into test

tubes. The cells were centrifuged at 2000 rpm for 15 minutes at room temperature. The cells were treated overnight with formalin to make a final concentration of 2% to inactivate the cells. Then the *S. aureus* cells were treated at 80°C for 5 minutes in a water bath. The cells were cooled immediately by immersing in an ice bath. Then cells were washed five minutes with PBS, pH 7.2 and 10% of *S. aureus* suspension was prepared in PBS. 2 folds serial dilution of antitoxins were added in U-shaped microtiter plate (25 µl/well). Amount of 25 µl of the prepared 10% SpA suspension was then added to each well and incubated at 37°C for 1 hr. with periodical shaking. 25 µl of *C. perfringens* toxin prepared in PBS were added to SpA mixture then incubated at 4°C. Agglutination was read within 2 hrs.

#### Detection of *C. perfringens* in fecal samples:

The prevalence of *C. perfringens* in feces was determined by selective culture, PCR, SpA and ELISA to permit validation of the ELISA, SpA and PCR.

Artificially contaminated fecal rabbit samples of enterotoxin for *C. perfringens* type A, B, C and D separately were prepared by adding 0.1 ml of toxin at concentration of 20 µg and 40 µg separately to 1 g of feces and 9 ml of water and centrifugation for 5 min at 500 xg. The double sandwich ELISA was performed according El Idrissi and Ward (1992) in 96-well disposable flat-bottomed plates to detect *C. perfringens* toxins in contaminated feces. As well as, SpA agglutination test (Subramanayam *et al.*, 2000) used for detection of *C. perfringens* toxins in the contaminated feces.

#### Sensitivity of the multiplex PCR

The sensitivity of the multiplex PCR assay for detection of *C. perfringens* in feces was conducted according to Kanakaraj *et al.* (1998). Artificially contaminated fecal rabbit samples of *C. perfringens* A, B, C and D were prepared by adding 0.1 ml of a 12 hrs BHI broth culture to 1 g of feces and 9 ml of water then centrifuged for 5 min at 500 xg. One ml of the supernatant was serially diluted in sterile water. From 0.8 ml aliquots of each dilution DNA template was extracted (Stahl *et al.*, 1988) and counts were performed by plating 100 µl aliquots on TSC agar. The sensitivity of the PCR assay was calculated as the number of colony forming units (CFU) of *C. perfringens* in the greatest dilution which was PCR positive.

### 3. Results and Discussion

*C. perfringens* type A ( $\alpha$ -toxin producer) is common in the intestinal tract of chicks, soil, dust-contaminated feed and litre (Kalender and Ertafi, 2005). The  $\alpha$ -toxin ( $\alpha$ ) the principal lethal toxin of *C.*

*perfringens* is a multifunctional phospholipase produced by nearly all isolates. The toxin is haemolytic, necrotizing and potently lethal. Detection of *C. perfringens* toxin types is critical for a better understanding of the epidemiology of *C. perfringens* infections and may be helpful in the development of effective preventive measures.

In the present study, 4 *C. perfringens* isolates (type A, B, C & D) were collected from chickens and reconfirmed on the basis of morphological, cultural and biochemical characteristics. All isolates were Gram-positive spore-forming bacilli as shown in Photo (1). Colonies of *C. perfringens* are up to 5 mm in diameter, circular, flat, greyish and surrounded by zone of double haemolysis after cultured anaerobically on blood agar at 37 °C for 48 hrs (Photo.2). The biochemical behaviour of the isolates complies with these of *Clostridium* typical reactions as described by (Quinn *et al.*, 2002). Toxins of *C. perfringens* isolates were detected using inoculation of guinea pig to detect necrosis as shown in photo. (3)

The collected strains were investigated for production of toxins by PCR. This test was established to replace animal testing and to reduce cost and time. Rapid detection of enterotoxigenic *Clostridium perfringens* in meat samples was accomplished by Yang *et al.* (2010) with an immunomagnetic separation polymerase chain reaction (IMS-PCR). Photo (4) shows amplification of alpha toxin gene (402 bp) from all isolates & amplification of beta toxin gene (236 bp) from *C. perfringens* type B & C, while epsilon toxin gene (541 bp) was recorded in *C. perfringens* type D. The  $\alpha$ -toxin is present in all types of *C. perfringens* and lies within the chromosome of the bacterial DNA (Albini *et al.*, 2008). Molecular typing allowed for an easier in vitro test (Effat *et al.*, 2007).

The development of a useful serological test is dependent upon the identification of defined antigens and the examination of the antibody responses to these antigens. Therefore, antisera were prepared from *C. perfringens* types A, B, C & D separately. Serum samples were collected from rabbits after inoculations with the isolates and the antibody titre against homologous isolate was estimated by ELISA & SpA agglutination test as shown in Tables (3&4). Specificity and avidity of antibody binding to target antigen is critical for the success of antibody-based pathogen detection methods (Bhunia, 1997).

The optical density (OD) of ELISA among the prepared hyperimmune sera was estimated as shown in Table (2) after application of checkerboard titration. It is clear that, positive ELISA OD 0.522, 0.687, 0.504 and 0.534 were recorded among the

prepared hyperimmune sera of *C. perfringens* type A, B, C, and D diluted to 1:800, 1:1600, 1:800 and 1:1600. Using an enzyme-linked immunosorbent assay (ELISA) for measuring levels of specific antibodies against alpha-toxin Heier *et al.* (2001) found a variation in level of maternal antibodies against  $\alpha$ -toxin in broilers. The variation in antibody levels between broiler flocks of different origin indicated that some parent flocks has raised an antibody response to naturally-occurring alpha-toxin. If broiler chickens are able to mount a similar response, this response may have value for protection against the disease, as well as diagnostic value to reveal subclinical disease in broiler flocks (Lovland *et al.*, 2003).

In the present study, SpA agglutination test was used for estimation of *C. perfringens* antibodies among the prepared hyperimmune sera. Coagglutination is similar to latex agglutination technique for detecting antigen protein A, a uniformly distributed cell wall component of *S. aureus* is able to bind to the Fc region of most IgG isotype antibodies leaving Fab region free to interact with antigens present in the applied specimens. The visible agglutination of *S. aureus* particles indicates the antigen-antibody reaction. Data present in Table (3) illustrated that positive coagglutination antibody titers could be detected at 1/4 up to 1/64. 1/16 was used as a CoA reagent for various tests in 12 studies and the results obtained are in agreement with Rahman *et al.* (1989) in *Salmonella* enterotoxin system and with Batra *et al.* (1989) in *Brucella* antigens.

Cross reactivity in vitro was tested to figure out the possible diagnosis of *C. perfringens* using concentrations of 20  $\mu\text{g}/\text{ml}$  toxins ( types A, B, C and D). In this study cross reactivity between *C. perfringens* types was tested as shown in Figures (1-5) using ELISA. These cross reactivity may be due to use of crude toxins which contain  $\alpha$ -toxins among all types.  $\alpha$ -toxin, a necrotizing toxin commonly produced by all five types of *C. perfringens*, is believed to be a major factor responsible for the organism tissue pathology and has been suggested to be a key virulence determinant and predominant product of *C. perfringens* type A (Scott *et al.*, 2004). Also Effat *et al.* (2007) revealed that  $\alpha$ -toxin gene is found in all types of *Clostridium perfringens*.

An attempt was carried out to detect *C. perfringens* in infected feces using ELISA, coagglutination test & PCR assay. Fecal samples were infected by 20 & 40  $\mu\text{g}/\text{ml}$  toxins (A, B, C & D). The infected samples were examined by double sandwich ELISA methods as shown in Tables (4-7). It is clear that 20  $\mu\text{g}/\text{ml}$  is a concentration of choice. The ELISA method of Vaikosen and Ikgatua (2005)

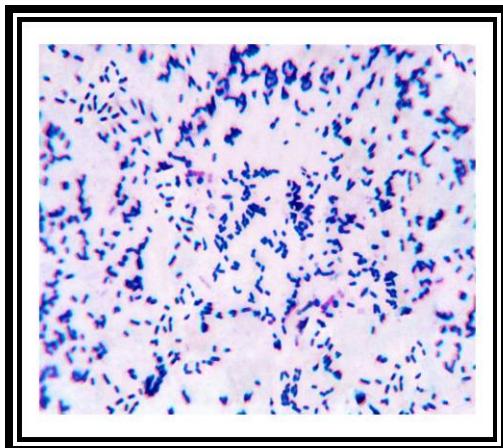

was able to detect as low as 0.1  $\mu\text{g}/\text{ml}$  of enterotoxin corrected optical density (OD) at 405nm, the value of 0.4 OD units was used to estimate the enterotoxin levels of the isolates, and mean value of 0.66 OD units for *C. perfringens* type D, while the mean value of 0.94 OD units for *C. perfringens* type C were obtained. The detection of *C. perfringens* in feces of horses by ELISA could be diagnostically beneficial in a clinical setting (Waggett *et al.*, 2010). Using specific antibodies for beta and epsilon toxins of *C. perfringens*, two double sandwich ELISAs were developed for detection of these toxins in buffers, culture supernatants and intestinal contents by El Idrissi and Ward (1992). In both assays absorbance readings were directly related to the  $\text{Log}_{10}$  of the toxin concentration over 3-4 points between 31 and 250  $\text{ng}/\text{ml}$  for beta toxin and between 8 and 125  $\text{ng}/\text{ml}$  for epsilon toxin. The reason for this difference may be due to we used crude toxins as antigens while El Idrissi & Ward (1992) used a purified activated epsilon toxin, which may have increased both the specificity and sensitivity of the test.

As shown in Tables (8-11) the infected fecal samples were analyzed by SpA agglutination test. The epsilon toxin was detected in five samples by coagglutination and mouse neutralization tests by Subramanyam *et al.* (2000), these samples were made by serial two-fold dilutions from 1/2 to 1/32. Previously Dobosch (1983) describe staphylococcal coagglutination procedure for assaying *C. perfringens* enterotoxin; its sensitivity and specificity were studied. *C. difficile* A and B toxins and *C. perfringens* type A enterotoxin was studied by Giulazian *et al.* (2008) employing the immunological test systems in the coagglutination test using the plates.

The sensitivity of PCR for detection of *C. perfringens* types were compared with conventional culture technique. As shown in Table (12) and photos.(5-8) *C. perfringens* could be isolated onto medium only from  $10^3$  dilution, meanwhile *C. perfringens* toxins could be detected from all dilutions of different *C. perfringens* types by PCR assay. PCR provides a simple and rapid assay for detection of *C. perfringens* under condition where the current levels of sensitivity and specificity are acceptable; it should be immediately useful in epidemiologic and diagnostic studies.

In conclusion, the *C. perfringens* toxin can be detected instantaneously (within 4 minutes) on a slide by SpA agglutination test. Moreover, this test requires minimum number and amounts of reagents which could be presented and used in the form of portable diagnostic kit for use in the farm premises. The results demonstrate the suitability and reliability of multiplex PCR for the routine diagnostic

laboratory. The procedure will improve the diagnosis of food-borne intoxications and will help to discover further epidemiological and aetiological aspects of these diseases.

# Comparative Study of Software Engineering Processes in Egyptian Cmmi Companies

Alaa El-Din Hamouda and Mohammad Abdрабو إلوهش

Computers & Systems Engineering Dept., Al-Azhar University Cairo, Egypt.  
[Alaa\\_ham@giga.net](mailto:Alaa_ham@giga.net), [eng.md.elwahsh@gmail.com](mailto:eng.md.elwahsh@gmail.com); [www.elwahsh.com](http://www.elwahsh.com)

**Abstract:** The Egyptian government has paid special attention to the software industry as Egypt to provide it with a competitive advantage that makes this emerging industry promising. Thus, the State has supported the Egyptian companies to make use of the Capability Maturity Model Integration (CMMI). Since 2009, more than thirty companies obtained the CMMI at different levels. However, these companies suffer from lack of a mechanism to exchange experience and information among themselves although they could be similar in the culture of their engineers and perhaps in the nature and size of their software projects. So, we provide in this research a survey to gauge the quality of methods, tools and processes used in these Egyptian companies winning the CMMI. Then we analyzed the results to reach the recommendations aimed at enriching the software industry in Egypt.

[Alaa El-Din Hamouda and Mohammad Abdрабو إلوهش. Comparative Study of Software Engineering Processes in Egyptian Cmmi Companies. Journal of American Science 2010;6(11):509-514]. (ISSN: 1545-1003).

**Keywords:** CMMI in Egypt, software engineering processes, survey.

## 1. Introduction

In 1993, the Software Engineering Institute (SEI) released the Capability Maturity Model Integration (CMMI) with five staged maturity levels as a means to both appraise maturity level and guide process improvement efforts for software organizations. This model has since been widely accepted around the world, especially in Egypt where the CMMI has helped many software companies [1, 2, 3, 4, and 5].

CMMI combines software engineering, systems engineering, integrated products and procurement to design and improve all types of processes. CMMI has become an international standard for devising software development processes and is credited with helping Egypt rise rapidly to become among the world's software exporters. CMMI provides guidance to improve organizations processes and ability to manage the development, acquisition, and maintenance of products or services. The process areas are grouped into four categories: Process Management, Project Management, Engineering, and Support [6, 7, 8, 9, and 10].

Around the world, there are fast growing CMMI companies. Many countries use the CMMI model extensively e.g. India, China, Japan, Australia, Russia, USA, S.Korea, France, Germany, Brazil, Argentine, Canada and Taiwan. For example in Taiwan seven companies hold Level 2 accreditation, two have Level 3 accreditation and one(IBM Taiwan) has already achieved Level 5 accreditation. In 2009

more than 500 companies in the U.S. were certified to CMMI standard [11, 12, and 14].

Today, use of CMMI in Software industry in Egypt has been increasing to improve software processes. By June 2009, thirty-one software companies achieved CMMI accreditation levels, from Level 2 to Level 5. One of the problems that face CMMI companies in Egypt is lack of conferences that enable specialists to meet to share their experience about software engineering processes. Also, there is lack of researches that reflect the experiences and provides comparative studies. So, we made the CMMI Survey in 2009 to help organizations identify the best practices and enhance the maturity of their processes. By investigating most of the organizations that have been appraised, processes automation, success factors, keep performance indicator (KPI), benefits of CMMI implementation are identified [13].

## 2. Survey Design

We designed a Survey for CMMI companies in Egypt. The target of the survey is to make a comparative study of the process implementation, best practices, tools, and techniques used in these companies. The target of these questions is to give informative details about the CMMI companies to get clear and transparent information about the software industry in Egypt [13]. These survey requirements were divided into twelve sections, covering most areas of operations in the maturity model with the aim of measuring the capacity of the second and third division levels.

The results were as follows: The first section was to get general information about the company characteristics in terms of size and structure, other sections of the survey focus on processes implementation and tools used for different process areas of levels two and three. Level two includes Project Management, Requirement Management, Measurements and Analysis, Quality Assurance and Configuration Management. Level three includes Technical Solutions, Product Integration, Risks Management, Testing, Decision Analysis and Resolutions , Process Improvement, and CMMI satisfaction[3,9].

The survey was launched in 2009. Through Software Engineering Competence Center (SECC) in the Egyptian Ministry of Communications, the thirty-one Egyptian CMMI companies were requested to fill the survey to answer 65 questions addressing different sections of programming activities in Egypt. Then four experts from software engineering processes and CMMI section were contacted to define the key points which Egyptian companies need to relay their experience. Based on these needs we divided the survey as follows:

- 1) General Information
- 2) Individual Evaluation System
- 3) Engineering Processes Group
- 4) Project Management
- 5) Requirement Management
- 6) Measurements and Analysis
- 7) Quality Assurance
- 8) Technical Solution and Product Integration
- 9) Testing
- 10) Risks
- 11) Process Improvement
- 12) Satisfaction with CMMI based processes

### **3. Survey Implementation**

This survey was sent to 31 companies in Egypt that obtained the Capability Maturity Model Integration (CMMI) at different levels: eighteen companies were granted the second level (58.2%), ten received third level (32.3%), one got level four (3.2%), and two obtained the fifth level (5.6%).

From the results of the survey, we find that 14 companies participated as follows: 8 companies got the second level (57.1%) got the third level (28, 6%), and two got the fifth level (14.3%). most companies responded to all questions included in the survey. However, some vague points were not answered by few companies.

### **4. Results and Evaluations**

#### **A. General Information**

As a result of evaluation, the following rates were obtained from responding companies:

- ❖ A percent of 58.3 % have projectized structures, while 41.7 % are matrix organizations. This is striking if we bear in mind that most companies and projects are individual and small-scale projects. The importance of the adoption of the Matrix Organization is demonstrated when the companies are large, including a multiplicity of departments and skills. But in a small institution, it is usually advisable to adopt a system of Projectized Organization, where the responsibilities and tasks are more specific and there is speed in decision-making, flexibility in management, and easy follow-up on the other hand. Please note that in medium-sized companies (where the number of employees is less than fifty) 50% of the employees use the matrix model. So we recommend that these medium-sized companies adopt a projectized system.
- ❖ 36% of the companies got the Capability Maturity Model Integration (CMMI) before 2006, 36.4% before 2007, and 27.6% by the year 2008.
- ❖ All companies on the second level have valid plans to get the third level in a year or two, which indicates:
  - a. Growing awareness of the importance of quality systems and the positive repercussions on companies.
  - b. Companies are satisfied with returns resulting from the application of quality systems (Return on Investment).
- ❖ All the companies that got the third level in re-evaluation (reappraisal) after expiry of the first evaluation aim at higher level of the CMMI Levels 4 and 5 but this is impaired by the financial constraints, as the Egyptian Government supports only the companies that plan to get the second and third levels.
- ❖ The ISO 9001 certification was a good start for Egyptian companies, as 43% of the participants, received the ISO certification before they got the CMMI. This can be explained as the required specifications in ISO 9001 focus on the administrative side, at the same time the CMMI standards focus on the specifications of the technical operations, especially in the third level and above. This is why we recommend the companies that got the ISO certification or wishing to start a quality journey to follow the experience gained and the methodology proposed by [Chanwoo, 2006].

#### **B. Individual Evaluation System**

Individual Evaluation is a key success factor for organization. Having good measures and processes for performance evaluation affects the employee's satisfaction and turn over rate. In 55% of the companies, where the individual survey system was applied the direct manager alone filled the survey. This reflects two facts:

- a. Companies need performance indicators which truly reflect the real level of performance of engineers.
- b. Companies need to design questionnaires on specific scientific basis which reflect the level of performance of software engineers from different points of view. For example, designing a system of individual performance appraisal method based on the Three-Hundred and Sixty Degrees method can be a good choice. Hence it is recommended that researchers in the field of software engineering would address this need and give it priority in their research.

#### C. Engineering Process Group (EPG)

At the beginning of the processes improvement initiative, there are usually some important questions, e.g. How many people are needed for the EPG? Should they be dedicated process engineers or normal software engineers who spend some time in processes? What are the criteria for EPG member selection? The paragraphs below help the decision maker through highlighting the actual performance.

- ❖ 83% of the companies that dealt with the survey are of small and medium SME.
- ❖ 53.8% of the companies prefer to have the engineering team dedicated to this work size (Static EPG), while in 46.2% of the companies, EPG members are originally working in software projects (such as a systems analyst, developer, tester) and those who deal with process improvement tasks would, take over these functions to complement their own tasks (Virtual EPG).

The average overall efforts to improve operations in companies have a monthly rate of 1.25 employees. This will be useful later to show the amount of spending on improving processes, calculate the resulting returns and consequently access the return on expenditure (Return on Investment, ROI).

#### D. Project Management (PM)

Project managers face challenges of selecting the suitable quick and detailed estimation techniques and the adopted software life cycle. They are also required to select the project management tools and decide about the meetings frequency. Challenge facing the project manager to select the appropriate method to estimate the size of the product backend

forums and then estimate the cost and time, has emerged from the questionnaire which also revealed that:

- ❖ 42.9% of the companies use the Microsoft Professional project management (Microsoft Project Professional).
- ❖ 36% use the Microsoft Advanced Project Management (Microsoft Enterprise Project).
- ❖ 21.1% are using a spreadsheet (Excel sheet). These rates are consistent with the nature of projects which are based on dealing with the user.
- ❖ 53. 8% Use Case Points (Use Case Point) as a tool to estimate the size of projects.
- ❖ 38.2% use point of the task (Function Point), and 8% use COSMIC tool.
- 78.6% have a preliminary technical assessment (Initial Estimation Technique), and 21.4% do not.

#### E. Requirement Management

A percent of 46.2% of the companies use spreadsheet software for management of requirements. However, complex software systems steadily increase the list of requirements which makes it difficult to manage and follow-up. It is also difficult to link design and test programs and schemes corresponding to each requirement (Traceability Matrix). Accordingly, we recommend, in such case, use of special programs to manage the requirements of software systems to enhance the efficiency of the management process requirements.

#### F. Measurements and Analysis (M&A)

The number of key performance indicators (KPI) in projects and institutions in general was great compared to company sizes. So as, each KPI has a cost for managing it (e.g. collecting KPI values, verifying their validity, and analyzing them), we recommend training specialists to calculate the cost of these indicators (cost/benefit analysis) in order to be able to take the right decision for selection of numbers and quality.

In 50% of the companies, key performance indicators for the (KPIs) are less than 4 and more than 7, and 33% less than 4, in 17% it is more than 4, this is compared to the number of key performance indicators where in 64.2% of companies the number of KPI is between 4 and 7, and in 30.8% the number of is less than 4, and in 23% is more than 7. We find that 85.7% of the companies take advantage of the actual analysis of performance indicators to improve operations.

#### G. Quality Assurance (QA)

How many process QA engineers are needed? Is it useful to get QA approval before a project is closure?

When should QA issues be escalated? The results below express the real situation in Egyptian CMMI Companies. The senior management support to a quality assurance is an essential element in the commitment of staff operations that are in line with quality systems. It has been found that 57.1% of the companies need to get the approval of the project manager of quality assurance team (QA approval) at the end of any project, and in 71.4% of the companies, the number of quality assurance engineers was more than three. These are good promising an indicator of the manager's concern to stress the value of the quality of operations and give it direct support.

#### H. Technical Solution and Product Integration

For developers, it is important to determine how unit testing is performed and to define dedicated positions for architecture, analysis, and design are used. It is equally important to define who is responsible for support documentation. The results of that survey are given below.

- ❖ 78.6% of the companies perform automatic unit testing, and 57.1% perform the testing manually. This reduces efficiency as much as it lowers the productivity of the developer/tester. These companies are recommended to adopt unit testing and general testing. We also recommend training developers on tools unit testing automatically, and training testers to use automated testing tools.
- ❖ 27.3% of the companies use dot-net (Dot Net) as a tool for program development. 27.3% use the Java language (Java), 9.1% use the Oracle (Oracle) language, while 36% use other languages such as Delphi (Delphi).
- ❖ There is no specialization in technical writing where developers and testers take the responsibility of preparing documents associated with the product code. This is, in most cases, not accomplished professionally which reduces companies' efficiency. So, we recommend that company's employee technical writer who would be responsible for documentation especially since the cost incurred may be less than the cost of employing a developer or tester.

#### I. Testing

- ❖ It is noted that the checking bugs (Bugs), and problem issues (Issues) are checked manually in 57.1% of the companies. Perhaps this makes it difficult to follow-up and may affect the quality of products and processes. Hence, we propose that companies automate this process, either through

their own software or through ready-made software.

- ❖ Manuscript rapid testing (rapid testing script) is very important to examine applications in a limited time. The importance of this testing is highlighted in the maintenance phase of software systems. However, we find that 71.4% of the companies do not have this facility. Therefore, we recommend its provision for testers and training them to use it.
- ❖ The rate of developers to testers in the companies was at an average of one laboratory for each 3.7 developers. This reflects the distribution of effort in software projects, where this ratio is severely limited if compared to the ratio of 1: 2 approximately [17] in COCOM I and COCOM II. This indicates a weak interest in testing the products adequately. So, it is recommended to invest more effort in testing products which would improve the quality and increase competitiveness of Egyptian software.
- ❖ 78% of the companies perform unit tests manually, and 57.1% do screening tests manually. This reduces efficiency as much as it reduces the productivity of the developer/tester. Thus, we recommend companies to adopt mechanical unit testing. We also recommend training developers to perform the Tools unit test automatically, and training examiners to use automated testing tools.

#### J. Risks

54.5% of the companies use spreadsheets to manage risks, 18.2% use radar (Radar), and 27.3% use other programs such as (Microsoft Project Server) for the management of risks.

#### K. Overall Satisfaction with CMMI

- ❖ Generally, the companies applying the CMMI are satisfied which is a good sign. However, there are complaints from the complexity of operations there is an urgent need to review the operations approved by each company in the system to alleviate any burden carried by these processes (Process overhead). To accomplish this, we recommend that companies work on some ideas inspired by the Agile Models and trying to integrate them in their quality system which is compatible with the CMMI, especially as most companies are small and thus need flexible and simple processes.
- ❖ 21% of the projects in the companies do not follow the processes set forth by the CMMI quality system. When these companies were asked, the answer was that pressure from

- customers to get the product forces them not to follow the internal CMMI quality systems. This in fact represents a threat to the quality of processes and then the quality of products in these projects. So, it is proposed that companies apply another Simple Process to speed the completion of work such as the Agile Model, and thus Subject all company projects whether complex processes or simple operations, to the internal quality system according to the standard set by the companies to follow the appropriate processes.
- ❖ The percentage of delay in software projects delivery date was 58% and the average percentage of projects costing more than the approved budget is estimated by 45.5%. This is consistent with global figures estimated by 75% and 50% respectively. It is observed that most international projects that suffer from delays and cost increase are large-scale projects, while the projects in the Egyptian companies are not huge. According to [18], the most important reasons at the global level are:
    - a. poor planning and management
    - b. changing objectives of projects during their implementation
    - c. Non-participation of senior management in the follow-up projects and consequently not giving enough support.

We find that the second and third reasons may not apply directly to the Egyptian companies which are relatively small in size. Also, the number of projects is limited, which reduces the likelihood of changing objectives and lack of support from senior management. Thus, the primary cause is the most influential and therefore it is recommended to raise the skills of project managers through training to use the specific and effective methods of project management software.

## 5. Conclusion

Through this paper we are providing the results of a questionnaire to investigate the processes and Tools used in CMMI software companies in Egypt. By analyzing the results and conclusion obtained, we recommend that:

1. Small and medium companies adopt a structural Projectized Organization process, where the responsibilities and tasks are more specific and there is speed in decision-making and flexibility in management and follow-up.
2. Training the responsible personal to estimate the cost of key performance indicators (analysis of the relationship between expenses and profit) in order to be able to reach a wise decision for selection of

performance indicators with respect to quality and quantity.

3. Carrying performance unit tests and general tests automatically. Also, training developers to perform the Tools unit tests automatically, and testers to automated testing tools.
4. Automation of the follow-up bugs (Bugs), and issues (Issues) either through their own software or through ready-made software's.
5. Training testers to prepare and implement rapid testing (rapid testing script) to support the maintenance of software products.
6. With the steady complexity of the code systems and growth of the list of requirements which is difficult to manage and follow-up, it becomes difficult to link it to design, test programs and plans corresponding to each requirement (Traceability Matrix). Preparation and use of special programs to manage the requirements of software systems, to enhance the efficiency of the management process requirements.
7. Exerting more effort in the work of a good testing of products in order to increase the quality and competitiveness of Egyptian software.
8. Companies employ a technical writer, especially since the cost incurred is less than that of employee a programmer or tester.
9. Enhancing skills of project managers through training on the unique and effective methods of project management software.
10. Companies prepare new classifications for simple operations (Simple Process) in order to be able to speed the completion of work by following the Agile model and thus subject all projects to their special quality system (both for complex or simple operations) according to the standard they set.
11. Companies holding ISO 9001 or wishing to start a trip to ISO quality should follow the experience gained and the methodology proposed in [19]. The ISO 9001 certification was a good start for many Egyptian companies. Forty-three percent of the participating companies received a certificate of the ISO before they got the Capability Maturity Model. This can be explained by the required specifications in both, where the ISO 9001 focuses on the administrative side, at the same time the Capability Maturity Model identifies standards of technical operations, notably in the third level and above.
12. There is an urgent need to review the operations approved by each company in its system, and for this process said companies try to make use of Agile models and integrate them in their quality system which is compatible with the CMMI to decrease the Process overhead,

especially as most companies are small and need to be flexible, and simple.

13. Researchers in the field of software engineering should study to find indications of a genuine performance which truly reflects the performance of engineers to design by questionnaires on the basis of special scientific programmed software which describe the performance of engineers from different points of view, for example, designing a system to assess individual performance depending on the method of Three Hundred and Sixty Degrees.

### **Future Work**

After publication of this paper we shall supply the participating companies with the results through the Egyptian Ministry of Communications represented by SECC. Through participation in Arab conferences we hope that government's private institutions Adopt these recommendations and spread them in their countries.

### **Acknowledgments**

We thank the Software Engineering Competence Center (SECC) especially Dr. Gamal Aly and Abeer Khedr for their support, and Dr. Mohammad Zaki for his valuable comments; we also thank all individuals who took the time to assist us in this survey. Finally, we thank Horizon Software Company as a sponsor of this work.

## Prevalence of *S. aureus* and *S. epidermidis* among patients with indwelling catheters and their antibiogram using some commonly used antibiotics.

\*De, N. and Godlove, M.

Department of Microbiology, Federal University of Technology, Yola, Adamawa State, Nigeria

e-mail: nanditamicrobio@yahoo.com

\*corresponding author

**Abstract:** The objectives of this study were to find the prevalence of *S. aureus* and *S. epidermidis* in urine samples of patients placed on catheter in Federal Medical Centre, Yola (FMCY) and State Specialist hospital, Yola (SSHY) and the efficacy of some commonly used antibiotics against the isolates of *S. aureus* and *S. epidermidis*. A total of one hundred and five samples (60 from SSHY and 45 from FMCY) were collected and inoculated into Cystine lactose electrolyte deficient (CLED) agar for isolation of Staphylococcal species. A total of seventy six presumptive Staphylococcal isolates were obtained on CLED agar and these isolates were identified using gram staining, morphological characteristics and standard biochemical tests. Serological studies revealed that out of 76 isolates, 56 were *S. epidermidis* (coagulase negative) and 20 were *S. aureus* (coagulase positive). Fifty one point eight percent (51.8%) of the isolates of *S. epidermidis* were sensitive to ceftazidime followed by ciprofloxacin (46.4 %) whereas 45% of the isolates of *S. aureus* were sensitive to ceftriaxone followed by cefotaxime and ciprofloxacin (40%). [De, N. and Godlove, M. Prevalence of *S. aureus* and *S. epidermidis* among patients with indwelling catheters and their antibiogram using some commonly used antibiotics. Journal of American Science 2010;6(11):515-520]. (ISSN: 1545-1003).

### Introduction

Urinary tract infections (UTIs) are the most common infections acquired in hospitals and long term care facilities. Several studies have estimated the incidence of health care associated UTIs at around 2-3 patients per 100 admissions (Kreiger *et al.*, 1998). Catheter associated urinary tract infections (CAUTIs) perhaps the largest institutional reservoir of nosocomial antibiotic resistant pathogens. This could lead to complications such as pyelonephritis and bacteremia (Nwankwo *et al.*, 2007). Glynn *et al.*, 2007 have indicated that between 75 and 80 % of all health care associated UTIs follow the insertion of a urinary catheter, and a study investigating 40 English hospitals estimated that around 26% of all hospitalized patients have a urinary catheter inserted during their stay in hospital. Use of catheters is common in long term care facilities and many patients are catheterized for long period, thus increasing their risk of acquiring a CAUTI (catheter associated urinary tract infection). Ouslander *et al.*, 1994 carried out a study on patients in nursing home and illustrated the problem of CAUTI in long term care of the

elderly. During the one year study period, 80% of the patients had atleast one CAUTI and 48% of the patients had two or more CAUTIs. Nwankwo *et al.*, 2007 carried out an investigation on catheter associated urinary tract infection in a tertiary health institution in Kano, Nigeria. The results show that out of 210 patients studied, 180 patients showed bacterial growth from the aspirated urine sample. The prevalence rates of the isolates for catheter tip and aspirated urine culture were *E. coli* (38.3%), 41.2%, *P. aeruginosa* 20%, 18.8%, *Proteus* sp. 12.7%, 11.8%, *S. aureus* 8.8%, 4.7%, *Streptococcus* sp. 1.1%, 7.1%, *C. freundii* 2.7%, 0%, *Candida* sp. 2.7%, 0% and *S. epidermidis* 1.1%, 0 % respectively.

*Staphylococcus aureus* causes a variety of suppurative infections and toxioses in humans. It causes superficial skin lesions such as boils, styes and furunculosis, more serious infections such as pneumonia, mastitis, phlebitis, meningitis and urinary tract infections and deep seated infections such as osteomyelitis and endocarditis. *S. aureus* is a major cause of hospital acquired infection of surgical wounds and infections associated with indwelling

medical devices (Todar, 2005). *S. epidermidis* is known to cause infection of native heart valves, intravenous catheters, and artificial heart valves. It is a common skin resident that is sometimes responsible for endocarditis and infections of patients with lowered resistance (e.g. wound infections, surgical infections, urinary tract infections). It can cause peritonitis receiving peritoneal dialysis usually introduced via a break in the patient's skin and also causes infections in prosthetic joints ((Baron *et al.*, 1994).

CoNS are the (coagulase negative *Staphylococcus*) quite essential pathogens of medical devices. The array of virulence factors produced by CoNS is meager compared with that of the virulence factors produced by *S. aureus*, but among these few factors are substances that promote bacterial adherence to and persist on foreign bodies. CoNS infection of intravenous catheter may or may not be accompanied by signs of inflammation at the site of catheter insertion, and the degree of systemic toxicity (including fever) ranges from minimal to moderately severe (Rupp and Archer, 1994).

Multidrug resistant *Staphylococcus* isolates have been recognized as one of the major challenges in control of hospital acquired infections and community associated infections. Bacteremia caused by *S. aureus* continues to be a common problem world wide and also the coagulase negative *Staphylococcus* and antibiotic sensitivity patterns are regarded with all seriousness in clinical practice and hospital acquired and community acquired infections. Martha *et al.* (2009) isolated MRSA from AIDS patients attending some public hospitals in Yola, Adamawa State, Nigeria. Shoba *et al.*, 2005 conducted a survey work on prevalence of *Staphylococcus* sp. among hospital personnel, environment and their antibiogram with special emphasis on methicillin resistance. They reported that resistance to oxacillin was 13.84% among the 65 staphylococcal isolates. Yenda *et al.*, 2010 isolated 60 isolates of *S. aureus* from patients attending State Specialist hospital and out of these 60 isolates, 85% of the isolates were resistant to ofloxacin and 80% of the isolates were resistant to ciprofloxacin.

FMCY and SSHY are the two largest hospitals in Adamawa State. Patients that need catheter devices or any prosthetic devices, generally attend these two hospitals. This present work was aimed at determination of

prevalence of *S. aureus* and *S. epidermidis* isolated from patients with indwelling catheters and their antibiogram in these two hospitals.

## Materials and Methods

### Study area:

The study area selected for this study was Jimeta-Yola, Adamawa State. The selected hospitals were Federal Medical Centre, Yola (FMCY) and State Specialist hospital, Yola (SSHY).

### Collection of samples:

According to Procter and Peters (1998), catheter urine samples should be collected not from the catheter bag but from the tube at upper connection. For collection of sample, the catheter tube was disconnected from the catheter bag and urine was collected into a wide mouth screw capped bottle and was covered after collection. Patient's age and gender were recorded for each of the sample. All the samples were analyzed within four hours of collection.

### Isolation of *Staphylococcus* sp.:

A loopful of urine sample was inoculated on CLED agar and was incubated at 37°C for 24 hours. The round cream and white colonies of 1-2 mm in diameter were collected and labeled. These were subcultured on blood agar and kept in refrigerator for identification purpose.

### Identification of Staphylococcal isolates:

The appearance and color of the colonies on CLED agar and Blood agar and the diameter of the colonies were noted. Gram staining was done following the procedure as described in Benson, 2002. The isolates were also identified using different biochemical tests like catalase test, coagulase test, sugar utilization tests using sucrose, mannitol, trehalose and also novobiocin test using novobiocin at 5 µg/ml (Benson, 2002).

Isolates were then tested for coagulase production using Staphytect Plus test method. The reagents were purchased from Sanofi Diagnostic Pasteur, France and the method was followed as instructed by manufacturer. One drop of test latex reagent was dispensed onto one of the circles on the reaction card and one drop of control latex was dispensed onto another circle.

A loop was used to pick up 5 average-size of suspected staphylococcal colonies onto a culture media plate and mix this in the control latex reagent. The colonies were smeared in order to cover the circle. A separate loop was then used to proceed in the same way with the test latex.

The card was rocked for 20 seconds and agglutination was observed under normal lighting conditions.

A result was reported positive if agglutination of the blue latex particles occurred within 20 sec. A result was reported negative if no agglutination occurred and a smooth blue suspension remained after 20 sec in the test circle.

#### **Antimicrobial susceptibility testing:**

All 76 isolates were used for this test using streak plate method. Sensitivity disks containing conventional antibiotics like augmentin (5 µg/ml), ofloxacin (5 µg/ml), ceftriaxone ((30 µg/ml), ceftazidime (5 µg/ml), cefotaxime (10 µg/ml), sparfloxacin (10 µg/ml) and ciprofloxacin (5 µg/ml) manufactured by BIOTECH LABS., England were used for sensitivity test. A loopful of growth of each isolate on blood agar was suspended in sterile water and then was diluted in steps of 1:10 to give turbidity equivalent to the 0.5 McFarland standard (a density of  $1 \times 10^8$  cells/ml) before inoculation (NCCLS, 2002). Diagnostic sensitivity test (DST) agar plates were inoculated with 0.5 ml of cell suspension of each isolate adjusted to  $1 \times 10^8$  using a sterile spreader. Sensitivity discs containing antibiotics were placed on the surface of each DST agar plate evenly seeded with the test organism and

was incubated for 24 hrs. at 37 °C. The zone size of 20 mm or less for ciprofloxacin and 15 mm or less for ofloxacin, augmentin and sparfloxacin was considered as resistant and for other antibiotics (cephalosporin drugs) the zone size of 24 mm or less was considered as resistant for *S. epidermidis* and *S. aureus*.

#### **Results**

##### **Description of samples:**

A total number of one hundred and five samples were collected from FMCY and SSHY from patients placed on catheter. Out of 105 samples, 45 samples were from FMCY while 60 from SSHY. Out of the 45 samples from FMCY, 29 were from female patients while 16 from male patients. Out of 60 samples from SSHY, 38 were from female while 22 from male patients.

##### **Isolation and identification of isolates:**

Seventy six discrete colonies were isolated from CLED agar plates. The isolates produced cream, yellow or white colonies on CLED and blood agar plates. All the 76 isolates were gram positive cocci. The results of biochemical tests are listed in Table 1.

For isolates A1-A20, the agglutination occurred within 20 seconds signifying the fact that the isolates were *S. aureus*. For B1-B56, there was no agglutination verifying that B12-B56 were not isolates of *S. aureus*.

##### **Results of antibiotic sensitivity test:**

The results are shown in Table 2 and Table 3. The percent efficacy of different antibiotics is listed in Table 4.

## Discussion

The results from this study show that *S. aureus* and *S. epidermidis* were isolated from the urine samples of patients placed on catheter devices. Jernigan and Farr, 1993 reported that the catheter related infections are mainly caused by *C. albicans*, *S. aureus* and *S. epidermidis*. Some studies showed that *S. epidermidis* is a significant nosocomial pathogen, preferentially affecting immunocompromised patients and the cause of septicemia has been frequently associated with wounds and catheters or others indwelling devices (Hunton *et al.*, 1985). CoNs are the most common pathogens complicating the use of intravenous catheters, hemodialysis shunt and grafts, cerebrospinal fluid shunts, peritoneal dialysis catheters, pacemakers wires and electrodes, prosthetic joints, vascular grafts and prosthetic valves (Rupp and Archer, 1994). The results obtained from this study also show that the prevalence of *S. epidermidis* (74%) is higher than that of *S. aureus* (26%) among patients placed on urinary catheter. This agrees with the findings of Buchman *et al.*, 2007 who reported that coagulase negative staphylococcus infections are associated with medical devices and removal of such devices is often required for cure. Fidalgo *et al.*, 1990 showed that *S. epidermidis* is the casual agent of true bacteremia on the basis of microbiologic, epidemiologic and prognostic data on 60 episodes of *S. epidermidis* bacteremia recorded in the hospital Covadonga of Oviedo, Spain during 1982-1986. Fifty one of SEB (*Staphylococcus epidermidis* bacteremia) were associated with indwelling devices, which in 44 cases were intravascular catheters; these included 23 central venous catheters and 21 peripheral intravascular catheters. The duration of catheterization ranged from 3 to 21 days for

patients with central venous catheters and from 5 to 27 days for patients with peripheral intravascular catheters. For catheter insertion, rigorous attention should be given to aseptic techniques which involve washing of hands, application of 2% chlorhexidine to the site before catheter insertion, using of normal saline to flush the devices e.g. arterial catheters. Failure to follow these steps during catheter insertion might be responsible for the prevalence of *S. epidermidis* and *S. aureus* in urine samples of catheter patients in FMC, Yola and SSHY, Yola.

In regard to percentage efficacy of different antibiotics, two isolates of *S. epidermidis* (B24 and B45) were resistant to all the antibiotics tested and less than 50% of the isolates of *S. aureus* were susceptible to all the six antibiotics tested. A feature of *S. epidermidis* is the high rate of multiresistant strains. In this study we found that 60% of the isolates of *S. epidermidis* were resistant to augmentin; 81% were resistant to ofloxacin, 57% to ceftriaxone, 48% to ceftazidime, 54% to cefotaxime, 82% to sparfloxacin, 53% to ciprofloxacin. It has been shown that between 75 and 85% of all health care associated UTIs follow the insertion of a urinary catheter and a study investigating 40 English hospitals estimated that around 26% of all hospitalized patients have a urinary catheter inserted during their stay in hospital (Glynn *et al.*, 2007). Ceftriaxone showed highest antibacterial activity against *S. aureus* isolates with percentage efficacy of 45% followed by ciprofloxacin, cefotaxime (40%) and ofloxacin and others (30%). This resistance might be attributed to the production of chemical substances and endotoxins by the isolates. Yenda *et al.*, 2010 isolated 60 isolates of *S. aureus* from patients attending State Specialist

hospital and out of these 60 isolates, 85% of the isolates were resistant to ofloxacin and 80% of the isolates were resistant to ciprofloxacin. Fidalgo *et al.*, 1990 reported among all isolates of SEB, 50% exhibited resistance to five antibiotics namely Penicillin G, ampicillin, oxacillin, erythromycin and clindamycin. This study shows that less than 50% of isolates of *S. aureus* and *S. epidermidis* were susceptible to quinolone antibiotics (Ofloxacin and sparfloxacin) and to some 3<sup>rd</sup> generation cephalosporins like cefotaxime and ceftriaxone.

## Biochemical and Molecular Genetic Studies on Rice Tolerance to Salinity

\*El-Mouhamady, A.A.; I.S.El-Demandash and K.A.Aboud

Department of Genetics and Cytology, National Research Center, Cairo, Egypt.

\*elmouhamady@yahoo.com    lola\_El-Demandash@yahoo.com    Kamal\_Aboud@yahoo.com

**Abstract:** The present investigation was carried under green house conditions from (october2009) to (march 2010) seasons included two conditions (normal irrigation and salinity) using model of half diallel analysis by five cultivars of rice "Gz1368-S-5-4, Hybrid1, Sakha102, Giza 181 and IET444". Five parents and ten crosses were grown under two conditions and the results showed that:

1. The most desirable mean value were positive and highly significant for heterosis, general and specific combining ability effects for all genotypes under normal and salinity conditions were observed from the genotypes.; Gz1368-S-5-4, hybrid1, IET1444, Gz1368-S-5-4 x hybrid 1, Gz1368-S-5-4 x IET1444, Hybrid 1 x IET1444, Sakha 102 x IET1444 and Giza 181 x IET 1444 under normal and salinity conditions.

2. From the foreign discussion, it could be concluded that the crosses Gz1368-S-5-4 x Hybrid 1, Gz1368-S-5-4 x IET1444, Hybrid 1 x IET1444 and Giza 181 x IET1444 were contained of 1, 5, 1 and 5 bands using PM15 primer, 6, 3, 6 and 6 bands using AY334988 primer and 6, 2, 4 and 5 bands using HL-17 primer, which indicated that these bands were found to be index and marker for salinity tolerance in rice by increasing  $K^+$  content and decreasing of  $Na^+$  content. Journal of American Science 2010;6(11):521-535]. (ISSN: 1545-1003).

**Key words:** Rice, salinity, yield components, some traits related to salinity

### 1. Introduction:

Rice is moderately susceptible to salinity. The degree of injury, however, depends on the nature and concentration of salts, soil pH, water regime, method of planting, seedling age, growth stage of the plant, duration of exposure to salt and temperature.

Most rice cultivars are severely injured in submerged soil cultured on EC of 8-10 dSm<sup>-1</sup> at 25 °C, sensitive ones are damaged even at 2 dSm<sup>-1</sup> (Mass and Hoffman, 1997). Rice that is tolerant to salinity during germination becomes very sensitive during the early seedling stage; gains tolerance vegetative growth again becomes sensitive during pollination and fertilization and then becomes increasingly more tolerant at maturity. Salinity during reproductive stage decreases grain yield much more than salinity during vegetative stage (Akbar and Ponnamperuma, 1982).

Symptoms of salt injury in rice are stunted growth, rolling of leaves, white leaf tips, white blotches in the laminae, drying of older leaves and poor root growth. The percentage of dead leaves is a good measure of salt injury (RRTC, 2002).

### 2. Materials and methods

The present study was carried out under green house conditions during October 2009 to march 2010. Five rice varieties utilized in this study namely, Gz1368-S-5-4, hybrid 1, Sakha 102, Giza 181 and IET1444 were grown on three successive dates of planting at fifteen days intervals in order to overcome the differences in flowering time for each parent. The pedigree of the parental varieties is shown in Table (1). Each parent was grown in five rows, each row was 5 meter long and contained 25 hills. At flowers, the six parents were diallel crossed, i.e., in all possible

Table (1):Origin and main characters of the five rice varieties used as parents in the studied diallel cross

Varieties	Origin	Type	Duration (days)	Grain type	Reaction to salinity
GZ1368-S-5-4	(IR1615-31/BG94-2) Egypt	Indica	140	Short	Tolerant
Hybrid 1	(IRmolesterility/G.178) Egypt	Japonica	135	Short	Moderate
Sakha 102	(Gz4098-7-1/Giz 177) Egypt	Japonica	125	Short	Susceptible
Giza 181	(IR1626-203/IR28//IR22) Egypt	Indica	145	Long	Susceptible
IET1444	(TN1/CO29) Egypt	Indica	135	Long	Tolerant

a,h, Japonica, I, Indica

combinations (excluding reciprocal) to produce following the method proposed by Jodon (1938) and modified by Butany (1961).

In 2010 season, the parents and their F<sub>1</sub> hybrid were growing in a randomized complete block design with three replications in two locations (normal and saline). These cultivars were taken from RRTC (Rice Research and Training Center, Sakha, Kafrel-sheikh).

Fertilizers were added as recommended rate and time of application (15 days after transplanting at the rate of 40 kg N/fed., and 15 kg P<sub>2</sub>O<sub>5</sub>/feddan) and hand weeding was done when it was needed and were chemical controlled by adding 2 liter Saturn/feddan, four days after transplanting. All the data were recorded on the parents and their crosses under two locations. All recommended agriculture practices were applied. At ripening each plant was harvested individually

### Soil analysis:

Before conducting the experiments, soil samples were taken from different sites of the experimental area. Each sample was taken from a depth of 0-30 cm, both soil samples normal and saline treatment. the chemical analysis was carried out for each soil extract 1:5 to estimate the soluble anions, cations and total dissolved salts (TDS). The electrical conductivity (EC) was estimated in the extract of the soil saturate paste. The procedure for preparation and measurements of the soil extract was taken according to the method of Black *et al.* (1965). The methods of Chapman and Parker (1961) of soil chemical analysis were followed. The description of both normal and saline types of soil used in the investigation are shown in Table (2).

Table(2): Some chemical characteristics of experimental soil at normal and saline soil (lyzimeter).

Characteristics	Normal soil (Tap water)	Saline water (Lyziemter)
EC (dS/m)	1.84	7.6-7.8
pH (1:2.5)	7.0	8.5
TDS mg/litre (ppm)	718.50	3216.7-4214.8
Ca <sup>++</sup>	3.90	17.80-19.250
Mg <sup>++</sup>	2.70	14.85
Na <sup>+</sup>	11.34	50.0-54.0
K <sup>+</sup>	0.43	0.14

Cl <sup>-</sup>	16.80	47.30
SO <sub>4</sub> <sup>2-</sup>	1.70	13.70
Texture	Clay	Clay

EC = Electrical conductivity

TDS = Total dissolved salts

\* Measure of soil saturation

\*\* Measure of soil water extract 1:5

For raising seedlings, wooden 60 x nurseries were used which irrigated by tap water. After thirty days from sowing, seedlings of each parent and their crosses were individually transplanted in 1 row, 1 m length for each variety, with a spacing of 15 x 15 cm between rows and recommended culture practices were followed. The plots were salinized 15 days after transplanting and salinization was fixed till harvesting. Plants were irrigated every day by auto-pumping the salt solution from the tanks. Drainage was practiced every 48 hours through bottom out lets and water electrical conductivity (EC) were measured through the crop season.

Studied characters:

A. Yield and its components characters:

1. Heading date (days)

It was determined as the number of days from date of sowing to the date of the first panicle exertion.

2. Plant height (cm):

Length of the main culm was measured from the soil surface to the tip of the main panicle at maturity

3. Number of filled grains per panicle:

Filled grains of the main panicle was separated and counted.

4. 1000-grain weight (g):

Was recorded as the weight of 1000 random filled grains per plant.

5. Grain yield per plant (g):

Was recorded as the weight of grain yield of each individual plant and adjusted to 14% moisture content.

B. Some characters related to salinity:

Were measured to determine the chemical characters Na<sup>+</sup> uptake, K<sup>+</sup> uptake Na/K ratio and salinity index for grain yield/plant.

Determination of Na<sup>+</sup> uptake, K<sup>+</sup> uptake and Na/K ratio:

Shoot sampling was determined 25 days from salinization by using different salinity levels when the sensitive parents were severely affected. the shoot samples were weighed and dried for three days at 70°C. samples were finally grounded and 1 gram dried powder from each sample was taken for Na<sup>+</sup> and K<sup>+</sup> determination by flame photometer.

Salinity index (SI):

The salinity index (SI) for each character was calculated by using the formula of Dwivedi *et al.* (1991).

$$SI = \frac{\text{Value of each character under saline situation}}{\text{value of each character under normal situation}} \times 100$$

Statistical analysis:

At first, the data were analyzed by using the ordinary analysis of variance to test the significance of differences among the genotypes studied (six parents and their crosses). If the genotypes mean squares were found to be significant, there was a need to proceed for further analysis; i.e., Griffing(1956) mode 1, method 2.

Estimation of heterosis effects:

The heterosis of an individual cross was determined for each trait as the increase of the F<sub>1</sub> hybrid mean over its better parent, (i.e. heterobeltiosis), as follows:

$$\frac{\bar{F}_1 - \bar{B.P.}}{\bar{B.P.}}$$

Heterosis over the better parent % =  $\frac{\bar{F}_1 - \bar{B.P.}}{\bar{B.P.}} \times 100$

Where:

$\bar{F}_1$  = Mean value of the first generation.

$\bar{B.P.}$  = Mean value of the better parent.

L.S.D. values were calculated to test the significance of the heterosis effects, according to the following formula suggested by Wyanne *et al.* (1970).

L.S.D. for heterosis over better parent

$$= t \sqrt{\frac{2MSe}{r}}$$

Where:

t = Tabulated value at the specified level of probability for the experimental error.

MSe = The experimental error mean squares

r = Number of replications.

r = Number of replications.

MSeGCA-Mse TERM/B+2

$$GCA/SCA = \frac{MSeGCA-Mse TERM}{MSeSCA-Mse TERM}$$

B: Number of parents

Mse TERM=mean square of error from ANOVA.

According to Griffing (1956).

Estimation of combining ability:

Griffing (1956) stated that the mathematical model in this case was as follows:

$$X_{ij} = U + g_i + g_j + s_{ij} + e_{ijk}$$

Where:

X<sub>ij</sub>= The value of a cross between parent (i) and parent (j)

U= The population mean

g<sub>i</sub>= The general combining ability (gca) effect of the i<sup>th</sup> parental variety.

g<sub>j</sub>=The general combining ability (gca) effect in j<sup>th</sup> parental variety.

s<sub>ij</sub>=Specific combining ability effect (sca) for the cross.

e<sub>ijk</sub> = The mean error effect; (i.e. the environmental effect associated with the individual observations)

Genotypes sum of squares was partitioned into GCAs and SCAs as follows:

SS due to GCA =

$$\frac{1}{P+2} \left( \sum i(x_i + x_{ii})^2 - \frac{4}{P} x^2 \right)$$

SS due to SCA =

$$\sum i < \sum jx_{ij}^2 - \frac{1}{P+2} \sum i(x_i + x_{ii})^2 + \frac{2}{(P+1)(P+2)} x^2$$

The estimates of general combining ability effects ( $\hat{g}_i$ ) and specific combining ability effects ( $\hat{s}_{ij}$ ) were computed as follows:

$$\hat{g}_i = \frac{1}{P+2} (x_i + x_{ii} - \frac{2}{P} X) ..$$

$$\hat{s}_{ij} = x_{ij} - \frac{1}{P+2} (x_i + x_{ii} + x_j + x_{jj}) + \frac{2}{(P+1)(P+2)} x ..$$

The variances of both effects and differences between effects were estimated as follows:

$$\text{var}(\hat{g}_i) = \frac{P-1}{P(P+2)} \sigma^2 e$$

$$\text{var}(\hat{s}_{ij}) = \frac{2P+P+2}{(P+1)(P+2)} \sigma^2 e(i \neq j)$$

$$\text{var}(\hat{s}_{ij} - \hat{s}_{ik}) = \frac{2(P+1)}{(P+2)} \sigma^2 e \quad (i \neq j, k, 1; j \neq K1 \text{ and } K \neq 1)$$

## 2. Biochemical and molecular genetic analysis

### 2.1. PCR-based DNA analysis:

DNA was extracted from the leaves of the selected plants of all genotypes studied which different reaction of salinity "tolerant, moderate and sensitive". The samples were single leaves for parents and first generation according to the method of Graham and Henry (1997).

### 2.2. Gel electrophoresis buffers

TBE buffer	10x
Tris	10.89
Boric acid	5.50 g
EDTA	0.74 g
H <sub>2</sub> O (dd) up to 100 mL	

### 2.3. Loading buffer:

Tris	10.89
Boric acid	5.50 g
EDTA	0.74 g
H <sub>2</sub> O (dd) up to 100 mL	

**Table (3):The primer names and sequences used in PCR analysis**

Primer names	Sequences
(PM15)	5'-CGGTTATGCCAACCGGCAT-3'
(AY334988)	5'-CGTTACCCCTTAAATTCTGA-3'
(HL-17)	5'-AATTCCCTCAGGTTCCCTAAC-3'

### 2.4. Agarose gel electrophoresis:

PCR amplification products were analyzed using 1.5% agarose gel electrophoresis in 1 x TBE buffer and stained with ethidium bromide. the run was performed at 100 V in Bio Rad submarine the bands of amplified DNA were visualized under UV light and the sizes of the fragments were estimated based on a DNA ladder of a 10 to 200 base pairs, and photographed with gel documentation system.

### 2.5. Gel analysis:

Gels were photographed under UV light with Polaroid film 667 and scanned with bio-rad video densitometer model 620, at a wave length of 557 software data analysis for Bio-Rad model 620 USA densitometer and computer were used.

## 3. Results and Discussion

Salinity is a major obstacle to increase production in rice growing areas. In Egypt rice is grown in the northern delta, whereas according to soil survey reports, it had been found that about 1.6 million feddan in the part of this area are damaged by excess soluble salts, exchangeable sodium accumulation and water logging conditions to an extent that causes crop yield reduction.

Rice is considered as moderately salt sensitive crop for the newly reclaimed saline areas. Therefore, developing salinity tolerance rice varieties is a very important approach not only for increasing yields, but also for conquering saline soils.

To develop and sustain high yielding rice varieties combined with salinity tolerance, it is needed to know adequate genetic information about the type and magnitude of the genetic and environmental variations within the genotypes.

### 1. Variation and interaction:

Mean squares of the ordinary analysis and combining ability analysis for all characters under normal and saline soils are presented in Table (4 and 5).

Mean squares of genotypes (parents and their crosses) were found to be highly significant for all characters studied at the normal and saline soil, indicating overall differences among these populations.

Both general and specific combining ability variances were found to be highly significant for all characters studied at two locations except plant height and Na/K ratio under normal conditions. These results would indicate the importance of both additive and non-additive genetic variances in determining the performance of these agronomic characters.

GCA/SCA ratio was used to clarify the nature of the gene action involved. GCA/SCA ratio were found to be greater than unity for grain yield/plant under all conditions, K<sup>+</sup> content, Na/K ratio and salinity index for grain yield/plant under normal and salinity conditions indicates that additive and additive x additive types of gene action were greater importance in the inheritance of these characters. It is therefore, could be concluded that selection procedures based on the accumulation of additive effects, would be successful in improving these characters. These findings were in agreement with those reported by Borgohain and Sharma (1998), El-Refaee (2002) and El-Mouhamady (2009).

### 2. Mean performance

The genotypes mean values for all studied character under normal and salinity conditions are presented in Tables (6 & 7).

For heading date. The earlier plants were obtained from the genotypes, GZ1368-S-5-4, hybrid 1, IET1444, GZ1368-S-5-4 x IET1444, Hybrid 1 x IET1444 and Giza 181 x IET1444 under both conditions. The mean values were ranged from 83.4 to 129.33 day for normal and salinity condition, respectively. These findings were in agreement with those reported by El-Said (2007) and El-Mouhamady (2009).

Regarding plant height, the parents; GZ1368-S-5-4, Hybrid 1 and IET1444 and the crosses; GZ1368-S-5-4 x

Hybrid 1, GZ1368-S-5-4 x IET1444 and Giza 181 x IET 1444 recorded the lowest values of plant height under all conditions. These results were in agreement with those obtained by Weerakoon (2008).

Concerning 1000-grain weight, the most desirable mean values were obtained from the genotypes; Hybrid 1, Sakha 102, IET1444, GZ1368-S-5-4 x Hybrid 1, GZ1368-S-5-4 x IET1444 and Giza 181 x IET 1444 under normal and salinity conditions. These findings were in harmony with those reported by Zhang *et al.* (2007), Weerakoon (2008) and El-Mouhamady (2009).

Regarding number of filled grains/panicle, the highest mean values were obtained from the genotypes; GZ1368-S-5-4, Hybrid 1, IET1444, GZ1368-S-5-4 x IET 1444, Hybrid 1 x IET 1444, Sakha 102 x IET 1444 and Giza 181 x IET 1444 under normal and salinity conditions.

With respect to grain yield/plant, the highest mean performance were showed from the genotypes; Hybrid 1, Sakha 102, IET 1444, GZ1368-S-5-4 x Hybrid 1, GZ1368-S-5-4 x IET1444, Hybrid 1 x IET 1444, Sakha 102 x IET 1444 and Giza 181 x IET 1444 under normal and salinity conditions. The values were ranged from 28.48 to 74.82 (g) for normal and salinity conditions. These results are in conformity with those reported by El-Said (2007) and El-Mouhamady (2009).

For Na<sup>+</sup> content, the most desirable mean values were obtained from the genotypes; Hybrid 1, IET1444, GZ1368-S-5-4 x IET1444, Hybrid 1 x IET1444 and Giza 181 x IET 1444 under normal and salinity conditions because these genotypes recorded the lowest level of Na<sup>+</sup> content from the soil as index for salinity tolerance in rice. These findings were in conformity with that reported by Won *et al.* (1992), Gonzalez *et al.* (1999), and Weerakoon *et al* (2008).

With respect to K<sup>+</sup> content, the genotypes; GZ1368-S-5-4, Hybrid 1, IET1444, GZ1368-S-5-4 x Hybrid 1, GZ1368-S-5-4 x IET1444, Hybrid 1 x IET 1444 and Giza 181 x IET1444 showed the highest mean values for this trait under both conditions. Similar results were obtained by Gonzalez *et al.* (1999) and Weerakoon *et al.* (2008).

Concerning Na/K ratio, the genotypes; Sakha 102, Giza 181, GZ1368-S-5-4 x Giza 181, Sakha 102 x Giza 181 and Sakha 102 x IET1444 gave the highest mean values under both normal and salinity conditions. These results were in agreement with those reported by Alam (1990), Gonzalez *et al.* (1999) and Weerakoon *et al.* (2008).

For salinity index for grain yield/plant, the parents; GZ1368-S-5-4, Hybrid 1, Sakha 102 and IET1444 and the crosses GZ1368-S-5-4 x ET1444, Hybrid 1 x Sakha 102, Hybrid 1 x IET1444, Sakha 102 x IET1444 and Giza 181 x IET1444 were recorded the highest mean values for this trait. Similar results were showed by El-Said (2007) and et al Weerakoon (2008).

### 3. Heterosis:

From Tables (8 and 9) observed the percentages of heterosis over better parents for all the characters studied under normal and salinity conditions.

With respect to heading date and plant height, heterosis percentages were highly significant and negative in the crosses, GZ1368-S-5-4xHybrid 1 and GZ1368-S-5-4 x IET1444 for heading date and the first cross in addition to Hybrid 1 x Sakha 102 and Sakha 102 x Giza 181 for plant height under all conditions, respectively which indicated, that additive gene action played an importance role to control this trait under salinity conditions.. These findings were inconformity with that reported by Sedeek (2006), weerakoon et al (2008) and El-Mouhamady (2009).

Highly significant and positive of heterosis over better parent were showed in the cross; GZ1368-S-5-4 x Giza 181 under all conditions only for 1000-grain weight and the values were 8.47 and 9.72% for normal and salinity conditions. it was found to be useful for specific combining ability which indicated, that additive gene action played an importance role to control this trait under salinity conditions. These results were obtained by El-Said (2007) and El-Mouhamady (2009).

Concerning number of grains/panicle heterosis percentages as deviation from better parents was highly significant and positive in the crosses, GZ1368-S-5-4 x Giza 181 , hybrid 1 x Sakha 102, Hybrid 1 x IET 1444, Sakha 102 x Giza 181, sakha 102 x IET1444 and Giza 181 x IET1444 under normal and salinity conditions and GZ1368-S-5-4 x sakha 102 under salinity conditions only which indicated, that additive gene action played an importance role to control this trait. Similar results were reported by El-Said (2007).

For grain yield/plant, the crosses, GZ1368-S-5-4 x Hybrid 1 under normal conditions, GZ1368-S-5-4 x IET1444 under salinity conditions and Giza 181 x IET1444 under normal and salinity conditions, respectively showed highly significant and positive of heterosis over better parent and the values were ranged from 11.22 to 11.40% under normal condition and from 4.59 to 10.78% under salinity conditions ,respectively. which indicated that additive gene action played an important role in the inheritance of grain yield/plant under salinity conditions. These results were reported by Zhang *et al.* (2007) and El-Mouhamady. (2009).

For Na<sup>+</sup> content, the crosses; GZ1368-S-5-4 x IET1444 , Hybrid 1 x IET1444 and Giza 181 x IET1444 under all conditions showed highly significant and negative of heterosis over better parent which indicated that these parents considered a good combiners for hybridization to make a programme for salinity tolerance . Similar results were obtained by El-Said (2007), Weerakoon *et al.* (2008) and El-Mouhamady (2009).

The genotypes, GZ1368-S-5-4 x Hybrid 1 , hybrid 1 x IET1444 and Sakha 102xGiza 181were showed highly significant and positive of heterosis over better-parent for k<sup>+</sup> content all conditions and the values were ranged from 2.98 to 133.3% and from 2.96 to 139.20% under normal and salinity conditions respectively. which indicated that , additive gene action played an important role in the inheritance of this trait.These findings were in conformity with those reported by Sedeek (2006), El-Said (2007), Zhang *et al.* (2007), Weerakorn *et al.* (2008) and El-Mouhamady (2009).

For Na/K ratio, all crosses showed highly significant and negative of heterosis over better parent for this trait under normal and salinity conditions. Similar results were obtained by Sedeek (2006) and Weerakoon et al (2008).

With respect to salinity index for grain yield/plant, six crosses were showed highly significant and negative of heterosis over better parent for example, GZ1368-S-5-4 x Hybrid 1, GZ1368-S-5-4 x Sakha 102, Hybrid 1 x Sakha 102 and Sakha 102x IET1444. It could be concluded that the most desirable crosses for all traits studied under both normal and salinity conditions were GZ1368-S-5-4 x Hybrid 1, GZ1368-S-5-4 x IET1444, hybrid 1 x IET1444 and Giza 181 x IET1444.

#### 4. Combining ability

##### 4.1. General combining ability

Estimates of the GCA effects of individual parental lines for all characters studied under normal and salinity conditions are present in Tables (10 and 11).

The varieties GZ1368-S-5-4, Hybrid 1 and IET1444 showed highly significant and negative of general combining ability effects under two conditions for heading date and plant height characters, indicating that these varieties can be considered as a good combiners for these traits under normal and salinity conditions, and found that earliness was controlled by over-dominance. These results were in agreement with the data obtained by Sedeek (2006), El-Said (007) and Weerakoon *et al.* (2008).

Highly significantly and positively of GCA effects was showed in the genotypes; Hybrid 1 and IET1444 for 1000-grain weight and grain yield/plant under the two conditions , while number of filled grains/panicle was under normal conditions only, it is clear that these varieties were found to be the best combiners for these traits and indicating that additive x additive types of gene action were of greater importance in the inheritance of this traits under both conditions. These results were in agreement with those reported by El-Mouhamady (2009).

The parents; Hybrid 1 and IET144 under both conditions and GZ1368-S-5-4 under normal conditions only showed significant and highly significant negative GCA effects for Na<sup>+</sup> content, While, hybrid 1 and IET1444 under two conditions and GZ1368-S-5-4 under normal conditions showed highly significant and positively of GCA effects for K<sup>+</sup> content.

On the other hand, the genotypes, sakha 102 under all conditions,Giza 181 under salinity conditions for Na/k ratio and the same cultivar in addition to IET1444 for salinity index for grain

yield/plant observed significant and highly significant and positive of GCA effects, which proving to be good combiners for these traits, proving to be good combiners for this traits, which indicating the importance of both additive and non-additive variances in the expression of this traits in rice. Similar results were obtained by Singh and Kumar (2005) and Weerakoon et al. (2008).

Since significant negative values of GCA effects would be of interest for earliness and short stature rice cultivars in Tables (10 and 11) for heading date, plant height and Na<sup>+</sup> content in the genotypes ; Hybrid 1 and IET1444 provide to be good combiners under both conditions, could be useful for rice breeders who breed for earliness or short stature rice cultivars and low level of Na<sup>+</sup> content considering the GCA effects for yield and its components, K<sup>+</sup> content, Na/K ratio and salinity index for grain yield/plant, it was suggested that population involving the parents GZ1368-S-5-4, Hybrid 1 and IET 1444 could be considered in making multiple crossing because they might possess desirable genes for earliness, short stature as well as high grain yielding ability under normal and salinity conditions. Accordingly, these parents would be the best choice as base populations.

From the foregoing discussion, it could be concluded that, the most desirable genotypes for grain yield and its components and some characters related to salinity under normal and salinity conditions were GZ1368-S-5-4, Hybrid 1, IET1444, GZ1368-S-5-4 x IET1444, Hybrid 1 x IET1444, Sakha 102 x IET1444 and Giza 181 x IET1444, which indicated the importance for the earlier selection for these traits under salinity conditions.

##### 4.2. Specific combining ability effects:

SCA effects for the parental combinations under the two conditions (normal and salinity) are shown in Tables (12 & 13).

For heading date, four out of ten hybrid combinations had negative and highly significant desirable SCA effects under normal and salinity conditions. The best crosses were GZ1368-S-5-4 x Hybrid 1, GZ1368-S-5-4 x IET1444, Sakha 102 x IET1444 and Giza 181 x IET1444 for this trait under two conditions. These results were in agreement with those reported by Aidy *et al* (2006) and El-Said (2007).

Concerning plant height, four out of ten hybrid studied showed highly significant and negative of SCA effects under both conditions. These results obtained in the crosses; GZ1368-S-5-4 x Hybrid 1, Hybrid 1 x Sakha 102, Sakha 102x Giza 181 and Giza 181 and x IET1444, indicated that additive and additive x additive types of gene action were of greater importance in the inheritance of plant

height and These crosses were found to be the useful crosses for heterosis. which indicated that these crosses were by Bindu and shashidhear (2006) and El-Mouhamady (2009).

For 1000-grain weight, the crosses; GZ1368-S-5-4 x Hybrid 1, GZ1368-S-5-4 x IET1444 , GZ1368-S-5-4 x Giza 181 and Giza 181x IET1444 showed highly significant and positive SCA effects under normal and salinity conditions. These crosses were found to be very important for salinity tolerance in rice by the interaction between additive and additive x additive gene actions These findings were in agreement with those reported by Weerakoon *et al.* (2008).

With respect to number of filled grains/panicle, six out of ten crosses studied had positive and highly significant of SCA effects under normal and salinity conditions. These crosses were GZ1368-S-5-4 x Hybrid 1, GZ1368-S-5-4 x IET 1444, Hybrid1 x Sakha102, Hybrid 1 x IET1444,Sakha 102xGiza 181 and Giza 181 x IET 1444. The same results were obtained by Bindu and shashidhear (2006) and El-Said (2007).

For grain yield/plant, four out of ten crosses showed highly significant and positive of SCA effects. The best of these crosses were GZ1368-S-5-4 x Hybrid 1 under salinity conditions, GZ1368-S-5-4 x IET1444,Sakha 102 X IET 1444 and Giza 181 x IET1444 under all conditions, which were found to show useful heterosis for this trait under normal and salinity conditions, which indicated that these crosses were found to be useful for salinity tolerance in rice and indicating the importance of both additive and non-additive variances in the expression of these trait in rice.. Similar results were showed by Aidy (2006), Bindu and shashidhear (2006), Abd El-Lateef *et al.* (2006) and Weerakoon *et al.* (2008).

Regarding of  $\text{Na}^+$  content, the crosses, GZ1368-S-5-4 x IET1444, Hybrid 1 x Sakha 102, Hybrid 1 x Giza 181,Sakha 102 x IET1444 and Giza 181 x IET1444 showed highly significant and negative of SCA effects under normal and salinity conditions, which indicated that these crosses were very important for development salinity tolerance in rice. Similar results were obtained by El-Mowafy (1954), Bindu and shashidhear (2006) and Weerakoon *et al* (2008).

The crosses; GZ1368-S-5-4 x Hybrid 1, GZ1368-S-5-4 x Sakha 102, Hybrid 1 x IET1444, Hybrid 1 x Sakha 102, Sakha 102xGiza 181, Sakha 102 x IET1444 and Giza 181 x IET1444 were

showed highly significantly and positively of SCA effects under all conditions for  $\text{K}^+$  content. These crosses were found to be useful for heterosis and important for salinity tolerance of rice. These results were in agreement with those reported by Bindu and shashidhear (2006) and Weerakoon *et al* (2008).

Highly significant and positive of SCA effects for Na/K ratio were found in the crosses; GZ1368-S-5-4 x Hybrid 1 and Hybrid 1 x IET1444 under salinity conditions only, proving to be the best crosses for this trait and indicating the importance of additive and non-additive genetic variance in the inheritance of these characters and that selection for these traits would be effective in early segregating generations. These results were in agreement with those reported by El-Mowafy (1994), Cheong *et al.* (1995) and El-Said (2007).

For salinity index for grain yield/plant, the crosses GZ1368-S-5-4 x IET 1444 and Giza 181 x IET 1444 showed significant and highly significant and positive of SCA effects for this trait. Similar results were showed by Cheong *et al.* (1995), Zhang *et al.* (2007) and El-Mouhamady (2009).

It was obvious in Tables (12 and 13) that most of the crosses showing high SCA effects involved diverse parents. The superior F's having SCA effects are expected to produce desirable transgressive segregates, provided that the desirable complementary genes and epistatic effects are coupled in the same direction to maximize these traits in view.

Also, desirable SCA effects in the crosses, GZ1368-S-5-4 x Hybrid 1, GZ1368-S-5-4 x IET1444 and Giza 181 x IET1444 might be recommended to be utilized in hybrid rice breeding. The population would posses desirable genetic for yield components and salinity traits, which indicated that this different origin of these parent would widen the genetic base for selection.

## 5.Biochemical genetic markers:

The importance and need of rice genotypes at global level requires evaluation of germplasm to assist the future of Salinity tolerance programs. Hence, it is essential top characterize rice genotypes using PCR-based markers such as PM15 primer in Table (14), Figure (1).

Table (12): Estimates of specific combining ability effects for the crosses evaluated for yield and its components characters studied under normal and salinity conditions.

The results indicated that the bands number 1, 2, 3, 9 and 10 were found in the parents; GZ1368-S-5-4, Hybrid 1, Sakha 2 and the crosses; GZ1368-S-5-4 x IET1444, Hybrid 1 x Sakha 102, Hybrid 1 x Giza 181 and Giza 181 x IET 1444, which indicated that these bands were common bands in these genotypes and were index for salinity tolerance in rice. This high degree of polymorphism for these DNA markers could be a very powerful tool for studying the phylogenetic relationships among rice genotypes.

These results were found by Champoux *et al.* (1995), Roy *et al.* (1996), Yadav *et al.* (1997), Price and Tomas (1997), Thank *et al.* (1999), Tripathy *et al.* (2000), Zhang *et al.* (2001), Courtois *et al.* (2003), Lanceras *et al.* (2004), Weerakoon *et al.* (2008) and El-Mouhamady. (2009).

The bands number 1, 2, 3, 8, 9 and 10 were appeared in the genotypes; GZ1368-S-5-4, Hybrid 1, IET1444, GZ1368-S-5-4x Hybrid 1, GZ1368-S-5-4 x Sakha

#### 4. Conclusion

1.The most desirable mean value , positive and highly significant for heterosis, general and specific combining ability effects for all genotypes under normal and salinity conditions were obtained from the genotypes.: GZ1368-S-5-4, IET1444, GZ1368-S-5-4 x hybrid 1, Gz1368-S-5-4 x IET1444 and Giza 181 x IET 1444 for all traits studied.  
 2.From the foreign discussion, it could be concluded that the crosses GZ1368-S-5-4 x Hybrid 1, G21368-S-5-4 x IET1444, Hybrid 1 x IET1444 and Giza 181 x IET1444 were contained of 1, 5, 1 and 5bands using PM15 primer, 6,

3, 6 and 6 bands using AY334988 and 6, 2, 4 and 5 bands using HL-17 primer, which indicated that these bands were found to be index and marker for salinity tolerance in rice by increasing K<sup>+</sup> content and decreasing of Na<sup>+</sup> content.  
 3.The crosses GZ1368-S-5-4 x hybrid 1and Giza 181 x IET 1444 were the best crosses for salinity tolerance in rice and were important for breeder to selection the cultivars for the earlier and short stature would be the best choice as base populations.

**Abstract:** Two field experiments were conducted during two successive seasons of 2008/2009 and 2009/2010 at the Agricultural Experiments Station of the National Research Centre at Nobariya, Behaira Governorate, Egypt, to study the effect of adding urea or ammonium sulphate at 2% to herbicide solution on weed control efficiency in onion fields. Weed control treatments were as follows: Metosulam at 20 ml/fed or Clodinafop-propargyl at 70g/fed with or without addition of urea or ammonium sulphate (AMS) at 2% of herbicide solution in comparison to Metosulam at 40 ml/fed, Clodinafop- propargyl at 140g/ fed, Metosulam at 20 ml + Clodinafop- propargyl at 70 g / fed, two hand hoeing and unweeded check. All weed control treatments significantly depressed weed growth when compared to the unweeded one. Two hand hoeing showed the best control of broadleaved weeds in both seasons, followed by that of Metosulam at 40 ml, Metosulam + urea and Metosulam + AMS treatments, respectively. Clodinafop – propargyl at 140 g, Clodinafop – propargyl at 70 g, Clodinafop – propargyl + urea, Clodinafop – propargyl + AMS and Metosulam + Clodinafop – propargyl were very effective in controlling most grass weeds. Meanwhile, hand hoeing, Metosulam + Clodinafop – propargyl, Metosulam at 40 ml and Clodinafop – propargyl at 140 g /fed were the most effective in controlling onion weeds. All herbicidal treatments as well as hand hoeing markedly increased onion yield in both seasons. Maximum values of bulb length, diameter, weight and bulb yield (t/fed) were recorded from Metosulam + Clodinafop – propargyl, Metosulam at 20 ml and hand hoeing twice.

**Keywords:** Onion, Urea, Ammonium sulphate, Metosulam, Clodinafop-propargyl, weeds.

### 1. Introduction:

Onion (*Allium cepa* L.) is one of the most important field and vegetable crops for both local or export market in Egypt. Weeds in transplanted onion fields not only compete with onion seedlings for growth factors but also act as hosts of insects and fungal diseases such as downy mildew that in turn infest onion plants (Ghalwash *et al.*, 2008). Unlike most crops, onion plants grow slowly and do not form a leaf canopy because of their upright growth habit. This character of onion makes competition with weeds very poor. Thus, onion is the least competitive crop against weeds (Karim *et al.*, 1998). Weed growth reduce the yield of transplanted onion by 26 – 48 % (Babiker and Ahmed, 1986).

Weed control in onion fields must be carried out, especially at the early developmental stages. Due to the severe shortage of hand labour with highly paid wages, hand weeding has become uneconomical processes. Consequently, chemical weed control would be a highly demanded alternative to decrease the cost and increase the economic return due to the increase in onion yield.

Effective weed control and high yield of onion were achieved by application of hand hoeing (Radwan and Hussein; 2001, El-Sayed *et al.*, 2002 and Ghalwash *et al.*, 2008), Clodinafop – propargyl (Khan *et al.*, 2005 and Ghalwash *et al.*, 2008) and Metosulam (El-Metwally, 2002; Sharara *et al.*, 2006; Ghalwash *et al.*, 2008 and El-Metwally and Saudy, 2009). However, the recommended dose of herbicide is relatively high and hence its cost is high and too expensive under the Egyptian conditions. Recently, some evidences have been gathered that adding some additives, especially the nitrogenous fertilizers to herbicide solution could increase its activity, consequently the dose could be lowered and its cost price could be decreased. Moreover, lowering the dose of any herbicide is much appreciated from the point of view of minimizing pollution. In addition, Metwally and Hassan (2001) and El-Metwally (2002) recorded that using some herbicides with urea or ammonium sulphate had higher efficiency in controlling annual weeds and increased yield and its components of wheat or maize as compared with other treatments used.

Therefore, the objective of this work was to study the effect of adding urea or ammonium sulphate to herbicide solutions on weed control efficiency in onion crop.

## 2. Materials and methods

Two field experiments were carried out during the two successive seasons of 2008/2009 and 2009/2010 at the Experimental Station of the National Research Centre at Nobariya, Behaira Governorate, Egypt, to study the influence of adding urea or ammonium sulphate at 2% (equall 4kg/fed) of herbicide solutions on weed control efficiency in onion crops. The soil of the experiments was sandy, the mechanical analysis (Piper, 1950) and chemical analysis (Jackson, 1960) of the soil were carried out before sowing and presented in Table (1).

**Table (1): Mechanical and chemical analysis of Nobariya soil before executing experiment.**

Components		Value
Mechanical analysis	Sand %	75.6
	Silt %	17.4
	Clay %	5.5

m. equivalent / 100 g soil

A complete randomized blocks design with three replications was used in the two seasons. Weed control treatments were as follows:

- 1- Metosulam (N- 2,6 – dichloro – 3 –methyl phenyl – 5.7 – dimethoxy – (1,2,4) Triazolo (1,5a) pyrimidine – 2- sulphona mide), known commercially as Sinal 10 Sc sprayed after 30 days from transplanting at the rate of 40 ml/ fed.
- 2- Metosulam at 20 ml/fed.
- 3- Metosulam at 20 ml + urea at 2%.

- 4- Metosulam at 20 ml +ammonium sulphate (AMS) at 2%.
- 5- Clodinafop – propargyl (Prop – 2 – ynyl – (R) – 2 – (4-(5-chloro- 3- fluoro pyridine – 2- yloxy) phenoxy) = propionate , known commercially as Topik 15 WP sprayed after 50 days from transplanting at the rate of 140g/fed.
- 6 - Clodinafop – propargyl at 70 g / fed.
- 7- Clodinafop – propargyl at 70 g + urea at 2%.
- 8- Clodinafop – propargyl at 70 g + AMS at 2%.
- 9- Metosulam at 20 ml + Clodinafop – propargyl at 70 g / fed.
- 10- Hand hoeing after 30 and 50 days from transplanting (DFT).
- 11- Unweeded check (control) without hoeing or herbicide.

The herbicides were applied with knapsack sprayer equipped with one nozzle boom and water volume was 200 L/ fed (fed=4200m<sup>2</sup>). The drip irrigated was the irrigation system. Each treatment plot consisted of 3 lateral lines, each was 10 m long, 70 cm distances between drip lateral lines. The treatments plot area was 21 m<sup>2</sup>. Onion plants were transplanted in two sides of drip lateral lines, 20 cm apart between the plants. Seedlings of onion cultivar (Giza 6) were transplanted at the last week of December in the two seasons. The previous summer crop in both seasons was peanut (*Arachis hypogaea* L.). All agronomic practices for growing onion were done as recommended.

Data recorded were:

### A -Weeds:

Weeds were hand pulled randomly from one square meter from each plot after 75 and 110 days after transplanting and then were identified and classified to broadleaved, grasses and total weeds. Number and dry weight of each category was estimated.

### B- Bulb characters and onion yield:

At harvest time, ten bulbs were chosen at random from each plot and the following data were recorded:

- 1- Bulb length    2 – Bulb diameter
- 3- Bulb weight    4- Bulb yield (t/fed)

### C- Some chemical constituents of onion bulbs:

- a- Nitrogen, phosphorus and potassium contents (NPK)

Nitrogen, phosphorus and potassium contents were determined in dried tissues of onion bulbs according to the official and modified methods of analysis (A.O.A.C., 1984).

### b- Total carbohydrate contents

Total carbohydrates in onion bulbs were extracted according to Herbert *et al.* (1971) and estimated colourimetrically by the phenol-sulphuric acid method as described by Montogomery (1961).

### Statistical analysis:

All data were statistically analyzed according to the technique of analysis of variance (ANOVA) of a randomized complete blocks design. Since the obtained results of the two seasons of experiment were with the same trend, combined analysis was followed for the two seasons (Little and Hills, 1978). Least significant difference (LSD) method was used to test the differences between treatment means at 5% level probability (Gomez and Gomez, 1984).

## 3. Results and Discussion:

### Effect of different weed control treatments on:

#### A- Onion weeds:

The common weeds in both growing seasons of onion crop were:

*Chenopodium album* L.; *Ammi majus* L.; *Coronopus squamatus*, L. *Melilotus indicus* L. and *Centaurea calcitrapa* as broadleaf weeds, while the grassy weeds were *Avena fatua* L.; *Lolium multiflorum* L. and L. The effect of different weed control treatments on number and dry weight of onion weeds after 75 and 110 days from transplanting are presented in Tables 2, 3 and 4.

#### 1- Broadleaved weeds:

The results in Table 2 showed significant effects on number and dry weight of broadleaved weeds after 75 and 110 days from transplanting in both seasons. Hand hoeing exerted the highest reduction in number and dry weight of broadleaved weeds, followed by Metosulam at 40 ml, Metosulam + urea and Metosulam + ammonium sulphate treatments, respectively. These treatments decreased dry weight of broadleaved weeds than unweeded treatment by about 84.2, 60.9, 59.6 and 59.1 % at 75 days and by 86.3, 66.7, 64.2 and 63.8 %, at 110 days from transplanting, respectively.

#### 2- Grass weeds:

Number and dry weight of grass weeds were significantly decreased by different weed control treatments (Table 3). Clodinafop - propargyl at 140 and 70 g with or without urea, ammonium sulphate or Metosulam were very effective in controlling most grass weeds at 75 and 110 days from transplanting. These treatments decreased dry weight of grass

weeds by 93.3, 91.1, 89.4, 89.2 and 86.6 % at 75 days and by 94.4, 91.8, 90.6, 89.7 and 89.6 %, at 110 days from transplanting.

#### 3- Total weeds:

It is obvious from the results in Table (4) that weed control treatments revealed significant decrease on number and dry weight of total weeds. Hand hoeing twice, Metosulam + Clodinafop – propargyl, Metosulam at 40ml and Clodinafop – propargyl at 140 g /fed recorded the highest efficiency in decreasing total number of weeds at 75 and 110 days from transplanting. These treatments reduced number of total weeds than unweeded check by 84.3, 68.1, 59.1 and 53.8 %, at 75 days and by 83.3, 69.7, 60.8 and 55.6%, at 110 days from transplanting. Two hand hoeing, Metosulam + Clodinafop – propargyl, Clodinafop – propargyl at 140 and 70 g /fed treatments were very effective in controlling onion weeds when compared with other weed control treatments at 75 days from transplanting. These treatments reduced the total dry weight of weeds by 85.0, 67.5, 59.2 and 57.4 %, respectively, as compared to unweeded check. With regard to dry weight of total weeds at 110 days from transplanting, results in Table (4) cleared that the highest efficiency in decreasing dry weight of total weeds was obtained from plots treated with hand hoeing, Metosulam + Clodinafop – propargyl, Clodinafop – propargyl at 140 g, Metosulam at 40 ml and Clodinafop – propargyl at 70 g /fed + urea. These treatments decreased dry weight of total weeds than unweeded treatment by 84.2, 72.8, 62.00, 59.6 and 54.9 %, respectively at 110 days from transplanting.

Generally, results in Tables 2, 3 and 4 revealed that all herbicidal treatments used alone or mixed with urea or ammonium sulphate and hand hoeing decreased statistically the number and dry weight of broad leaved, grasses and total weeds grown with onion crop as compared with unweeded treatment. These results may be due to the inhibitory effect of herbicidal treatments on weeds growth. Two hand hoeing, Metosulam + Clodinafop – propargyl, Metosulam at 40 ml, Clodinafop – propargyl at 140 g and Metosulam + urea were the most effective for controlling the weeds. Also, Clodinafop – propargyl at 70 g, Clodinafop – propargyl + urea, Metosulam + ammonium sulphate, Metosulam + urea and Clodinafop – propargyl + ammonium sulphate treatments produced a promising effect against weed prevailing in onion fields compared with unweeded treatment. Such results may be due to that urea or ammonium sulphate had capacity to give synergistic effects with herbicides used that reflected by the higher reduction in weed growth. Similar results on the synergistic effect of herbicide and ammonium

sulphate on broad leaved weeds were obtained with Abouziena *et al.* (2009-a). In this connection, it is worthy to mention that Suwnnamek and Parker (1975) found that the synergistic mechanism of urea or ammonium sulphate when mixed with Glyphosate could be attributed to some degree of activation inside the weed plants. Abouziena *et al.* (2009-b) reported that adding AMS to the glyphosate solution increased absorption and translocation of glyphosate to 90 and 67%, respectively. Similar results were

recorded by many investigators, who showed that effective control of weeds could be obtained with Metosulam(Sharara *et al.*,2006; Ghalwash *et al.*, 2008 and El-Metwally and Saudy, 2009 ), Clodinafop – propargyl (Saini and Angiras, 2005; El-Metwally and El- Rokiek,2007 and Ghalwash *et al.*, 2008 ) as well as hand hoeing twice (Ishwar *et al.*, 2000; Ved-Prakash *et al.*,2000; Kolhe, 2001 and Ghalwash *et al.*, 2008).

**Table (2): Effect of herbicide treatments alone or mixed with urea or ammonium sulphate (AMS) on number and dry weight of broadleaved weeds after 75 and 110 days from transplanting (Combined analysis for 2008 / 2009 and 2009/2 010 seasons).**

**B – Bulb criteria and onion:****1 – Bulb length:**

Bulb length significantly influenced by the different weed control treatments in both seasons (Table 5). The highest values of bulb length were recorded with Metosulam + Clodinafop – propargyl, Metosulam at 20 ml, Metosulam + urea, hand hoeing and Clodinafop – propargyl at 140 g, respectively. On the other side, unweeded plots resulted in the lowest values of bulb length. Similar results were recorded by Rizk *et al.* (1995).

**2 – Bulb diameter:**

Results in Table (5) indicated that maximum bulb diameter was obtained from the application of Metosulam + Clodinafop – propargyl followed by Metosulam at 20 ml, hand hoeing twice, Metosulam + ammonium sulphate and Metosulam + urea. These treatments increased the bulb diameter by 43.3, 36.2, 31.2, 26.1 and 24.1 %, over unweeded check. These results are coincided with those reported by Ghosheh (2004) and Ghalwash *et al.* (2008).

**3 – Bulb weight:**

Controlling onion weeds with Metosulam + Clodinafop – propargyl recorded the highest values of bulb weight followed by Metosulam at 20 ml, hand hoeing twice, Metosulam + ammonium sulphate and Metosulam + urea, respectively (Table 5). Formentioned superior treatments increased bulb weight than unweeded treatment by 125.6, 100.0, 86.1, 77.0 and 70.3 %, respectively. Chemical and mechanical weed control treatments reduced weed competition and thus afforded more efficient

utilization of available resources to onion plants to produce plants having more bulb diameter, length and weight than weedy check plants. The same conclusion was mentioned by Radwan and Hussein (2001); El-Sayed *et al.* (2002); Ghosheh (2004) and Ghalwash *et al.* (2008).

**4 – Yield of bulbs/ fed:**

The results in Table (5) indicate that Metosulam + Clodinafop – propargyl gave the highest onion yield and recorded 6.43 ton / fed increases over weedy check treatment, followed by Metosulam at 20 ml , hand hoeing twice, Metosulam + ammonium sulphate and Metosulam + urea. The superiority of herbicidal treatments and hand hoeing treatment might be attributed to that onion plants exposed to low weed competition as a result of eliminating weed and its negative impacts on onion plants. Weeds compete with onion plants for water, light and nutrients and the feasibility of maintaining high yield with good quality in absence of effective weed control is strongly doubtful. The above results are in agreement with those obtained by Sanjeev *et al.* (2003); Ghosheh (2004); Sharara *et al.* (2006) and Ghalwash, *et al.* (2008).

**C- Some chemical constituents of onion bulbs:****Nitrogen, phosphorus and potassium contents:**

The results in Table (6) indicate that there were significant increases in the contents of N, P and K in onion bulbs due to different herbicide treatments alone or in combination with urea or ammonium sulfate in comparison to the corresponding controls.

Maximum level of N content in bulbs was recorded with Metosulam + Clodinafop – propargyl followed by combined treatment of Clodinafop – propargyl with ammonium sulfate and its single treatment at 70g / fed. Phosphorus content in onion bulb was significantly less in all treatments relative to unweeded check, except in Metosulam + Clodinafop–propargyl treatments. Moreover, the content of K in onion bulbs (Table 6) exhibited the highest value with the combined treatment of Clodinafop – propargyl and ammonium sulfate followed by Metosulam at 40 ml/fed. Significant increment of nutrient contents in bulb onion (Table 6) may be attributed to the reduction of weed competition with onion plant due to the herbicide treatments alone, their combinations with urea or ammonium sulfate (Metwally and Hassan, 2001, El-Metwally, 2002 and

Sharara, *et al.*, 2006), or hand hoeing (Radwan and Hussein, 2001 and El-Sayed *et al.*, 2002).

#### Total carbohydrate contents

Using the herbicides alone as well as their combinations with urea or ammonium sulfate caused significant increase in total carbohydrate contents in onion bulbs (Table 6). Hand hoeing was the most effective in increasing total carbohydrate as compared to control followed by Metosulam + urea (Table 6). On the other hand, the least carbohydrate content was recorded in onion bulbs of that unweeded plots. The results of increasing carbohydrate contents in bulbs of onion due to hand hoeing or herbicide treatments alone or their combination with urea or ammonium sulfate were previously mentioned by Rizk, *et al.* (1995); Metwally and Hassan, 2001 and El-Sayed *et al.* (2002).

**Table (5): Effect of herbicide treatments alone or mixed with urea or ammonium sulphate on bulb criteria and onion yield at harvest (Combined analysis for 2008 / 2009 and 2009 /2010 seasons).**

Treatments	Bulb length (cm)	% of increasing	Bulb diameter (cm)	% of increasing	Bulb weight (g)	% of increasing	Bulb yield (t / fed)	% of increasing

**Abstract:** A survey of the prevalence of gastro-intestinal tract (GIT) parasites in 240 sheep was conducted in different area in the zoo garden (110) and in Sinai district (130) during the period of March 2009 to February 2010. The overall prevalence of infections with nematodes; fasciola and coccidiosis in sheep in Sinai and zoo garden were 66/240 (27.5%); 24/240 (10.0%) and 16/240 (6.7%) respectively. Of the 240 examined sheep, 12.5%; 0.0% and 8.6 % young lambs (1-6 month), 37.7%; 6.9 % and 9.2 % immature sheep (>6-12 months) and 17.1 %; 21.4 % and 1.4 % adult sheep (>one yr) were infested with nematodes, fasciola and coccidia respectively. Most of the animals examined during the present survey had low to moderate infestation. Serum biochemical parameters revealed that serum calcium, inorganic phosphorus, magnesium, copper and iron levels were significantly decreased in all parasitic infested animals. All treated sheep showed significant improvement & disappearance of most clinical signs and significant decrease of egg per gram (EPG) with complete disappearance of eggs in 5<sup>th</sup> day; 4<sup>th</sup> day and 6<sup>th</sup> day post treatment with albendazole (valbazine); doramectin (dectomax) and trichlabendazole (fasinex) respectively. There were gradual increases in the levels of biochemical parameters in 3 groups after one and two weeks post treatment and their levels reached nearly similar to standard levels after 3 week post treatment. Study surveys suggest, appropriate parasitic control approach be explored and tried in order to alleviate the problem of worm burden.

[Abouzeid. N.Z.; Selim. A. M. and El-Hady K. M. Prevalence of gastrointestinal parasites infections in sheep in the Zoo garden and Sinai district and study the efficacy of anthelmintic drugs in the treatment of these parasites. Journal of American Science 2010;6(11):544-551]. (ISSN: 1545-1003).

**Key words:** gastro intestinal parasites, sheep, Zoo garden, Sinai, anthelmintics & biochemical parameters.

## 1. Introduction

Gastrointestinal tract (GIT) parasites are known to be widespread in animals. The direct losses caused by these parasites are attributed to acute illness and death, premature slaughter and rejection of some parts at meat inspection. Indirect losses include the diminution of productive potential such as decreased growth rate, weight loss in young growing animals and late maturity of slaughter stock (**Hansen and Perry 1994**). The infections are either clinical or sub clinical, the latter being the most common and of great economic importance (**Allonby and Urquhart 1972; Msanga 1985; Makundi et al 1998**). Although clinical parasitism has received considerable attention as a result of obvious severity, the study of parasitism in herds without clinical signs of infection has been largely neglected. A review of the literature, however, indicates that only a limited number of studies have been undertaken to provide information on the prevalence, distribution and epidemiology of various species of parasites in sheep . A study was designed to determine the prevalence and intensity of GIT helminthes in sheep in the zoo garden and in

Sinai district and determine the efficacy of anthelmintics in treatment of gastrointestinal nematodes and fasciola.

## 2. Material and Methods

### 2.1. Animals

Sheep used in this study belonged to Sinai district and zoo garden during March 2009 to February 2010. A total of 240 sheep of all sexes and ages, categorized into: young stock (1-6months) [n =40], immature (6-12months) [n =130] and adult (>one yr) [n =70] were used in the study. The animals had not been drenched for at least 8 week prior to sampling. The study herd selection was carried out with the help of veterinarians who were trained to carry out veterinary services in their respective wards or villages in Sinai. Due to the absence of written records, the age of animal was estimated by dentition. Jugular blood for serum collection was also harvested from treated groups in Sinai before and weekly (up to 3 weeks) after treatment. Obtained sera were used to determined serum biochemical parameters.

## 2.2. Sampling and faecal analysis

The faecal samples were collected per rectum and or freshly dropped faeces with new, unused gloves for each animal. Collected samples were put into faecal pots, labelled and kept cool prior to transportation to the laboratory where they were immediately examined or stored at refrigerated temperature ( $4^{\circ}\text{C}$ ) for a maximum of one day before processing. The sedimentation and floatation technique as described by *Soulsby, (1986)* was used to detect the presence of eggs of liver fluke (*fasciola*) and nematodes in the samples. The presence of coccidian oocysts was also recorded. Worm identification through culturing faecal samples were done according to (*Abd El-Gwad, 1974*) and the identification of gastrointestinal nematodes larvae were done according to *Moning (1963)*. The degree of infestation was determined by counting the ova per gram faeces through MC Master Technique according to *Moning (1963)* (100-250 EPG – Not a significant amount ; 250-500 EPG – Low infection level ; 500-1000 EPG – Moderate infection level and >1,000 EPG – High infection level).

The degree of anaemia was determined through The FAMACHA<sup>©</sup> system (system involves checking the color of the mucous membrane of the eye in order to determine the extent of anemia and thus, the level of infestation by internal parasites (*Waller, 2004*). The system categorizes animals on a scale of 1 to 5, with 5 being reserved for the most anemic animals.

## 2.3. Studying the efficacy of valbazine, dectomax and fasinex

Fifteen naturally infested sheep in Sinai were selected and classified into 3 groups.

**1<sup>st</sup> group:** five sheep naturally infested with gastrointestinal nematodes and administered orally with albendazole tablet (Valbazine) at dose level 10 mg/kg B.W.

**2<sup>nd</sup> group:** five sheep naturally infested with gastrointestinal nematodes and administered S/C with doramectin (dectomax) at dose level 200 µg/kg B.W.

**3<sup>rd</sup> group:** five sheep naturally infested with *fasciola* and administered orally with trichlabendazole (fasinex) at dose level 12 mg/kg B.W.

Daily observation of all treated sheep and record any changes of clinical signs. Faeces from each sheep were examined daily to evaluate the efficacy of the used drugs using the following equation (Clearance % =  $a - b/a \times 100$ ). Where  $a$  = mean No. of EPG recorded at zero day;  $b$  = mean No. of EPG recorded at day of observation. Serum samples

of sheep in the 3 groups before and weekly (until 3 week) after treatment were subjected to determine the calcium, inorganic phosphorus, Magnesium, iron and copper by buck scientific atomic absorption spectrophotometer according to *Official Method of Analysis (1974)*.

## 2.4. Statistical analysis

The statistical analysis of data using T. test and ANOVA was carried out according to the method of *Snedecor and Cochran (1989)*

## 3. Results

Regarding to clinical signs due to parasitic infestation which were varied from asymptomatic to adverse signs as diarrhea, paleness or ictric of visible mucous membrane (more than 3 scores), emaciation, shedding of wool and submandibular edema.

### The overall prevalence rates

The overall prevalence of infections with nematodes; *fasciola* and coccidiosis in sheep in Sinai and zoo garden were 66/240 (27.5%); 24/240 (10.0%) and 16/240 (6.7%) respectively (Tabel 1 and Fig. 1&2).

**Table 1.** Farm prevalence of parasites according to localities

Locality	NO	Nematodes		Fasciola		Coccidia	
		+ve	%	+ve	%	+ve	%
Sinai	130	32	24.6	5	3.8	4	3.1
Zoo	110	34	30.9*	19	17.3**	12	10.9**
Total	240	66	27.5	24	10.0	16	6.7

At the column level \*Significant at  $\geq 0.05$  \*\* significant at 0.01

### Prevalances of GIT parasite infection in animals Nematodes

Nematodes formed the most prevalent gastrointestinal infection with average prevalence of 27.5 % (66 out of 240). Of the 40 young stock (lambs) examined, 5 (12.5 %) were positive for nematodes eggs; out of 130 immature sheep, 49 (37.7%) were infected, while out of 70 adult sheep 12 (17.1%). Egg excretion rate was significant high in the zoo garden (30.9%) than in Sinai (24.6%). The observed threshold level of egg numbers in this study may be regarded as low to moderate that mainly manifests as sub-clinical infections (Tabel 2 and Fig. 1&2).

**Table 2.** Prevalence of faecal gastrointestinal nematodes egg counts in lambs (1-6 months), immature (6-12 months) and adult sheep (> one year)

Localities	Lambs (1-6 months)		Immature (6-12 months)		Adult (> one year)		Overall	
	No	+ve & %	No	+ve & %	No	+ve & %	No	%

At the row level \*Significant at  $\geq 0.05$  \*\* significant at 0.01

Column has different letter was significant

**Fasciolasis**

Overall, *Fasciola* eggs were detected 24 out of 240 (10.0%) of examined samples. The highest prevalence rate occurred in adult sheep (21.4%). The prevalence rates of fascioliasis in zoo garden (17.3%) was higher than that in Sinai (3.8%) (Table 3 and Fig. 1&2).

**Table 3.** Prevalence of fasciolaisis in lambs (1-6 months), immature (6-12 months) and adult sheep (> one year)

Localities	Lambs (1-6 months)		Immature (6-12 months)		Adult (> one year)		Overall	
	No.	+ve & %	No.	+ve & %	No.	+ve & %	No.	+ve & %

Total	35	3 (8.6)	130	12 (9.2)	70	1 (1.4)	240	16 (6.7)

At the row level \*Significant at  $\geq 0.05$  \*\* significant at 0.01. Column has different letter was significant**Mixed infection**

There were 10 out of 240 samples had mixed nematodes and fasciola infestations. Whereas mixed nematodes and coccidia spp. was recovered in 15 samples.

**Faecal culture to infested sheep with GIN**

*Haemonchus Spp.*, *Ostertagia Spp.*, *Strongylus Spp.*, *Chabertia Spp.*, *Trichostrongylus Spp.* and *Cooperia Spp.* were recovered in the faecal culture of gastrointestinal nematodes positive samples (66 samples). There were 26 out of 66 (27.5) had single infestation with one nematode parasite (ten had only *Haemonchus Spp*, seven had only *Ostertagia* spp., five had only *Trichostrongylus Spp* and four had only *Strongylus* spp.). Whereas 12 animals had mixed infestation with two nematodes (three had *Haemonchus Spp* and *Ostertagia* spp, two had *Haemonchus Spp.* and *Strongylus* spp., three had *Ostertagia* spp and *Trichostrongylus* spp. and four had *Ostertagia* spp. and *Strongylus* spp.). The others 28 gastrointestinal nematodes positive sheep had mixed infestation with more than 2 nematodes spp. There was significant correlation between FAMACHA score and parasitic infestations especially those infested with *haemonchus* spp.

#### Efficacy of valbazine, dectomax and dasinex on naturally infested sheep

All treated sheep showed significant improvement and disappearance of most clinical signs (diarrhea was decreased; mm became rosy red; improvement of body weight and disappearance of submandibular edema). Parasitological examination revealed that a significant decrease of EPG with complete disappearance of eggs in 5<sup>th</sup> day; 4<sup>th</sup> day and 6<sup>th</sup> day post treatment in the 1<sup>st</sup>, 2<sup>nd</sup> and 3<sup>rd</sup> group respectively. Serum biochemical parameter revealed that serum calcium, inorganic phosphorus, magnesium, copper and iron levels were significantly decreased in all parasitic infested animals. There were gradual increases in the levels of these elements in 3 groups after one and two weeks post treatment and their levels reached nearly similar to standard levels after 3 week post treatment (Table 5).

**Table 5.** Serum biochemical results before and after treatment with valbazine, dectomax and dasinex.

	Period / Element	Ca	P	Mg	Cu	Fe

#### 4. Discussion

Gastrointestinal parasite infections are a world-wide problem for both small- and large-scale farmers. Infection by gastrointestinal parasites in sheep can result in severe losses. Economic losses are caused by gastrointestinal parasites in a variety of ways: they cause losses through lowered fertility, reduced work capacity, involuntary culling, a reduction in food intake and lower weight gains, treatment costs, and mortality in heavily parasitized animals (**Hansen and Perry 1994 and Waller, 2006**).

Regarding to clinical signs due to parasitic infestation were varied from asymptomatic to adverse signs as diarrhea, paleness or ictric of visible mucous membrane, emaciation, shedding of wool and submandibular edema. The clinical finding of parasitic infestation varied depending on the number of infective stage and the time taken after ingestion. A similar signs were observed by **Maingi and Mathenge, (1995) and Anwaar (2000)**.

With regard to the level of parasitic infestation by parasitological examination of 240 faecal samples revealed that gastrointestinal nematodes, fasciola eggs and coccidia oocysts were detected in 66 (27.5 %), 24 (10.0%) and 16 (6.7%) examined faecal samples respectively. The prevalence of gastrointestinal parasites was higher in zoo garden than that in Sinai. This variation may be due to different management system. This result was concordant with that recorded by **Hashem, (1997); Zakaria (2001); Arafa et al., (2007) and Ibrahim et al., (2008)**. But this result was lower than that recorded by **Abd El-Tawab, (1998); Anwaar, (2000) and Al-Gaabary et al., (2007)**. This variation may be attributed to the variation in climatic which necessary for development of infective larvae and to the different methods used in diagnostic, also the

percentage of infestation varies from time to time according animal species, location and season.

Regarding to the relation between gastrointestinal infestation and age, the rate of infestation was highest among young animals and decrease with age. This result was agreement with that recorded by **Dikov and Nekipelova (1984) and Abd El-Salam and Mahran (2004)**. This may be attributed to the development of immunity against gastrointestinal nematodes, while the rate of fasciola increases with the age. This might be due to the fact that young animals have less chance to take the infestation than adults as most breeders keep them indoors fed on concentrate and fresh water (**Abd El-Tawab 1998**). Moreover sheep don't normally develop a protective immune response to re-infection with fascioliasis (**Radostits et al., 2010**).

The observed threshold level of egg numbers in this study may be regarded as low to moderate that mainly manifests as sub-clinical infections (**Waruiru et al 2005**). The effects of these infections can be aggravated by the frequent drought that occurs in some of the study areas (**Anonymous 2005**). This is described as the most economically important form of infection since it occurs in most of the cases leading to unthriftiness and animals are more susceptible to other infections and are continuously contaminating pastures (**Ocaido et al 1996**).

*Haemonchus Spp., Ostertagia Spp., Strongylus Spp. Chaberia Spp., Trichostrongylus Spp. and Cooperia Spp.* were recovered in the faecal culture of positive samples against gastrointestinal nematodes (66 samples). Nearly similar results were reported by **Zaghawa et al., (1992); Abd Rabo, et al., (1993); Costa et al., (2007) and Tariq et al., (2008)**.

There were 26 out of 66 (27.5) had single infestation with one nematode parasite (10 had only *Haemonchus Spp.*, 7 had only *Ostertagia spp.*, 5 had

only *Trichostrongylus Spp* and 4 had only *Strongylus spp.*). Whereas 12 animals had mixed infestation with two nematodes (3 had *Haemonchus Spp* and *Ostertagia*, 2 had *Haemonchus Spp* and *Strongylus*. 3 had *Ostertagia spp* and *Trichostrongylus spp.* and 4 had *Ostertagia spp.* and *Strongylus spp.*). The others 28 gastrointestinal nematodes positive sheep had mixed infestation with more than 2 nematodes spp. There were 10 out of 240 samples had mixed nematodes and fasciola infestations. Whereas mixed nematodes and coccidia spp. was recovered in 15 samples. These results were agreement with **Hashem (1997), Saleh et al., (2006) and Radostits et al., (2010) and Osman, (2008)**.

Coccidial oocysts that were detected in 6.7% of all animals sampled were sporadic and the burden was light. This parasite is probably not an important factor affecting the health of sheep in the study area. Coccidiosis is more important where animals are housed or confined in small areas. The disease is also more important in young animals. However, they are sources of stress and weight loss to animals when they occur in large numbers (**Maingi, et al., 1993**).

With regard to the efficacy of anthelmintics against gastrointestinal nematodes and fasciola revealed that all treated sheep showed significant improvement and disappearance of most clinical signs (diarrhea was decreased; mm became rosy red; improvement of body weight and disappearance of submandibular edema). These results were concordant with those reported by **Marques et al., (1996); Tinar et al., (1997) and Radostits et al., (2010)**. Parasitological examination revealed that a significant decrease of EPG with complete disappearance of eggs in 5<sup>th</sup> day; 4<sup>th</sup> day and 6<sup>th</sup> day post treatment in the 1<sup>st</sup>; 2<sup>nd</sup> and 3<sup>rd</sup> group respectively. These results were nearly similar to those obtained by **Sabry, (1994); Varma and Panda, (1998) and Dorchies et al., (2001)**. While **Waruiru et al., (1998) and Hertzberg et al., (2001)** reported that gastrointestinal nematodes eggs disappeared after 2-3 weeks post treatment with valbazine (5 mg/kg BW) and after 8 weeks post treatment with dectomax respectively. Moreover **Zakaria (2001)** reported that fasciola eggs were disappeared after 2-3 weeks post treatment with fasenix. This variation may be due to lower dose used by those authors.

Serum biochemical parameter revealed that serum calcium, inorganic phosphorus, magnesium, copper and iron levels were significantly decreased in all parasitic infested animals. These results may be due to impaired absorption or increase excretion of concerned elements on consequence to gastrointestinal parasites and fasciola infestation. Similar results were observed by **Aly and El-Gwady, (1991); Ali et al., (1994); Koski and Scott, (2001)**;

**Zakaria, (2001) and Süleyman et al., (2007)**. There were gradual increases in the levels of these elements in 3 groups after one and two weeks post treatment and their levels reached nearly similar to standard levels after 3 week post. These results were in coincidence with **Varma and Panda, (1998); Dorchies et al., (2001)**.

It could be concluded that most of the animals examined during the present survey had low to moderate parasitic infestation, suggesting that the infections were usually sub-clinical. Appropriate GIT parasite control strategy is needed which should be based on cost effective studies to optimise production.

**Abstract:** The epidemic increase in the prevalence of obesity is now seen in most countries. Dietary composition, the relative proportions of calories coming from fats, carbohydrates, protein and intake of fiber has been suspected of playing a role in obesity. So, the aim of the present study was to analyze the diet quality and also to determine if an association exists between obesity and the relative percentage of fats, carbohydrates, protein and fiber in the diets of children and adolescent. A cross-sectional survey, comprised 5760 children (2638 boys and 3122 girls) was recruited from 6 public schools. Each child underwent a complete physical examination, including anthropometric measures. Body mass index (BMI) was calculated as weight (in kilograms) divided by height (in meters) squared. Only one thousand and one hundred children of the total sample (19.1%), (417 boys and 683 girls, aged 13.43±2.65 years), with the complaint of obesity, were included .Repeated Twenty-four hour recall method, record food intake for three scattered days (3 recalls), includes one day as a holiday was done to assess the nutritional status of obese children. Nutrient intake were calculated using the computer program World Food Dietary Assessment System<sup>(1)</sup> compared with National Research Council USA1989<sup>(2)</sup>,while vitamins and minerals were compared with USDA, 2005<sup>(3)</sup> . This study highlights the importance of nutritional data that it is not what you eat but rather how much the total number of calories consumed which contributes to obesity. Success in obesity prevention is most likely to be achieved when preventive measures are initiated early and sustained throughout childhood and adolescence. More researches must be done for more evaluation, also, to achieve physical activity and life style for obese children and adolescence.

**Keywords:** Diet quality, obese, children, adolescents.

### 1. Introduction:

The epidemic increase in the prevalence of obesity is now seen in most countries. Several studies have examined relations between nutrients, particularly dietary fat and obesity, but the epidemiological evidence remains controversial<sup>(4)</sup>.

Dietary composition, the relative proportions of calories coming from fats, carbohydrates, protein and intake of fiber has been suspected of playing a role in obesity. However, few studies have examined the association between excess weight and the consumption of these nutrients and the results are inconsistent. Many studies found that higher total energy intake significantly increased the odds of obesity but, the composition of their diets, the relative percentages of carbohydrates, protein, fats, and fiber was generally not a factor. So, it seems that for obesity, quantity (total energy intake) is more important than quality (the balance of nutrients consumed)<sup>(5, 6)</sup>

Dietary pattern analysis; based on the concept that foods eaten together; are as important as a reductive methodology characterized by a single food or nutrient analysis. Dietary pattern analysis is a better method to examine the effect of overall diet: food and nutrients are not eaten in isolation, and the

single food or nutrient approach will not take into account the complex interaction between food and nutrients<sup>(7)</sup>.

The aim of the present study was to analyze the diet quality and also to determine if an association exists between obesity and the relative percentage of fats, carbohydrates, protein and fiber in the diets of children and adolescent.

### 2. Subject and Methods:

This study was conducted by the National Research Centre, Egypt, through a project titled: "Obesity Profile among Egyptian School Children and Adolescents: Early Diagnosis of Metabolic Syndrome and Nutritional Intervention".

It was a cross-sectional survey, comprised 5760 children (2638 boys and 3122 girls). The pupils were recruited from 6 public schools (two Primary , two preparatory and two secondary schools) situated in Giza governorate, during the period of October, 2007 to April 2009. Permission to perform the study was granted by the Ministry of Education, and the directors of the schools. Parents were informed about the purpose of the study and their research permission in the form of written consent was obtained. The

protocol was approved by the "Ethical Committee" of the "National Research Centre".

Each child underwent a complete physical examination, including anthropometric measures. Their pubertal development stages were assessed using the criteria of Tanner stages. The height and the weight were measured. The height was measured to the nearest 0.1 cm on a Holtain portable anthropometer, and the weight was determined to the nearest 0.01 kg on a Seca scale Balance with the subject dressed minimum clothes and no shoes. Body mass index (BMI) was calculated as weight (in kilograms) divided by height (in meters) squared.

Of the total sample, one thousand and one hundred children only (19.1%), (417 boys and 683 girls, aged  $13.43 \pm 2.65$  years), diagnosed as having obesity, were included. These children were required to meet the following inclusion criteria: age, 7–18 years and BMI, greater than the 95<sup>th</sup> percentile for age and gender based on the Egyptian Growth Reference Charts 2002<sup>(8)</sup>. Children were excluded if they had a prior major illness, including type 1 or 2 diabetes, received medications or had a condition known to influence body composition, insulin action or insulin secretion (e.g. glucocorticoids therapy, hypothyroidism and Cushing's disease).

Assessment of the nutritional status of the students included the following:

Repeated Twenty-four hour recall method, record food intake for three scattered days (3 recalls), includes one day as a holiday. Data were collected by qualified dietary staffs, by personal interview. Detailed description of all food and beverages consumed, including cooking methods and the amount of each ingredient, was recorded. The conversion of household measures to grams was achieved through the use of prepared list of commonly used household measures in Egypt. Nutrient intake were calculated using the computer program<sup>(1)</sup>. The daily intakes of calories and protein were compared with National Research Council<sup>(2)</sup>, while vitamins and minerals were compared with USDA<sup>(3)</sup>.

### 3. Results

#### Prevalence of obesity

**Table 1- Distribution of the sample**

	Sex	N	Obese		Overweight	
			N	%	N	%
STUDENTS AGED 7 -12 YEARS	Boys	859	30	3.5	66	7.7
	Girls	1193	92	7.7	151	12.7
SYUDENTS AGED 13-18 YEARS	Boys	1779	144	8.1	177	9.9
	Girls	1929	196	10.2	244	12.4
Total		5760	462	8.02	638	11.07

The Prevalence of obesity of our sample is represented in table (1). In our sample of 2052 children aged 7 to 12 years, we found that 30 boys and 92 girls were obese (BMI>95<sup>th</sup> percentile). Over weight (BMI >85<sup>th</sup> and <95<sup>th</sup> percentile) was represented by 66&151 boys and girls respectively.

The prevalence of obesity in the total sample (3708 children aged 13 to 18 years) was 144 boys(9.9%) and 196 girls(12.4%) , while, 177 boys and 244 girls were overweight.

#### Nutrition

Food quality analysis showed that the obese children consumed more calories than the recommended dietary allowance (RDAs) for the same age. However, they consumed the relative average percentage of calories from carbohydrates, protein and fats

Table (2) represents the obese boys and girls aged 7 to 12 years. They had higher energy intake than RDA, while the % calories from protein are on the low normal % of RDAs. The %calories from fat are within the normal % of RDAs, but the percentage from saturated fat are high. The% calories from CHO are within high normal%. The consumed dietary fibers are higher than RDA.

Table (3) represents the amount of some nutrients of consumed food items. We found deficiency of some vitamins and minerals as E, calcium and, potassium.

Analysis of food of female adolescent aged 13-18 years showed that they are consuming higher% of total energy intake than RDAs. However, the % calories from protein and fats are at low normal RDA %. The percentage calories from CHO are at the high normal RDAs range. The consumed amount of fibers is higher than RDAs (table 4). Vitamin D, E and calcium are deficient in their eating food. While, copper, sodium, manganese and other nutrients are very high than normal (Table 5).

On the other hand, the male adolescents of the same age have a high total energy intake than RDA. The percentage of calories from protein, CHO and fat are within normal range, while dietary fiber intake are low than normal (Table 6).

Table (7) showed the nutrients of their eaten food in relation to RDAs.

**Table 2: Daily intake of selected nutrients by obese boys and girls aged 7 to 12 years**

Nutrient	Minimum	Maximum	Mean	SD	RDAs

#### 4. Discussion:

Although obesity was rarely observed among children and adolescent 30 years ago, it is now evident among children in all ages <sup>(9)</sup>.

Childhood obesity is an independent risk factor for adult overweight and obesity <sup>(10)</sup>, with obese children having at least a 25%-50% increased risk of being obese as adults.

A nutrition survey was done to characterize the quality of diets consumed by obese children and adolescent. The analysis of data revealed that our sample of overweight and obese children consumed energy intake higher than RDAs, however, the composition of their diets –the relative percentage of carbohydrates, protein, and fats are within the RDAs for the same age and sex, while the fiber intake was higher than RDAs except in male adolescent.

In our study, the % of calories from protein is at the low normal range in both sexes and in different age group. Langlois,et al <sup>(11)</sup>, found no significant relationship between obesity and the percentage of calories derived from proteins, while a prospective study in 2006, found an inverse relationship between protein intake and five year differences in waist

circumference <sup>(12)</sup>. Ludwig et al <sup>(13)</sup> found a positive relationship between protein intake and body weight.

The percentages of calories derived from carbohydrate are at high normal range value in children and adolescent either male or female. Tucker & Kano, <sup>(14)</sup> and Davis et al <sup>(15)</sup>, showed no association between carbohydrate consumption and excess weight. Other search adjusted that a higher percentage of calories coming from carbohydrate was negatively associated with obesity among men <sup>(16)</sup>.

Many literature studied fat as one of the most nutrient in obesity because of their high caloric count (9 kilocalories per gram versus 4Kcal per gram for each CHO & protein).They assumed that excess consumption may contribute to higher energy intake <sup>(17)</sup>. In our study, we found the % of calories from fat are within normal range of RDAs in both sexes and in different age. Langlois, etal, <sup>(18)</sup> found no association between fat intake and obesity among men and women. Some studies have examined specific types of fat, because it has been suggested that saturated, monounsaturated and polyunsaturated fats might have different effects on adiposity <sup>(19)</sup>. In our results, saturated fat is higher than normal. Moussavi et al <sup>(6)</sup>

found a positive association between saturated fat intake and obesity prevalence, while Bhargava & Gutjrie<sup>(20)</sup> found no relation between saturated fat and BMI.

Dietary fiber delays gastric emptying and thereby, contributes to a sensation of fullness, so, it has been studied as a preventive factor in the developing obesity<sup>(18)</sup>. In the present study the mean average of dietary fiber are higher than RDA in children and in female adolescent, while in male adolescent, we found it less than normal. Newby et al,<sup>(21)</sup> showed no association between dietary fiber intake and annual BMI changes in boys and girls. Hassapidou et al,<sup>(22)</sup> found that fiber intake were significantly lower in overweight boys while no significance among girls.

Concerning micronutrient intake : Calcium intake level among Egyptian adolescents is far below the recommended international figures to prevent osteoporosis, the results of a national survey (DNPCNCD) carried out by the National Nutrition Institute, Egypt<sup>(23)</sup>, reported that, the 25<sup>th</sup> percentile of the daily calcium intake among adolescents aged 10-18 years was 323.5g, while the 50 and 75 percentiles were 494.8g and 704.2 respectively, this is agreed with our results as we found deficiency of calcium in all age groups

Vitamin D deficiency is highly prevalent among children and adolescents worldwide. The high rates of vitamin D deficiency during childhood are of major public health relevance<sup>(24)</sup>. Our results found vitamin D and vitamin E deficiency in all age groups.

Two epidemiologic studies published in the early 1960s noted an association between overweight status among children and adolescents and iron deficiency<sup>(25, 26)</sup>.

Saloojee H,et al,<sup>(27)</sup>. & Bhatia D et al,<sup>(28)</sup>, found that there was a greater prevalence of iron deficiency in overweight and obese children and adolescents. Obese children and especially female adolescents are at risk of increased morbidity starting already in childhood or adolescence. Interestingly, despite their excessive dietary and caloric intake, obese children and adolescents may be at risk of iron deficiency anaemia because they tend to consume unbalanced meals, particularly rich in carbohydrates and fat, this is agreed with our results as we found iron deficiency among adolescent girls (table 5).

This study highlights the importance of nutritional data that it is not what you eat but rather how much the total number of calories consumed which contributes to obesity. Success in obesity prevention is most likely to be achieved when preventive measures are initiated early and sustained throughout childhood and adolescence. More

researches must be done for more evaluation, also, to achieve physical activity and healthy life style for obese children and adolescence.

# Eusyllinae, Anoplosyllinae, and Exogoninae (Polychaeta: Syllidae) for the Mediterranean Coasts of Egypt, Together the Description of One New Species

F. A. Abd-Elnaby<sup>1</sup> and G. San Martín<sup>2</sup>

<sup>1</sup>National Institute of Oceanography and Fisheries, Alexandria, Egypt

<sup>2</sup> Departamento de Biología (Zoología), Facultad de Ciencias, Universidad Autónoma de Madrid, calle Darwin, 2, 28049 Madrid, Spain.

**Abstract:** In this paper, 18 species of the subfamilies Exogoninae, Anoplosyllinae, and Eusyllinae (Syllidae, Polychaeta) are reported from the Mediterranean Egyptian coasts, 8 of them are new records for the area: *Odontosyllis fulgurans* (Audouin and Milne Edwards, 1833); *Syllides japonicus* Imajima, 1966; *Salvatoria clavata* (Claparede, 1863); *Salvatoria euritmica* (Sardá, 1984); *Sphaerosyllis glandulata* Perkins, 1981; *Parapionosyllis labornica* Cognetti, 1965; *Sphaerosyllis* sp.; and *Prospaerosyllis* sp. Five species were reported previously in the area. Four species are new records for Mediterranean Sea: *Palposyllis prosostoma* Hartmann-Schröder, 1977; *Paraehleria weissmaniodes* (Augener, 1913); *Streptosyllis compoyi* Brito, Núñez and San Martín, 2000; and *Exogone africana* Hartmann-Schröder, 1974; *P. weissmaniodes* and *Exogone africana* are two widely distributed Indo-Pacific species, so they could be considered as Lessepsian migrants. Finally, one new species is described, *Parapionosyllis aegyptia*.

[F. A. Abd-Elnaby<sup>1</sup> and G. San Martín. Eusyllinae, Anoplosyllinae, and Exogoninae (Polychaeta: Syllidae) for the Mediterranean Coasts of Egypt, Together the Description of One New Species. Journal of American Science 2010;6(11):559-566]. (ISSN: 1545-1003).

**Keywords:** *Eusyllinae, Anoplosyllinae, Exogoninae, Taxonomy, Mediterranean, Egypt, New species.*

## 1. Introduction:

Syllidae represent one of the most diverse and systematically challenging families of Polychaeta (Glasby, 2000; Rouse & Pleijel, 2001; San Martín, 2003, 2005; San Martín & Hutchings, 2006; Aguado & San Martín, 2009). It is a widely distributed group, found from the intertidal zone to the abyssal plains all over the world (Glasby, 2000), but less common at depth, with some species symbiotic or parasitic on other marine invertebrates (Martín and Britayev, 1998).

This family is currently divided into 5 subfamilies (Aguado & San Martín 2009): Eusyllinae Malaquin, 1893; Exogoninae Langerhans, 1879; Autolytinae Langerhans, 1879; Syllinae Grube, 1850; and the recently erected Anoplosyllinae Aguado and San Martín , 2009.

To detect newly recorded or new species we will depend on accurate taxonomic identifications and the local biodiversity. The possible existence of complexes of species, whose identity is blurred under one common specific name are present (Aguado and San Martín, 2007).

Knowledge about Polychaetes in the Egyptian waters is still far from complete; as result of less taxonomical studies and less sufficient data about this group. This paper is the second report about

Egyptian Syllids, collected from the Northwestern Coast of Egypt through Salsabeel cruise, Autumn 2008 and Spring 2009, also from Gamasa (Spring 2009), under the frame work organized by National Institute of Oceanography and fisheries branch Alexandria, and from Port Said Harbour (Spring 2008), to study the benthic invertebrates. While the first report about syllid and sabellid species in the Northwestern coast of Egypt, were done by Selim (2008a & b respectively), Abd- Elnaby (2009) also studied polychaetes in Gamasa.

Generally, scarce attention has been given to the polychaetes in Egyptian waters. Fauvel (1927) recorded 8 syllid species from the Suez Canal waters of which 6 belonging to genus *Syllis*. On his work on the polychaetes collected from the fishery grounds near Alexandria, Fauvel (1937) gave a checklist of polychaetes recorded in this area.

Only 16 species of Syllidae were recorded in that paper. More recently, Selim (1978) reported two syllids species in the Eastern Harbour of Alexandria, namely *Syllis* (*Typosyllis*) *variegata* and *Trypanosyllis zebra*. Later, the same author (Selim, 1996) added 6 syllid species from Alexandria coast (*Branchiosyllis exilis*, *Syllis gracilis*, *S. hyalinae*, *S. mediterranea*, *S. prolifera* and *S. variegata*). Finally, Abd-Elnaby (1999) recorded 7 syllid species, and

later (2005) 21 species from Alexandria coast.

The Syllidae of the neighbouring areas were studied by several authors; from Aegean Sea by Çınar & Ergen (2002); Çınar (2003); and Çınar (2005); from Israel and the Gulf of Elat by Ben-Eliah (1977a & 1977b), and anteriorly Fauvel (1955, 1957), from Cyprus by Ben-Eliah (1972), Çınar (2003a&b) and Çınar & Ergen (2003); Lebanon by Aguado & San Martín (2007), and from Turkey by Ergen (1976). A checklist, distribution, and ecological features of Syllidae and other polychaetes from Greece can be reported in Simboura & Nicolaïdou (2001), also from Cyprus by many authors, the most recent one Musco et al. (2005), and the biogeographic revision on Syllidae from the Mediterranean Sea (East and West areas) was carried out by Musco & Giangrande (2005).

During the present study 18 species were recorded, 11 of which are new records for the Egyptian waters. Four species are considered as new species for Mediterranean Sea. Three species are considered as new species, although two of them are under process of description, and one species is described here as new for Science. In this paper, detailed description is given also of some interesting species.

## 2. Materials and methods

Two cruises were carried out on the Northwestern Mediterranean coast of Egypt; on two stations (El Hammam, El Alamein), during Autumn 2008 and Spring 2009, and also one collection Spring 2008. The stations are; Port Said Harbour (station 1), in which samples were collected during Spring 2008, and Gamasa (station2, Spring 2009), depth ranging from 0 .25m to 20 m. (Fig. 1). Sediment samples were collected by a Van Veen grab; while, samples from Port Said Harbour were collected by knife and net used for collecting fauna. Sediment samples were washed up and sieved through 0.3 µm sieve, then sorted under Stereomicroscope. Specimens of Syllidae were extracted and fixed in 10 % formaldehyde in sea water-solution. Examinations and identification were done by using compound microscope. Drawings were made by a camera lucida. The specimens were Preserved in the Marine Reference Collection Center of National Institute of Oceanography and Fisheries, Alexandria, under Code Number (N. Sp. 2/8/3).

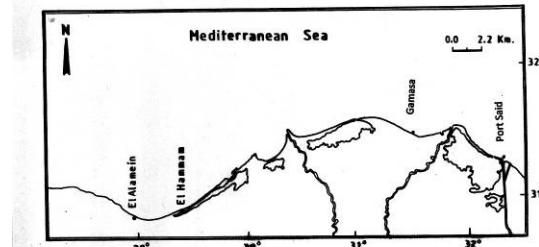

Fig. (1) Map showing the sampling sites, (North western Coast of Egypt, Gamasa and Port Said).

## 3. Results

In the present study, 18 species belonging to the subfamilies Exogoninae, Anoplosyllinae and Eusyllinae (Syllidae, Polychaeta) were recorded and identified from the Mediterranean Egyptian coasts, 8 of them considered new records for the Egyptian Mediterranean waters: *Odontosyllis fulgurans* (Audouin and Milne Edwards, 1833); *Syllides japonicus* Imajima, 1966; *Salvatoria clavata* (Claparede, 1863); *Salvatoria euritmica* (Sarda, 1984); *Sphaerosyllis glandulata* Perkins, 1981; *Parapionosyllis labronica* Cognetti, 1965; *Sphaerosyllis* sp.; and *Prospaerosyllis* sp.; the two later are new species in process of description, although a description of both without any specific name is given by San Martín (2003). Five species were reported previously from different places of Egypt. In addition, four species are considered as a new records for the Mediterranean Sea (*Palposyllis prosostoma* Hartmann-Schröder, 1977; *Paraehlersia weissmanioides* (Augener, 1913); *Streptosyllis compoysi* Brito, Núñez and San Martín, 2000; and *Exogone africana* Hartmann-Schröder, 1974). Finally one species *Parapionosyllis aegyptia* is described as new species. The locations, dates , depth, number of specimens and geographical distribution are presented in Table (1).

\*= New species, \*\*= New record for Mediterranean Sea, \*\*\*= New record for Egyptian waters, \*\*\*\*= Recorded before from Egyptian waters

The most important species will be described in details.

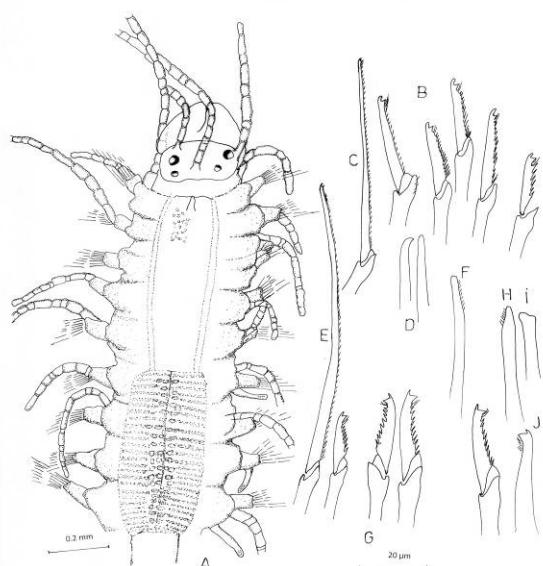

Fig. (2): *Paraehlersia weissmannioides* A: anterior part of body, B: anterior setae, C: spiniger-like compoundseta, anteriorly D: anterior acicula, E: spiniger-like compound seta posterior parapodia F: anterior dorsal simple seta, G: posterior setae, H: dorsal simple seta, posterior parapodia I: acicula, J: ventral simple seta.

Fig. 2 A-J. *Paraehlersia weissmannioides* (Augener, 1913).

*Ehlersia ferrugina* non Langerhans. Böggemann & Westheide, 2004: 418, fig. 6. *Paraehlersia weissmannioides* San Martin & Hutchings, 2006: 312, figs. 43A-C, 47A-I, 48 A-F, 49 D-F.

Material examined. Port Said 0.25 m depth, Spring 2008, one specimen.

Description. Body broad anteriorly, tapered posteriorly, 11 mm long, 0.2 mm wide, with 41 chaetigers (fig. 2 A). Prostomium oval (75 µm), 4 eyes in trapezoidal arrangement, and 2 anterior eye-spots; lateral antenna 162.5 µm long, midian antenna 150 µm long. Palps broad (87.5 µm), basally fused. Dorsal tentacular cirri 147.5-162.5 µm long, ventral tentacular cirri about one third in length of dorsal tentacular cirri. Antennae, tentacular and anterior dorsal cirri; elongated, indistinctly articulated; articulation variable with short and long articles, up to 22 articles; dorsal cirri becoming progressively smoother posteriorly. Infracirral papillae not seen. Parapodia conical, slightly elongate. Ventral cirri digitiform, slightly longer than parapodial lobes. Parapodia with 12-15 falcigerous compound chaetae; blades strongly bidentate, with fine spines on margin (fig. 2 B), 2-3 distalmost ones longer than remaining (30-42.5 µm) (fig. 2 C). Most dorsal compound chaetae, spiniger-like, blades (75 µm long) on midbody, and about 93 µm on posterior parapodia

with fine spines on margin (figs. 2 C, E), absent on most posterior parapodia; indistinctly bidentate. Compound falcigers becoming wider progressively along body, with stronger proximal tooth, slightly hooked (fig. 2G). Dorsal simple chaetae appear from chaetiger 19, truncate, bifid with short spines margin (fig. 2 F, H). Ventral simple chaetae on posterior parapodia, thick, with few long spines on margin, strongly bidentate, proximal tooth large, slightly hooked, and distal one shorter than proximal one (fig. 2 J).

Anterior parapodia with 2-3 slender aciculae, two of them distally rounded with small bending tip and one straight (fig. 2D); from proventricular segments onwards, acicula solitary, with oblique, short tip (fig. 2 I). Pharynx through 6 segments; pharyngeal tooth anteriorly located. Proventricle, rectangular through 4 segments with about 21 muscle cell rows.

Distribution: Australia, Seychelles. New report for the Mediterranean Sea.

Remarks: The Egyptian specimen is similar to Australian ones; it is likely an Indo-Pacific migrant through Suez Canal.

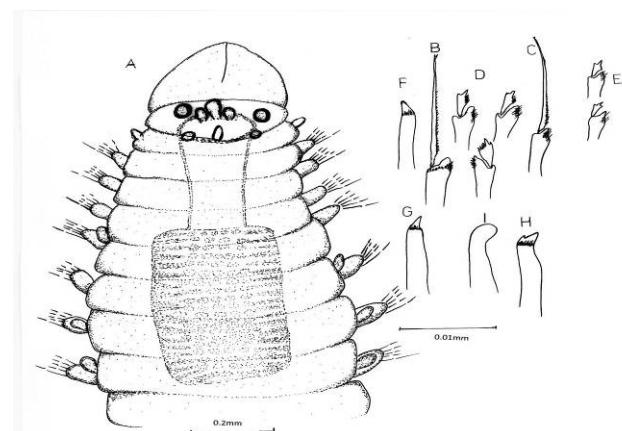

Fig. (3): *Exogone africana* A: anterior part of body, B: anterior spiniger-like seta, C: posterior spiniger-like seta, D: anterior falcigers setae, E: posterior falcigers setae, F: anterior dorsal simple seta, G: posterior dorsal simple seta, H: ventral simple seta, I: acicula.

Fig. 3 A-I. *Exogone africana* Hartmann- Schröder, 1974

*Exogone verugera africana* Hartmann-Schröder, 1974a:137, figs. 164-168; 1979; 108, figs.164-168.

*Exogone africana* San Martín, 2005: 143, fig. 90 a-f.

Material examined. Port Said, 0.25 m depth, on fouling, Spring 2008, 2 specimens.

Description. Body small, slender, relatively broad anteriorly, 3 mm long, 0.23 mm wide, 28 chaetigers. Prostomium oval (fig. 3 A); 4 eyes in trapezoidal arrangement. Antennae short, oval, close to each other, inserted between anterior to eyes; median antenna slightly longer and thicker than lateral one. Palps broad, longer than prostomium, totally fused, with a dorsal furrow (fig. 3A). Peristomium shorter than subsequent segments; one pair of small, papilliform tentacular cirri. Dorsal cirri similar to antennae and tentacular cirri, slightly longer than lateral antennae, present on all segments. Compound chaetae of two types on all parapodia: 1-2 spiniger-like, with long blades 31  $\mu\text{m}$  long (fig. 3 B) on anterior parapodia, slightly short on posterior one (25-27.5  $\mu\text{m}$ ), distally bifid, with short marginal spines (fig. 3 C), and 4 compound chaetae with short falcigerous blades about 7.5  $\mu\text{m}$ , bidentate, subdistal tooth long and distal tooth short, moderate marginal spines (fig. 3 D); posterior falcigers smaller, three in number, blades about 5  $\mu\text{m}$  long (fig. 3 E). Dorsal simple chaetae from anterior segments, with rounded tips (fig. 3 F), subdistally serrated, thicker posteriorly with pointed tip (fig. 3 G). Ventral simple chaetae on posterior parapodia, sigmoid, thick, with some short spines on base of teeth, bidentate, subdistal tooth longer and thicker than distal tooth (fig. 3 H). Acicula solitary, slender, distally rounded (fig. 3 I). Pharynx long, through 4 segments; pharyngeal tooth located on anterior rim. Proventricle occupying 4 segments with 18 muscle cell rows. Pygidium with 2 long anal cirri.

Distribution: Circumtropical. First report to the Mediterranean Sea.

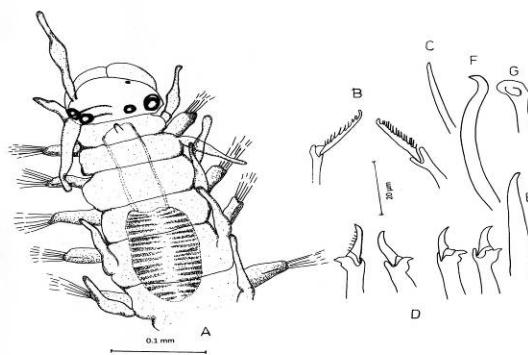

Fig. (4): *Parapionosyllis* n. sp. A: anterior part of body, B: anterior setae, C: anterior dorsal simple seta, D: posterior setae, E: posterior dorsal simple seta, F: posterior ventral simple seta, G: acicula.

Fig. 4 A-G. *Parapionosyllis aegyptia* n. sp.

Material examined. El Alamein 20 m depth, Autumn 2008. Holotype and Paratype, coarse sand.

Description. Holotype 3.5 mm, 0.15mm wide 29 chaetigers (fig. 4 A). Prostomium ovate, wider than long; 2 pairs of eyes, anterior pair larger than posterior ones, arranged in trapezoidal arrangement, and 2 small anterior eye-spots. Antennae spindle-shaped to bowling-pin shaped, longer than prostomium; median antenna (77.6  $\mu\text{m}$ ) slightly longer than lateral ones (67.5  $\mu\text{m}$ ), arising between anterior eyes; lateral antennae arising on anterior margin of prostomium (right one missing on holotype). Palps basally fused, shorter than prostomium. Peristomium with 2 pairs of bowling-pin shaped tentacular cirri, smaller than antennae. Parapodia somewhat elongated (32.5  $\mu\text{m}$ ). Dorsal cirri bowling-pin shaped, from 36- 45 $\mu\text{m}$  in length anteriorly to 65 $\mu\text{m}$  on posterior parapodia. Ventral cirri digitiform, shorter than parapodial lobes.

Anterior parapodia with 7 compound falcigers, unidentate with hooked tips and serrated margin (fig. 4 B); about 10  $\mu\text{m}$  long; shafts becoming posteriorly thick with long curved acute tip, blades with serrated margin on 2 most dorsal ones, and 4-5 unidentate curved, smooth (fig. 4 D). Superior dorsal simple chaetae thin with pointed tip, present in all parapodia, except first one (fig. 4 C), become thicker posteriorly (fig. 4 E). Ventral simple chaetae unidentate, sigmoid (fig. 4 F). Acicula solitary, bent with hollow rounded tip (fig. 4 G). Pharynx extending through 3.5 setigers; mid dorsal tooth on anterior edge. Proventricle extending through 2.5 segments, with 17 rows of muscle cells. Glands small, with granular material, pair on each segment, present from first chaetiger.

Remarks. About 16 species are recognized as *Parapionosyllis*, 6 of them recorded in the Mediterranean Sea. The most similar species is *P. labronica* also found in this collection; both species have posterior compound chaetae with thick shafts, distally curved, and short, unidentate blades, smooth or almost smooth. However, the anterior compound chaetae of *Parapionosyllis aegyptia* are more elongated and provided with somewhat longer spines on margin, and the dorsal simple chaetae are different, being smooth and unidentate in *P. aegyptia* and provided with a sub-distal, thick spine and others shorter, in *P. labronica*. The remaining Mediterranean species are clearly different of these two species, because they have longer compound chaetae (see San Martín, 2003); also, other species of other seas also have more elongated compound chaetae and different dorsal simple chaetae.

Etymology. The species is named after the country in which has been found, Egypt.

#### 4. Discussion

The number of Syllids recorded on Egyptian waters reach about 60 species, a low number when compared with the 190 Syllid species were reported by Musco and Giangrande (2005) from the whole Mediterranean waters, which represents the 31.6 % of the total Mediterranean Syllidae. Also, many other species may possibly remain unreported because of the most coastal area of Egypt are unexplored and many studies are still needed.

Tovar- Hernández *et al.* (2002) referred to the dominance and diversity of syllid members in carbonate sediments, this observation was confirmed by Selim (2008), where El Hammam and El Alamein coasts contain carbonate bottom sediments.

Most of the studied species are well known, common and widely reported for Mediterranean and Atlantic Ocean. The analysis of samples resulted into 18 species, 11 of them new record for the Egyptian Mediterranean waters. Four species were reported previously, (*Brevicirrosyllis weismanni* Langerhans, 1879; *Parapionosyllis elegans* (Pierantoni, 1903); *P.brevicirra* Day, 1954 and *Sphaerosyllis taylori* Perkins, 1981, from many Mediterranean coastal areas and one more (*Salvatoria vieitezii* San Martín 1984) from the Suez Canal. Two of the studied syllids are considered apparently cosmopolitan: *Salvatoria clavata*, and *Odontosyllis fulgurans*. In addition, 11 species were known before from Spanish coasts, only 4 species were previously recorded in Greece, 9 from North West Italian, 9 from Turkish Aegean and 6 from Cyprus. Also four species are considered as a new record for Mediterranean Sea: *Palposyllis prosostoma* Hartmann-Schröder, 1977; *Paraehlersia weissmanioides* (Augener, 1913); *Streptosyllis compoysi* Brito, Núñez and San Martín, 2000; and *Exogone africana* Hartmann-Schröder, 1974.

According to geographic distribution through literature there are 9 species belong to Atlantic-Mediterranean category and one species (*Salvatoria vieitezii*) was recorded before from Suez Canal (Selim, 2009), and four species are new for Mediterranean, that means they are Lessepsian migrants; 3 species are amphi-Atlantic, *Sphaerosyllis taylori*, *Sphaerosyllis glandulata* and *Salvatoria vieitezii*. Two species are considered cosmopolitan species, *Odontosyllis fulgurans* and *Salvatoria clavata* and five species are considered Atlantic-Pacific categories.

In spite of it, many new recorded species usually discovered by way in new researches, still more not recorded until now, more studies requisite to be done along the Mediterranean and Red Sea coasts of Egypt to cover this point.

The present study showed richness of

Eusyllinae, Anoplosyllinae and Exogoninae species inhabiting Egyptian water benthic assemblage.

## Re-introduction of Elephant's Infant into Wild Group: First Attempt and Case Study from North-West India

**Ritesh Joshi**

Doon Institute of Engineering and Technology,  
Shyampur, Rishikesh, Dehradun, 249 204, Uttarakhand, India  
E-mail: [ritesh\\_joshi2325@yahoo.com](mailto:ritesh_joshi2325@yahoo.com)

**Abstract:** Elephant's infant is considered extremely difficult to re-introduce into the wild. On 21<sup>st</sup> of November 2009, an eight day old elephant's infant was found strayed from its group at Shyampur forest of the Haridwar forest division. For the first time in the history of Uttarakhand, attempts had been made by forest officials to re-introduce the orphaned baby elephant into the wild. It is noteworthy that during the introduction attempts, group of seven elephants had taken the baby within group, but left her behind after a while. They had responded from all directions to the cries of the baby elephant but the attempts were in vain. Radha – the domesticated elephant at Chilla forest of the Rajaji National Park nurtured the infant for 10 days before infant's death and Radha's behaviour always illuminated something new about elephant's life. It was the first attempt to re-introduce the infant to wild in north-west India in which some lessons came forward and could be helpful in management of elephants and in documentation of conservation-oriented action plan. Additionally, studies on the behaviour of wild elephants are highly required and recommended so that we can ensure the future survival of this endangered species.

[Ritesh Joshi. Re-introduction of Elephant's Infant into Wild Group: First Attempt and Case Study from North-West India. Journal of American Science 2010;6(11):567-570]. (ISSN: 1545-1003).

**Keywords:** Asian elephants, infant, re-introduction, conservation, north-west India

### Introduction

Elephants live in a matriarchal society where the oldest female is the leader. Allomothering in sub-adult and adult females is one of the important factor to survival of elephant's calves, which also decreases the mortality among newly-born calves. In elephant societies, groups have well established home ranges within which all members live in a coordinated manner besides, elephants have strict social bonds, sometimes association among different groups occurring specially during their migration. Elephants are always known for their strong memory, close relationship and cooperativeness. Here, I report a case study of elephant's infant re-introduction / translocation to wild group and on the failure of conservation operation. Such reports are largely absent from the wildlife literature despite their importance in illustrating success and failures of such operations.

On 19<sup>th</sup> of November 2009, merely 7-8 days old female elephant was found strayed from group at Papri Paraw forest of the Shyampur forest of the Haridwar forest division. She was grasped in a nullah (narrow patch of torrential rivulet, natural trench) and was trying to come out from there. After receiving the message from a Gujjar residing near the spot, forest officials started rescue operation and after rescuing her

successfully they shifted orphaned baby to Chilla forest range of the Rajaji National Park, where several other domesticated elephants are kept under the care of mahawats. The calf was healthy and was not suffering from any severe disease or infection. Park officials gave her all the required treatment and facilities along with routine checkups from veterinary officers (Wildlife Institute of India, State Govt. & experts from Delhi). Under the treatment she was fed with lactogen, calcium, coconut oil, olive oil and ORS liquid. In practical it was really a challenge to protect her in artificial environment and under human care.

### Re-introduction of calf into the group

After a day on 20<sup>th</sup> of November 2009, I along with forest officer of Chilla range planned to re-introduce the calf into the group as this was only the appropriate method for her survival. Initials were taken on the morning of 21<sup>st</sup> of November. Forest staff had made an in-depth survey of the area from where the calf had been rescued. At the same duration I collected information about the area and elephant's movement from locals and from Gujjars. As per information collected and field investigation it came to our notice that a group of 07 elephants (02 adult females, 03 sub-adult females, 01 juvenile male and 01 calf) were

moving within the range and during the past two nights (19<sup>th</sup> & 20<sup>th</sup> November) elephant's roaring/vocalization was perceived by Gujjars living near to spot. Only 08 days old infant was on an attempt to go back into the wild. For the first time in the history of Uttarakhand, attempts were been made by forest officials to re-introduce the orphaned baby elephant into the wild.

Figure 1. Forest officials at the site, where re-introduction attempts were made.

At sharp 03 pm after locating the group inside dense forest, we moved to the site where elephant group was moving (07 kilometers faraway) along with the infant. We selected evening hours for the operation because evening hours are the best timings as far elephant's sighting is concerned and during the same hours elephants are known to emerge out from the forest to open areas and near to water sources. When we reached the spot suddenly elephants that were spread randomly started incessant audible communication, besides rumbling sounds were also observed at short interval. At that moment all elephants collected together and tried to approach us speedily. I with a fellow rapidly brought the infant towards group and at the same moment the group started approaching us slowly with very antagonistic behaviour. I realized a very serious threat regarding to our life but a key-view of saving infant's life made us courageous. When barely 20 meters distance remained between us and the elephant's group, I pushed the baby towards them and quickly returned back with other fellows watching the incidence from a distance.

Suddenly and surprisingly group approached the infant, smelled it and after few seconds returned back inside the forest and left the baby alone. A threat was clearly visible among all of them, which might be of human touching or our presence and stench. After few minutes we again made an effort to re-introduce the infant into the group and keeping the view I again

brought up the infant towards the older cow, which was standing to some distance along with two sub-adult cows. When I just came nearer to the cows, I left the spot quickly and watched the incidence from a distance hiding myself behind the tree. I was shocked to see that the same behaviour was repeated by the elephants. They again approached the infant and after giving her greetings returned back speedily inside the forest. But this encouraged the infant and she walked slowly towards the group and joined them but again the group sprinted away. Baby tried to enter within the group several times and this moved her about a kilometer further but the group didn't accept the infant. It is noteworthy that during the introduction attempts, group of seven elephants had taken the baby within the group, but left her behind after a while. They had responded from all directions to the cries of the baby elephant but finally the attempt got unsuccessful.

Figure 2. Constructive efforts: officials brought the infant towards the wild group while re-introducing the infant into the group at Papri paraw area, Haridwar forest division.

All this happened in about three hours and after a while day light became mild and slowly it became too hard for us to see easily with naked eyes but efforts carried out by infant were continued to join the group; it might be she identified her elder ones. Miserably we reallocated the baby into the vehicle and moved away from the spot and infant was again shifted to Chilla forest for care. In that way our attempt to re-introduce the calf with the group had failed, which if had got successful would have become the first ever historical conservation effort in north-west India and could have acted as a milestone in Asian elephant's management and conservation.

### **Love of Radha**

But for the failed effort there was a shining light among the clouds, which was the bond of love between Radha and baby elephant. Radha is a domesticated elephant at Chilla and was brought from Delhi zoo during 2007-2008. She entirely adopted the baby after three days and her behaviour was surprisingly changed. I have kept my observations on both of them as part of my long-term study on Asian elephant's behaviour. Radha nurtured the infant for about 10 days before infant's death and was very serious about it. She always (24 hours) remained close with the baby and doesn't let anyone to move near to the infant. Interestingly she even didn't depart to drink water alone. Unfortunately on 29<sup>th</sup> of November the biased chain, which was in Radha's hind feet, injured the baby while searching the baby and due to this infant felled down in a small trench. After the day baby got distressed and her movements became restricted. Very unfortunately on 2<sup>nd</sup> of December 2009 infant died during night hours.

Figure 3. Bond of Love: Radha with infant at Chilla forest range of Rajaji National Park

#### *Changes in the behaviour of Radha*

Surprisingly and notably the behaviour of Radha was changed just after the death of infant. She was feeling alone and searching for the infant again and again. The baby died near to her forefeet and during early morning when mahawat reached to her to feed the

baby and knew about infant's death, they faced problem in shifting the infant due to abnormal behaviour of Radha. For 2-3 days drastic changes were observed in the behaviour of Radha, which also include the unusualness in feeding.

#### **Current scenario of rescue operations**

After two years, young elephants can begin to look after themselves, but this doesn't bode well for newly-born babies. Infant survival after the rescue is too much controversial. I personally observed that saving a rescued baby elephant is a tough task as wild animals are nature-born and need sensitive parental care besides; the chances of infection during human care are quite large. During September 2005 and May 2008 a 02 years female and a 01 month male baby elephants were rescued from Dehradun (Doiwala forest) and Haridwar (Chiriacpur forest) forest divisions and shifted to Chilla forest for care. Unfortunately, both of them died during care.

Figure 4. Infant feeding on lactogen milk from bottle fixed pipe under care of Radha and mahawat

Mentioned is the third case of such type where we are unable to save the infant. Additionally against to this we have two examples in which elephant's infant had been successfully rescued and shifted to Chilla forest range for care. During 1997 a male elephant (Raja) was separated from group at Haridwar – Dehradun railway track (Motichur – Kansrao rail section) while three members of his group died due to collision with speeding train. Unfortunately after successful capturing he was brought to Chilla forest of the Rajaji National Park. Another such case happened during 2000, when a male baby elephant (Yogi) was shifted to Chilla forest after being rescued from Rishikesh – Dehradun national highway while he strayed from his group.

On the other hand our rescue operations need drastic changes, which include action oriented research on elephant's behaviour. Despite shifting, infant can be re-introduced to possible group on on-spot introduction basis. Additionally, extensive research studies are required on such elephant groups to know more about their behaviour and on the basis of which some recommendations could be given. During June 2000 and January 2001, two elephant's calves died due to collision with train in Haridwar – Dehradun railway track, which is passing in between Rajaji National Park and surprisingly fellows were continuously observed near to their dead bodies for about a day (24 hours), which creates a big problem for forest officials. During May 2007 and March 2008 at Shyampur forest, March 2009 at Chilla forest and October 2009 near to Doiwala forest such type of incidences occurred in which strayed and rescued elephant infants were accepted and brought back by their group members.

### **Recommendations**

1. It was observed during previous year cases that whenever an infant was rescued and shifted to some other place, group was always found wandering near to spot for about two to three days while searching for baby elephant and screaming sounds were always perceived by locals. During 2008 when a one month old male infant was drift down in Rawasan river (Chiriapur forest, Haridwar forest division) and separated from group, forest staff brought the baby to Chilla forest with the view to save him. At that time elephant's movements and vocalizations were continuously observed at Pili forest, just two kilometers away from the spot from where the calf was rescued.

Therefore, based on some previous practical cases and observations it is recommended that during any such case, a small eco-friendly (small wooden pieces, twigs with leaves, fodder species and if possible dung piles may be spread) rough circular fencing of about 20-30 meter (depending upon available space and requirement) should be made and infant should be released inside it. All this will need on-spot operation; for example after releasing the infant, for feeding and care, mahawats, veterinary doctors and wildlife biologists should be deputed for providing extensive care. And during whole of the process a departmental team should be appointed to look after the incidence for example threat from other animals. This can allow the group to bring their baby

safely and is only the method to re-introduce the infant into the group. As elephants are highly social in nature even they were observed to mourn for fellows, besides, their memories are quite strong and therefore, it could save the life of infant.

2. One possibility during the operation is that the selected group may be wrong one wrong, secondly that baby was not rescued before the eyes of her mother and the elephants could smell a lot of human touch, which scared them. Therefore, strong patrolling to search exact group after observing their activities, baby should be touched and feed by only one or two allocated person (mahawats). Even with human touch possibilities of infection may be enhanced.
3. A detailed research is needed to understand the behaviour of elephants in the wild.
4. Despite carnivores several cases of elephants are in front of us and we have learned a lot, therefore, a research oriented action plan is required to be made, which should be entirely practical and could be implemented in field conditions.
5. If not re-introduced and shifted to some other protected area, proper care should be given and precautions should be taken as per the environmental / field conditions.

### **Acknowledgements**

I am thankful to SERC – DST, Govt. of India for providing financial support for studying the elephants of Rajaji National Park. Thanks are due to Dr. Rambir Singh, Director, DST, New Delhi, Mr. C. M. Dobhal, Director and Mr. O. P. Bhatt, Chairman of Doon Institute of Engineering & Technology, Uttarakhand and to Mr. M. S. Negi, Forest Range Officer, Chilla, Rajaji National Park, Mr. Sandeep Rawat, *The Tribune*, Mr. Naveen Pandey and Raju Pushola, *Dainik Jagran* for their cooperation and suggestions during the field work and preparation of this manuscript.

[tariq\\_cp@hotmail.com](mailto:tariq_cp@hotmail.com)

**Abstract:** With the increase in applications using ontologies to represent semantic information, the issue of partially reusing the ontologies is getting more focus of researchers. Ontology construction from scratch is protracted and labor intensive job. Therefore, it is good to fabricate the ontologies by reusing the existing ontologies. Existing techniques for partially importing the ontology do not consider the user choice while selecting the most relevant ontologies for reusing. Most of the approaches have restriction on the size of ontology that is to be modularized. An approach for partially importing the ontologies has been presented in this paper. The proposed technique selects important keywords from a document by calculating term frequency, IR measure and precision along with class match measure to rank the most relevant ontologies. An algorithm to extract ontology fragments has been presented. This algorithm is independent of the size of ontology being reused.

[Tayybah Kiren, Muhammad Shoaib, Muhammad Tariq Pervez, Sonia Majid, Qazi Mudassar Illyas. AN Approach To Partially Import The Ontologies On Semantic Web Based Upon User Choice. Journal of American Science 2010;6(11):571-581]. (ISSN: 1545-1003).

**Keywords:** semantic web; ontology; partial import; knowledge management; user choice; term frequency

## 1. Introduction

Semantic Web is a new generation of the existing World Wide Web in which contents can be expressed in a way that their meanings are easily explicable by the search engines and it has become easier to access, share and assimilate data (Berners and Handler, 2001). Ontology is a way of formally representing a set of concepts within a domain and the relationships between those concepts. It describes the properties of that domain, and may be used to define the domain (Gruber, 1993). Ontology construction from scratch is regarded as a very protracted and labor-intensive job (Craven et al., 2000; Kietz et al., 2000; Maedche and Volz, 2001; Shamsfard and Barforoush, 2002; Khan and Luo, 2002). A better approach is to build the ontologies by reusing the existing ontologies. Many techniques have been devised so far to reuse the ontologies.

A lot of care is needed to select axioms to be copied because very small negligence in this decision can lead to information loss and even making the structure of resulting ontology awkward (Handle and Schenber, 2002). On the other hand, the technique proposed in (Bezerra et al., 2008) does not give much attention towards combining the modules to construct a partially imported ontology.

The techniques proposed in (Stuckenschmidt and Klein, 2004; Grau et al., 2005) divide all ontologies into modules. This is somehow complicated and computationally expensive task especially in cases when a large number of relevant ontologies are available. These approaches also do not give much consideration to the user's choice while selecting the relevant ontologies and relevant module.

This paper presents an approach, which has already been published in form of dissertation of the first author of this manuscript, for partially importing the ontologies. The proposed technique selects important keywords from a document by calculating Term Frequency (TF). It uses IR measure and precision along with Class Match Measure (CMM) to rank the most relevant ontologies. It also gives an algorithm to extract ontology fragments that is independent of the size of ontology being reused. Thus an ontology is constructed by partial reuse mechanism based on user choice and having no irrelevant details. Partially importing mechanism presented in the paper is very simple and having less computational complexities.

The rest of this paper is structured as follows: In section 2, the previous approaches for reusing the ontologies are described. In section 3, we give materials and methods for the proposed approach. In section 4, we present results and

discussion of the proposed approach. Section 5 presents conclusions. And the last section of paper comprises of the future recommendations.

## 2. Related Work

In this section, we give brief overview of some available approaches to partially import ontologies.

Stuckenschmidt et al., (2004) proposed a method to reuse the ontologies by partitioning the large ontologies into small portions or parts according to their class hierarchy structure. This method firstly creates a weighted graph of the ontology to be reused and then identifies the possible partitions from this dependency graph. Difficulty with this approach is that it is only effective for very large ontologies, and this is actually ontology partitioning algorithm but not a complete methodology to reuse the ontologies (Bezerra et al., 2008).

Bezerra et al., (2008) developed a tool for extorting modules from Ontologies. Their approach was based on OOP standards like encapsulation and information hiding. The extorted module was independent and could be easily exchanged with another module with same interface as the implementation details of the module was hidden from the imported ontology. Their approach concentrates more on digging out the relevant module rather than combining the modules to make ontology.

It is a promising approach but there are some deficiencies; like because of hidden implementation, the imported module might give rise to confusion at the end of person using the partially imported ontology and also their approach does not give much attention towards combining these modules to make a partially imported ontology (Grau et al., 2005).

Grau et al., (2009) introduced a module extraction approach based on logic. This approach allows extracting the modules that are based on locality. They proposed an algorithm to build a locality based module. This algorithm divides the ontology into two parts and initializes one part explicitly as void and second portion as the whole ontology. Then it performs locality test which moves the non local axioms to the first part with respect to the given signature. It performs the same thing until all the axioms in the second module are visited. These modules had the advantage that they are small in size. But at the same time the main flaw with this approach is that relationships among classes are not imported correctly, in other words, the modules are based on syntactic positioning (Grau et al., 2009).

## 3. Materials and Methods

This section describes the proposed technique in detail. We have divided the proposed approach into three modules. Algorithm of each module has also been presented. Figure 1 gives the overview of the proposed technique

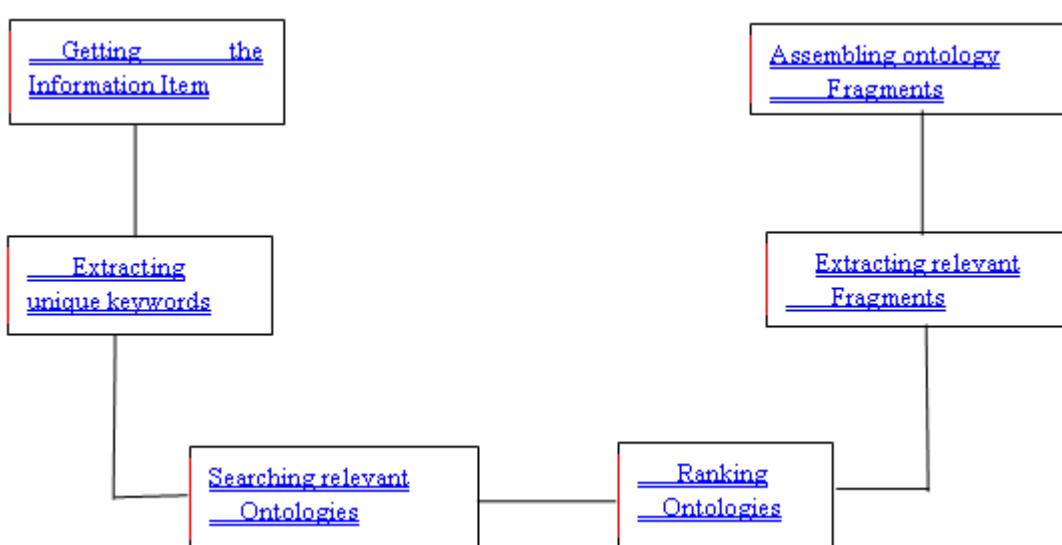

Figure 1. Graphical view of the proposed technique

The proposed technique performs its task in the following three modules.

1. Extracting keywords
2. Retrieval of relevant ontologies

### 3. Partially importing the ontologies

#### 3.1. Extracting Keywords

**Input:** Information item

**Output:** list of keywords

In this module the system takes information item of user's interest. This information item may be a dynamic web page, a web page saved in a local directory or data from some online or offline repository. This document is then passed to a keyword extracting mechanism. The mechanism also sorts the important keywords from the set of extracted keywords.

The steps followed in this module are:

##### 3.1.1. Getting the Information Item

In this step, any information item as per user's interest is received. The information item is received with its full completeness. This information item may be a dynamic/static web page, a web page stored in local directory or a document from an online or offline repository. The document is taken for the purpose of extracting keywords as if a user is exploring/reading some document and he/she wants to search ontology for some keyword (e.g. department, faculty etc). The interest/choice of the user is given much importance because different users have different types of needs, caliber and domain of interest. The benefit of giving the choice to user to select document according to his/her interest is that the user has knowledge about the information item, extracted keywords and thus retrieval of relevant ontologies is easy and comfortable.

##### 3.1.2. Extracting unique keywords

In this step, we extract unique words from the information item. In the extracted unique words the unwanted words like stop words and other signs are not included. As they are neither unique words nor of interest to the user. First the information item is converted to plain text. Then unique keywords are extracted from it and TF of each keyword is computed. The formula for calculating TF as given by (Yates and Neto, 2005)

$$tf_{i,j} = n_{i,j} / \sum_k n_{k,j} \quad (1)$$

Where  $n_{i,j}$  is the number of times a word  $t_i$  appears in the document  $p_j$  and the denominator in the above equation is sum of occurrences of all the

words in the document. After this, the words with TF value above the threshold 0.043 are selected.

#### Algorithm for Extracting Keywords

The processing steps for the Module of extracting keywords are illustrated in an algorithmic form below:

**ALGORITHM:** Generating a set of unique keywords from an information item.

**INPUT:** Information item

**OUTPUT:** Set of keywords.

**STEP1:** /\*getting the Information item

    1.1: Get the document (information item) with its full completeness

**STEP2:** /\* Extracting unique keywords

    2.1: **IF** it is a web page

        2.2: Convert the web page into UTF-8 encoding

        2.3: Perform preprocessing on the page (e.g. Removing HTML tags, Multimedia Contents, links, frames etc)

        2.4: **ELSE GOTO** step 2.5.

        2.5: Convert the document to plain text (Removing stop words etc.)

**End If**

    2.6: Parse the whole document in separate words

    2.8 Compute number of times each word appears in the document

    2.9 Compute the total number of time all the words appear in the document

    2.10 Compute TF (Term frequency) of each word by dividing the results of Step 2.8 by 2.9

    2.11: Save words with TF value above the threshold.

**END**

Algorithm of extracting keywords shows a complete process of extracting keywords from an information item. If an information item is a web page then following two steps are performed: 1) the information item is converted into a UTF-8 encoding document. 2) A preprocessing is performed in which the HTML tags, multimedia contents, links and frames etc. are removed. The purpose of performing preprocessing is to reduce the size and complexity of the information item. Then the information item is converted to a plain text. Now, in the whole information item, each word's occurrence is computed. Then, an aggregation of all word's occurrences in the information item is computed. Finally TF of each word is computed by dividing the occurrence of a single word by the total occurrences

of all words in the information item. Figure 2 shows graphical representation of this algorithm.

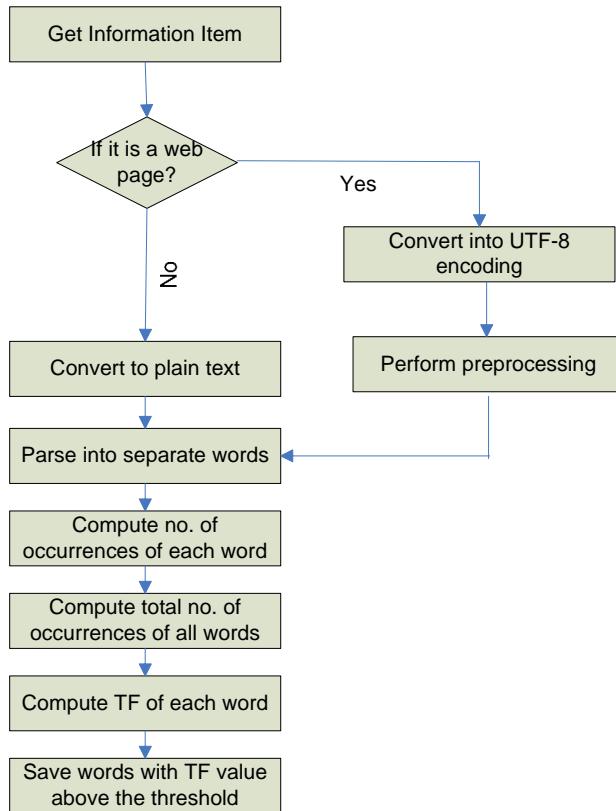

Figure. 2. Graphical view of algorithm of extracting keywords

### 3.2. Retrieval of relevant ontologies

**Input:** Set of keywords

**Output:** List of relevant ontologies

This module uses the list of keywords generated by the module of extracting keywords as an input. After retrieving the ontologies relevant to the set of keywords, this module ranks the ontologies on the basis of their similarity to the keywords set. The module performs the following two steps:

#### 3.2.1. Searching ontologies

This step is concerned with giving a query consisting of keyword(s) to the ontology search engine and saving the set of relevant ontologies retrieved. Output of this step will be a set of retrieved ontologies from the Semantic Web.

#### 3.2.2. Ranking the Ontologies

**Input:** List of ontologies

**Output:** Set of most relevant ontologies

This step of the proposed technique is concerned with re-Ranking of the list of ontologies retrieved using the CMM, IR measure and precision. First we find out that to which extent the class of ontology is matched to the keywords, which is determined by CMM. The formula for CMM is as given by (Alani and Brewster, 2008).

$$\text{CMM } (o, K) = \alpha E(o, K) + \beta P(o, T)$$

The number of classes of ontology is calculated whose labels match with the K. Then this information is used to calculate the CMM. Where  $\alpha$  and  $\beta$  are the measures of exact and partial match. Now the Precision of ontologies selected is calculated. Precision is based upon the user choice, mean, if the user thinks that the document is relevant. Formula for the precision is as given by (Yates and Neto, 2005).

$$P = |R_a| / |A|$$

The ontologies retrieved are ranked according to the decreasing order of precision and CMM.

Algorithm of this module is divided into two parts/algorithms:

- 1 Algorithm for retrieving ontologies
- 2 Algorithm for ranking/retrieving most relevant ontologies

#### ALGORITHM: Retrieving Ontologies

**Input:** A list of keywords

**Output:** A list of ontologies: List\_Ontologies

1. Get a list of keywords
2. Provide the list of keywords to the search engine
3. Save the relevant ontologies in List\_Ontologies

Return List\_Ontologies

End

#### ALGORITHM: Retrieving Most Relevant Ontologies

**Input:** A list of relevant ontologies: List\_Ontologies

**Output:** A list of most relevant ontologies: List\_MostRel\_Ontl

**For** each ontology in List\_Ontologies to length (List\_Ontologies) **do**

Calculate CMM of List\_Ontologies [ontology] as per equation 2

Apply IR measure and precision on List\_Ontologies[ontology] as per equation 3

List\_MostRel\_Ontl[ontology]=List\_Ontologies[ontology]

**End For**

```

Sort List_MostRel_Ontl in decreasing order of
precision and CMM
Return List_MostRel_Ontl
End

```

### 3.3. Partially Importing the Ontologies

**Input:** Output of Module 1 and Module 2

**Output:** Partial ontology

This module of the proposed technique is concerned with actually making it possible to generate the ontology through partial importing from the other ontologies. It performs its task by pursuing the following steps:

#### 3.3.1. Extracting relevant fragments

This step deals with the finding and retrieval of the fragments or portions of the selected ontologies that best match the set of important words. An algorithm is designed to extract relevant fragments from selected ontologies. Figure 3 shows graphical representation of the algorithm.

**ALGORITHM:** Generating fragments of ontologies relevant to the set of keywords.

**INPUT:** An ontology and set of keywords

**OUTPUT:** A relevant ontology fragment

1.1: Create **TobeKept**- A data structure containing nodes included in the retrieved fragment

1.2 Create **TobeChecked**-A data structure containing all the nodes in the ontology

1.3: Current=first element of TobeChecked

1.4: **WHILE** not end of TobeChecked DO

1.5: x = Current

1.6: Compare x with set of keywords

1.7: **IF** matched with any one from the set

1.8:**IF** x  $\notin$  TobeKept

1.9: Insert it and only its direct subclasses and properties into the TobeKept (by Referring to its child nodes)

**END IF**

**END IF**

1.10: Current=next element of the TobeChecked

**END {WHILE}**

**Return** TobeKept

**END**

#### 3.3.2. Assembling the Fragments

This is the final step of our proposed approach where we will finally construct ontology by assembling the ontology fragments resulted from step 1 and by adding the classes and properties that are defined specifically for that ontology.

## 4. Results and Discussion

In this section, we validate the proposed technique and present its result. As an experiment we use a document stored in our local disk as the information item. This document is about a university which is organizing a software exhibition where PhD thesis (S/W Products) is placed. Hence, we construct ontology about the university described in the document. We show that how our proposed technique is used to construct a partially imported ontology of the university described in the document.

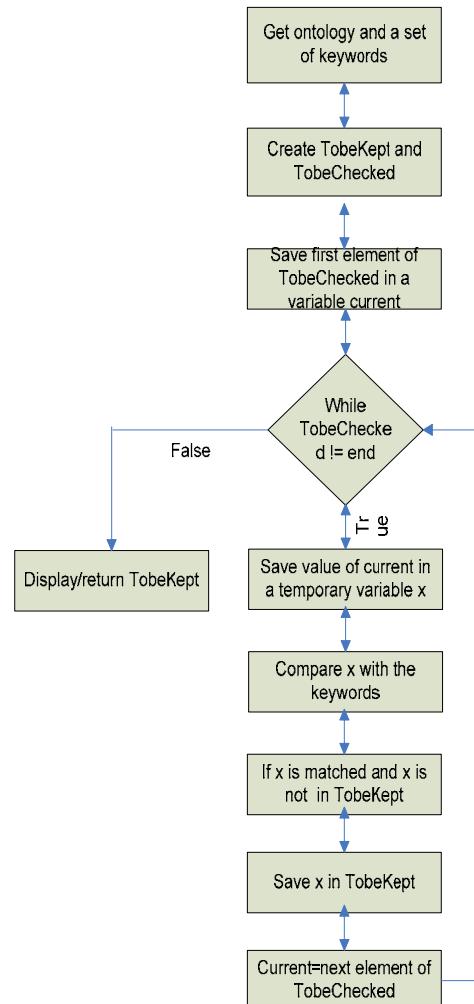

Figure 3. Flow diagram of algorithm of generating fragments of ontologies

### Module 1: Extracting keywords

The document is fed into a keyword extractor (Webseo, 2010). We calculate the TF value of each keyword extracted by the keyword extractor and select the words with TF value above the

threshold value 0.043. Following table shows the list of keywords and their TF values. There are a total of 25 keywords extracted.

As table 1 shows, the set of keywords having TF value greater than 0.043 is K= {University, Department, Thesis, Faculty, Dean, Magazine, Institute, Exhibition, Publisher}.

#### **Module 2: Retrieval of relevant ontologies**

Using the available list of keywords (table 1) related ontologies can be searched from the web. SWOOGLE (Swoogle, 2010) is used for this purpose. Table 2 shows the set of ontologies present on web that are considered to be relevant to the set of keywords according to the professionals.

Once ontologies are retrieved, we re-Rank and then select the most relevant ontologies from the resulting ontologies using the precision measure which is based on the user choice and the CMM value. Table 2 shows re-ranking of the ontologies.

In this experiment we use threshold value of 30% for precision and 4.0 for CMM. Only the ontologies with CMM greater than or equal to 4.0 according to (Tun and Dong, 2008), and precision greater than 30 %, are selected as shown in table 4.

### Module 3: Constructing partially imported ontology

Now, from the above five most relevant ontologies we extract the most relevant fragments using the proposed algorithm for extracting relevant fragments. For example, I use two ontologies (Maponto, 2010; Org, 2010). Ontology in (Maponto,

2010) contains the classes and relationships mentioned in the table 5 in it. This is clear that if we want to reuse this ontology it is not suitable to import the whole ontology because of space complexity. Therefore, instead of importing the whole ontology only a relevant portion of ontology is extracted using the proposed algorithm.

Table 5: Table for TobeChecked

S.No	Classes	Direct classes and properties
1	Work	Research Course, Work Title
2	Journal	
3	School	
4	Faculty	Professor, Lecturer, Post Doc, Teacher of
5	Worker	Faculty, Admin Staff, Assistant
6	Periodical	Journal, Magazine
7	Article	Book article, Journal article, Conference Paper, Technical Report
8	Thesis	Master Thesis, Doctoral Thesis
9	Professor	Full Professor, Associate Professor, Dean, Visiting Professor, Tenured
10	Admin Staff	Director, Dean, System Staff, Clinical Staff
11	University	Master Degree from, Doctoral Degree from
12	Person	Student, Member, Research Interest, email Address, Person Name, Age
13	Student	Undergraduate Student, Graduate Student, Takes course
14	Magazine	
15	Department	
16	Dean	
17	Organization	Department, School, Institute, University, Research group, Affiliated Organization
18	Research Group	
19	Research Assistant	
20	Doctoral Thesis	
21	Publication	Thesis, Book, Manual, Publication author, Publication Research, Pub Title, Periodical
22	Course	Has TAs, has Instructor

Now for extracting the classes that are partially or exactly matched with the set of keywords is done by traversing table 5. In the 1st iteration the ‘Work’ is not matched with any of the keyword, therefore, the algorithm again goes to step 1.4

(Algorithm of generating fragments). Now, the next element is ‘Journal’ which is also not matched with any keyword. This process will be repeated until table 5 is finished. Table 6 shows the contents of TobeKept.

Table 6: Table for TobeKept

S.No	Classes	Direct Subclasses and Properties
1	Faculty member	Professor, Lecturer
2	Thesis	Master Thesis, PhD Thesis, Supervised by
3	University	Has
4	Magazine

S/W Product	Presented

Figure 6 shows the graphical representation of the ontology constructed by assembling the above fragments and with adding some new classes and relations.

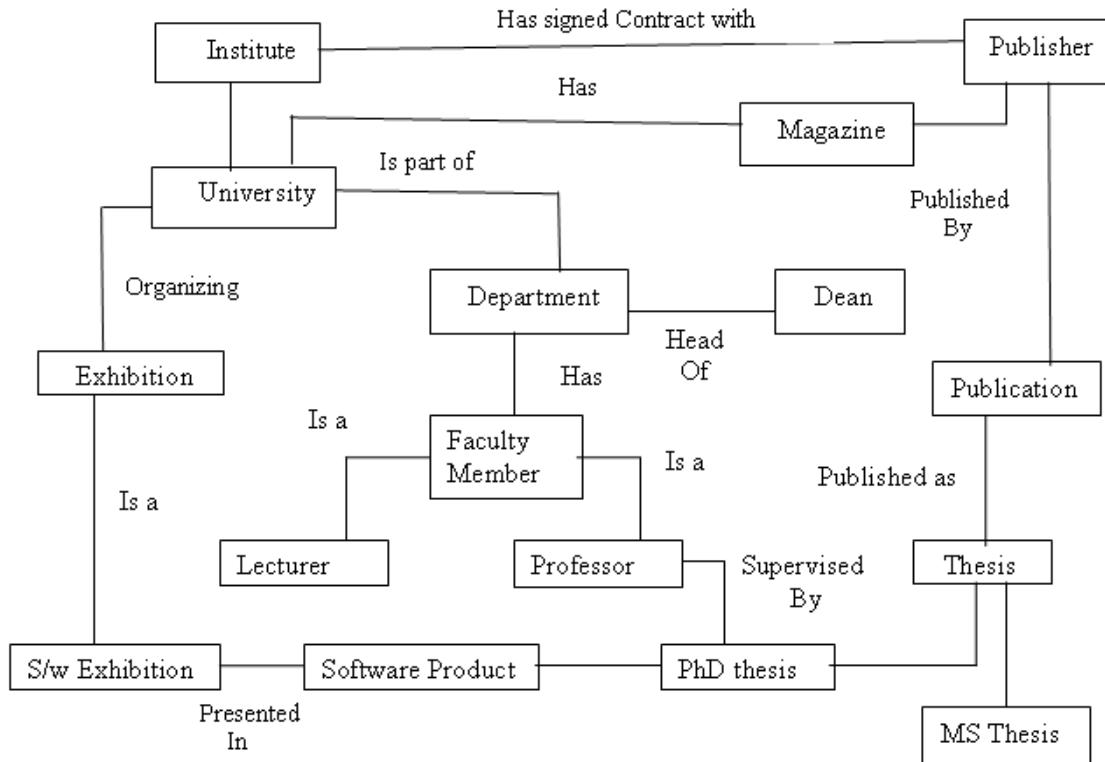

Figure. 6. Graphical representation of Resulting ontology

The resulting ontology is created by reusing the fragments extracted from the existing ontologies. It also contains some other classes and relations that are unique to it. The resulting ontology is the ontology of university that is organizing a software exhibition where the PhD thesis is published as a publication in a magazine. University has department and department has faculty member which include both lecturers and professors and a PhD thesis is supervised by a professor. Department is headed by Dean. Institute has signed a contract with a publisher and institute is a university in our example. Resulting ontology has no irrelevant details, thus reducing the large memory requirement for storing it.

## 5. Conclusions

This paper proposes an approach to partially import the ontologies based upon the user choice. It allows a user to built ontology of any document available at any source. This approach extracts keywords from the document of interest to user by including an important measure term frequency. Then it searches the existing ontologies from the web relevant to these keywords, ranks them and selects the most relevant ontologies with the help of precision measures and CMM, taking into account the user's choice. Then it traverses through the ontology and selects the classes which are matched to

any of the set of keywords along with their direct subclasses and properties, and makes a fragment of it. Then it constructs a partially imported ontology by defining some new classes and properties according to requirement and assembling and including the fragments extracted from the existing ontology. The end result of our approach is an ontology which is constructed by partial reuse mechanism based on user choice and having no irrelevant details. Hence it is concluded that if we partially import the ontologies according to the user choice then we result with the partially imported ontology which do not contain the extra details and also the partially importing mechanism is very simple with very less computational complexities.

## 6. Future Recommendations

The proposed technique has not been implemented. Work can be carried out with the aim to develop a complete application that enables the user to partially import the ontologies. This approach will be applied for knowledge management and knowledge management is an asset for success and survival in an increasingly competitive and global market, so using ontologies for the knowledge management in a good way by partially importing the ontologies is the need of time and this is area where research can be carried out.

It is needed to explore more robust strategies to evaluate the quality of the resulting partially imported ontology by our approach. Fragment ranking can improve the quality of our resulting ontology. The research can be carried out in order to implement ontology fragments by fragment ranking.

## Acknowledgements

We are thankful to the Higher education Commission of Pakistan for her generous financial support. This research paper is extracted from dissertation of the first author. She is very grateful to her supervisor and colleagues who helped her in extracting, writing and finalizing this research paper from her dissertation.

# The Use of Lemongrass Extracts as Antimicrobial and Food Additive Potential in Yoghurt

Shaaban, M. Abd-El Fattah<sup>\*1</sup>; Abo sree, Yahia Hassan<sup>1</sup>; Hala M. Bayoum<sup>2</sup> and Hesham A. Eissa<sup>3</sup>

Food Toxins and contaminants Department<sup>1</sup>, Dairy Department<sup>2</sup>, Food Technology Department<sup>3</sup>, National Research Centre, Cairo, Egypt.

<sup>\*</sup>shaabanmostafa@yahoo.com

**Abstract:** The following study was conducted to investigate the antifungal and food additive potential of medicinal plants. herbal decoction and essential oil (EO) extracts of *Cymbopogon flexuosus* (lemongrass) leaves and stems were tested for their inhibitory action against spoilage organisms and mycotoxins formation in two separated experiments. In the first experiment, yeast- extract sucrose medium (YES) was used as a basal medium to examine the mold growth and mycotoxin production by three pathogenic fungi: *Aspergillus flavus* (*A. flavus*), *Aspergillus parasiticus* (*A. parasiticus*) and *Aspergillus ochraceus* (*A. ochraceus*). The YES medium was supplemented with four different concentrations of Lemongrass oil, inoculated with 1-mL of a spore suspension containing  $10^5$ - $10^6$  conidia of each test mold and then incubated at 28°C for 14 days. After incubation period, cultures were analyzed for mycelial dry weight and mycotoxin accumulation. In the second experiment, yoghurt medium was used as a basal medium and the same system of study was applied in two different degrees of temperature (5°C and 28°C) for 4 weeks. Evaluation of the Lemongrass oil activity in yoghurt samples focused on the microbial stability of yoghurt, sensory evaluation as well as mold growth and mycotoxin formation. In the 1<sup>st</sup> experiment, the level of 0.1% of the EO extract was effective in inhibition both mold growth and mycotoxin production for all tested molds, and 0.3 % extract completely prevented the growth and toxin production. whereas, 1% of the decoction extract was effective. So, the EO extract was the suitable agent in the second experiment. It is of interest to note that while reduction in mold growth due to increasing extract concentrations was observed, the most striking effect was the reduction of mycotoxin production. The obtained data from the second experiment showed that the EO extract (0.1% concentration) inhibited viable yeasts and preserved yoghurt for over 28 days at 5°C. Also, the inhibitory action of the EO extract against yeasts was concentration dependent. The maximum inhibitory effect was found when the extract level increased above 0.1%. Incubation temperature had an important role in growth and mycotoxin production in yoghurt medium. During cold storage for 28 days at 5°C, the different concentrations of the EO extract added to yoghurt samples displayed different titratable acidity and total bacterial cells and pH than the control yoghurt ( $p < 0.05$ ). Overall sensory acceptability of yoghurt supplemented with the EO extract was higher than that of the control yoghurt prepared without the EO extract. The results indicate that the addition of the appropriate the EO concentration (0.1%, w/v) improved the physicochemical properties as well as sensory characteristics of yoghurt, could be used for decontamination of dairy products such as yoghurt from mycotoxicogenic fungi and mycotoxins formation, beside its beneficial properties as a functional food.

[Shaaban, M. Abd-El Fattah; Abo sree, Yahia Hassan; Hala M. Bayoum and Hesham A. Eissa. The Use of Lemongrass Extracts as Antimicrobial and Food Additive Potential in Yoghurt. Journal of American Science 2010;6(11):582-594]. (ISSN: 1545-1003).

**Key words:** Yoghurt, lemongrass, molds, yeasts, mycotoxins, aflatoxins, ochratoxin A, food additives.

## 1. Introduction:

Yoghurt in addition to its high nutritional value, it possesses antagonistic and therapeutic values. The valuable sensory characteristics of yoghurt are due to its content of carbonyls, mainly acetaldehyde, acetone, diacetyl and ethanol, produced by yoghurt bacteria. Yoghurt provides higher levels of protein, carbohydrate, calcium and certain B vitamins than milk (Gurr, 1987; Deeth and Tamime, 1984). The shelf life of yoghurt is short, i.e., one day under ambient condition (25–30°C) and around five days at 7 °C, which hinders its commercialization (Salji, 1987). Yoghurt defects

due to microbial contamination are widely reported in literature; the most frequent contaminants are yeasts and moulds (Spolaor *et al.*, 1988; and Abdel-Fattah and Abdel-Salam 2004) usually causing the swelling of packs, the presence of superficial coloured spots and abnormal tastes (Ottogalli, 1991). The low pH of yoghurt offers a selective environment for the growth of acid tolerant yeasts and molds (Banaquio *et al.*, 1981, Spillmann and Geiges, 1983). Therefore, it is not surprising that various investigators have found that yeasts are the primary spoilage microorganisms for yoghurt and that fruits, flavors, and colouring agents are frequent

contamination sources (Main, 1984; Weber and Broich, 1986). The spoilage of yoghurt by yeasts has been generally characterized by yeasty offflavors, loss of textural quality due to gas production, and swelling and occasional rupturing of the product containers (Davis, 1974). As a result, there is an apparent need for an effective preservation method to control acid-tolerant spoilage yeasts and molds in yoghurt.

Micotoxigenic Fungi and Pathogenic bacteria can grow at refrigeration temperature to numbers, which can result in an infection. For this reason dairy products should be kept well covered to prevent contamination, should ideally be consumed within two days of opening, or used in cooked foods after that two-day period (Potter and Hotchkiss, 1995). Mycotoxins may be found in milk products, originating from three possible sources: raw milk (such as aflatoxin M1 which present as a consequence of aflatoxin B1 metabolism by the animal); growth of a toxigenic fungal strain on product and mycotoxins synthesis, and production of these toxins in dried milk used to make milk product (Jose *et al.*, 1988).

Hence, it is highly desirable to prevent mould growth or to prevent mycotoxins formation in contaminated food. Several chemicals have been used to detoxify mycotoxins but these chemicals can not be added to foods to prevent mycotoxins formation because of their hazardous effect on human health. In recent years, studies on the natural antifungal agents, herbs and spices, have been reported by numerous investigators (Afrodit, *et al.*, 1995; Hiroshi and Sato, 2002; and Abd-EL Fattah and Abdel-Salam, 2004). They found that some herbs and spices had antifungal effect against some kinds of mycotoxic fungi, such as *A. flavus*, *A. ochraceous* and *A. parasiticus*, in synthetic medium. Among herbs and spices used, were sage, thyme, rosemary, mint, and Lemongrass.

*Cymbopogon flexuosus* (Lemongrass) is an economically important plant that has been used for centuries, as a medicine because of its wide-ranging therapeutic properties included relief of rheumatic and other pain and healing effect on ulcers (Fenwick *et al.*, 1990). Flavonoids extracted from Lemongrass are of considerable interest as natural plant components with antioxidant and antifungal activity (Pratt and Hudson, 1991; Nieto *et al.*, 1993; and Abu-Seif, *et al.*, 2009). Of the flavonoids present in Lemongrass, licochalcone A and licochalcone B which have equal antioxidant activity of vitamin E, and glabrene which is 3 times as active when compared with vitamin E (Okuda *et al.*, 1989).

One objective of the present study was to investigate the inhibitory action of Lemongrass oil

against spoilage organisms and mycotoxins formation in yoghurt under laboratory conditions. The use of Lemongrass herb in this study was due that Lemongrass is naturally occurring material, widely cultivated, cheap, had a medical functions and safe. These properties and the antifungal activity, if possible, make lemongrass oil may be potential multi-functional food additives. The physic-chemical properties, colour characteristics, total phenol content, microorganisms, sensory evaluation and the effect of storage time at 5°C for 2 months of yoghurt were also studied.

## 2. Materials and methods

### 2.1- Experimental design.

Depending on our previous results (Abdel-Fattah, 2002; Abdel-Fattah and Abdel-Salam, 2004 and Abu-Seif, *et al.*, 2009), concerning the antimicrobial effects of herbal extracts, this study was achieved. Two separated experiments were carried out during this study. The first experiment was to examine the best of the tow different extracts of Lemongrass, essential oil (EO) extract and decoction extract as antifungal agents. In the second experiment, the best extract selected from the first study was used on yoghurt medium, to test its antifungal effects and to study the physico-chemical properties, colour characteristics, total phenol content, as well as microbial stability and sensory evaluation of yoghurt during storage time at 5°C for 4 weeks.

### 2.2- Organisms.

*a- Fungal strains:* *Aspergillus flavus* (*A. flavus*), aflatoxigenic local strain; *Aspergillus parasiticus* (*A.parasiticus*) NRRL 2999 and *Aspergillus ochraceus* (*A.ochraceus*) NRRL 3174, were obtained as lyophilized preparation from the Mycotoxin lab., National Research Center, Dokki, Giza, Egypt.

*b- Bacterial strains:* Starter culture of Yoghurt *Streptococcus salivarius* subsp. *thermophilus* and *Lactobacillus delbrueckii* subsp. *bulgaricus* (1:1) was obtained from HACCP certified and ISO22000: 2005 Dairy Company, and used as a source of the starter culture.

### 2.3- Milk used for making of lab. Yoghurt:

Raw buffalo's milk used for making yoghurt, the milk was obtained from a dairy farm at Agriculture faculty, Cairo University Governorate. Starter cultures used for making plain yoghurt Old plain yoghurt obtained from HACCP certified & ISO22000: 2005 Dairy Company was used as a source of the starter culture.

#### 2.4- Plant material:

Lemongrass powder (leaves and stems) was purchased from an Egyptian local market (Harraz Co., Cairo, Egypt).

#### 2.5- Mycotoxins standards:

All standards of Mycotoxins (Aflatoxins, B<sub>1</sub>, B<sub>1</sub>, G<sub>1</sub>, G<sub>2</sub>, and ochratoxin A) were purchased from sigma company, USA.

#### 2.6- Analytical methods:

##### 2.6.1- Extract preparations of Plant material:

Lemongrass powder was purchased from a local market and the samples were extracted as follow:

a- Preparation of herbal decoction: Decoctions of lemongrass leaves were prepared by boiling the powder material at solid: liquid ratio 1:10 with distilled water for 5 minutes. The vessel containing the decoction and herb was then covered and removed from the heat and allowed to cool for 5 minutes. The herbal material and liquid was then strained through cheese cloth and the resulting decoction placed into 100 mL reagent bottles which had been kept for use as the test decoction (Abdel-Fattah and Abdel- Salam, 2004).

b- Preparation of herbal Oil: Briefly, 250 gm fresh plant material (leaves and stems) of lemongrass plant was put in a round bottom flask and 1000 mL distilled water was added before subjecting to hydro-distillation (Bankole and Joda, 2004) for 6 hours. The oil was recovered and dried over anhydrous sodium sulphate.

##### 2.6.2- Spore suspension of fungal strains:

These culture strains were grown on (PDA) slants for 10 days at 25 °C Until will sporulated . the spores were washed from the slants with a sterile 0.01% solution of tween 80 as a spore dispersal agent. The final spore preparations were resuspended in the appropriate volume of sterile saline to yield a direct microscopic count of approximately 10<sup>5</sup>-10<sup>6</sup> spores /mL, of each tested fungus.

##### 2.6.3- Preparation of yoghurt containing Lemongrass essential oil:

Raw buffalo's milk was subjected to a heat treatment at 72°C for 2 seconds to kill microorganisms followed by cooling to 40 – 45°C. Oil extract of Lemongrass was added to milk before processing with different concentrations. As starter culture yoghurt (*L.bulgaricus* and *S. thermophilus*) was added (1.5%) to the milk, followed by mixing,

and packed in sterilized glass capped cups 100 mL capacity, followed by incubation at 40°C for 3 hours till gel forms (pH 4.5). Freshly yoghurt was cooled and stored at refrigeration at 5°C till examination to slow down the physical, chemical and microbiological analysis.

##### 2.6.4- Antifungal assay:

2.6.4.1- With yeast extract sucrose medium (YES): Yeast extract- sucrose (YES) broth (2% yeast extract, 15% sucrose) was used in the 1st experiment as a basal medium for mould growth and mycotoxin production in stationary cultures (Davis *et al.*, 1966). Each medium (50 mL) in 250 mL Erlenmeyer flasks was sterilized at 121°C for 15 min. For each organism used, the appropriate amounts of lemongrass EO and lemongrass decoctions were added into sterile YES to obtain the concentrations of 0.05, 0.1, 0.3, 0.5 and 1.0 %. YES without any herbal extract added served as control. Each flask with or without appropriate extract was inoculated with 0.1 mL spore suspension, then cultures were incubated at 28°C in the dark for 14 days. Each concentration of tested extracts was tested twice, sometimes three times.

2.6.4.2- With yoghurt medium: The same antifungal assay on YES, was applied on yoghurt medium except that extract used was the EO extract, added to milk before processing and the culture media were incubated at two different temperature, 5 and 28 °C for 35 days. Yoghurt medium were inoculated with mycotoxicogenic fungi and stored for 35 days at 5 and 28 °C. Semi quantitative assay of the tested oil extract was conducted according to Harboure (1973).

##### 2.6.4.3- Evaluation of antifungal properties of lemongrass extracts.

a- *With YES broth media:* Contents of flasks, with and without (serve as the control) lemongrass extracts, were analyzed in triplicates for dry weight of mycelium and mycotoxin accumulation. Dry weight of mycelium was determined according the method of Davis *et al.*, (1966). Aflatoxins were extracted and determined according to the AOAC methods, (1980). Ochratoxin A (OA) was extracted and determined according to the method of Scott *et al.*, (1971). Percent reduction or accumulation over control, in growth or mycotoxin production was calculated by the following equation:

$$\text{Percent reduction} = 100 - \{(A_1 / A_0) * 100\}$$

$$\text{Accumulation over control} = \{(A_1 / A_0) * 100\} - 100$$

Were:  $A_1$  = The amount obtained by treatment.

$A_0$  = The amount obtained by control.

b- *With yoghurt medium:* Fungal growth of all tested molds were visually assessed using a semi-quantitative scale, Viz.(0) no growth; (1) very little growth covered the surface of the plate; (2) 25 % of the plate surface covered; (3) 50% of the plate surface covered; (4) 75 % of the plate surface covered and (5) 100% of the plate surface covered. Yoghurt medium were examined for the presence of aflatoxin production as described by the AOAC methods, (1980). For ochratoxin A, cultures were extracted, and OA levels were determined as described by Valenta and Michael, (1996).

#### 2.6.5- Microbiological stability of yoghurt:

The microbial stability of yoghurt containing the EO extract of lemongrass during storage at refrigerator (5°C) for 28 days were investigated. The populations of total bacteria, yeast and molds were determined by the method of Sadler, *et al.*, (1992). The counts of total bacteria (TPC), yeast and molds (Y&M) calculated per one gram of all yoghurt slices using plate count agar and malt extract agar (Merck KGaA, Darmstadt, Germany). The number of colonies (TPC or Y&M) that appeared on the plates was counted and expressed as Colony Forming Unit (CFU/g).

#### 2.6.6- Determination of pH:

The pH of fruit sample was measured using a combination pH electrode with a digital pH meter (HANNA, HI 902 meter, Germany) standardized with stirring as described in (AOAC, 2000).

#### 2.6.7- Determination of total soluble solids (TSS):

The percent total soluble solids, expressed as oBrix, were determined with a refractometer (ATAGO, Japan).

#### 2.6.8- Determination of Titratable acidity (TA):

Titratable acidity were determined as described by (Tung *et al.*, 1995) by using approximately 10 g portion of yoghurt sample blended with 100 mL distilled water for 30 sec in blender and was titrated to pH 8.0 with a 0.1N NaOH solution. The end point was determined with a pH-meter. Titratable acids in the sample were calculated as percent of lactic acid.

### 2.6.9- Viscosity measurements:

The viscosity measurements were carried out using a HAAKE viscometers (HAAKE, Mess-Technik GmbHu. Co., Germany) with thermostatic bath to control the working temperature within the

temperature of 25°C. Results of viscosity were expressed in centipoise (cP) according to the method of Ibarz *et al.*, (1994).

#### 2.6.10- Total phenol determination:

Total phenol content of the untreated and treated samples was measured by the method of Amerine and Ough (1980), the absorbance was measured at 765nm using Spectrophotometer, UVD-3500, Labomed, USA and the results were expressed as milligram of garlic acid as standard equivalent per gram.

#### 2.6.11- Colour characteristics determinations:

Colour is one of the more important quality parameters in processed products. Undoubtedly, possible colour changes would influence the Organolytic properties of samples and would limit their potential applications.

Hunter  $a^*$ ,  $b^*$  and  $L^*$  parameters were measured with a colour difference meter using a spectrophotometer (Tristimulus Colour Machine) with the CIE lab colour scale (Hunter, Lab Scan XE - Reston VA, USA) in the reflection mode. The instrument was standardized each time with white tile of Hunter Lab Colour Standard (LX No.16379):  $X=72.26$ ,  $Y=81.94$  and  $Z=88.14$  ( $L^*=92.46$ ;  $a^*=-0.86$ ;  $b^*=-0.16$ ) (Sapers and Douglas, 1987). Colour difference, Delta E, was calculated from  $a^*$ ,  $b^*$  and  $L^*$  parameters, using Hunter-Scotfield's equation (Hunter., 1975) as follows.

Delta E = ( $\delta a^2 + \delta b^2 + \delta L^2$ )<sup>1/2</sup> ----(1)  
 where : a -  $a_o$ , b -  $b_o$  and L -  $L_o$ ; subscript "o"  
 indicates colour of control or untreated sample.

The Hue-Angle ( $H^*$ ), Chroma ( $C^*$ ) and Browning Index ( $B_I$ ) was calculated according to the method of Palou *et al.*, (1999) as follows:

$$C^* = \text{square root of } [a^{2*} + b^{2*}] \quad \dots \dots \dots \quad (3)$$

Where:  $X = (a^* + 1.75L^*) / (5.645L^* + a^* - 3.012b^*)$

#### 2.6.12- Sensory Evaluation:

Sensory evaluation of the studied was carried out included 20 experienced panelists. The attributes such as: flavour intensity, body, texture and colour were organolptically assessed at stated by (Crandall, *et al.*, 1990). The all tested samples subjected to sensory evaluation after 28 days in yoghurt samples.

## 2.7- Statistical Analysis:

Analyses for experiments were performed in duplicated, and results were averaged. A Duncan Multiple Range Test was carried out by means of the "shortest significant ranges SSR" (Larmond, 1974)

to determine the differences between the treatments using HDSS statistical analysis program.

### 3. Results and Discussion:

#### 3.1- Antifungal effect of the two different extracts of lemongrass on YES borth medium:

Data presented in Table (1) clearly indicate that mould growth by all tested strains, were suppressed by lemongrass oil extract or decoctionextract. The inhibitory effect of these extracts was proportional with their concentrations. Slightly effect on fungal growth was observed when low concentration (0.05% and 0.1%, respectively) of the EO extract and decoction extract were applied, whereas high concentrations of these extracts inhibited fungal growth and, consequently, mycotoxin formation. The maximum inhibitory effect of these extracts were recorded at the level 1 % and 0.3% for decoction extract and EO extract, respectively (Table, 1).

In regard to Table (2), *A. ochraceus* was more sensitive one for the two lemongrass extracts than the two other molds. The EO extract was more effective agent on mycelial growth than decoction extract. The inhibitory effect of the two different extracts on mycelial growth according to the mold type, may be rankled as follow: *A.ochraceus* > *A.flavus* > *A. parasiticus*, for the EO extract. However, for decoction extract were: *A.ochraceus* > *A. parasiticus* > *A.flavus*. These differences in the inhibitory effect may be mainly due to interfering some factors: the mold type, incubation temperature and type of extract and subsequently the differences in the chemical composition for each extract. In this respect, many publications indicated that the compositions and concentrations of compounds within the distinct types of herbal extract preparations would differ and play an important role in its antifungal activity action (Buchanan and Shepard, 1981; Lienert *et al.*, and Nass *et al.*, 1998; and Abdel-Fattah and Abdel-Salsm, 2004). Also, El Gendy and Marth, 1980, reported that temperature is one factor affects mold growth and mycotoxin production by toxigenic aspergilli and penecillus and in the presence of lactic acid bacteria. Abdel-Fattah, (2002), found that mold type and incubation temperature were important factors affecting mold growth and aflatoxin production by *A. flavus* and *A. parasiticus* in media contained solvent extracts of licorice.

Data represented in Table (2) clearly indicate that increasing levels of the extract, in YES broth media, resulted in detection of decreasing levels of mycotoxin production. At the lowest level (0.05% extract), reduction in mycotoxin production was slightly decreased in the media supplemented

with decoction extract compared to those supplemented with oil extract. Increasing extract concentrations caused a linear depression in mycotoxin formation by the all tested molds, but the maximum inhibitory effect was differ, and this may be referred that organism was more variable in its reaction to the extract. This trend indicates that extract inhibited mycotoxin formation by inhibiting the mould growth. In a similar study, Masood and Ranjan (1991) reported that extracts of *Argemone mexicana* and *cyperus rotundus* inhibited aflatoxin production by inhibiting the growth of *A. flavus*. Also, Mahmoud, (1994), found that extracts of *lupinus* and *xanthium punens* inhibited aflatoxin production by inhibiting the growth of *A. flavus*.

Reduction of fungal growth and mycotoxin production by the EO extract in our study was due to interference by active principles of these extracts. Such interference may be at the biosynthetic levels. In this respect, Kumar and Prasad (1992) suggested that growth and aflatoxin production by *A. flavus* are proportionate processes. However, Bhatnagar and McCromick (1987) reported that the growth and aflatoxin production by *A. parasiticus* are independent phenomena. On the other hand, Abu-Seif, *et al.*, (2009) reported that oil extract of lemongrass leaves and stems, completely inhibited mycelial growth and mycotoxin production of *A. flavus*, *A. parasiticus* and *A. ochraceus* at level (0.3 %) of YES broth medium.

Data represented in Table (1) showed that there were a considerable differences in mold or mycotoxin inhibition in YES medium supplemented with the EO extract or the decoction extract, in trend to EO extract. Therefore, the EO extract of Lemongrass leaves and stems was selected, as the best, to examine its antimicrobial effect on yoghurt medium.

#### 3.2- Antifungal effect of lemongrass oil on yoghurt medium:

Results obtained from Table (3) showed that increasing levels of EO extract added to yoghurt either incubated at 5 or 28 °C for 28 days, an inhibitory effect was noted on the growth of the all tested molds. At the lowest concentrations of extract (0.05%), the mold growth by the tested molds, were comparatively no changed over control. However, increasing concentration level up to 0.1% completely prevented the mold growth, either when the media incubated at 5or 28 °C. These results also indicate that growth was influenced by both mold type and incubation temperature. Also, these results revealed that 28 °C was the optimum incubation temperature for growth and consequently, mycotoxin formation occurred in this study.

**Table (1): Mold growth (mg/50 mL media) and percent reduction of the tested molds as affected by the two different extracts of lemongrass on YES broth media for 14 days at 28° C.**

Each value represents the mean of three replicates.

The mold growth was higher by *A. flavus* and *A. ochraceus* than *A. parasiticus*. Also, growth was influenced by mold type and temperature degree of incubation. Temperature is one factor which affects mold growth and mycotoxin production. Other publications supported our results (EL-Gendy and Marth, 1980; Maschaly and El-Deeb, 1982, Abdel-Fattah, 2002, and Abdel-Fattah and Abdel-Salam, 2004). When mycotoxin production was

determined in the media incubated at 5 and 28°C, the effect of EO extract was even more striking (Tables 4 and 5). Increasing concentration of extract resulted in detection of decreasing levels of mycotoxin production. At the lowest level of extract (0.05%), a great reduction mycotoxin production were found, and the reduction was especially pronounced with aflatoxins and ochratoxin A. No toxin was detected when the extract level increased to 0.1%.

**Table (3): Effect of various concentrations of lemongrass essential oil on molds incubated for 28 days at 5 and 28°C.**

Extract , %	<i>A. flavus</i>		<i>A. parasitics</i>		<i>A. ochraceus</i>

1.0	0	0	0	0	0	0

(0) no growth; (1) very little growth ; (2) 25 % of the plate surface covered with mycelia ; (3) 50% of the plate surface covered with mycelia; (4) 75 % of the plate surface covered with mycelia and (5) 100% of the plate surface covered with mycelia.

Regarding results represented in Tables (3, 4 and 5), the lack of mycotoxin production on yoghurt raises questions concerning the reasons for this phenomenon. The possibility that ingredients contained in yoghurt, but not in YES, might be inhibitory to growth and toxin production was considered. These results may be supported by those obtained by Montagna *et al.*, (1998), Velluti *et al.*, (2003), and Abdel-Fattah and Abdel-Salam, (2004).

It is possible that antifungal activity of the used lemongrass EO in this study is due to an unidentified component of the antioxidants extracted (perhaps phenols, flavonoids, flavones, etc). In this respect, Rosenthal *et al.*, (1997) reported that phenols play an important role as antifungal agents. They found that

ferulic acid, p-coumaric acid and other plant cell wall phenols, had antifungal actions in microorganisms isolated from dairy products. Also, Abu-seif *et al.*, (2009), found that phenolic compounds extracted from Lemongrass leaves had antifungal effects on *A. flavus* and *A. parasiticus*. In the present investigation, the lemongrass EO and its components exhibited efficacy against *A. flavus*, *A. parasiticus*, *A. ochraceous* and mycotoxin production, emphasising their significance in quantitative as well as qualitative control of herbal raw materials because tropical and subtropical countries are chiefly affected by mycotoxins (Singh *et al.*, 2008; Abu-Seif, *et al.*, 2009).

**Table (4): Effect of various concentrations of lemongrass essential oil on mycotoxin production in yoghurt medium for 28 days at 5 and 28°C.**

3.3- The effect of essential oil of lemongrass on the log (CFU/gm) of growth yeast and molds (Y&M) and bacteria in yoghurt during storage at refrigerator for 4 weeks.

The microbial stability of yoghurt supplemented with extracts of lemongrass during storage at refrigerator (5°C) for 4 weeks were investigated. Tropical spices (lemongrass) may prove useful in preservation of yoghurt by hurdle technology (Ejechi, *et al.*, 1998). Total microbial count of different yoghurt treatments with 0.0, 0.05, 0.1, and 0.3 % of lemongrass EO, and of untreated yoghurt were followed up through 4 weeks at 5°C. The effect of treating yoghurts with the studied various volatile or essential oil extract and stored at 5°C for 4 weeks on inhibiting the microbial counts are seen in Table (6). It can be observed that the yoghurt treated with low concentration of lemongrass EO have the highest inhibition of yeast and molds (Y&M) and bacteria (B) followed by those treated with high concentration of lemongrass EO after 4 weeks at 5°C. Untreated yoghurt was 6.75 log (CFU/gm) of B compared to 0.00 log (CFU/gm) in case of those Y&M. Whereas, the yoghurt treated with 0.5% lemongrass was 0.00 log (CFU/gm) of Y&M and 6.10 log (CFU/gm) of B.

The results from Table (6) showed that the yoghurt treated with high concentration of lemongrass has also the highest reduction of Y&M and B followed by low concentration of lemongrass, but untreated samples were the lowest reduction of Y&M and B for 4 weeks stored at 5°C.

These results are partially confirmed by those of Kanako *et al.*, (1998). They found that Lemongrass and clove exhibiting strong anti-fungal activity for 30 days. Whereas no colonies were seen for 30 days and fungal growth was inhibited for more than 30 days. On the other hand, Sebti and Tantaoui, (1994) showed that cinnamon powder

although very efficient at inhibiting the fungi, imported a dark colour to the papers and therefore is not recommended. While, cinnamon water extract did not inhibit fungal growth up to concentration of 80 g/kg (8%). Also, results from Table (6) showed that refrigeration temperature 4 °C of yoghurt could enhance the inhibitory effect of lemongrass EO. These results nearly in consistent with results given by Eissa *et al.*, (2003a, b), Eissa *et al.*, (2008) and Ting and Deibel, (1992) who appeared that refrigeration temperature (5°C) could enhance the inhibitory effect of some spices extracts but not others. When 0.5 or 1.0 % cloves were tested, the organism died more rapidly in tryptic soy broth at 24°C than at 5°C. Whereas, > 5 log reduction in CFU was observed after 7 days of incubation at 5°C and after 3 h incubation at 24°C in tryptic soy broth.

In general, the refrigeration of yoghurt effects increased the inhibition of bacteria, yeast and mold counts. Also, the results showed that the yoghurt treated with different concentrations of lemongrass EO were observed no browning and lowest microbial count (T & M and B) during storage at 5°C for 4 weeks. There are only a few reports on antimicrobial activity of lemongrass EO against some food borne bacteria (Oussalah *et al.*, 2006) and fungi (Anthony *et al.*, 2003). Lemongrass EO as preservatives may be due to it contain aldehydes and volatile compounds that have efficient on inhibition of browning and inhibition of growth microorganisms. Zaika, (1988) reported that food product safety and shelf life depend in some part on the type, quantity, and character of volatile oil spices extracts added to the products. Then, our results showed that refrigerating at 5°C and 0.05% volatile or essential oil extracts treatments caused a marked reduction in yeast and bacteria populations with acceptable taste and extension shelf life of yoghurt up to 5 weeks.

**Table 6. Effect of lemongrass essential oil on the number of colonies (TPC or Y&M) that appeared on the plates and expressed as the log (CFU/gm) in yoghurt during storage at refrigerator (5 °C) for 4 weeks.**

### 3.4- Effect of lemongrass EO on physico-chemical content in yoghurt during storage time:

#### Quality evaluation of yoghurt products.

The following discussion of the chemical characteristics for fresh, products and lemongrass EO pre-treated yoghurt is based on the data given in table (7). The pH of fresh and treated yoghurt ranged from 4.04 to 4.49 showing a increase in pH values. The increase in pH was directly related to increase lemongrass EO concentrations in yoghurt. TSS (g/Kg) of yoghurt products after 28 days storage was lower than the fresh yogurts. Whereas, the increase of TSS was obvious with increasing of lemongrass EO concentration. This increase of TSS was attributed to the greater degree of tissue breakdown, releasing more components that contribute to soluble solids (Tung *et al.*, 1995). The TSS / acid ratio is the major analytical measurement for quality in fresh

and treated yoghurt. The TSS / acid ratio of fresh, and treated yoghurt was increased by increasing of lemongrass EO concentration. TSS / acid ratio was shown to be correlated with sweetness but not so closely with flavour (Guyer, *et al.*, 1993).

Titratable acidity of yoghurt products was lower than fresh yoghurt (Table 7), which may due to enzymatic desertification and degradation of pectin resulting in an increased of total acid.

The viscosity (cP) was selected as a measure of yoghurt quality. However, the viscosity between fresh and treated yoghurt samples were decreased from 2.92 cP to 2.64 by increasing the lemongrass EO concentration in yoghurt than fresh sample (2.86 cP), respectively as seen in Table (7). Total phenol content were decreased also by increasing of lemongrass EO concentration in all yoghurt samples, as seen in table (7).

**Table (7): Effect of Concentrations on physico-chemical properties in yoghurt at zero time and after 28 days at 5 °C.**

Extract level,%	TSS		pH		% acidity		TSS/acidity		Viscosity (cP)		Total Phenols	
	at zero time	after 28 days	at zero time	after 28 days	at zero time	after 28 days						
0.0	7.50	6.00	4.04	4.39	0.94	0.94	7.8	6.38	2.86	2.60	1342.85	1342.85
0.05	7.00	6.00	4.00	4.30	0.96	0.92	7.4	6.51	2.92	2.80	1345.97	1345.97
0.1	7.50	7.00	4.08	4.39	0.97	0.94	7.7	7.44	2.75	2.60	1338.17	1338.17
0.3	8.00	7.00	4.11	4.49	0.98	0.95	8.17	7.36	2.64	2.52	1317.87	1317.87

### 3.5- Effect of lemongrass EO concentrations and storage on Colour characteristics of yoghurt:

#### a- Colour parameters during storage time of yoghurt:

Tristimulus Reflectance Colourimetry (TRC) measuring the reflectance L\*, a\* and b\* values) was used to follow the extent of browning in yoghurt and change of colour in foods (Sapers and Douglas., 1987). The results in Table (8) showed change of colour in yoghurt during storage time up to 28 days at 5°C. These results illustrated the changes in colour of yoghurt in terms of redness a\*, yellowness b\* and lightness L\* during 28 days of storage at 5°C. In addition to determination of the lightness L\*, redness a\* and yellowness b\*, for

experimented yoghurt. Hue angle (H\*) as well as the chromaticity (C\*) were determined. Hue is the aspect of colour that we describe by words such as green, blue, yellow or red. The chroma refers to reflection at given wavelength and indicates how much a colour differs from gray (Eissa and Moharram, 2001). The equations No. 1, 2, 3 and 4 are showed the DE, B<sub>1</sub>, H\* and C\*.

The H\* values were closely stable in all samples with increasing of storage time up to 28 days at 5°C. The chromaticity (C\*) increased by the increasing of stoarge time in yoghurt up to 28 days. Thereafter, no relation was noticed. It can be observed that the a\*-value of the fresh yoghurt was -2.22 compared to -2.27 after 7 days, -2.39 after 14

days and increased -2.18 after 28 days, as seen in Table (8).

Regarding the lightness L\* and the yellowness b\*. It is clear that the lightness L\* as well as the yellowness b\* were decreased as a result of increasing the time of storage up to 28 days. The effect of storage time on increasing the a\*-value from -2.22 at zero time days to -2.18 after 28 days was noticed. The change in colour may be referred to chemical changes occurred during storage (Kumar *et al.*, 2006).

The analysis of variance identified the significant ( $p<0.05$ ) effect of storage time on Hunter values of yoghurt. Although the a-value showed a definite increased trend throughout storage, the L-value decreased and the b-value increased as the yoghurt storage aged, as seen in Table (8).

It can be concluded that the storage of yoghurt slightly inhibited the changes in colour yoghurt. The total colour differences (DE) increased by the increasing of storage time in yoghurt up to 28 days as presented in Table 1, total colour differences of yoghurt were small, which almost correspond to the sensory difference threshold (Rohm and Jaros, 1996b). However, greatly different values of DE were found for yoghurts at 7, 14 and 28 days of storage and at different concentrations lemongrass

EO treated samples. The almost identical colour values found in yoghurt could be attributed to their similar structure. The browning index (B<sub>I</sub>) increased by the increasing of storage time in yoghurt up to 28 days, especially in high concentration treated yoghurt (0.3%). Thereafter, no relation was noticed.

#### b- Non-enzymatic browning of yoghurt samples:

Non-enzymatic browning in yoghurt is only one component that determines overall colour and might not be a problem at low levels. The effects of heat treatment of milk and yoghurt products in the inhibition of the browning reaction are listed in Tables (8). It is obvious that the yoghurt product treated and untreated yoghurt samples inhibits the development of A 420 nm and red colour a\*. For example, the A420 nm and a\*-value of fresh yoghurt was 64.34 compared to 64.11, 64.36 and 61.56 in case of the different concentrations of lemongrass EO yoghurt samples, respectively. Crandall *et al.*, (1986) concluded that two measures of browning were used, colour a\* or L\* and absorbance at 420nm where the higher numbers indicate increased absorbance due to the formation of brown pigments. Browning is also indicated by a decrease in the colour L\* toward black and an increase in the colour a\* toward brown or red.

**Table (8): Effect of on colour characteristics in yoghurt during storage at 5 °C for 28 days.**

Extract level%	L*	a*	b*	Delta E	C*	H*	B <sub>I</sub>	OD 420 nm

0.3	92.4	-2.59	13.75	14.03	13.99	79.33	24.82	60.63

#### 3.6- Sensory evaluation of Yoghurt:

The results of sensory evaluation of the products based on colour, odour, taste, texture and

appearance are shown in Table (9). Sensory evaluation of the yoghurt samples was carried out during 4 weeks of samples at 5°C by 20 experienced

panels using 10 points scales. Difference in sensory properties of yoghurt samples due to the effect of different concentrations of lemongrass EO was determined by analysis of variance (ANOVA). Sensory attributes are of great importance to measure consumer attitudes and their influence on food choice and acceptability. The colour of yoghurt is the first quality attribute used to judge acceptability of yoghurt products. The change in colour may be referred to chemical changes occurred during storage of yoghurt samples (Young-Hee, and Song Sun, 2009). The mean value of flavor or odour scores as well as the overall mean score for the texture of yoghurt for all treatments of the tested yoghurt samples were affected by refrigeration and by increasing concentration of lemongrass EO up to 0.3 % (Table, 9). These levels of score indicate the importance of the lemongrass EO in keeping a texture for the tested yoghurt. However, there were significant differences between the individual ripening. Samples pre-treated for 0.3% lemongrass EO showed the highest score (8.25) in texture stored at 5°C. In general, the lemongrass EO pretreated yoghurt samples received higher sensory scores than

untreated sample, but the differences were nonsignificant ( $P<0.05$ ) for all samples (Table, 9). Samples treated with 0.05 and 0.1 % EO extract generally had better score for all sensory characteristics at all samples. On the contrary, the sample treated with 0.3% EO extract had lower score for all sensory characteristics at all samples especially in taste characteristics. However, concentration of lemongrass EO had a positive influence on acceptability of colour and flavor of yoghurt samples. Also, increased concentration of lemongrass EO showed that the same odour, colour texture and acceptability characteristics in hoghurt samples. However, all sensory scores were in the acceptable range, which greater than 5 scores.

It is clear that the the lemongrass EO pretreated yoghurt gave higher mean panel scores (8.0- 8.5) than the untreated yoghurt sample, which were the most preferred in all the studied characteristics. The lemongrass EO pretreated yoghurt samples with different concentrations had a non-significant difference ( $P<0.05$ ) between these samples.

**Table (9): effect of lemongrass EO concentrations on sensory evaluation of youghurt stored at 5°C for 28 days.**

Extract level, %	Appearance	Texture	Colour	Taste	Odour
0.0	8.13 <sup>A</sup>	8.13 <sup>A</sup>	8.75 <sup>A</sup>	8.50 <sup>A</sup>	8.13 <sup>A</sup>
0.05	8.02 <sup>A</sup>	8.03 <sup>A</sup>	8.50 <sup>A</sup>	7.13 <sup>B</sup>	7.85 <sup>A</sup>
0.1	8.50 <sup>A</sup>	8.13 <sup>A</sup>	8.50 <sup>A</sup>	7.13 <sup>B</sup>	7.79 <sup>A</sup>
0.3	8.63 <sup>A</sup>	8.25 <sup>A</sup>	8.38 <sup>A</sup>	6.88 <sup>B</sup>	7.65 <sup>A</sup>
LSD	NS	NS	NS	S	NS

LSD = least significant difference at 0.05 level.

NS = non significant

S = significant

#### 4- Conclusion:

While the primary function of Lemongrass may not be preservative in nature, it has preservative properties, which may useful in built-in safety systems in food. In addition, Lemongrass herb is cheap, safe, and had a medical functions. Our results show that water extract from Lemongrass, at level 0.1% was effective agent to inactivate mold growth and mycotoxin formation and increasing level to 0.3% completely prevented both mold growth and mycotoxin production , for the all tested molds, in YES broth medium. However, in yoghurt medium its inhibitory effect was different according to mold type, supplemented concentration and constituents of the used medium. Its evident from our data that, if possible, a sufficient amount of lemongrass EO to prevent mold growth needs to be used if one wishes to prevent mycotoxin production. It can be concluded from the results of this work that

of lemongrass EO treatments with refrigeration at 5°C may serve as alternative to conventional chemical preservatives in the preservation of yoghurt by hurdle technology.

**Abstract:** This study was carried out on 360 freshwater fishes (240 *Oreochromis* species and 120 *Clarias gariepinus*). They were collected from different governorates and during different seasons. Naturally infected fishes showed clinical abnormalities such as skin darkening, exophthalmia, corneal opacity, abdominal distention, ulceration of the skin and cotton wool like growths on various parts of the body. Fishes were then subjected to post mortem examination which revealed many abnormalities. Mycological examination revealed the isolation of 2081 fungal isolates from 150 diseased and 210 apparently healthy fish samples (1658 mould and 423 yeast isolates), of which 1334 were isolated from *Oreochromis* species and 747 isolates from *Clarias gariepinus*. Isolated moulds belonged to the following genera: *Saprolegnia* (4.2%), *Aspergillus* (43.0%), *Fusarium* (14.1%), *Mucor* (14), *Penicillium* (17.2), *Rhizopus* (4.8%), *Scopulariopsis* (1.2%), *Paecilomyces* (1%) and *Curvularia* (0.4%). Yeasts isolated also from both fish species had the following incidence: *Candida albicans* (35.9 %), other *Candida* species (19.1%), *Rhodotorula* species (31.4%) and *Torulopsis* species (13.5%). Experimental infection with the most predominant fungi (*Aspergillus flavus*, *Fusarium* species and *Candida albicans*) was conducted to evaluate the pathogenicity of these isolates. Clinical pictures of experimentally infected fish were similar to those of natural infection. Inoculated fungi were re-isolated from different organs. Results were confirmed with histopathological examination, which revealed the presence of fungal hyphae and spores in different organs.

**Keywords:** Mycotic infection, *Oreochromis* species, *Clarias gariepinus*, Moulds, Yeasts, *Aspergillus*, *Fusarium*, *Candida*, *Penicillium*.

## 1. Introduction

Many of the fungi that affect fishes are considered opportunists, attacking the fishes when they are stressed or immunocompromised because of unfavorable environmental conditions, or secondary to bacterial or viral infections, or when they have lost their mucus protection because of trauma or excessive handling (Roberts 1989 and Quiniou *et al.*, 1998). Mycotic infections of fishes by Oomycetes are wide spread in freshwater and represent the most important fungal group affecting wild and cultured fishes. The *Saprolegniaceae*, in particular members of the genus *Saprolegnia*, are responsible for significant infections involving both living, dead fishes and eggs. Oomycetes are classical saprophytic opportunities, multiplying on fishes that are physically injured, stressed or infected (Pickering and Willoughby, 1982). Members of this group are generally considered agents of secondary infection arising from conditions such as bacterial infections, poor husbandry, and infestation by parasite and social interaction. However, there are several reports of Oomycetes as primary infectious agents of fishes (Pickering and Christie, 1980) and their eggs (Walser

and Phelps, 1993). Moreover, there are other fungi that have been implicated in fish diseases. Some of the genera involved include *Aspergillus* (Salem *et al.*, 1989b), *Fusarium* (Bisht *et al.*, 2000), *Ichthyophonus* (Faisal *et al.*, 1985), *Branchiomyces* (Easa 1984), *Phoma* (Hatai *et al.*, 1986), *Paecilomyces* (Lightner *et al.*, 1988), *Exophialia* (Langdon and MacDonald 1987), *Phialophora* (Ellis *et al.*, 1983), *Rhizomucor* (Wolf and Smith 1999) and *Candida* (Neish and Hughes 1980). Most of these are multiple case reports or single, and causing systemic disease with high mortality rates in fishes. The objective of this study was to determine the types of fungal pathogens affecting freshwater fishes specially those causing high mortality rates, elucidation of the incidence and distribution of such pathogens in *Oreochromis* species and *Clarias gariepinus*, studying the seasonal variations enhancing fungal diseases of fishes and determination of the pathogenicity of the most prevalent isolated fungi.

## 2. Material and Methods

A total number of 360 fish were observed for their behavior, external lesions prior to autopsy. Then they were killed and examined. The examination included external changes as well as examination of internal organs. Wet mount preparation of fish samples were commonly made in 10% KOH. A simple stain such as lactophenol cotton blue was used. The preparation was examined microscopically after about 30 minutes for fungal elements. Mycological examination was done according to and (1993 Noga). Identification of moulds was carried out according to Refai (1987). Identification of yeasts: Plates were examined microscopically for the presence of chlamydospores, arthrospores and blastospores (Refai, 1987) and the scheme of identification of yeasts given by Terrence (1971). Urease test (Cruickshank *et al.*, 1975). Suspected *Candida* species were scratched onto rice or corn meal agar for pseudohyphae and chlamydospores production (Larone, 1987) and a confirmatory identification was carried out by germ tube test (Martin, 1979).

### Histopathological examination:

Tissue samples were prepared according to Roberts 1989. and stained by periodic acid Schiff's (PAS) and GMS (Sheehan and Hrapchak 1980).

### Experimental infection:

A total of 120 *Oreochromis* species with 30-40 g average body weight were used. They were divided into four equal groups (each one contained 30 fish). Each group were subdivided into three sub-groups, each contained 10 fish.

**Preparation of spores suspension for experimental infection:** Inocula were prepared by spreading 5 ml of sterile phosphate buffer saline over the plates containing 7- 10 day old pure cultures of *Aspergillus flavus* and *Fusarium* sp. The spores were harvested by gentle washing of the surface of the colonies with sterile loop, then transferred aseptically to sterile flasks. Two drops of tween 80 were added to avoid clumping of spores in case of *Aspergillus flavus* group. Spores were counted by aid of haemocytometer and suspension was diluted to reach  $9 \times 10^4$  spores/ml for both *Aspergillus flavus* and *Fusarium* sp.

**Preparation of yeast suspension for experimental infection:** A loopfull of one day old pure yeast culture of *Candida albicans* was added to test tube containing 5 ml of sterile phosphate buffer saline and mixed gently to reach equal distribution. Spores were counted by using haemocytometer then

suspension was adjusted to reach  $2 \times 10^3$  *Candida* spores per ml.

## 3. Results and Discussion

Mycological examination revealed the isolation of 2081 fungal isolates from 150 diseased and 210 apparently healthy fish samples, of which 1334 were isolated from *Oreochromis* species and 747 isolates from *Clarias gariepinus*. Identification of fungi into yeasts and moulds revealed that the percentage of moulds was slightly higher in *Oreochromis* species (80.5%) in comparison to that in *Clarias gariepinus* (78.2 %). On other hand, the rate of yeast isolates per fish was slightly higher in *Clarias gariepinus*. Isolated moulds belonged to the following genera: Saprolegnia, Aspergillus, Fusarium, Mucor, Penicillium, Rhizopus, Scopulariopsis, Paeciliomyces and Curvularia. The same fungal isolates were reported by Abdel Alim (1992) and Khalil (1993).

The Incidence of moulds in diseased and apparently healthy fishes were recorded in (Fig.1&2), also the incidences of isolated moulds from different organs of *Oreochromis* species (Fig.3) and *Clarias gariepinus* (Fig.4) were detected. Seasonal incidences were seen in (Fig. 5). As these isolates were recovered from apparently healthy and clinically diseased *Oreochromis* species and *Clarias gariepinus* This was expected, as almost all these fungi were categorized by Shaheen (1986) as normal mycoflora. This does not mean that they cannot produce disease. They can better be considered as opportunistic fungi (Refai, 1987) as many of them possess virulence factors, which enable them to cause diseases (Refai *et al.*, 2004), particularly under favourable predisposing condition. Regarding to seasonal incidence *Saprolegnia* species were isolated with high incidence in Winter, followed by early Spring and late Autumn. This result agrees with Naguib (1994), who stated that the seasonal variations play an important role in spreading of the *Saprolegnia* infection among freshwater fishes especially during late Autumn, Winter and early Spring, where the water temperature was low.

The Incidence of moulds in diseased and apparently healthy fishes were recorded in (Fig.1&2), also the incidences of isolated moulds from different organs of *Oreochromis* species (Fig.3) and *Clarias gariepinus* (Fig.4) were detected. Seasonal incidences were seen in (Fig. 5). As these isolates were recovered from apparently healthy and clinically diseased *Oreochromis* species and *Clarias gariepinus* This was expected, as almost all these fungi were categorized by Shaheen (1986) as normal mycoflora.

This does not mean that they cannot produce disease. They can better be considered as opportunistic fungi (Refaai, 1987) as many of them possess virulence factors, which enable them to cause diseases (Refaai *et al.*, 2004), particularly under favourable predisposing condition. Regarding to seasonal incidence *Saprolegnia* species were isolated with high incidence in Winter, followed by early Spring and late Autumn. This result agrees with Naguib (1994), who stated that the seasonal variations play an important role in spreading of the *Saprolegnia* infection among freshwater fishes especially during late Autumn, Winter and early Spring, where the water temperature was low.

Clinical findings of *Oreochromis* species inoculated with *Aspergillus flavus*, *Fusarium* species and *Candida albicans* revealed that exophthalmia (Photo.21), skin darkening (Photo.22), cotton wool-like growth on various parts of the body (Photo.23&24), moderate abdominal distention (Photo.25) and corneal opacity and haemorrhages all over the body surface (Photo.26). These results are supported by Marzouk *et al.*(2003).

Postmortem finding revealed congestion and ulceration of gills (Photo.27), haemorrhagic abdominal fluids, necrotic foci within liver and distention of gall bladder (Photo.28), multiple nodules within spleen (Photo.29) and severe intestinal congestion (Photo.30) were also observed. On the other hand, no clinical or postmortem changes

were detected on fish groups maintained at 18°C. These findings are in agreement with those of Refai *et al.* (1987).

It can be concluded from the results obtained in the present work that, though most fungi isolated from fishes are considered by several authors as normal mycoflora, yet we could prove in the present study that many fungi can cause natural infections. This was confirmed by histopathological reactions characteristic of fungal infection in naturally infected fishes, and the presence of fungal elements in the lesions. This was substantiated also by experimental infection of fish that induced similar findings as the natural infection, i.e. a clear application of Koch's postulate. This conclusion should direct our attention to the possible role of fungi in affecting fishes industry.

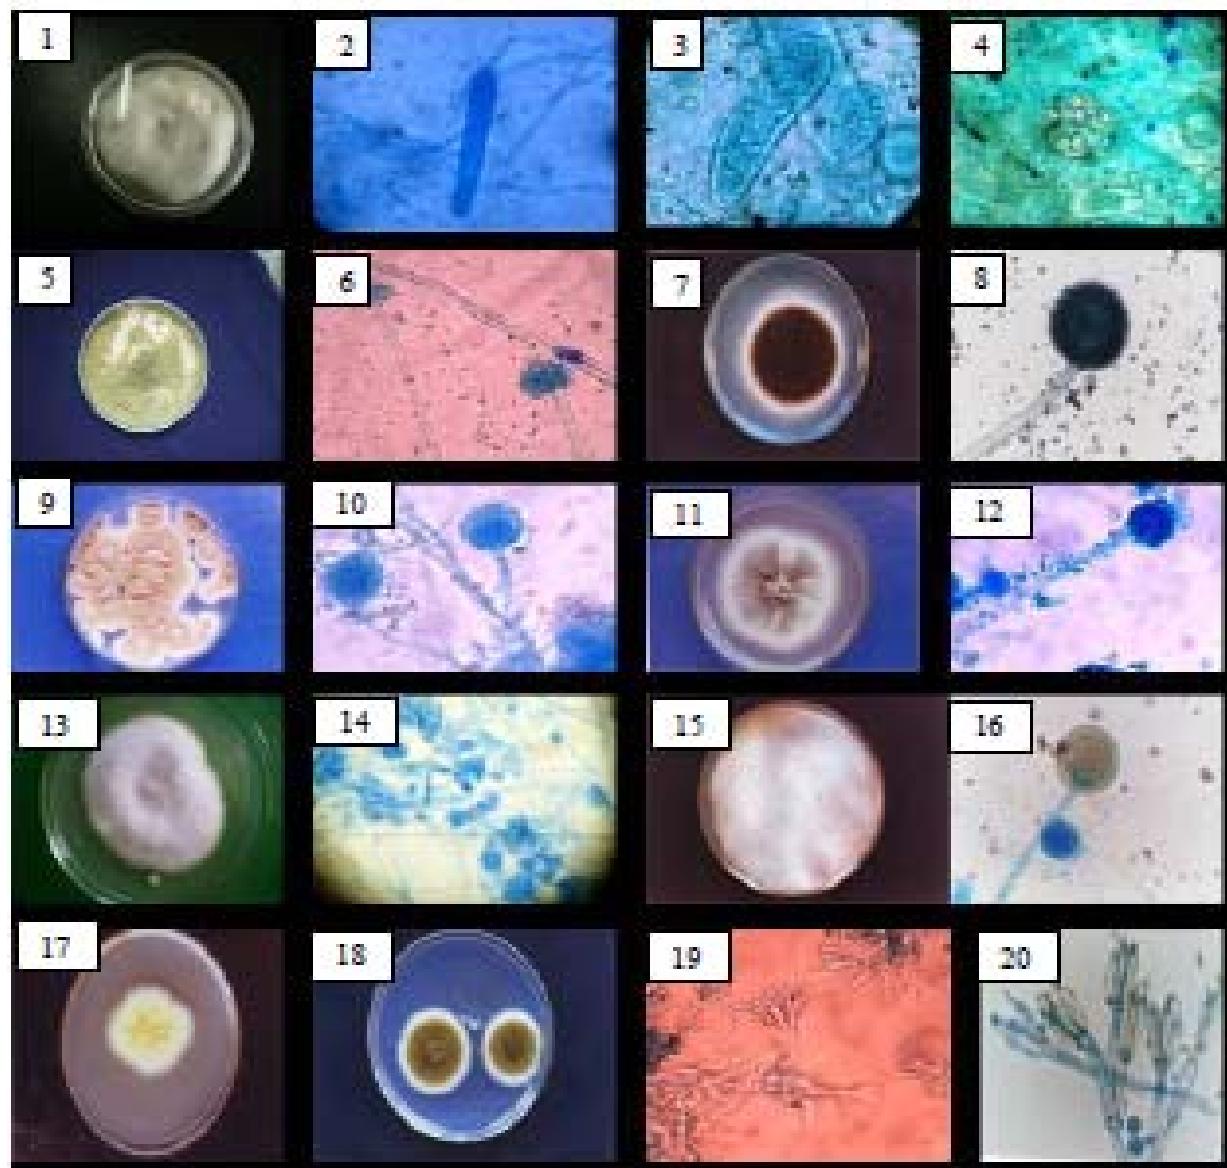

The pathological changes and the fungal elements in tissue sections in naturally infected fishes of various organs are described under each of the following photos (31-39.), stained by either PAS or GMS stains.

**Abstract:** Some fish species are suffering from continuous depletion due to devastating environmental changes at their native aquatic environment. Qarun Lake and Suez Gulf are among the most vulnerable areas. Thus, representative fish samples from those areas were inspected for the presence of any fish pathogenic bacteria. The inspected samples included six different species; *Epinephelus tukina*, *Siganus rivulatus*, and *Dedalechilus labiosus* native to Suez Gulf at Suez governorate; *Tilapia zilli*, *Mugil capito* and *Solea vulgaris* native to Qarun Lake at El-Fayoum governorate. A total of 600 samples were examined throughout the different year seasons. Gram positive and negative fish pathogenic bacteria were isolated from a total of 245 fish sample. Among those samples, the following bacteria were retrieved in the following percentages respectively, 17.55% (*V. anguillarum*), 16.73% (*V. alginolyticus*), 15.51% (*P. piscicida*), 15.91% (*Ps. fluorescens*), 13.46% (*S. enterica*), 11.02% (*A. hydrophila*), 6.12% (*A. sobria*) and 3.67% were infected with *Staph. aureus*. The *Siganus rivulatus* was the highest infected fish species with a prevalence of 8.33%, while *Mugil capito* was the lowest infected species (5.67%). The highest total prevalence of bacterial infection was recorded in summer season (40.81%) while the lowest was recorded in winter (15.91%). The aforementioned bacterial isolates were successfully re-isolated from experimentally infected fish. The retrieved isolates were matched against standard isolates as well as confirmed to be positive using semi-automated (API 20 E) and conventional biochemical tests.

### 1. INTRODUCTION

Fisheries represent an important sector in the Egyptian national income structure. In the fisheries economy, marine fishes represent the major investment choices for the national fishermen. Marine fishes are liable to variable number of environmental stressors, including chemical, natural and biological invaders. Such stressors are the main predisposing factors for the chronic immune-suppression of marine aquatic animals in the affected marine habitat. As an ultimate fate for the staggering immuno-suppression of fishes, bacterial invasion will be the most probable event (Ellis, 1999). Further, the bacterial invasion of any marine species could possibly exacerbate under the triggering effect of the fluctuating climatic changes (Wedemeyer, 1996).

The prevalence of bacterial pathogens have been well documented in several cultured and wild freshwater fish species, however; only a few bacteriological surveys have involved the marine species disease outbreaks (Alicia, et al 2005).

On the long run water resources will be the most limiting factor of aquaculture development in Egypt. Therefore, marine fisheries are the immediate

alternative for water needed for mariculture (Sadek, 2000).

The present work was planned to isolate and identify the most predominant bacterial pathogens in some marine fishes, native to both Suez Gulf and Lake Qarun. Further, work aimed to evaluate the seasonal variation of bacterial isolates among the examined fishes.

### 2. MATERIALS AND METHODS

#### 2.1. Sampling and processing

Six hundred (600) marine fishes of six different species were freshly captured from two localities in Egypt, (Suez Gulf and Lake Qarun) through the different seasons of the year.

On each season, twenty-five fish of each species were collected and examined. Fish species, numbers of fishes, average body weights and localities are shown in table (1). Clinical and P.M examination were carried out using the methods described by (Buller, 2004).

Samples from gills, liver, spleen, kidney and external lesions from fishes were cultured on general

and selective media; tryptic soy agar and tryptic soy broth (Difco) supplemented with 1.5% (w/v) NaCl, marine agar ( Difco), and thiosulphate–citrate–bile salt–sucrose agar (TCBS, Difco). Aeromonas agar base medium supplemented with ampicillin, pseudomonas agar base medium supplemented 2 % NaCl and Azide blood agar supplemented with 2 % NaCl. All the inoculated media were incubated at 22 °C for 48 hours.

## 2.2. Identification of the isolates

Pure cultures of the isolates were identified by biochemical characterization following the criteria proposed by those described in the Bergey's Manual of Determinative Bacteriology, (Garrity, 2001). Final confirmation of each strain was achieved using the analytical profile index of API20-E system (Buller, 2004).

## 2.3. Experimental infection

A total of 70 apparently healthy *O. niloticus* fish, weighting  $50 \pm 5$  gram were selected for determination of the pathogenicity of the most prevalent bacterial isolates. Fishes were divided into seven groups each contained 10 fish. The inocula prepared for bacterial isolates as I/P injections were prepared according to (Austin & Austin, 2007). Fish were observed daily for 15 days. Six groups were consistently inoculated I/P with the bacterial suspension of (*Aeromonas hydrophila*, *Pseudomonas fluorescens*, *Vibrio anguillarum*, *Pasteurella piscicida*, *Streptococcus fecalis* and *Staphylococcus aureus*) at a dose of  $0.2 \text{ ml}$  of ( $3 \times 10^7 \text{ CFU}$ ) while the control group (group 7) were injected I/P with  $0.2 \text{ ml}$  of sterile tryptic soy broth according to Hussain (2002).

## 3. RESULTS

### 3.1. Clinical examination:

Clinical signs included generalized hemorrhages (Fig 1). Some fishes showed bilateral exophthalmia and opacity (Fig 2), scale detachment and skin darkening. Gills were congested (Fig 3) while in others appeared to be pale with accumulation of excessive amount of mucus. Ascitis was observed in some fishes. Vent inflammation as well as prolapse were also observed.

Necropsy findings of naturally infected marine fishes exhibited sero-sanguinous fluid in the abdominal cavity. Liver was pale in some fishes (Fig 4), while in others was congest, haemorrhagic with numerous randomly scattered whitish nodules (Fig 5). Spleen and kidneys were congested and enlarged in some fishes. The intestines were haemorrhagic, inflamed with congestion of blood vessels. In other samples, the intestines were seen filled with gases.

### 3.2. Isolation and identification of the bacterial isolates:

Biochemical characteristics of the Gram negative bacterial spp. isolated from examined fishes are shown in Table (2).

Results indicated that 245 naturally collected fishes out of 600 were found to be infected with different types of bacteria. The culture results demonstrated that (203) fishes were found to be infected with Gram-negative bacteria and only (42) fishes were infected with Gram-positive bacteria. 17.50 % of the infected fishes were positive for *V. anguillarum*, (16.73%) for *V. alginolyticus*, (15.51%) for *P. piscicida*, (15.91%) for *Ps. fluorescens*, (13.46%) for *S. fecalis*, (11.02%) for *A. hydrophila*, (6.12%) for *A. sobria* and (3.67%) of the surveyed fishes were infected with *Staph. aureus*. The total prevalence of bacterial isolates is shown in table (3). Moreover, the results revealed that *Siganus rivulatus* was the most infected fish spp (50 %), followed by *E. tuvina* (42 %), *S. vulgaris* (41 %), *Tilapia spp.* (40 %), *M. sahlae* (38 %), while *M. capito* was the lowest infected spp (34 %).

Prevalence of bacterial infections for fishes collected from both Suez Gulf and Lake Qarun was illustrated in table (4). The results revealed that: The total prevalence of bacterial infections for fishes collected from the Gulf of Suez (53.06%) was higher than that recorded for those collected from Lake Qarun (46.93%).

### 3.3. Seasonal prevalence:

Results indicated that, the highest total prevalence of bacterial infections among the naturally infected marine fishes was recorded in the summer season (40.81%), followed by autumn (25.71%), then spring (17.14%). On the other hand the minimal prevalence of infection was recorded in winter (15.91%). table (5).

The highest prevalence of bacterial infection among the naturally infected marine fishes in winter season, was recorded for *Ps. fluorescens* (7.75%) while the lowest one (0.40%) was recorded for *V. anguillarum*. on the other hand *P. piscicida*, *S. fecalis* and *Staph. aureus* were not recorded. For spring season, the highest prevalence of bacterial infection (3.67%) was recorded for *A. sobria* and *V. anguillarum*, while the lowest (1.22%) was recorded for *Ps. fluorescens* and *S. fecalis*. The highest prevalence of bacterial infection (9.38%) in summer season was recorded for *V. anguillarum*, while the lowest (0.40%) was recorded for *A. sobria*. The highest prevalence of bacterial infection (5.30%) in autumn season was recorded for *V. alginolyticus* and *P. piscicida* while the lowest (0.40%) was recorded

for *A. sobria*. The Prevalence of different types of bacterial infections in the different seasons is illustrated in table (5).

### 3.4. Results of experimental infection:

Mortality patterns in experimentally infected *O. niloticus* with the different bacterial isolates (Table 6). Experimentally infected *O. niloticus* with the different isolates were characterized by septicemic lesions nearly similar to those of naturally infected fishes. Experimentally infected fish showed haemorrhagic patches distributed on different parts of the body surfaces , fin and tail rot (Fig. 6). Some fish exhibited typical ulcers (Fig.7). Some cases showed inflammation of the vent (Fig. 8). Necropsy findings showed, congestion of Liver. Spleen and kidneys were congested and enlarged. Gall bladder was distended. The gut was haemorrhagic and filled with yellowish content. Serous to sero-sanguinous

fluid in the abdominal cavity was noticed in some cases.

Re-isolation of all inoculated bacterial isolates was obtained from dead and sacrificed fish. Moreover, the results of the culture and biochemical characteristics of the re-isolated bacterial isolates revealed the same morpho-chemical characteristics of the inoculated bacterial isolates.

Number of I/P inoculated fishes per each group were 10.

#### 4. DISCUSSION

Septicemic bacterial infections such as vibrios, aeromonads, pseudomonads, photobacteria, streptococci and staphylococci were recorded in several fingerlings, juveniles, adults and brood stocks of some marine fish species (Alicia *et al.*, 2005 and Samuelsson *et al.*, 2006).

In regards to bacterial pathogens that have been isolated, results came in this study revealed that Gram-negative bacteria prevailed the Gram-positive isolates with *Vibrio anguillarum*, *Vibrio alginolyticus*, *Pasteurella piscicida* (*photobacterium damsella* subspp *piscicida*), *Pseudomonas fluorescens*, *Streptococcus fecalis*, *Aeromonas hydrophila*, *Aeromonas sobria* and *Staphylococcus aureus* were the most common isolated spp. Results are supported by those reported by Zorrilla *et al.* (2003) who declared that the main pathogenic microorganisms isolated from diseased gilt-head seabream in the marine water at south western Spain were; *Vibrio* spp, *Pseudomonas* spp, *P. piscicida*, *Flavobacteria maritimus*, *Aeromonas* spp and Gram positive bacteria were also isolated but in low prevalence.

In concern to the total prevalence of bacterial infections in the naturally infected marine fishes (40.83 %) which may appear to be lower than those reported by some authors for freshwater fishes as Soliman (1999) who noticed that the total bacterial prevalence was (65%). This difference could be due to the unfavorable effect of the salinity of marine water on the viability of bacterial pathogens.

In regard to the localities of isolation, results revealed that the prevalence of bacterial infections was higher (53.06%) in fishes collected from the Gulf of Suez than that (46.93%) recorded for Lake Qarun. This may be explained by the fact that Lake Qarun is the largest reservoir of agricultural and sewage drainage of Fayoum province as well as the

drainage from fish farms established around the lake (Mansour & Sidky, 2003).

The high prevalence of isolation recorded from the Gulf of Suez may in part be attributed to the stress induced by high crude oil pollution at the Gulf water which is maintained by the low water flow, low water exchange rates and daily crowded ship traffic crossing the gulf as well as industrial effluents from oil refineries. All these factors are compromising to the fish immune system ending up with marked increase in the magnitude of bacterial infections.

Study declared that marine fish can succumb MAS, as supported by Larsen & Jensen (1977) who isolated *A. hydrophila* from ulcer disease in Cod, *Gadus morhua* L., a strictly marine fish. Authors added that motile aeromonas group especially *A. hydrophila* is considered as one of the most important pathogen responsible for haemorrhagic septicemia in a wide variety of marine water fish. Moreover, Vethaak (1992) isolated *A. hydrophila* from ulcers, lesions, and blood of ulcerated European flounder

Results pointed out that the highest prevalence of *A. hydrophila* was recorded in winter season (5.71%) followed by spring (2.85%), while in summer and autumn the results were the same (1.22%). These results were supported by Pathak *et al.* (1988) who suggested that the highest isolation rates of *A. hydrophila* occurred during late winter followed by a progressive decline in density during summer and monsoon seasons. Moreover, Popovic *et al.* (2000) mentioned that there was clear seasonality in the prevalence of *A. hydrophila* as there were no isolates recovered in the summer months. On contrast, Meyer (1970) reported that the most epizootics of motile aeromonads were generally reported in spring and early summer.

In regards to the seasonal prevalence of *A. sobria*, our study recorded that the highest prevalence e of *A. sobria* septicemia was recorded during the spring (3.67%) followed by winter (1.63%) while the minimal prevalence e of infection (0.40%) was recorded during the summer and autumn. Results are in accordance with those obtained by Wahli *et al.* (2005) who noticed that mortalities due to *A. sobria* peaked during the low water temperatures of winter time and reached levels. On contrary, the results are not in concordance with those obtained by Kooj *et al.* (1988) who demonstrated that the highest prevalence of Aeromonads in marine water have been obtained in the warmer months.

The pathogenicity of *A. hydrophila* for experimentally infected *Oreochromis niloticus* fishes may be attributed to toxins and extracellular enzymes produced by *A. hydrophila* (Saavedra *et al.*, 2004).

In regards to the total prevalence of pseudomonas septicemia, the study recorded that (15.91%) of infected fish were positive for pseudomonas infection. These results are in concordance with those obtained by Hussain (2002) who reported that (15.27 %) of naturally infected marine fishes were positive for *Ps. fluorescens* septicemia. on contrast, results are lower than those reported by Khan *et al.* (1981) who reported that *Pseudomonas* spp accounted for (72 %) of the mortalities recorded in captive Atlantic cod, *Gadus morhus* L associated with fin rot disease.

The highest prevalence of *Ps. fluorescens* septicemia was recorded during the winter season (7.75%) followed by autumn (4.48%) summer (2.44%) and spring (1.22%), this reveals that *Ps. fluorescens* has certain affinity to low temperature for propagation and wide spreading infection (El-Moghazy, 2004). Results were supported by Golomazou *et al.* (2006) who demonstrated that the Pseudomonads were isolated mainly in cold months of winter. On the contrary, results are not in accordance with those obtained by Hoda *et al.* (1999) who revealed that the prevalence of pseudomonads was lower in winter than summer. This may also be attributed to amplified activity of proteinases produced by pseudomonads at the low temperature (10-25°C) that play significant role in the pathogenesis of pseudomonas septicemia (Hoshino *et al.*, 1997).

The pathogenicity of *Ps. fluorescence* for experimentally infected *Oreochromis niloticus* may be attributed to the production of extracellular enzymes and lethal toxins El-Attar & Moustaf (1996).

In regards to the total prevalence of vibriosis recorded (34.28%), result are in accordance with those reported by Khan *et al.* (1981) who recorded that vibrios accounted for (28%) of mortalities in captive Atlantic cod, *Gadus morhus* L associated with fin rot disease. the results are lower than those recorded by Zorrilla *et al.* (2003) who recorded that the prevalence of vibrios among diseased gilthead sea bream, *Sparus aurata* L in southwestern Spain was (69.90%).

*V. anguillarum* in this study was the *Vibrio* spp most frequently isolated as (17.55%) of the infected cases were positive for *V. anguillarum*. this is in accordance with Zorrilla *et al.* (2003). On the other hand *V. alginolyticus* was the cause of (16.73%) of the recorded cases. Such high prevalence of *V. alginolyticus* could explain its importance in mariculture as supported by Zhu *et al.* (2000) who suggested that *V. alginolyticus* causes great harm to a wide variety of marine fishes.

The highest prevalence of *V. anguillarum* infection was recorded during the summer (9.38%), followed by autumn (4.08%), spring (3.67%), and only (0.4%) were recorded in winter. On the other hand the highest prevalence e of *V. alginolyticus* infection was recorded in summer (8.57%), autumn (5.30%), spring (2.04%) and (0.81%) in winter. The results of the seasonal prevalence of *Vibrio* spp are in concordance with those reported by Roberts (2001) who demonstrated that in wild, vibriosis normally occurs in fish in late summer when the temperatures are high. On the other hand, (Golomazou *et al.* (2006) reported that *V. alginolyticus* were not associated with a particular season.

The pathogenicity of *V. anguillarum* for experimentally infected *O. niloticus* may be attributed to extracellular toxins and enzymes produced by the bacterium (Nottage & Birkbeck, 1987).

In respect to the total prevalence of *P. piscicida* in this study recorded that (15.51%) of diseased fish were positive for *P. piscicida*. The results are higher than those recorded by Balebona *et al.* (1998) who declared that (6.7%) of diseased gilt-head sea bream, *Sparus aurata* L. in southwestern Spain were infected with *P. piscicida*. On the other hand results are lower than those recorded by Athanassopoulou *et al.* (1999) who recorded that the prevalence of *P. piscicida* in diseased Cuvier, *Puntazzo puntazzo* L. collected from marine aquaculture systems in Greece was (80%).

Seasonally, the highest prevalence e of *P. piscicida* was recorded during summer season (7.75%) , autumn (5.30%) followed by the spring

(2.44%) on the other hand, it was not recorded in winter. Results are in concordance with those reported by Magarinos *et al.* (1996) who declared that *P. piscicida* causes high fish mortality only when the water is warm. On the other hand, Mladineo *et al.* (2006) suggested that temperature has no strong influence on the course of pasteurellosis.

The pathogenicity of *P. piscicida* for experimentally injected *O. niloticus* may be attributed to extracellular products of the bacterium (Nakai *et al.*, 1992).

In regards to the total prevalence of streptococcal septicemia, results indicated that (13.46 %) of infected fishes were positive for streptococcal infection. Results were higher than that recorded by Zorrilla *et al.* (2003) who recorded (7%) of bacterial infection affecting cultured gilthead sea bream, *Sparus aurata* L was attributed to Gram-positive bacteria. Hussain (2002) recorded that (6.25 %) of naturally infected marine fish were positive for streptococcal septicemia.

In regards to the seasonal prevalence of streptococcal septicemia, the highest prevalence of the streptococcal infection was recorded in summer season (6.16%) followed by autumn (4.08%) and spring (1.22 %) on the other hand it was not recorded during the winter. These results are in accordance with those obtained by Varvarigos (1997) who revealed that *Streptococcus* spp cause septicemia to all farmed species mainly during late spring and early summer when sea water temperatures are high.

In concern to the experimental infection of *O. niloticus* with *S. fecalis*, the pathogenicity of streptococci may be attributed to the effect of exotoxins produced by the bacterium (Kimura & kusuda, 1979 and Woo, 1999).

The total prevalence of *Staph. aureus* infections was (3.67%). Results were lower than those recorded by Athanassopoulou *et al.* (1999), who recoded that the total prevalence of *Staph. epidermidis* among diseased *Puntazzo puntazzo* in marine aquaculture systems in Greece was (10 %). Moreover, Zorrilla *et al.* (2003) recorded that (7%) of bacterial infections affecting gilthead sea bream *Sparus aurata* L. were attributed to Gram-positive bacteria.

Seasonally the highest recorded prevalence of Staphylococcal infection was recorded in the summer season (2.85%) followed by autumn (0.81%) with no records in spring or winter. Results are supported by Varvarigos (2001) who declared that *Staphylococcus* spp causing septicemia to all farmed species during high temperature of sea water in late spring and early summer.

Results of experimental infection of *O. niloticus* with *Staph. aureus* were in accordance with Huang (2000) who indicates that staphylococci can be a possible cause of mortalities and losses among fishes.

From the present study it was concluded that bacterial pathogens are the most significant microbial agents affecting marine fishes and climatic changes may plays a great role in modulating the occurrence of bacterial fish diseases.

# Effect of Antioxidant on Lead-Induced Oxidative Damage and Reproductive Dysfunction in Male Rabbits

**\*El-Tohamy, M.M., and El-Nattat,W.S.**

Department of Animal Reproduction and A.I., National Research Centre, Cairo, Egypt.

**\*eltohamymagda@yahoo.com**

**Abstract:** The objective of this study was to characterize the Lead toxicity syndrome, to assess biomarkers that may be most useful for detecting toxicant-induced reproductive dysfunction, and to determine whether supplemental vitamin C would tend to alleviate the lead toxicity in rabbits. To test the hypothesis that the level of lead exposure is associated with an adverse effect on semen quality, in terms of sperm concentration, morphology, motility to assess antioxidant as important markers of disease using total antioxidant status. Adverse effects of lead on the testes may be mediated by oxidative damage and subsequent lipid peroxidation. The effect of lead acetate administration on testicular, hepatic and renal functions and the biomarker of effect for them were investigated in the present study with a trial of treatment by vitamin C. 35 male rabbits were divided into five groups. One control group and four groups received orally low and high doses of lead acetate (10.8 and 15 mg/kg b.wt., respectively). One low and one high received, in addition, 1 g vitamin C / L in drinking water. SOD,  $\gamma$ -GT, AST, ALT, cholinesterase, acid phosphatase, and LDH activities were measured in both serum and semen. Also semen characteristics were measured. Results concerning all the enzymes were promising. SOD, LDH, ALT and acid phosphatase activities in serum and semen were obviously affected by lead. Vitamin C was a good antioxidant that recuperates from the normal enzymatic status in both serum and semen. In conclusion, lead levels led to testicular hypo function, which is supported by the results of semen picture. The hazardous effect of lead led to disturbance in the activities of enzymes under investigation such as SOD,  $\gamma$ -GT, LDH, AST, ALT, Cholinesterase, Acid phosphatase. Vitamin C proved its antioxidant effect on recuperating from the normal status of enzymes in semen and serum. LDH and prostatic acid phosphatase are shown to be biomarkers of testicular dysfunction, while LDH, ALT may be used as biomarkers for hepatic and renal dysfunction. This study established the principle that lead toxicity can be prevented and makes it worthwhile to establish an acceptable treatment or preventive regimen in the light of the present results. [El-Tohamy, M.M., and El-Nattat,W.S. Effect of Antioxidant on Lead-Induced Oxidative Damage and Reproductive Dysfunction in Male Rabbits. Journal of American Science 2010;6(11):613-622]. (ISSN: 1545-1003).

**Keywords:** Effect; Antioxidant; Lead; Oxidative Damage; Reproductive Dysfunction; Male; Rabbit

## 1. Introduction:

Lead is a male reproductive toxicant (Winder, 1989), the primary mechanism of the toxic action of lead appears to be a disruption of the hypothalamic control of pituitary hormone secretion and in turn, spermatogenesis (Sokol, 1987). Since males do not possess accessory reproductive organs, reproductive potential relates to three factors; sperm availability, quality and quantity (Tsuiji and Karagatzides, 2001).

Reactive oxygen species (ROS) have been shown to have an important role in the normal functioning of a reproductive system and in the pathogenesis of infertility. ROS may also play a role in other reproductive organ diseases. Oxidative stress develops when there is an imbalance between the generation of ROS and the scavenging capacity of antioxidants in the reproductive tract. It affects both natural and assisted fertility. Because assisted reproductive techniques are used extensively in the treatment of infertility, it is critical to understand the in-vitro conditions that affect fertilization and embryo

development. Treatments that reduce oxidative stress may help infertility that is caused by this imbalance. Such strategies include identifying the source of excessive generation of ROS, treating the primary cause, and in-vitro and in-vivo supplementation of antioxidants. Research is in progress to identify the mechanisms that are involved in the etiology of reproductive diseases caused by ROS, and to create effective strategies that can counteract oxidative stress (Agarwal and Allamaneni, 2004).

This effect is associated with indicators of oxidative stress.. The present study showed that rabbits subjected to lead and cadmium had increased serum levels of LPO. This may be a result of either overproduction of ROS or accumulation of ROS resulting from dysfunction of antioxidants/antioxidants during lead exposures.

Exposures of experimental rabbits to lead induce oxidative stress, but to date, no examination of this phenomenon has been reported. Exposure to lead and cadmium results in decreased nitric oxide production in rabbits. And inhibition of NO synthesis

leads to a marked decrease in GSH synthesis through down regulation of the rate-limiting enzyme. Elevated serum (LPO) some possible mechanisms for the lead induced -oxidative stress is discussed. Pb exerts at a dose encountered exerts adverse effects on the male reproductive system, and this effect is associated with indicators of oxidative stress.

The imbalance between (ROS) production and (TAC) in seminal fluid indicates oxidative stress and is correlated with male infertility. A composite ROS-TAC score may be more strongly correlated with infertility than ROS or TAC alone recent scientific evidence revealed that a condition known as "oxidative stress" may, in fact, is a common factor in some of the causes of male infertility. Oxidative stress in the semen occurs when the level of ROS (reactive Oxygen Species) is greater than the TAC (Total Antioxidant Capacity). Although low levels of ROS are needed to normal sperm function, high levels of ROS clearly impair fertility. Antioxidants are substances that protect cellular components from damaging oxidative reactions by reaction with the free radicals and other reactive oxygen species.

The specific aims of the present study are to determine the efficacy of Vitamin C to improve reproductive performance of rabbits. There is growing evidence that oxidative stress significantly impairs sperm function, and plays a major role in the etiology of defective sperm function.

This may lead to the onset of male infertility via mechanisms involving the induction of per oxidative damage to the plasma membrane; both spermatozoa and seminal plasma possess antioxidant systems capable of counteracting the harmful effects of ROS. Studies have demonstrated that infertile male is more likely than fertile ones to have depressed (TAC) and lower levels of individual antioxidants (Smith *et al.*, 1996Lewis *et al.*, 1995). ROS is thought to be involved in many aspects of male infertility, where spermatozoa are rendered dysfunctional by lipid peroxidation and altered membrane function, together with impaired metabolism, morphology, motility, and fertility.

On the other hand, there is another category of enzymes, which act on superoxide radicals to eliminate its hazardous effects. The inhibition of these enzymes by lead causes the increase of superoxide radicals  $O_2^-$  and its accumulation inside the cell leading to its death (Mylroie *et al.*, 1986). Vitamins A, E, D and C were recorded to have antioxidant activities. Their antagonistic effects to superoxide accumulation varied from one vitamin to the other.

In this study, Vitamin C is used to investigate its antioxidant activity for decreasing the inhibitory effect of lead acetate on serum and semen

enzymes in New Zealand rabbits and monitoring the biomarker of effect on the vitality of the male.

## 2. Materials and methods

### Experimental design:

35 mature male rabbits (2.5 kg average) were raised in the animal house at National Research Centre (NRC), they were divided into 5 equal numbered groups (n=7). The first group was adopted as a control group (distilled water treated). The second and third were dosed 10.8 mg lead acetate/kg b.wt. Orally and considered as the low dose group. The fourth and fifth groups were dosed 15 mg lead acetate/kg b.wt. and considered as the high dose group. All the groups received their dosage orally dissolved in distilled water using animal gavages. The four latter groups were treated 5 consequent days/week, and the treatment expended for 8 weeks. The third and fifth groups obtained in addition to the lead acetate doses, vitamin C in concentration of 1 g / litre drinking water every day without disturbance. All lived in animals were sacrificed on the day after the last dose.

### Semen collection:

Semen was collected from bucks using a rabbit AV and a teaser female (Hafez, 1970). The collection was achieved from the end of the fourth week until the end of the experiment for the routine evaluation of both live sperm and sperm abnormalities percentage using eosin aniline stain and before the slaughter immediately for enzyme determination.

### Blood sampling:

Blood was collected while sacrificing animals in sterilized capped tubes and sterilized heparinized tubes (for SOD determination). The tubes were incubated at 37°C for 10 minutes in a slope position, and then centrifuged at 3500 rpm for 10 minutes. Serum was collected and immediately tested for the enzymes.

The whole heparinized blood was treated according to the following method: 0.5 ml of whole blood was centrifuged for 10 minutes at 3000 rpm and then the plasma was aspirate off. Then erythrocytes were washed four times with 3 ml of 0.9% NaCl solution and centrifuged for 10 minutes at 3000 rpm after each wash. The washed and centrifuged erythrocytes were made up to 2.0 ml with cold redistilled water, mixed and left to stand at +4°C for 15 minutes. The lysate was diluted with 0.01 mmol/l phosphate buffer pH 7.0 (Randox, Cat. No. SD 124). so that the % inhibition falls between 10% and 60%. A 25 folds dilution of lysate is recommended (final dilution factor = 100).

Enzymatic analysis in blood and semen:

- 1- In erythrocytes:
- i- Superoxide dismutase (SOD) in whole blood according to Wooliams et al. (1983) using *kits purchased from Randox, UK.*
- 2- In serum and whole semen
- i- Aspartate amino transferase (AST), alanine amino transferase (ALT) according to Bergmeyer (1978) and lactate dehydrogenase (LDH) according to Buhl and Jackson (1978) using *kits purchased from Stanbio, Texas, USA.*
- ii- Cholinesterase according to Den Blawen et al. (1983), Acid phosphatase according to Moss (1984) and □□GT according to Szasz (1969) using *kits purchased from Quimica Clinica Aplicada S.A., Spain.*
- iii- The MDH 586 method was used to determine MDA activity as described by Gerard et al., 1998) and measured at 586.
- iv- All enzymes were measured using Shimadzu Spectrophotometer with different wavelengths specific for each enzyme.

Statistical analysis:

Data were analyzed using one-way ANOVA to determine whether the effect of lead (Pb) and vit.

**Table 1- The effect of lead acetate alone or in the addition of vitamin C on semen characteristics in the male rabbits.**

Treatment Biomarkers	Group I (Control) (n=12)	Group II Low Lead (n=36)	Group III (lowLead+C) (n=12)	Group IV (high Lead) = (n=7)	Group V (high Lead+C) (n=28)

Same superscript are non significantly different within row (P<0.05) Duncan test

The results of present study showed that lead acetate significantly affected the semen characteristic in both group II and IV, while; vitamin C corrected these adverse effects (table 1). This agrees with the finding of El-Nattat et al. (2000). Low lead exposure was more consistently associated with indicators of sperm production than was semen lead. Measurement of semen leads may not be a valuable

C gave a significant difference than control group or not ( $H_0$ ). The results were accepted at a level of 95% confidence. Statistical analysis using SPSS (Statistical package for social science) version 12, software package for data analysis (Saeys et al., 2007) was done.

### 3. Results and Discussion:

We previously reported that dietary exposure to lead resulted in suppressed spermatogenesis and testosterone levels without significant changes in luteinizing hormone.(El-tahamy 2003). The result showed that exposure to concentrations of inorganic lead ( micrograms/dl in blood impaired male reproductive function by reducing the sperm count, volume, density or changing sperm motility and morphology. Semen analysis (Table 1) revealed that the lead treated groups were significantly ( $P<0.01$ ) lower in mass motility, individual motility, sperm concentration / ml semen, live sperm %, while, they were significantly ( $P<0.01$ ) higher in the total primary sperm abnormalities %, then the control group. Vitamin C has ameliorated the hazardous effect of lead in both groups (III and V).

adjunct to conventional blood lead monitoring for investigations of male reproductive system toxicity.

The results also showed that vitamin C supplementation reduced ROS generation and improved semen quality. The beneficial effect of vitamin C in improving fertilization rate was possibly due to a reduction in lipid per oxidation potential. Seminal plasma confers some protection against ROS

damage because it contains enzymes that scavenge ROS.

High lead exposure induces oxidative stress in animal. Oxidative stress is an imbalance between the free radical production and antioxidant defense systems of the body (Yao et al., 2006 and Urso et al, 2003).

Antioxidants present in the seminal plasma are the most important form of protection available to spermatozoa against (ROS) (Aitken, 1999). They provide a defense mechanism through 3 levels of protection, prevention, interception and repair. A growing body of evidence suggests that low seminal (TAC) is related to male infertility (Sikka, 2001). Thus, it is important to ensure that any measurement of seminal TAC is accurate and reliable and easy as a diagnostic tool in the evaluation and follow up of male infertility. In a normal situation, the cellular antioxidant mechanisms present in almost all tissues and their secretions are likely to quench those ROS and protect against oxidative damage (Jones, et al., 1979). Antioxidant supplementation can theoretically protect and prevent such per oxidative damage. To evaluate this oxidative stress and determine the role of antioxidants have a great potential in therapeutic practice. Studies on how these cellular changes caused by LPO effect seminal parameters and sperm function and whether they could be reversed by antioxidants are open to further investigations.

Antioxidants, in general, are free radical scavengers that suppress the formation of ROS and/or

oppose their actions. SOD is well known biological antioxidants that convert superoxide (O<sub>2</sub>) and peroxide (HO) radicals to form O<sub>2</sub> and H<sub>2</sub>O. SOD protects against spontaneous O<sub>2</sub> toxicity and LPO (Fridovich, 1985). SOD and catalase also remove O<sub>2</sub> and play an important role in protecting spermatozoa. In spermatozoa, production of (MDA) an end-product of LPO induced by ferrous ion promoters, has been reported (Bell et al., 1993). Seminal plasma possesses major antioxidant defenses, including enzymatic and non enzymatic antioxidants. Chain-breaking antioxidants trap ROS directly to prevent amplification of radical formation and subsequent damage to sperm.

The results (Table 2). showed that ROS combined with total antioxidants capacity could predict fertility in male. Oxidative stress in the semen occurs when the level of ROS is greater than the TAC. Although low levels of ROS are needed to normal sperm function, high levels of ROS clearly impair fertility. Supplementation of vitamin C improved sperm motility and reproductive efficiency, and reduced the production of free radicals which can improve rabbit semen quality. The conclusion is that the antioxidants used are effective in combating cell damaging free radicals, which are known to contribute towards testicular function. Lipid peroxidation considered to be the key mechanism of ROS-induced sperm damage, which leads to loss of sperm motility.

**Table 2. The effect of lead acetate alone or in the addition of vitamin C on MDA and TAC in the semen of male rabbits.**

parameters Groups	Control	Low dose lead acetate(10.8mg/Kg b.wt)	High dose lead acetate(15.mg/Kg b.wt)	Low dose lead acetate + vit. C (1g/L drinking water)	High dose lead acetate + vit. C (1g/L D water)
MDA serum Nmol/ml	10.98 ±0.37 <sup>b</sup>	14.79±0.21 <sup>ac</sup>	18.28±0.25 <sup>ac</sup>	11.62±0.14 <sup>b</sup>	10.36±0.15 <sup>b</sup>

a: Significant change when comparing all groups with the control group

b: Significant change when comparing all groups with lead acetate

c: Significant change when comparing all groups with lead acetate + vit.C

The results showed that supplementation of vitamin C had beneficial effects on semen characteristics. The beneficial effects of vitamin C can be attributed to the fact that vitamin C is a very

efficient antioxidant and a scavenger of oxygen free radicals who are toxic byproducts of many metabolic processes. Vitamin C is important in maintains the physiological integrity of the testes. Supplementation

of vitamin C improved sperm motility and reproductive efficiency and reduced the production of free radicals which can improve rabbit semen quality. The study required to determine whether vitamin C and other naturally occurring compounds can function as effective free radical trapping antioxidants, thereby preventing testicular peroxidative injury.

Vitamin C is essential to the body as both an antioxidant and as a nutritional supplement. Numerous antioxidants have proven beneficial in treating male infertility, such as Vitamin C and E, glutathione, Zinc and Selenium (Sinclair, 2000). Antioxidants can protect against the damaging effect of leukocyte-derived reactive oxygen species on sperm movement and may be of clinical value (Baker et al., 1996). The production of ROS is a normal physiological event in various organs, including the testes. Overproduction of ROS, can be detrimental to sperm, which associated with male infertility (Akiyama, 1999).

The results of the present study showed that lead acetate significantly affected the semen characteristic in both group and IV, while vitamin C corrected these adverse effects (table 1). The role of some enzymes markers are greatly influencing by heavy metals. Most of them contain a sulphydryl group. Such group is a target for metals. Others like some metal-enzymes have a prosthetic group that may be replaced by these metals leading to an inhibition of enzyme activity (WHO, 1993). These suppression masks their physiological actions specially those enzymes related to superoxide radicals  $O_2^-$  that accumulates inside the cells leading to the deterioration and death of the cells.. SOD is one of these enzymes (Patra et al., 1999). The results indicated that lead acetate induced an exaggerated inhibitory effect for the SOD. As lead mimics Cd in replacing Zn in its sites, this suggested the interaction of lead with the Cu, Zn and Mn , moieties such as interaction has been demonstrated where lead replaces Zn to form Cu-Pb-SOD (Bauer et al., 1980) Vitamin C ameliorate the inhibitory action of lead by removing ROS once formed, thus preventing radical chain Reactions. This observation supports the hypothesis that SOD activity is stimulated by an increased superoxide radical generation associated with the decline of SOD and glutathione peroxides (GSH-Px) Allen and Balin, (1989) generated by the inhibitory action of lead; on the other hand, the antioxidants refresh the enzyme's activity and antagonize the inhibitory effect of lead.

Lactate dehydrogenase plays an important role in the intermediary metabolism as a link between

amino acid metabolism and the citric acid cycle where it converts lactate into pyruvate(Table 3).. The serum lactate dehydrogenase is cytosolic, and in cellular damage the liver, lung, muscle, kidney, testicles or heart releases it into systemic circulation (Bhargava et al., 1978). In the present study, there was a decrease in the activity of the LDH in serum due to the lead intoxication. This agrees with the findings of Yagminas et al. (1990), while, it recuperates its activity values around the control LDH activity due to the treatment with vitamin C in both semen and serum. This decrease in LDH activity may be due to an inhibitory effect induced by the dose levels of lead, although an increase in the enzyme leakage may be present. On the other hand, in the semen the leakage from testicular and glandular tissues was significant, approximately twice to four times than the treated groups with vitamin C and triple the control group. Gulvik (1989) recorded a reduced activity of LDH in the testicular tissue. This result agrees with our findings that LDH is a sensitive and convenient biosensor for detection of heavy metal salts (Fennouh et al., 1998).

The role of some enzyme markers is greatly influenced by heavy metals. Most of them contain sulphydryl group (-SH) at their site of the action (Keogh, 1992), such group is a target for metals. Others like some metal-enzymes have a prosthetic group that may be replaced by these metals leading to an inhibition of enzyme activity (WHO, 1993). These suppression masks their physiological actions, especially those enzymes related to superoxide radicals  $O_2^-$  that accumulate inside the cells leading to the deterioration and death of the cells. SOD is one of those enzymes (Patra et al., 1999).

The results indicated that lead acetate induced an exaggerated inhibitory effect for the SOD. As lead mimics Cd in replacing Zn in its sites, this suggested the interaction of lead with the Cu, Zn and Mn moieties. Such interaction has been demonstrated where lead replaced Zn to form Cu-Pb-SOD (Bauer et al., 1980). Vitamin C ameliorates the inhibitory action of lead by removing ROS once formed, thus preventing radical chain reactions. This observation supports the hypothesis that SOD activity is stimulated by an increased superoxide radical generation associated with the decline of SOD and glutathione peroxidase (GSH-Px) (Allen and Balin, 1989) generated by the inhibitory action of lead, while, on the other hand, the antioxidant refreshes the enzyme activity and antagonizes the inhibitory effect of lead.

Certain enzymes, proenzymes, and their substrates are present at all times in the circulation of normal individuals and perform a physiological function in blood. Pseudo cholinesterase is one of these enzymes (functional enzymes). They are synthesized in the liver but present in blood in equivalent or higher concentrations than in tissues (table 4). While, nonfunctional plasma enzymes

which have the unknown physiological function in blood, only provide valuable diagnostic and prognostic clinical evidence in the case of dysfunction and diseases. These nonfunctional plasma enzymes include those in exocrine secretions and true Intracellular enzymes. Prostatic acid phosphatase is one of those categories (Rodwell, 1991).

The  $\gamma$ -glutamyl transferase, an enzyme that supports the transfer of certain amino acids into the GSH, which reduces, peroxides accumulation into the

RBCs and other cells. It is presented in abundant in the plasma membrane of renal tubular cells and in the endoplasmic reticulum of the hepatocytes (Murray,

1991). In the present study, the results showed a significant increase in the enzyme activity in case of high dose of lead acetate (14.09 U/l) than the control group. This indicates that there is a destruction of the enzyme in the store cells, and release in the blood serum (Murray, 1991). Therefore, the activity in the store cells like hepatocytes and renal tubular cells is decreased (Sivaprasad et al., 2002). Murray (1991) reported that high malonylaldehyde levels (a compound indicator on lipid peroxides) along with lowered activities of catalase, SOD, glutathione peroxidase, glutathione metabolizing enzymes (glutathione reductase, glucose-6-phosphate dehydrogenase, glutathione-S-transferase) indicate that the cells are under deteriorating stress factors including heavy metals. He recorded that a powerful antioxidant can reverse the oxidative damage by bringing about an improvement in the reductive status of the cell. The present study proved that vitamin C has stored the integrity of cells and reduced the leakage of enzymes outside the damaged cells, in addition, to its antioxidant effect via an indirect way. Moreover, vitamin C may help in decreasing the superoxide radical's accumulation inside the cells, although the SOD activity is inhibited by the hand make of lead, , it conserves the soundness of the cells in return, no leakage of enzymes and no increased enzyme activity in the serum than the normal. This is in agreement with the proposal of Sivaprasad et al. (2002). Upasani and Balaraman (2001) concluded that vitamin C had a significant antioxidant activity thereby protecting the organs from the lead-induced toxicity.

Lactate dehydrogenase plays an important role in the intermediary metabolism as a link between amino acid metabolism and the citric acid cycle where it converts lactate into pyruvate. The serum lactate dehydrogenase is cytosolic, and in cellular damage the liver, lung, muscle, kidney, testicles or heart releases it into systemic circulation (Bhargava et al., 1978). In the present study, there was a decrease in the activity of the LDH in serum due to the lead intoxication. This agrees with the findings of Yagminas et al. (1990), while, it recuperates its activity values around the control LDH activity due to the treatment with vitamin C in both semen and serum. This decrease in LDH activity may be due to an inhibitory effect induced by the dose levels of lead, although an increase in the enzyme leakage may be present. On the other hand, in the semen the leakage from testicular and glandular tissues was significant, approximately twice to four times than the treated groups with vitamin C and triple the control group. Gulvik (1989) recorded a reduced activity of LDH in the testicular tissue. This result agrees with our findings that LDH is a sensitive and

convenient biosensor for detection of heavy metal salts (Fennouh et al., 1998).

Many authors have discussed the effect of lead on AST and ALT in the serum (Randhawa et al., 1995; and El-Nattat, 1997). While, in liver cell culture Gutierrez et al. (1992) found that LC<sub>50</sub> of lead acetate (100 micromole) caused significant leakage of ALT and AST into the medium. This concludes that leakage cytoplasmic enzymes appear to be a sensitive indicator of cellular injury produced by heavy metals. In the current study, lead acetate executed the leaked enzymes leading to increase in activity in the serum and semen, while, on offering vitamin C the hazardous effect was removed, and the leakage was decreased. This was obvious via the decrease in ALT activity in the serum and semen.

Cholinesterases are enzymes, which hydrolyze esters of choline to give choline and the acid. Two types have been distinguished, true and pseudo. True cholinesterase is thought to be responsible for the destruction of acetylcholine.

The neuromuscular junction and is found in nerve tissue and in the red blood cells. Pseudocholinesterases are found in various tissues such as liver, heart muscle and intestine and also present in plasma or serum (Varley, 1976). The heavy metal ions (mercury, lead, cadmium, arsenic and some others) and their organic compounds belong to noncompetitive inhibitors of enzymes. They may block the -SH groups that make part of the catalytic site of the enzyme (Stroev, 1989). A significant reduction in the activity of cholinesterase was found in the serum of bucks received a dose of 15 mg/kg b.wt. This indicates that lead had reduced the cholinesterase in the serum. This may affect the role of pseudocholinesterase in the serum and liver in case of hypnotic's administration, e.g. succinylcholine (muscle relaxants). The same results were obtained in the semen, which indicates that the enzyme behaves like that in the serum and liver.

The acid phosphatase is present in high concentration in the prostate gland, erythrocytes, platelets, reticuloendothelial cells, liver, spleen and kidney. Its increase in the serum may be due to a carcinoma in the prostate, particularly if the cancer has spread beyond the capsule of the gland or has metastasized (Krupp et al., 1987). In the present study, the total and prostatic acid phosphatase activity, in the serum of lead and lead + vitamin C treated groups, were significantly increased than in the control serum. On the other hand, the lead groups treated with vitamin C showed a significantly higher level of the enzyme activity than the lead groups alone, which indicates that a tumor is present in the prostate gland or in the hemopoietic system as the vitamin could not cure it or ameliorate the case.

Moreover, the semen of those groups didn't show significant change only in the high lead dose. This agrees with the findings of Othman and El Missiry (1998).

In conclusion, lead exposure led to testicular disturbed hypo function, which is supported by the results of semen picture. The hazardous effect of lead led to disturbance in the activities of these enzymes under investigation, SOD,  $\text{GOT}$ , LDH, AST, ALT, cholinesterase, acid phosphatase, Vitamin C proved its antioxidant effect on recuperating from the normal status of enzymes in semen and serum thus counteracts the hazardous oxidant effect of lead inside the different organs. LDH and the prostatic acid phosphatase are shown to be biomarkers for testicular dysfunction, while the ALT and LDH may be used as biomarkers for hepatic and renal dysfunction. Lead exposure may acutely induce oxidative stress and enhance antioxidant defenses and decreased lipid peroxidation in animal.

# Tara Gum Carbamate: A New Thickening System for Cotton Printing Using Vat Dyes

**A. Hebeish<sup>1</sup>, A.A. Ragheb<sup>1</sup>, S.H.Nassar<sup>1</sup>, E.Allam<sup>2</sup> and J.I. Abd El -Thalouth<sup>2</sup>**

<sup>1</sup>Textile Research Division, National Research Center Dokki , Cairo Egypt

<sup>2</sup> Faculty of Applied Arts, Helwan University, Cairo, Egypt

**Abstract:** Green technology-based textile thickeners, namely, glactomannan was isolated from tara seeds and harnessed to vat printing of cotton fabrics before and after being carbamated. Carbamation was effected through reaction with urea at 160 °C for 15 and 90 min. to produce tara carbamate derivatives having 1% N and 3.12 % N respectively. These derivatives are soluble in water at room temperature and characterized by non-Newtonian pseudoplastic behaviour. However, for a given rate of shear, tara carbamate derivative having 1% N exhibits lower apparent viscosity than the derivative with 3.12 % N. On the other hand the apparent viscosity of pastes prepared from these two derivatives increases by storing for 24 or 48 hours before commence measuring. Prints could successfully be achieved using either of the two new tara carbamate derivatives in single use or in admixture with conventional thickener viz. Lameprint A6. Colour strength (K/S) values of prints prepared using the new tara carbamate –based thickeners are higher than those obtained with the conventional thickener, meanwhile the overall fastness properties of all prints are equal, irrespective of the thickener used.

**Keywords:** Tara Gum Carbamate; System; Print; Vat Dye

## 1. Introduction:

Tara gum is obtained from the kernels (seeds) of the tara shrub *Caesalpinia*, sometimes referred to as *Caesalpinia tinctoria* (H.B.K.) or *Caesalpinia pectinata* (Cav.)<sup>(1)</sup>. This legume is native to northern regions of Africa and South America. It is mainly distributed in the valley area in the middle of the east Andes and in the sea shore desert along the Pacific ocean<sup>(2)</sup>. Peru is the primary commercial source of tara<sup>(3)</sup>.

Vat dyes give a wide range of bright colours resistant to wet treatment and weather conditions; hence they occupy one of the prominent places among the other classes of dyes. They are used for printing cellulosic fabrics and also proteinic fabrics. At any event, however, although this group of dyes embrace a wide range of molecular structure types which are often complex yet all contain one or more carbonyl (=C=O) groups<sup>(4,5)</sup>. When they are treated with reducing agents, the carbonyl groups combine with hydrogen to form the leuco compounds, which contain secondary hydroxyl group. These compounds do not dissolve in water but form soluble sodium derivatives in the presence of alkalis. On oxidation the sodium compounds are converted to the insoluble coloured derivatives<sup>(6)</sup>.

Urea, on the other hand is one of the most important materials used in the field of textile finishing and printing. In the latter it acts as a solvent for dye and it promotes the dye migration from the printed film to the fibre interior. It has been reported<sup>(7)</sup> that urea reacts with alcohol and polyhydric alcohols to bring about the corresponding carbamate derivatives. A temperature range from 160 – 190 °C was reported as optimal for carbamate derived from urea and alcohols. Furthermore, it was shown that under such high temperature urea decomposes with loss of ammonia to form cyanic acid. The latter reacts with the alcohol to yield carbamates.

In a very recent study we have reported on the synthesis, characterization and application of carboxymethyl tara derivatives in reactive printing of cotton fabrics. Results were so promising that they stimulate current work especially after the search revealed that no systematic study was so far carried out on carbamation of tara gum.

Obviously, then, current work is undertaken with a view to carbamate tara gum by reacting it with urea and harness the obtained derivatives in printing cotton fabrics with vat dyes. The work involves technical applications in textile chemical technology evaluation of the tara carbamate derivatives through monitoring the nitrogen content as a measure for the

extent of carbamation, the rheological properties of the derivatives –based thickeners, printability of the tara carbamate derivatives alone as well as in admixture with the universe commercial thickener (Lame Print A6) and, properties of the prints. A comparison is also made between Vat prints obtained with the new tara carbamate derivatives and prints obtained using Lame Print A6.

## 2. Experimental

### 2.1. Materials

2.1.1. Cotton fabric: Cotton fabric: Mill desized, Kier boiled and bleached poplin cotton fabric ( $140 \text{ g/m}^2$ ) produced by Misr/helwan for Spinning and Weaving Company was used throughout the present work.

2.1.2. Plant seeds: Dry clean seeds of tara were obtained from tara shrub. They were kindly supplied by EL-Khawaga Farm at EL-Khatatba, Menufia. The seeds are composed of three components namely hull, endosperm, and germ obtained from ripe pods. The latter is rich in pyrogallol tannin. The gum is collected in the endosperm and composed mainly of galactomannan; the molar ratio of mannose to galactose is  $3:1^{(8,9)}$ .

2.1.3. Thickening agent: Lameprint A6, commercial plant seed gum ether, manufactured by Grunau, Germany, was kindly supplied by Misr/El-Mahala for spinning and weaving. It is resistant to metal salts, non-ionic, no residues. It is recommended for printing with Vat dyes and Rapidogen and Neutrogen dyes, fast colour salts and aniline salt.

2.1.4. Vat dyes: Two different Novatic microperle Vat dyes manufactured by Atul LTD, Gujarat, India were employed. These dyes were Novatic Orange 3G Microperle (C.I. Vat Orange 15) and Novatic Blue RS Microperle (C.I. Vat Blue 4).

2.1.5. Other chemicals: Urea and Sodium carbonate were of laboratory grade chemicals whereas ethyl alcohol was of technical grade. Sodium sulphoxalate formaldehyde (Rongalite C) as a reducing agent. Hostapal CV-ET (non -ionic detergent).

### 2.2. Methods:

2.2.1. Preparation of carbamate derivatives: After being isolated from the tara seeds, galactomannan gum was allowed to react with urea using the solid state technique as follows:

The gum and urea (1:1) were mixed well in the solid state using a laboratory mixer. The mixture was transferred to a porcelain crucible then subjected to high temperature ( $160^\circ\text{C}$ ) for different periods of time (15, 30, 45, 60, and 90 min). At this end the

thermally treated mixture was dissolved in distilled water at room temperature, precipitated with commercial ethyl alcohol, filtered on a sintered glass funnel and washed several times with 75% ethyl alcohol then purified.

2.2.2. Purification: The prepared carbamate derivatives prepared as described above were purified by extraction in soxhlet using 75% ethyl alcohol, and the purified derivatives were dried in a desiccator containing calcium chloride.

2.2.3. Preparation of the printing paste: This is done according to the popular potash / Rongalite process. The following is the recipe which has been employed:

#### Preparation of the thickening agent:

Thickening Agent*	X	g
Water	1000 - X	g
Total	1000	g

\*The thickening agent used were Tara carbamate derivative, 2.5 g, or commercial thickening agent namely Lameprint A6 6g.

#### Preparation of stock thickener:

Thickening agent	-----	600	g
Glycerine	-----	80	g
Potassium carbonate	-----	150	g
Rongalite C	-----	150	g
Water	-----	20	g
Total	-----	1000	g

#### Preparation of the printing paste:

Novatic microperle dye	-----	20	g
Water	-----	180	g
Stock thickener	-----	800	g
Total	-----	1000	g

The required amount of dyestuff was pasted with warm water and stirred well to make homogenous suspension paste. The previously prepared stock thickening was added into the paste and mixed thoroughly.

2.2.4. Printing technique: All the printing pastes were applied to cotton fabric as per flat screen printing.

2.2.5. Steaming: After printing and drying, the printed goods were subjected to steaming at  $100-102^\circ\text{C}$  for 10 minutes.

2.2.6. Washing: After steaming the printed goods were washed with cold water to remove the thickening agent and alkali and the vat dye was oxidized with dilute sodium perborate 5 g/l followed by washing thoroughly, soaping at the boil in a solution containing 2 g/l non-ionic detergent namely Hostapal CV, and cold water, air dried and assessed for K/S and overall fastness properties.

### 2.3. Analysis and Measurements:

#### 2.3.1. Determination of nitrogen content:

The nitrogen content of the purified tara gum carbamate derivatives was determined at Micro Analytical Laboratory, NRC, Egypt.

2.3.2. Determination of the rheological properties<sup>(10)</sup>: The rheological properties of the printing pastes were measured using Rheomat-15 at 25°C and the apparent viscosity ( $\eta$ ) at various rates of shear was calculated from the shearing stress ( $\tau$ ) and rates of shear (D) as follows:

$$\eta = \frac{\tau}{D}$$

#### 2.3.3. COLOUR MEASUREMENTS<sup>(11, 12)</sup>:

The colour strength, expressed as K/S and the overall fastness properties (washing, perspiration and crocking) were assessed according to the standard methods.

### 3. Results and Discussion:

#### 3.1. Tentative Reaction Mechanism of Carbamation of Tara Gum:

**Table I: Effect of time of carbamation of tara gum on the nitrogen, carbon, and hydrogen contents of the obtained products\*.**

Time of reaction in minutes	%N	%C	%H	Solubility in	
				Water	Ethyl alcohol
0	0	38.67	6.55	Swelled only	Insoluble
15	1	38.69	4.81	Soluble	Insoluble
30	1.63	37.46	4.86	Soluble	Insoluble
45	2.08	37.25	5.4	Soluble	Insoluble
60	2.28	37.85	5	Soluble	Insoluble
90	3.12	36.67	6.22	Soluble	Insoluble

\* The reaction was carried out at 160 °C; the ratio of urea: gum is 1:1

#### 3.2. Dependence of Carbamation on Reaction Time:

It is seen (Table I) that, the percent nitrogen increases significantly by prolonging the duration of carbamation from 15 to 90 minutes. A nitrogen content of 1 % could be achieved with the derivative when urea was allowed to react with the tara gum for 15 minutes. This is against a nitrogen content of 3.12 % for a reaction time of 90 minutes. Trials have been made to increase the duration of carbamation more than 90 minutes. Allowing the carbamation reaction to proceed for 120, 150 or 180 minutes brings about tara gum derivatives which are insoluble in water. Longer durations cause charring of the reaction mixture.

Table I shows the element analysis, namely carbon and hydrogen of the derivatives under

To start with, tara galactomannan gum was isolated from tara seeds according to the procedure described elsewhere<sup>(13)</sup>. The obtained dry gum was allowed to react with urea using the solid state technique<sup>(14)</sup>. The reaction was conducted as detailed in the experimental section, at 160 °C for different intervals of time (15 to 90 minutes). The reaction may be drawn as follows:

Previous reports<sup>(7)</sup> have also disclosed that urea decomposes at high temperature and loses ammonia to form cyanic acid (HN = C = O) which react with the hydroxyl groups of the carbohydrate to give the carbamate derivative. Thus:

After the necessary purification, obtained tara gum carbamate derivatives were analyzed for nitrogen which is an indication of the degree of carbamate substitution in the molecule. The results obtained are given in Table I.

Time of reaction in minutes	%N	%C	%H	Solubility in	
				Water	Ethyl alcohol
0	0	38.67	6.55	Swelled only	Insoluble
15	1	38.69	4.81	Soluble	Insoluble
30	1.63	37.46	4.86	Soluble	Insoluble
45	2.08	37.25	5.4	Soluble	Insoluble
60	2.28	37.85	5	Soluble	Insoluble
90	3.12	36.67	6.22	Soluble	Insoluble

investigation. It also shows the solubility of these derivatives. While the results of carbon and hydrogen are self explanatory, the derivatives are soluble in water but are insoluble in ethyl alcohol. Insolubility in water is encountered when these derivatives were prepared under the influence of reaction time longer than 90 minutes as indicated above.

#### 3.3. Rheology:

The scientific study of the mechanical properties such as flow, ductility and plasticity of concentrated colloidal system has been termed rheology<sup>(15)</sup>. Textile printers have long been aware of the empirical relationship between the characteristic flow properties of the various thickening agents, their

use, and their suitability for printing various types of design.<sup>(15,16)</sup>

It is, therefore, of interest to investigate the rheological characteristic of pastes of the prepared carbamate tara gum derivatives. Hence aqueous pastes at a concentration of 2 % were prepared and their rheological properties were measured using Rheomat-15 immediately after preparation and also after storing of their pastes for 24 and 48 hours.

The investigation performed permits to obtain experimental rheograms (up and down flow curves), in which the ordinate represents the values of X proportional to the shearing stress ( $\tau$ ), and the abscissa represents the values of Y proportional to the rate of shear (D) as shown from figures 1,2 and 3 for the freshly prepared pastes and after storing of their pastes for 24 and 48 hours respectively.

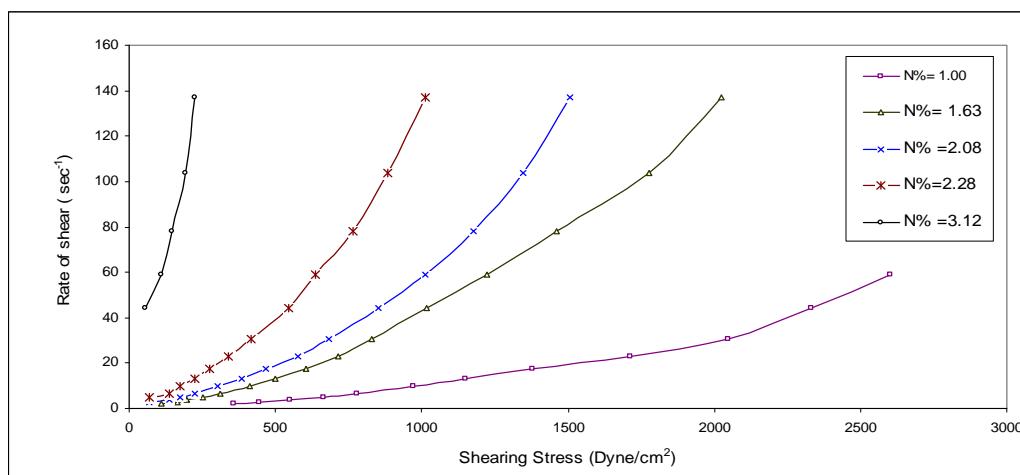

It is obvious (figure 1) that all the examined samples, of % N equal to 1.63, 2.08 , 2.28 and 3.12 are characterized by a non-Newtonian pseudoplastic behaviour, since the up and down flow curves are coincident. This means that, if the viscosity (resistance to flow) of these pastes is measured using a large applied force (shearing stress) which causes a high velocity of flow (shear rate), the apparent viscosity is less than that of the same paste determined with smaller force and at lower rate of flow<sup>(16)</sup>. In this system, i.e. pseudoplastic, no time dependent effects are observed, i.e. as soon as the applied force is removed, the paste rebuilds itself and retains its original viscosity immediately.

It is also clear from (figure 1) that, in spite of the fact that all the pastes are characterized by pseudoplasticity, yet the degree of carbamation, (i.e. % N) plays a dominant role on the viscometric properties of these pastes. As the degree of

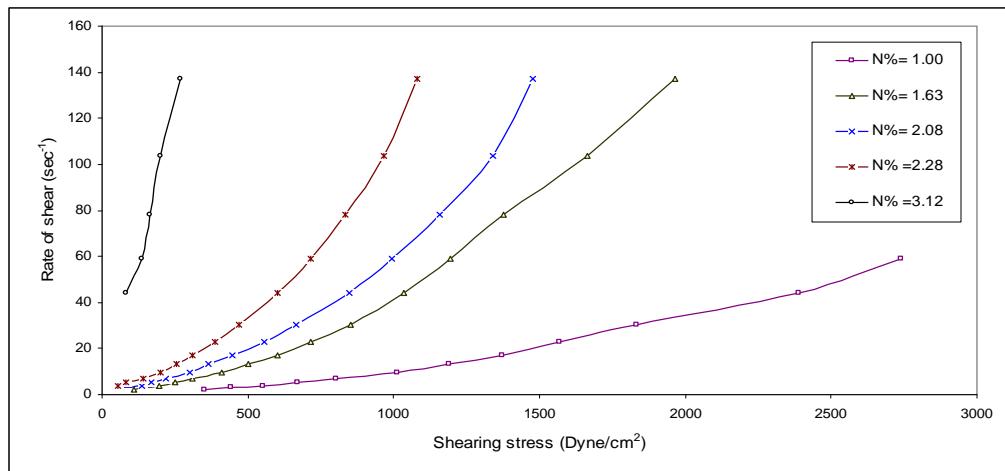

carbamation increases, the rheogram is shifted regularly near the rate of shear axis which indicates a decrease in the apparent viscosity at a constant rate of shear. This will be discussed later.

Figures 2 and 3 depict the effect of storing of carbamated tara gum pastes on their rheological properties. On comparing figures 2 and 3 with figures 1, one would realize that storing of these pastes has no effect on the rheological properties of these pastes, since they are still characterized by non-Newtonian pseudoplastic properties after storing. However, a close examination of these rheograms would reveal that, the location of the rheogram with respect to the rate of shear depends on the time of storing. As the latter increases the location of the rheogram is shifted far from the rate of shear axis indicating an increase in apparent viscosity by storing at a constant rate of shear. This state of affairs is more clarified in Tables II, III and IV.

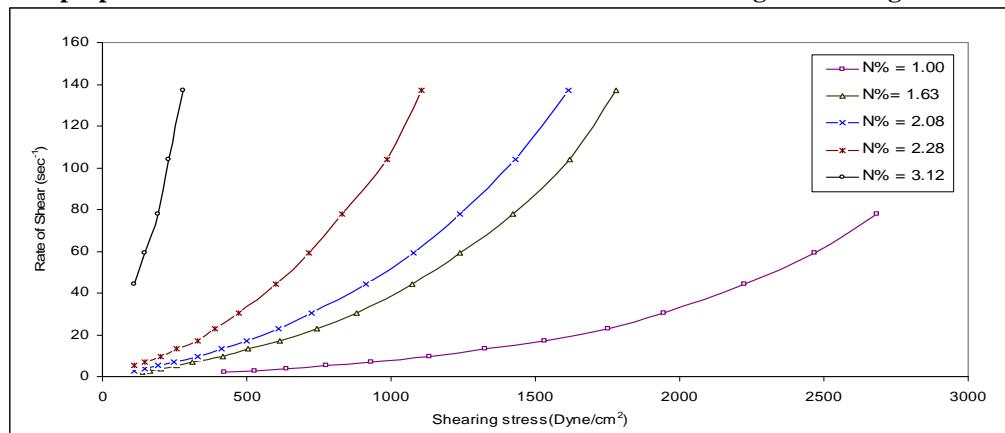

Table II shows that as the degree of carbamation (expressed as % N) of tara gum increases, the apparent viscosity at a given rate of shear decreases. For example at a rate of shear  $5.139 \text{ sec}^{-1}$ , the apparent viscosity decreases from 128.9 to 13.32 poise by increasing the nitrogen content from 1 % to 2.28 %. This indicates that higher extents of carbamation of tara gum are accompanied by higher thermal molecular degradation of the gum. It is understandable that carbamate derivatives with higher nitrogen content could be achieved at relatively longer reaction duration at a temperature as high as  $160^\circ\text{C}$ . Under such conditions thermal hydrolytic decomposition of the derivative inevitably occurs. Once this is the case, the molecular weight and therefore, apparent viscosity decreases.

**Figure 1: Effect of degree of carbamation of tara gum expressed as %N on the rheological properties of pastes freshly prepared thereof.**

**Figure 2:** Effect of degree of carbamation of tara gum expressed as %N on the rheological properties of pastes prepared thereof then stored for 24 hours before commencing the rheological measurements.

**Figure 3:** Effect of degree of carbamation of tara gum expressed as %N on the rheological properties of pastes prepared thereof then stored for 48 hours before commencing the rheological measurements.

**Table II:** Effect of nitrogen content of tara gum carbamate derivatives on the apparent viscosity of their freshly prepared pastes.

\* The concentration of the pastes was 2%.

For the sake of verifying the effect of storing of the pastes under investigation on their apparent viscosity at specific rate of shear, comparison is made among Tables II, III and IV. For instance, at a rate of shear of 9.771 sec.<sup>-1</sup>, freshly prepared paste exhibits apparent viscosity value of 99.197 poise. This value increases to 103.68 poise and 116 poise after storing the paste for 24 hours and 48 hours respectively. This is, indeed, the case regardless of the extent of carbamation.

The increase in viscosity of carbamated tara gum by storing calls for formation of crosslinks between adjacent galactomannan tara gum chains. It is also likely that, besides exerting cross linking, storing acts in favour of inducing higher swellability of the derivative leading ultimately to increased viscosity.

### 3.4. Printing:

Vat dyes are found amongst the oldest natural colouring materials used for textiles<sup>(5)</sup>. They

include a wide range of structural types and often the molecules are complex, but they all contain one or more carbonyl groups ( $=\text{C}=\text{O}$ ), which, when treated with reducing agents combine with hydrogen to form leuco compounds containing ( $\equiv\text{C}-\text{OH}$ ) groups. These secondary alcohols do not dissolve in water but form soluble sodium derivatives ( $\equiv\text{C}-\text{ONa}$ ) in the presence of alkalies. On exposure to air, or oxidation with a suitable oxidizing agent, the sodium compound is converted to the insoluble coloured derivatives through the following reactions:

Hence printing with these dyes need a thickening agent which is not affected by the necessary auxiliaries added to the vat dye printing paste, i.e. reducing agent and alkali.

This work's objective is to introduce tara gum carbamate derivative as a new thickener for printing cotton fabrics with vat dyes.

Hence, different printing pastes thickened by tara gum carbamate derivative and containing Novatic Orange 3G (C.I. Vat orange 15) were prepared. Tara gum carbamate derivatives having

different nitrogen contents viz. 1, 1.63, 2.08, 2.28 and 3.12 % N were used.

Another two printing pastes containing the same Vat dye and thickened by a conventional commercial thickening agent namely Lameprint A6 were also prepared. This conventional thickener is recommended, in practice, for vat printing. Furthermore, a series of printing pastes thickened by a mixture of tara carbamate derivatives and the commercial Lameprint A6 thickener at a ratio of 1:1 (wt/wt) was prepared.

The so prepared pastes were employed for screen printing of cotton fabrics. This was done immediately after the preparation of the printing paste or after storing of the pastes for 24 or 48 hours before commence printing. After printing and drying the printed goods were subjected to steaming at 100-102 °C for 10 minutes followed by washing with cold water, oxidation with 5 g/l sodium perborate solution followed by a thorough wash, soaping at the boil, washing thoroughly and finally drying at room temperature. After being conditioned, the printed goods were assessed for measuring K/S and overall fastness properties. The results obtained with Novatic Orange 3G are set out in table V. Printing was performed using the freshly prepared pastes and after the latter were stored for 24 or 48 hours before commence printing.

**Table V: Colour strength, expressed as K/S of cotton fabric samples printed using pastes thickened by tara gum carbamate derivative, Lame Print A6 or mixture of both when printing was performed using freshly prepared pastes, 24 hours and 48 hours stored pastes containing Vat dye namely Novatic Orange 3G. Fastness properties are also shown when only freshly prepared thickeners were used as example.**

Thickening agent	K/S			Washing fastness		Rubbing fastness		Perspiration fastness			
	a	b	c	Alt.	St.	Dry	Wet	Acidic		Alkaline

(a) Freshly prepared pastes (b) 24 hours pastes (c) 48 hours stored pastes. St: Staining; Alt: Alteration

### 3.4.1. Colour strength (K/S):

Results of table V disclose that the K/S value of the printed goods depends on: (1) % N of the tara gum carbamate thickener which, in turn, speaks of its nature and (2) the time elapsed before commence printing. In combination with this is the nature of the dye. When we have used different vat dyes under identical conditions, different K/S values were obtained.

Table V reveals that the K/S values of Novative Orange 3G on cotton fabric samples printed using tara gum carbamate are generally higher than their corresponding samples printed using the commercial thickener (Lameprint A6). The highest K/S value (2.06) is obtained upon using the carbamate thickener with 1% N, while the lowest K/S value (1.58) is obtained when a carbamate thickener having 3.12 % N was used. This is against K/S value of 1.48 obtained on using the commercial thickening agent. Similar trend was observed when other Vat dyes were used.

The superiority of tara gum carbamate with the lowest nitrogen content (1 %) within the range studied suggests that subjecting tara gum to carbamation for only 15 minutes at 160 °C is sufficient to convert the gum into a stable thickener with high ability to transfer the dye from the printing paste to the fabric. That is, this particular tara gum carbamate is capable of swelling, dispersing and jumping in an aqueous medium without complete elimination of intermolecular forces between themselves and water. Similar observation was reported<sup>(17)</sup> for cyanoethyl starch derivative having 1.75 % N.

Tables V shows the colour strength (K/S) of fabric samples printed using the pastes after being stored for 24 and 48 hours before commence printing respectively. As is evident storing decreases the K/S values and, the longer the storing the higher is the decrease in K/S. This suggests that the reducing agent undergoes partial decomposition under the influence of alkali and long storing at temperature of ca 30 °C as storing was carried out at ambient conditions. Storing of the pastes, before commence printing was performed during summer time in Cairo when a temperature as high as 40 °C could be encountered.

### 3.4.2. Fastness properties:

Table V shows the overall fastness properties including colour fastness to rubbing, to washing and to perspiration of the cotton fabric samples printed using tara gum carbamate derivatives. It is clear that these properties are almost identical to their corresponding samples printed using the commercial thickening agent (Lameprint A6). In

all cases rubbing fastness is ranging from 3-4 to 4 whereas, the washing and perspiration fastness properties range from 4 to 4-5.

### 3.4.3. Thickener Mixture:

Printing pastes containing the said vat dye and thickened by a mixture (1:1) of tara gum carbamate thickener and Lameprint A6 conventional thickener were prepared and used for printing cotton fabrics. The printed goods were monitored for colour strength (K/S) and overall colour fastness properties. Results obtained are set out in Tables V.

It is clear (Table V) that the highest K/S is obtained when the paste is thickened by a mixture containing the carbamate derivative having the lowest nitrogen content (1 % N). Increasing the degree of carbamation is accompanied by a decrease in K/S. This holds good for all derivatives with one exception; carbamate derivative having 3.12 % in the mixture brings about prints with marginally higher K/S than carbamate derivative having 2.28 % N in the mixture.

The effect of storing before commence printing of pastes thickened by tara gum carbamate / Lameprint A6 mixture may be realized from Table V. As is evident storing is accompanied by a decrease in K/S values. This is rather in accordance with the above results obtained upon using pastes thickened by only tara gum carbamate derivative and, therefore, could be interpreted on similar lines.

## 4. Conclusion

Tara gum carbamate derivatives can be used successfully in printing cotton fabrics with vat dyes. In most cases the lower the nitrogen content, the higher the K/S. Samples printed using carbamated tara gum, in most cases, acquire higher K/S values than those obtained using Lameprint A6 commercial thickening agent. The overall fastness properties of the prints are nearly, identical, and in all cases ranging between good to very good for rubbing and very good to excellent for washing and perspiration.

**Abstract:** Desertification is considered as an important problem facing arid and semi-arid regions, as Egypt. These processes are resulted either from human activities or adverse natural conditions. However, the combination of both is often applicable. The aim of this study is the identification of areas sensitive to desertification in the north coast of Egypt. Based on the MEDALUS approach and the characteristics of the study area regional model developed using GIS. Three main indicators of desertification, including: soil, vegetation and climate were considered. The several sub-indicators affecting the quality of each main indicator were identified. Based on the MEDALUS approach, each sub-indicator was quantified according to its quality and given a weighting of between 1 and 2. Arc-GIS 9.2 was used to analyze and prepare the layers of quality maps using the geometric mean to integrate the individual sub-indicator. ETM and SRTM satellite images, geologic and soil maps were used as main sources for calculating the Environmental Sensitivity Areas Index (ESAI) for desertification. The results show that the soil of the north coast is characterized mainly by high sensitive areas for desertification (44.01 % of the total area), distributed mostly in the north western coast and the northern part of Sinai, where the soil quality, climatic quality and vegetation quality are low, while, 9.37 % of the total area exhibit are sensitive. The areas of moderate sensitive to desertification revealed in the studied area, representing an area of 3834.577 Km<sup>2</sup> (11.04 %) of the total area. The low sensitivity areas for desertification exhibit the whole area of the Nile Delta, as they represent 27.17 % of the total area (i.e. 9434.928 Km<sup>2</sup>). The low sensitivity for desertification is due to the good vegetation cover and soil quality. It can be concluded that implementing the maps of sensitivity to desertification is rather useful in the arid and semi arid areas as they give a more likely quantitative trend for frequency of sensitive areas. The integration of different factors contributing to desertification sensitivity may lead to plan a successful combating. The usage of space data and GIS proved to be suitable tools to rely on estimation and to fulfill the needed large computational requirements. They are also useful in visualizing the sensitivity situation of different desertification parameters.

## 1. Introduction:

Desertification is defined in the first art of the convention to combat desertification as “land degradation in arid, semiarid and dry sub-humid areas resulting from climatic variations and human activities”. Its consequence includes a set of important processes, which are active in arid and semi arid environment, where water is the main limiting factor of land use performance in such an ecosystem (UNEP, 1992). Desertification sensitivity can be defined, in this context, as the response of the environment, or part of it, to a change in one or more external factors (Batterbury and Warren, 2001). Environmental systems are generally in a state of dynamic equilibrium with external driving forces. Small changes in the driving forces, such as climate or imposed land use tend to be accommodated partially by a small change in the equilibrium and partially by being absorbed or buffered by the system (Tucker et al. 1991). Desertification of an area will

proceed if certain land components are brought beyond the specific threshold, beyond which further change produces irreversible changes (Nicholson et al. 1998).

The MEDALUS method (Kosmas et al. 1999) identifies regions that are an environmentally sensitive area (ESAs). In this model, different types of ESAs to desertification can be analyzed in terms of various parameters such as landforms, soil, geology, vegetation, climate and human actions. Each of these parameters is grouped into various uniform classes and weighting factor is assigned to each class. Then four layers are evaluated soil quality, and management quality. After determined indices for each layer, the ESAs to desertification are defined by combining the four quality layer. All the data defining the four main layers are introduced in a regional geographical information system (GIS), and overlain in accordance with the developed algorithm

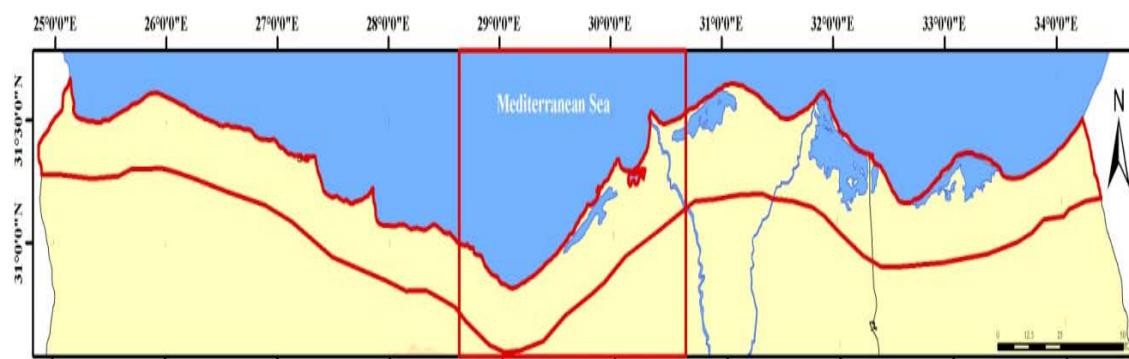

which takes the geometric mean to compile maps of ESAs to desertification.

In order to implement the UNCCD (United Nation Convention to Combat Desertification, 1996) plane, it requires reliable and up-to-date information. Not only the real-time information, but also, the analysis and technical methodologies that integrate this information to generate environmental, soil, water geo-spatial database together with environmental sensitivity maps. In this context, the Egyptian government prepared the national action plane (NAP) in 2005 in order to identify the sensitive area to desertification. It was possible to subdivide

the territory into four geographical areas on a basis of environmental farm Agro Ecological Zones characterized. Each of the Agro ecological Zones is characterized by specific environmental conditions. The Agro-ecological regions include the following;

1. North Coastal Zone
2. Nile Valley and Delta
3. The Inland Sinai and Eastern Desert
4. The Western Desert

The main aim was the assessment of most important factors affecting desertification in the study area (north coastal zone) by modifying MEDALUS system.

**Figure (1). The area of study**

## 2. Materials and methods

### 2.1. Study area

The study area represents the northern coastal zone of Egypt in a buffer zone of 20 Km from the coast line with the Mediterranean Sea. It extends from Rafah in the east on the border with Palestine to Al-Saloum in the west on the border with Libya (Figure, 1), representing an area of 32242.43 km<sup>2</sup>. The mean annual temperature of the representative metrological stations (19 stations distributed in the whole area) reaches its maximum during July and August, then decreases gradually to their minimum in December and January, enjoys a typical Mediterranean climate, being strongly influenced by the presence of the sea. The rainy season starts in October to January are the rainiest months, and the dry season extends for seven months. The study area is suffering mostly from high to moderate relative humidity. The maximum relative humidity occurs at July and August. Different investigations indicate that the wind speed, at an altitude of 10 meters, range between 3.8 to 5.2 m/sec. The prevailing wind is mostly from the north however, 25% of windy day record southerly dusty warm storms. The later harm

cultivation and causes soil water loss through its influence on increasing evapo-transpiration.

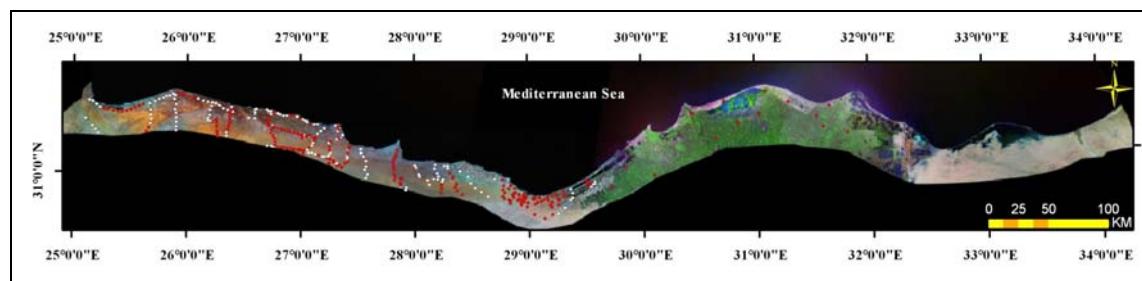

### 2.2. Methods

This study is based on multi concept data, thus the materials of different nature such as satellite data, thematic maps, ground truth geography and topographic data were used. Hybrid classification of ETM Landsat image (figure, 2) was the main mapping tools. Image analysis was made accordance with field observation. A number of 162 soil profiles representing the mapping units were studied. The soil sample was collected, analysed and classified to the level of the sub-great group according to (USDA, 2004). Arc-GIS, version 9.2 has been used as the main GIS software for producing geo-referenced maps.

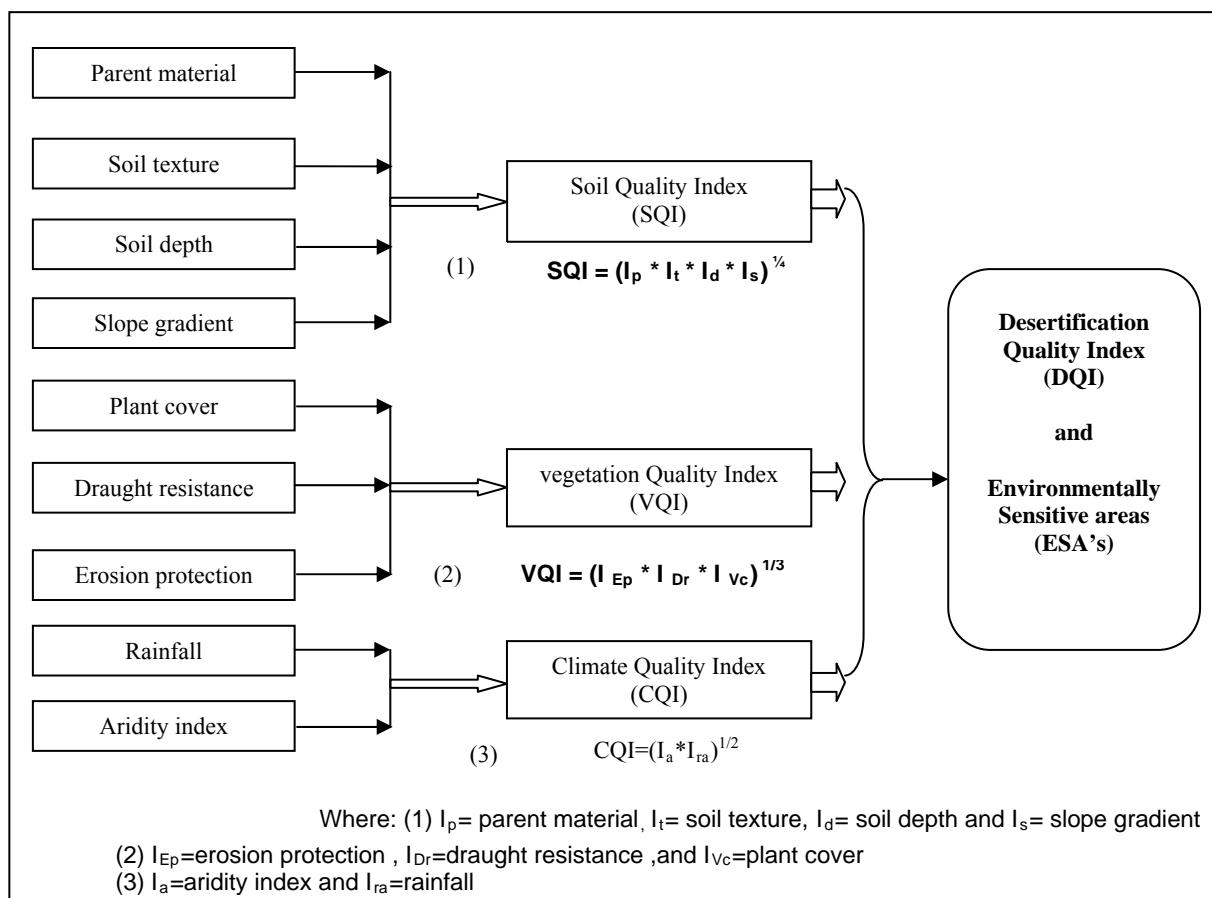

This study used spatial analyses in a Geographic Information System (GIS) to assess and map the environmental sensitivity to desertification in the north coastal zone of Egypt depending upon the soils, climate, vegetation and management quality indices. Concerning the data required for estimating the Environmental Sensitivity to desertification, the indices of soils, vegetation,

climate and management were computed. The main input data for calculating these indices include land surveying and laboratory analyses, Landsat ETM+ image (path 177 / row 39), Digital Elevation Model (DEM), climatic data and geological map of the studied areas (CONOCO, 1989). The satellite images were processed using the ERDAS

IMAGINE 8.3 system. Different enhancement and classification techniques were tried to specify the optimal ones for the study purposes. Computational and map editing functions were performed using Arc-GIS 9.2 to find out the environmental sensitivity areas (ESA's) (figure, 3).

**Figure (2) Location of the observation points plotted over Landsat satellite image**

**Figure (3) Flow chart of mapping Environmentally Sensitive Areas (ESA's)**

The hypotheses used by the MEDALUS model for the identification of sensitive areas derive from research and field experiments activities. The model applies a geometrical average of the quality indices used in order to provide sensitivity diagnosis. The model implicitly assumes that each of the indices taken individually has only a limited capacity to influence the final value of the ESAs index and that only when several parameters have a high score, an area can be assigned to a high sensitivity class (Kosmas et al. 1999). The quality indices used for assessing the desertification sensitivity were calculated and displayed as GIS ready maps from which class areas were deduced, and then the Desertification Sensitivity Index (DSI) was calculated in the polygonal attribute tables linked with the geographic coverage using the spatial analyst tool in Arc GIS 9.2 software.

#### 2.2.1. Mapping Soil Quality Index (SQI)

Soil is the dominant factor of the terrestrial ecosystems in the arid and semi arid and dry zones, particularly through its effect on biomass production (Basso et al, 1998). Four soil parameters, related to water availability and erosion resistance, were considered (I.e. parent material, soil texture, soil depth and slope gradient) following Medalu's project methodology (European Commission, 1999). Weighting factors were assigned to each category of the considered parameters, based on (Gad and Lotfy, 2007). The soil Quality Index (SQI) was computed based on the following equation:

$$SQI = (I_p * I_t * I_d * I_s)^{1/4}$$

Where  $I_p$  index of parent material,  $I_t$  indexed of soil texture,  $I_d$  index of soil depth,  $I_s$  indexed of the slope gradient). (Tables, 1 to 4) demonstrate the assigned indexes for different categories of each parameter. The soil Quality Index (SQI) was calculated based on the following equation, and classified according to categories shown in (table, 5).

**Table (1) Classes and assigned weighting index for parent material**

Class	Description	Score
Coherent: Limestone, dolomite, non-friable sandstone, hard limestone layer.	Good	1.0
Moderately coherent: Marine limestone, friable sandstone	Moderate	1.5
Soft to friable: Calcareous clay, clay, sandy formation, alluvium and colluvium	Poor	2

**Table (2) Classes and assigned weighting index for soil depth**

Class	Description	Score
Very deep	Soil thickness is more than 1 meter	1
Moderately deep	Soil thickness ranges from <1m to 0.5 m	1.33
Not deep	Soil thickness ranges from <0.5m to 0.25 m	1.66
Very thin	Soil thickness 0.15 m	2.00

**Table (3) Classes and assigned weighting index for soil texture**

Classes	Texture	Description	Score	
			Areas dominated by water erosion	Areas dominated by wind erosion
Not very light to average	Loamy sand, Sandy loam, Balanced	1		1
Fine to average	Loamy clay, Clayey sand, Sandy clay	1.33		1.66
Fine	Clayey, Clay loam	1.66		2
Coarse	Sandy to very Sandy	2		2

**Table (4) Classes and assigned weighting index for Slope gradient**

Classes	Description	Score
< 6%	Gentle	1
6 – 18 %	Not very gentle	1.33
19 – 35 %	Abrupt	1.66
> 35 %	Very abrupt	2

**Table (5) Classification of soil quality index**

Class	Description	Range
1	High quality	>1.13
2	Moderate quality	1.13 to 1.45
3	Low quality	> 1.46

### 2.2.2. Mapping Vegetation quality index (VQI)

Vegetation quality was evaluated according to (Basso et al 2000) in terms of three aspects (i.e. erosion protection to the soils, drought resistance and plant cover) (table, 6). The mosaiced landsat satellite image (Fig. 2) is the main material used to map vegetation and plant cover classes. Rating values for erosion protection, drought resistance and vegetal cover classes were adapted based on (OSS, 2004). Vegetation Quality Index was calculated according to the following equation, while VQI was classified based on the ranges indicated in the (European Commission, 1999) (table, 7).

$$VQI = (I_{Ep} * I_{Dr} * I_{Vc})^{1/3}$$

Where:  $I_{Ep}$  index of erosion protection,  $I_{Dr}$  index of drought resistance and  $I_{Vc}$  index of vegetation cover).

#### c) Mapping Climatic quality index (CQI)

Climatic quality is assessed by using parameters that influence water availability to plants such as the amount of rainfall, air temperature and aridity, as well as climate hazards, which might inhibit plant growth (Thornes, 1995). Table (8) reveals the classification categories of climatic quality index according to (OSS, 2004). The Climate quality index is evaluated through the Aridity Index (AI), using the methodology developed by FMA in accordance with the following formula. In the current study, rainfall and evapotranspiration data on a number of 19 metrological stations were used to calculate the CSI as follows;

$$CQI = P/PET$$

Where: P is average annual precipitation, and ETP is average annual Potential Evapotranspiration.

### 2.2.3 Mapping Environmentally Sensitive Areas (ESA's) to Desertification

ArcGIS9 software was used to map ESA's to Desertification (Kosmas et al, 1999) by integrating all data concerning the soil and vegetation. Different quality indices were calculated and displayed as GIS ready maps from which class areas were deduced. The Desertification Sensitivity Index (DSI) was computed in the polygonal attribute tables linked with the geographic coverage based on the following equation;

$$DSI = (SQI * VQI * CQI)^{1/3}$$

Classification of (DSI) was done according to the values of Medalus project Mediterranean desertification and land use Manual (table, 9) (European Commission, 1999).

**Table (6) Classes and assigned weighting index for different vegetation parameters**

Class	Description	$I_{Ep}$	$I_{Dr}$	$I_{Vc}$
1	Perennial cultivation	1	1	1
2	Halophytes	1.33	1	1.33
3	Temporal and orchards, mixed with crop land	1.66	1.33	1.66
4	Saharan vegetation < 40%	2	1.66	1
5	Saharan vegetation > 40%	2	1	1

**Table (7) Classification of vegetation quality index (VQI)**

Class	Description	Range
1	Good	< 1.2
2	Average	1.2 to 1.4
3	Weak	1.4 to 1.6
4	Very weak	> 1.6

**Table (8) Classification of Climatic quality index (CQI)**

Class number	Climatic zone	P/PET	CQI
1	Hyper-Arid	< 0.05	2
2	Arid	0.05 – 2.0	1.75
3	Semi-Arid	0.20 – 0.50	1.50
4	Dry Sub-Humid	0.50 – 0.65	1.25
5	Humid	> 0.65	1

**Table (9) Ranges and classes of desertification sensitivity index (DSI)**

Classes	DSI	Description
1	> 1.2	Non affected areas or very low sensitive areas to desertification
2	1.2 < DSI < 1.3	Low sensitive areas to desertification
3	1.3 < DSI < 1.4	Medium sensitive areas to desertification
4	1.3 > DSI < 1.6	Sensitive areas to desertification
5	DSI > 1.6	Very sensitive areas to desertification

### 3. Results and Discussion:

The environmental sensitivity area to desertification is a complex concept to rationalize since, depending on the context. It can be caused by many different factors operating in isolation or in association (Rubio, 1995, Thernes, 1995, UNEP, 1992 and Basso et. al., 2000). ESAs can be considered, in general, as a specific and delimited entity in which environmental and socio-economical factors are not balanced or are not sustainable for that particular environment. The various types of ESA's to desertification can be distinguished and mapped by using certain key indicators for assessing the land capability to withstand further degradation, or the land suitability for supporting specific types of land use. The key indicators for defining ESA's to desertification, which can be used at a regional or national level, can be divided into four broad categories defining the qualities of soil, climate, vegetation, and land management (Kosmas et. al. 1999). The Environmental Sensitivity Index (ESI) to desertification of an area can also be seen as the result of the interactions among elementary factors (information layers) that are differently linked to direct and indirect degradation or desertification phenomena (Basso et. al. 1998). Severe, irreversible environmental degradation phenomena could be resulted from a combination of poor management quality together with various combinations of critical environmental factors (soil, climate, and vegetation).

#### 3.1 Soil Quality Index (SQI)

Soil is an essential factor in evaluating the environmental sensitivity of an ecosystem, especially in the arid and semi-arid zones. Soil properties related to desertification phenomena affect the water storage and retention capacity and erosion resistance.

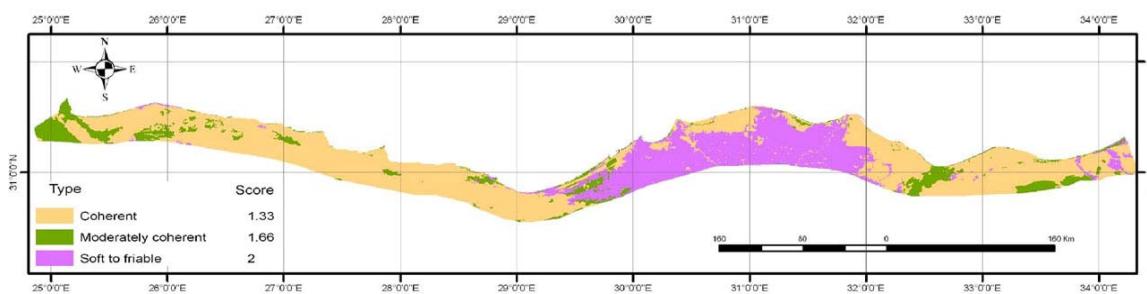

##### 3.1.1. Parent material

Parent material is considered a very important factor for determining the susceptibility to desertification. (Table, 10 and Figure, 4) represent the types, scores and areas of the parent materials of the northern coast of Egypt.

The results show that 61.79 % of the study area ( $21454.32 \text{ Km}^2$ ) originated from coherent parent material. It dominates the eastern and western part of the study area. This type of parent material is the least susceptible to desertification and takes a score of 1.00 on the desertification sensitivity index. The moderately coherent parent material such as marine limestone and friable sandstone covers  $3852.66 \text{ Km}^2$  representing 11.1 % of the study area. This type of parent material is moderately susceptible to desertification, and it takes a score of 1.5 on the desertification sensitivity index. The soils originated from soft to friable covers 27.12% ( $9415.03 \text{ Km}^2$ ). It dominates the northern part of Nile delta of the study area. This type of parent material is the most susceptible to desertification and takes a score of 2.00 on the desertification sensitivity index.

**Table (10) Types and scores of the parent materials in the studied area**

Type	score	Area Km <sup>2</sup>	Area %
Coherent: Limestone, dolomite, non-friable sandstone, hard limestone layer	1.00	21454.32	61.79
Moderately coherent: Marine limestone, friable sandstone	1.50	3852.66	11.10
Soft to friable: Calcareous clay, clay, sandy formation, alluvium and colluvium	2.00	9415.03	27.12
<b>Total</b>		<b>34722.01</b>	<b>100.00</b>

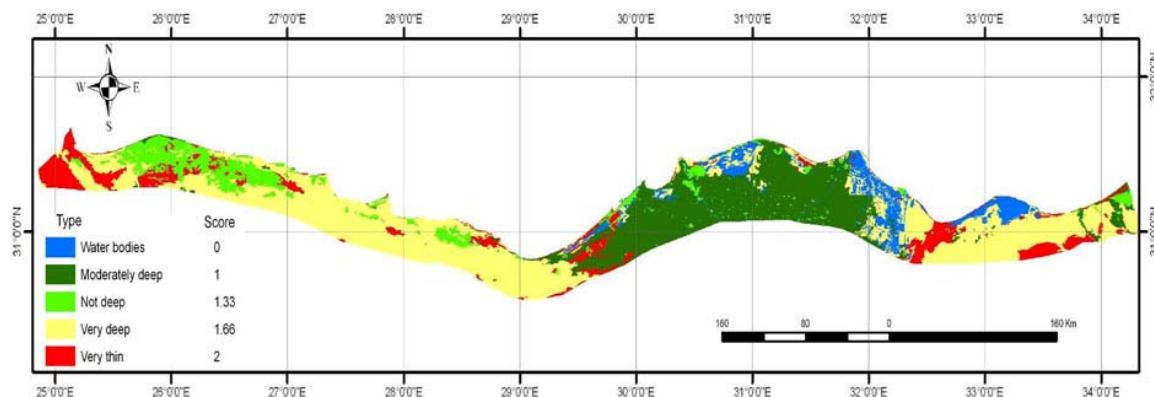

**Figure (4) soil parent types and scores of the north coast of Egypt**

### 3.1.2. Soil depth

Soil depth is a very important factor for determining the susceptibility to desertification, the deeper the soil the lesser sensitive to desertification and vice versa. As illustrated in (table, 11 and figure, 5) the very deep soil covers an area of  $15295.11 \text{ Km}^2$  representing 44.05 % of the total area. It dominates in the eastern and western part of the study area and represented by a score of 1.00 on the desertification sensitivity index. The moderately deep soil covers 27.12 % ( $9415.03 \text{ Km}^2$ ) of the study area. This class dominates in the northern Nile delta part of the study area. The moderately deep soil takes a score of 1.33 on the desertification sensitivity index. Not deep soil is more susceptible to desertification than very deep and moderately deep soils. It covers an area of  $3679.62 \text{ Km}^2$ , representing 10.60 % of the study area. It is located in eastern Sinai and the most western part of the study area. The not deep soil takes a score of 1.66 on the desertification sensitivity index. The very thin soil is the most susceptible to desertification. It covers 11.10 % ( $3852.66 \text{ Km}^2$ ) of the study area. It is located in western Sinai, western Nile delta and western most part of the study area. The very thin soil takes a score of 2.00 on the desertification sensitivity index.

**Table (11) distribution of soil depth classes and assigned scores in the studied area**

Type	score	Area Km <sup>2</sup>	Area %
Water bodies and urban	0.00	2479.58	7.14
Very deep	1.00	15295.11	44.05
Moderately deep	1.33	9415.03	27.12
Not deep	1.66	3679.62	10.60
Very thin	2.00	3852.66	11.10
<b>Total</b>		<b>34722.01</b>	<b>100.00</b>

**Figure (5) soil depth classes and scores of the northwestern coast of Egypt**

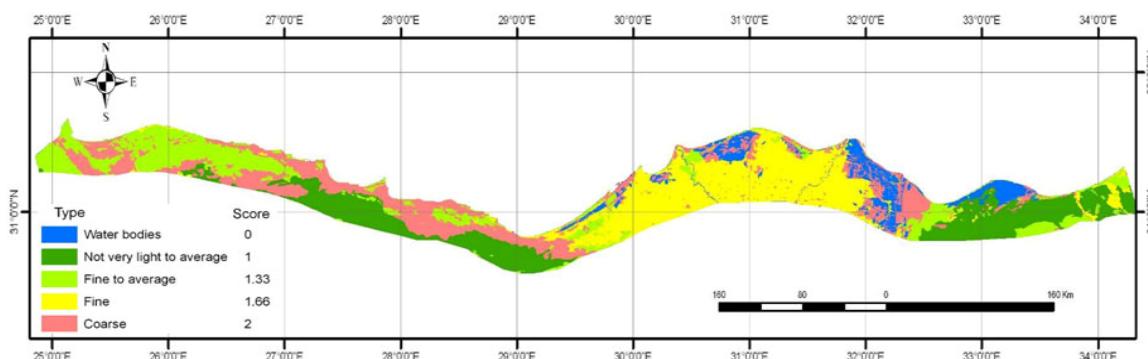

### 3.1.3. Soil texture

Soil texture is a very important factor for determining the susceptibility to desertification, (table, 12 and figure, 6) represents the types, scores and areas of the soil texture the north coast of Egypt.

The soil is divided into four classes according to its texture not very light to average is least susceptible to desertification. It represents 21.29 % of the north coast of Egypt, and it covers an area of 7393.43Km<sup>2</sup>. It dominates Nile delta part of the study area. It takes a score of 1.00 on the desertification sensitivity index. While, 20.48% (7111.32 Km<sup>2</sup>) of the studied area is moderately susceptible to desertification, which classified as Fine to average soil texture. It dominates the northern Nile delta part of the study area and takes a score of 1.33 on the desertification sensitivity index. Nevertheless, the fine soil texture covers 27.12 % (9415.03Km<sup>2</sup>) of the studied area. It is located in the north western part of Sinai and takes a score of 1.66 on the desertification sensitivity index. The rest of the studied area is classified as coarse soil texture, which is the most susceptible to desertification. It covers 23.97 % of the study area (8322.65 Km<sup>2</sup>). It is located in the eastern Sinai and western coast of the study area and takes a score of 2.00 on the desertification sensitivity index.

**Table (12) Distribution of soil texture classes and assigned scores in the studied area**

Type	score	Area Km <sup>2</sup>	Area %
Water bodies and urban	0.00	2479.58	7.14
Not very light to average	1.00	7393.43	21.29
Fine to average	1.33	7111.32	20.48
Fine	1.66	9415.03	27.12
Coarse	2.00	8322.65	23.97
<b>Total</b>		<b>34722.01</b>	<b>100.00</b>

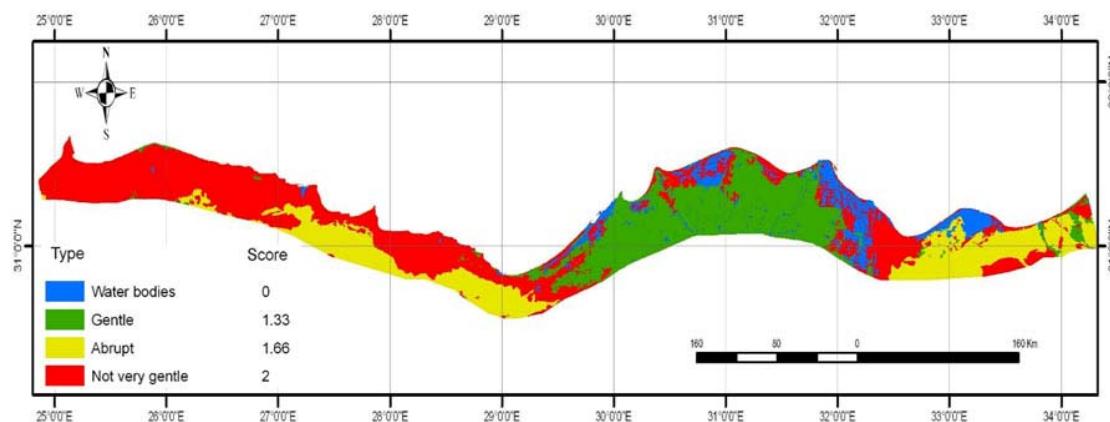

**Figure (6) soil texture classes and scores of the northwestern coast of Egypt**

### 3.1.4. Surface slope

Soil surface slope is very important factor for determining the susceptibility to desertification, (table 13 and figure, 7). The soil surface slope is divided into three classes. The Gently slope soil with surface slope of less than 6 % which is the least susceptible to desertification. It represents 27.12 % (9415.03.11Km<sup>2</sup>) of the studied area. It dominates in the Nile delta part of the studied area and takes a score of 1.00 on the desertification sensitivity index. While, the majority 43.24 % of the studied area slope is located in the Gently undulating class where surface slope between 6 and 18 % which is moderately susceptible to desertification. It dominates the northern western coastal part and takes a score of 1.33 on the desertification sensitivity index. The rest of the studied area is classified as undulating soil with surface slope between 19 and 35 % which is the most susceptible to desertification. It covers 21.29 % of the study area covers 7393.43 Km<sup>2</sup>. It is located in the western part of Sinai and eastern part of the northwestern coastal part and takes a score of 1.66 on the desertification sensitivity index.

**Table (13) Distribution of slope classes and assigned scores in the studied area**

Type	score	Area Km <sup>2</sup>	Area %
Water bodies and urban	0.00	2900.54	8.35
< 6%	1.00	9415.03	27.12
6 – 18 %	1.33	15013.00	43.24
19 – 35 %	1.66	7393.43	21.29
<b>Total</b>		<b>34722.01</b>	<b>100.00</b>

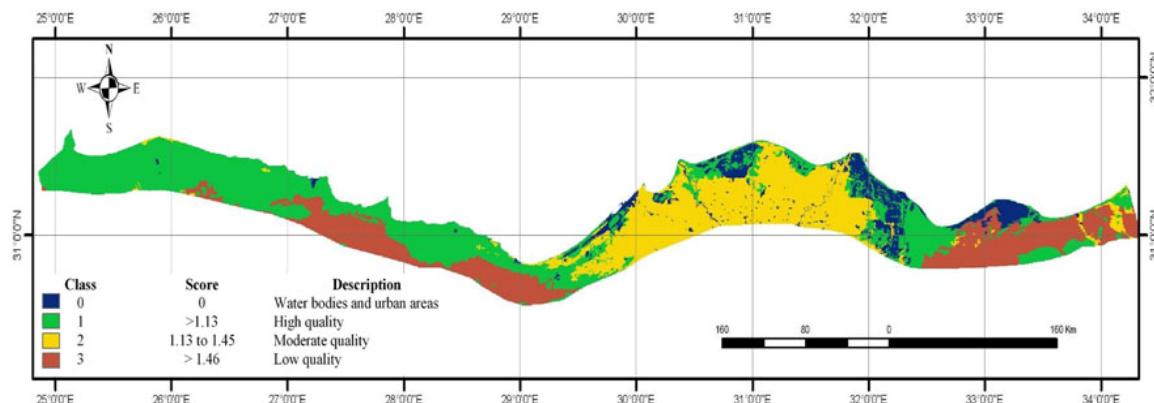

**Figure (7) Surface slope classes and scores of the northwestern coast of Egypt**

### 3.1.5. Soil Quality index

The soil quality index (SQI) was evaluated depend upon the drainage condition, rock fragments (%) slope gradient (%), soil texture class, soil depth (cm) and the parent material (Figure, 8 and table, 14). The layer of soil quality index of the studied area, indicate that the areas of high soil quality index (value <1.13) is found in large areas especially in the north western coast as it dominates an area of 14982.47 km<sup>2</sup> i.e. 43.15 % of the total area. The areas of moderate quality index (value = 1.13 – 1.45) represents 27.17% of the total area i.e. 9434.93Km<sup>2</sup> as it found mainly in the north coast of the Nile Delta. The areas of low soil quality index (value >1.45) represents 21.27 % of the total area i.e. 7386.66Km<sup>2</sup>, it found mainly in the north coast of Sinai. The low soil quality dominates the areas which characterized by sandy texture, shallow depth and poor drainage soils.

**Table (14) Soil Quality Index of the northwestern coast of Egypt**

Class	Score	Description	Area%	Area Km <sup>2</sup>
0	0	Water bodies and urban areas	8.40	2917.95
1	>1.13	High quality	43.15	14982.47
2	1.13 to 1.45	Moderate quality	27.17	9434.93
3	> 1.46	Low quality	21.27	7386.66
<b>Total</b>			<b>100</b>	<b>34722.01</b>

**Figure (8) Soil Quality Index of the northwestern coast of Egypt**

### 3.2. Vegetation Quality layers

The ETM satellite images were classified, and field validation was performed to convert the unsupervised classes to vegetation type. Different vegetation types were given score values evaluating vegetation cover type, erosion protection and drought resistance, and hence calculating the vegetation quality index (VQI).

#### 3.2.1. Plant cover

Vegetation cover plays an important role in mitigating the effects of desertification and land degradation phenomena. The percentage of vegetation is a function of both man-made agriculture and natural vegetation coverage. The percentage of vegetation cover is a necessary input in a multi-criteria model to assess the vegetation quality index.

Hyperid classification of ETM images resulted in identifying a number of four vegetation classes. Each of these classes was given a score evaluating vegetation cover, erosion protection and drought resistance (Figure, 9 and table, 15).

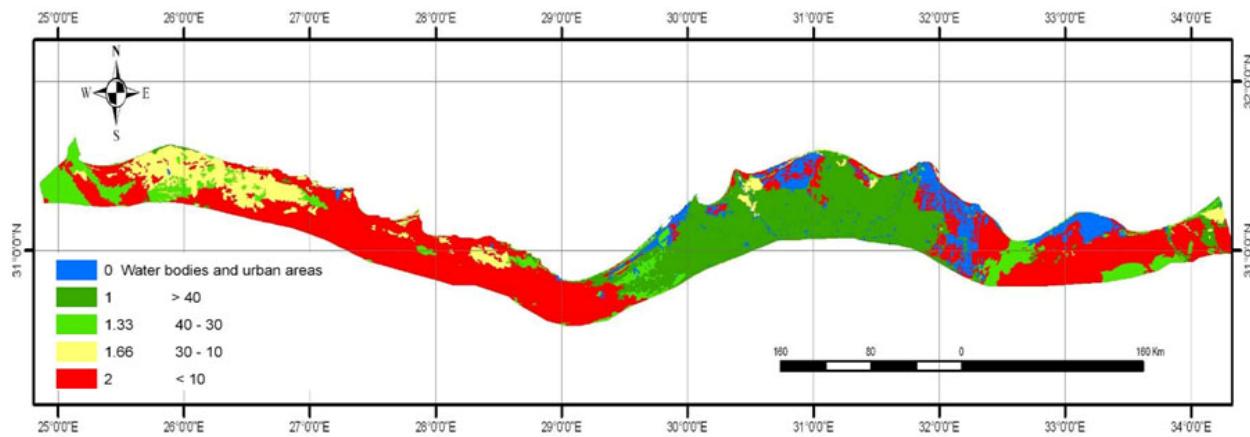

**Table (15) List of the vegetation covers categories and their area percentage**

Vegetation cover %	Value	Area Km <sup>2</sup>	Area %
Water bodies and urban areas	0.00	2900.54	8.35
Vegetation cover > 40%	1.00	9415.03	27.12
Vegetation cover (40 – 30 %)	1.33	3852.66	11.10
Vegetation cover (30 – 10%)	1.66	3258.66	9.39
Vegetation cover <10%	2.00	15295.11	44.05
<b>Total</b>		<b>34722.00</b>	<b>100.00</b>

As illustrated in (table, 15) 44.05% of the vegetation cover is very weak and sensitive to desertification. This category is distributed along the whole study area with higher concentration in the western section (northwestern part). Whilst, distributed as a few scattered areas in the middle section (northern Nile delta region) particularly in the sand dune areas and sabkhas. Nevertheless, the dense vegetation cover > 40% is representing a small area of 9415.03 km<sup>2</sup> (8.35%). This category occupies most of the middle section (northern part of the Nile Delta region) while it represents a minor area in the western section (northern western desert) and occupies a very minor area in the eastern section (northern Sinai). The rest of the study area has vegetation cover between 40 and 10%, distributed in the whole study area.

**Table (16) Vegetation resistance to drought**

Type	Value	Area km <sup>2</sup>	Area %	Drought Resistance
Water bodies and urban areas	0.00	2900.54	8.35	
Evergreen trees; Bedrocks; Bare soils	1.00	13267.69	38.21	Very high
Orchards; Deciduous trees	1.33	3258.66	9.39	High
Shrubs	1.66	7901.68	22.76	Moderate
Annual crops; Very low vegetated	2.00	7393.43	21.29	Low
<b>Total</b>		<b>34722.01</b>	<b>100.00</b>	

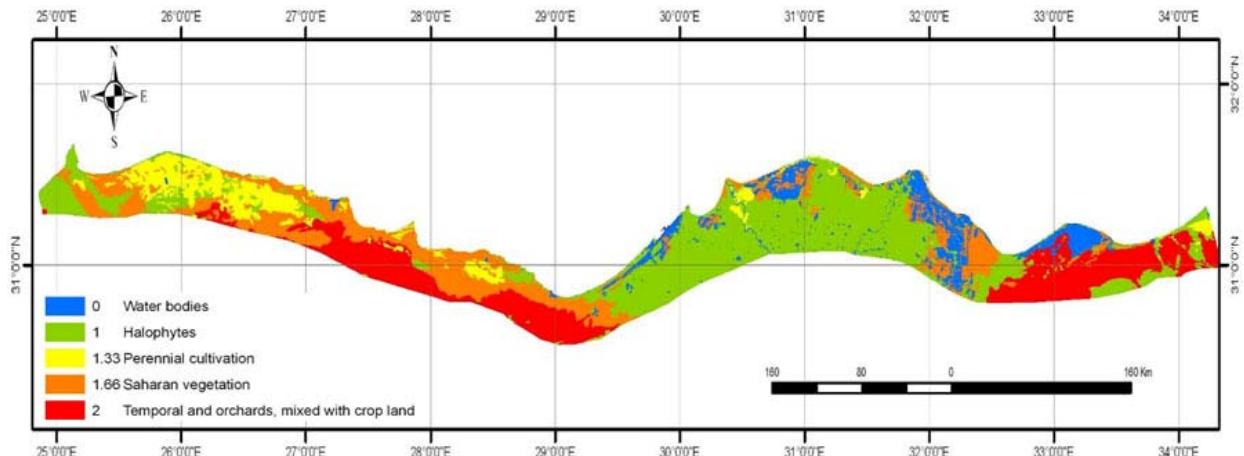

**Figure (9) vegetation cover percentage of the northwestern coast of Egypt**

### 3.2.2. Vegetation drought resistance

According to the universal standard classification for the susceptibility of vegetated land to drought and therefore its resistance, the study area in reflection to vegetation cover classified into five categories of drought resistance (Figure,10 and Table, 16).

Evergreen trees, bedrocks and bare soils; this category represents a significant area of about 38% of the study area. This category shows very high vegetation drought resistance with value of 1.0. It occupies most of the middle section (northern part of the Nile Delta region) and some areas in the western section (northern western coast). There are some scattered areas in the eastern section (northern Sinai) particularly the area of El-Tina plain and Wadi Al-Arish. Orchards and deciduous trees; this category occupies just 9% of the study area which is distributed in all the study area. This category shows high drought resistance with value of 1.33. The majority of this category is located in the western section (northern western desert) and few areas in the middle section around Lake El-Borouls and few areas near Rafah on the eastern border with Palestine. Shrubs; this category represents about 23% of the study area with moderate drought resistance of value of 1.66. The majority of this category occupies the western section (northern western desert). There are some areas of this category in the middle section around the coastal lagoons of Lake Manzala and lake Borouls. However, in the eastern section (northern Sinai) El-Tina plain and east of Suez Canal shows this moderate of drought resistance category. Annual crops and very low vegetated land; this category is the lowest category of drought resistance and it occupies 21% of the study area. This category is distributed in both the eastern and western sections (i.e. northern Sinai and north western desert). The terrain and geomorphological landforms in these two sections are the key constrains of this category to be low drought resistance.

**Figure (10) vegetation resistant to drought in the north coast of Egypt**

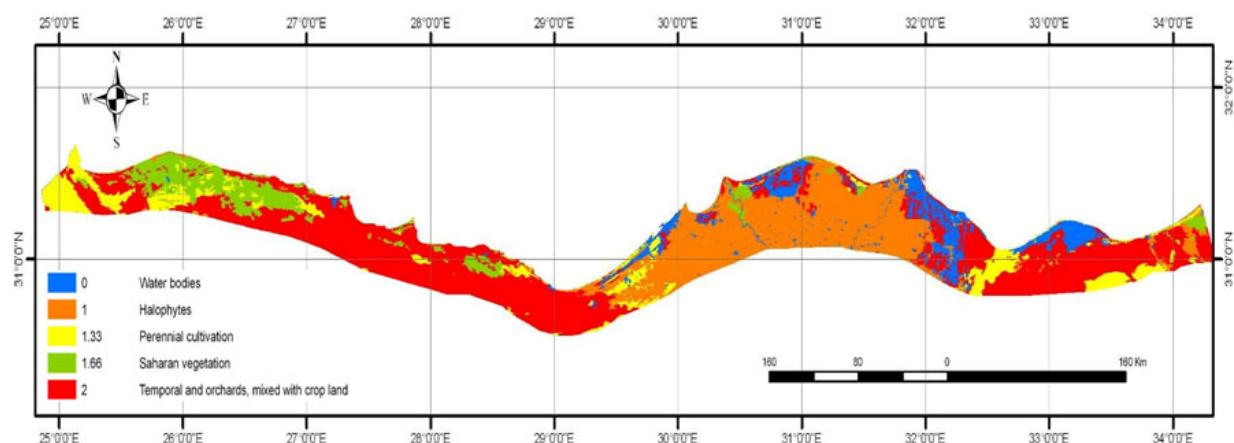

### 3.2.3. Vegetation erosion protection

Vegetation erosion resistance shows how much land, and its vegetation cover is resistant to erosion. The study area in reflection to the vegetation cover shows five categories of erosion resistance (Figure, 11 and Table 17).

Evergreen trees and bedrocks; this category represents a significant area of about 27% of the study area. This category shows very high vegetation erosion resistance with value of 1.0. It occupies most of the middle section (northern part of the Nile Delta region) and some areas in the western section (northern western desert) particularly the area close to the border. There are some scattered areas in the eastern section (northern Sinai) particularly the area of El-Tina plain and Wadi Al-Arish. Shrubs; this category occupies just 11% of the study area which is distributed in all the study area. This category shows high erosion resistance with value of 1.33 which located in the eastern section (northern Sinai) and western section (northern western desert). There are minor areas in the middle section around Lake El-Borouls and in the area west Gamasa. Annual crops; this category represents about 9% of the study area with moderate drought resistance of value of 1.66. The majority of this category occupies the western section (northern western desert) and as some patches in the eastern section (northern Sinai) close to Rafah. Bare soils; this category is the lowest category of erosion resistance, and it occupies 44% of the study area. This category occupies most of the eastern and western sections (i.e. northern Sinai and north western desert). The terrain and geomorphological landforms in these two sections are the key constraints of this category to be low erosion resistance. There are a few scattered areas in the middle section (northern Nile Delta region) particularly, in the sand sheets and sand dune areas.

**Table (17) erosion resistance of each vegetation category**

Type	Value	Area km <sup>2</sup>	Area %	Erosion resistance
Water bodies and urban areas	0.00	2900.54	8.35	
Evergreen trees; Bedrocks	1.00	9415.03	27.12	Very high
Shrubs	1.33	3852.66	11.10	High
Annual crops	1.66	3258.66	9.39	Moderate
Bare soils	2.00	15295.11	44.05	Low
<b>Total</b>		<b>34722.01</b>	<b>100.00</b>	

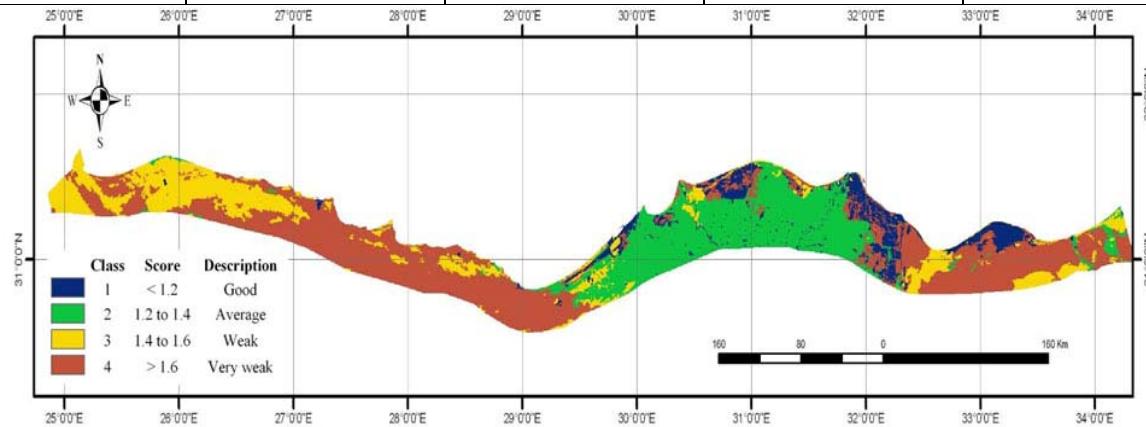

**Figure (11) vegetation erosion protection in the north coast of Egypt**

### 3.2.4. Vegetation Quality index

The plant cover (%), erosion protection, and drought resistance parameters were used for assessing the vegetation quality index (VQI). As illustrated in (figure, 12 and table, 18) the areas of low vegetation quality (Value <1.20) dominate coastal parts near the northern lakes, it represents 8.40 % of the total area (i.e. 2917.95 Km<sup>2</sup>), the moderate vegetation quality index (Value 1.2 – 1.4) dominates the north parts of the Nile Delta, it represents 27.17 % of the total area (i.e. 9434.93 Km<sup>2</sup>). The weak (Value 1.4 – 1.6) and very weak sensitive vegetation index (Value >1.60) dominates the rest of the coast representing 11.04 and 52.38 % of the total area (i.e. 3834.58 and 18534.56 Km<sup>2</sup> respectively). The low vegetation index is due to the low density of plant cover.

**Table (18) Vegetation Quality Index of the studied area**

Class	Score	Description	Area %	Area Km <sup>2</sup>
1	< 1.2	Good	8.40	2917.95
2	1.2 to 1.4	Average	27.17	9434.93
3	1.4 to 1.6	Weak	11.04	3834.58
4	> 1.6	Very weak	53.38	18534.56
<b>Total</b>			<b>100</b>	<b>34722.01</b>

**Figure (12) Vegetation Quality Index of the north coast of Egypt**

### 3.2.5. Climatic Quality Index

Climate quality index (CQI) is assessed depend upon the amount of rainfall, aridity and slope aspect parameters. The amount of rainfall and aridity are the same in the studied area, but the microclimate is differ from place to another depend on the surface slope and slope aspect. The digital elevation model (DEM) of the depression was established and used for extracting the slope and aspect. The climatic quality index layer of the area refer that the northwestern coast of Egypt is characterized by a low (>1.80) climatic quality index.

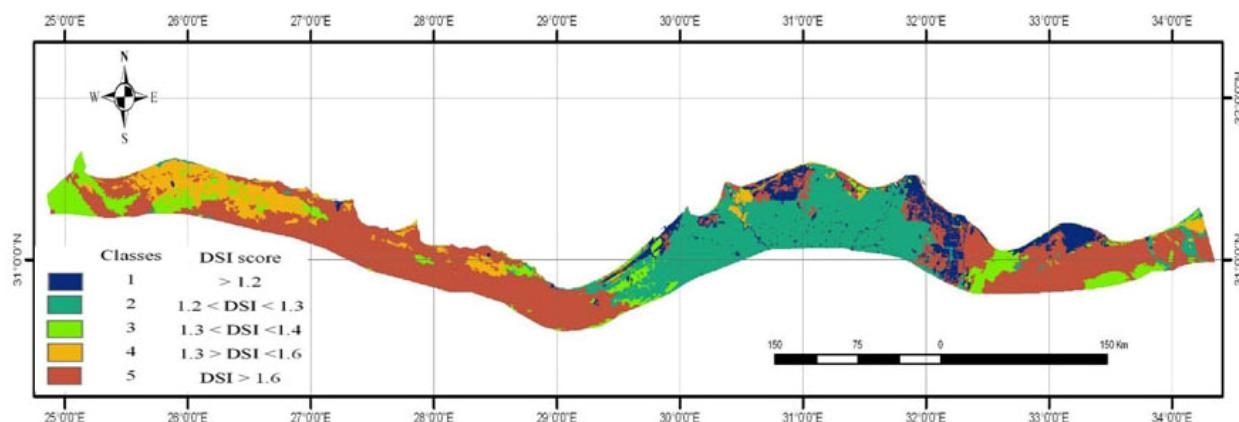

### 3.3. Desertification sensitivity index of the north coast of Egypt

The abovementioned layers (soil, vegetation and climate indices) were driven together to assess the environmentally sensitive areas (ESA's) to desertification, on basis of the calculated desertification sensitivity index (DSI). As revealed from (figure, 13 and table 19) the high sensitive areas for desertification in the area (44.01 % of the total area) are found in north western coast and the northern part of Sinai, where the soil quality, climatic quality and vegetation quality are low.

The sensitive areas are found where the vegetation cover is low, it found in Sidi Barrani and El Salum areas where, the sensitive areas represent 9.37 % of the total studied. The areas of moderate sensitive to desertification, revealed in the studied area, representing an area of 3834.577 Km<sup>2</sup> (11.04 %) of the total area. The low sensitivity areas for desertification exhibit the whole area of the Nile Delta, as they represent 27.17 % of the total area (i.e. 9434.928 Km<sup>2</sup>). The low sensitivity for desertification is due to the good vegetation cover and soil quality.

**Table (19) Environmentally Sensitive Areas to desertification in the north coast of Egypt**

Classes	DSI score	Description	area %	area Km <sup>2</sup>
1	> 1.2	Non affected areas or very low sensitive areas to desertification	8.403747	2917.95
2	1.2 < DSI < 1.3	Low sensitive areas to desertification	27.17276	9434.928
3	1.3 < DSI < 1.4	Medium sensitive areas to desertification	11.04365	3834.577
4	1.3 > DSI < 1.6	Sensitive areas to desertification	9.371228	3253.879
5	DSI > 1.6	Very sensitive areas to desertification	44.00862	15280.68
Total			100	34722.01

**Figure (13) Environmentally Sensitive Areas to desertification in the north coast**

#### 4. Conclusions and Recommendations

It can be concluded that the assessment of desertification sensitivity is rather important to plan combating actions and to improve the employment of natural resources. Remote sensing, in addition to thematic maps, may supply valuable information concerning the soil and vegetation quality at the general scale. However, for more detailed scales, conventional field observation would be essential.

Remote sensing, in addition to thematic maps, may supply valuable information concerning the soil and vegetation quality. However, field validation is rather important for reliable information. The Geographic Information System (GIS) is a valuable tool to store, retrieve and manipulate the huge amount of data needed to compute and map different quality indices to desertification.

It can be recommended that mathematical modeling should be developed for the operational monitoring of different elements contributing in desertification sensitivity.

Multi scale mapping of ESA's are needed to point out the risk magnitude and causes of degradation in problematic areas.

The Egyptian north coast is susceptible to very high-to-high desertification sensitivity, however the Nile Valley is moderately sensitive because of its vegetation cover.

# Efficiency of Natural Minerals in Presence of Different Nitrogen Forms and Potassium Dissolving Bacteria on Peanut and Sesame Yields

Gehan H. Youssef, Wafaa M. A. Seddik and Mona A. Osman

Soil, Water and Environ. Research Institute, agricultural Research Center (ARC), Giza, Egypt

**Abstract:** A field experiment was carried out for two summer seasons at Ismailia Agric. Res. Station to study the effect of some natural minerals combined with potassium dissolving bacteria inoculation in the presence of different nitrogen forms on chemical properties of soil, nutritional status and yield of peanut-sesame. Each experiment was designed in a split-split design with three replications. Three forms of nitrogen fertilizer were included along with two natural minerals, in a presence of potassium dissolving bacteria inoculation, as well as one mineral fertilizer as source potassium fertilizer. Furthermore, data show high significant increases in available N due to the application of ammonium nitrate in combination with feldspar, and calcium nitrate in combination with potassium sulfate in a presence of inoculation for peanut and sesame, respectively. However, application of calcium nitrate combined with potassium sulfate, and ammonium nitrate in combination with feldspar, in a presence of inoculation, led to significant increases in K available in soil for peanut and sesame, respectively. Oppositely, the pH values, different to those of EC, decreased either for inoculation or non-inoculation as compared to control. In spite of that, the values of EC and pH of soil were higher with application of either bentonite or bentonite + feldspar in a presence of all nitrogen fertilizer forms. Generally, the highest EC values in soil, after the two studied seasons were encountered with calcium nitrate fertilizer as well as bentonite mineral. Moreover, applying feldspar mineral and ammonium nitrate treatments had recorded the highest values of yield components as well as nutrient (N and K) uptake by either peanut or sesame crops, particularly in the presence of inoculation as compared to those given by other treatments. [Gehan H. Youssef, Wafaa M. A. Seddik and Mona A. Osman. Efficiency of Natural Minerals in Presence of Different Nitrogen Forms and Potassium Dissolving Bacteria on Peanut and Sesame Yields. Journal of American Science 2010;6(11):647-660]. (ISSN: 1545-1003).

**Keywords:** Efficiency; Natural Mineral; Nitrogen; Potassium; Bacteria

## 1. Introduction:

Sandy soils represent the most desert area in Egypt, and they are usually deficient in organic matter and plant nutrients (Abdel Wahab et al, 2003). Potassium is one of the three essential element viz., NPK, for the growth and reproduction of plants; it plays vital roles in its nutrition. The crop production in Egypt relies completely on imports to meet its annual requirement of potash fertilizers; besides the high cost of conventional, water-soluble K fertilizers constrains their use by most of the farmers in the country. In order to reduce the dependence on imported potash, feldspar potash mineral contains 11.25 % K<sub>2</sub>O and therefore, it could be a potential K-source for crop production. New approaches are needed to unlock K from the silicate structure of this mineral in order to render K more available for plant nutrition (Badr, 2006). Many researchers showed that microbes can accelerate weathering of minerals and rocks by producing organic acids, phenolic compounds, siderophores and possibly other metabolites, which influence pH and redox conditions. In addition, direct contact between bacteria and minerals may be important in mineral

alteration reaction, as microbial surfaces can be complex with metal ions. Some recent reports showed that silicate dissolving bacteria played a promotion role in the release of Si, Fe and K from feldspar (Badr, 2006).

According to Abdel Wahab et al., (2003), the highest values of growth and green yield of pea were obtained in case of organic compost application in combination with chemical or natural sources of P and K. Also, the applied natural sources of P and K gave an almost similar trend to that obtained with the chemical ones combined with the organic compost. The concentrations of phosphorus and potassium in plant tissues increased with increasing compost levels irrespective of their sources. In addition, the combined treatment of organic compost with both sources of P-K achieved the highest values of P and K concentrations in plant tissues.

Significant increases were obtained in height of main stem, branch stem length, number of branches, main stem diameter and leaf area of olive seedlings treated with compost fortified with plant guard and feldspar compared with the control treatment. The same trend was also observed

concerning the application of compost and feldspar on micro and macronutrient contents in leaves of the mentioned olive seedlings (Abd El-Motty et al., 2009).

Biofertilizers have been used as sources to improve the status of plant nutrients in sustainable agriculture. Inoculation with bacterial strain *Bacillus edaphicus NBT* was found to increase root and shoot growth of cotton and rape. Strain NBT could mobilize potassium efficiently in both plants when illite was added to the soil. In cotton and rape growing on soils treated with insoluble potassium and inoculated with strain NBT, the potassium content was increased by 30 and 26 %, respectively. Bacterial inoculation also resulted in higher N and P contents of above ground plant components (Sheng, 2005).

Rock P and K applied either singly or in combination did not significantly enhance soil availability of P and K, indicating their unsuitability for direct application. PSB (phosphate solubilizing bacteria) was a more potent P-solubilizer than KSB (potassium solubilizing bacteria), and co-inoculation of PSB and KSB resulted in consistently higher P and K availability than in the control without bacterial inoculum and without rock material fertilizer. Combined together, rock material and both bacterial strains consistently increased further mineral availability, uptake and plant growth of pepper and cucumber plants, suggesting their potential use as fertilizer (Han et al., 2006).

Phosphorus and potassium nutritional status in the soil were markedly improved through inoculation with solubilizing bacteria (*Bacillus mucilaginosus*); groundnut plant dry matter increased by 125 % and the oil content 35.41 % were increased through bacterium inoculation (Sugumaran and Janarthanam, 2007).

Recently, the treatment of *Bacillus circulans* + rock phosphate + feldspar was superior in plant height, number of branches, number of nodules per plant and fresh yield (ton/fed.) of snap bean plants when compared with control and the un-inoculated plants. The NPK analysis of shoot dry matter of snap plants showed that as a result of addition of alternatives and the viability of *B. circulans*, there was marked increases in phosphorus and potassium solubilization (Massoud et al., 2009).

The objective of this study was to determine the efficiency of using different natural mineral as alternative potassium fertilizer in the presence of nitrogen forms and potassium dissolving bacteria inoculation adopted for peanut and sesame plants grown on sandy soil.

## 2. Materials and methods

Two summer successive field experiments were carried out on peanut (*Arachis hypogaea*) – sesame (*Sesamum indicum*) cropping sequence in a sandy soil under drip irrigation system at Ismailia Agric. Res. Station (A.R.C).

Some physical and chemical characteristics of the studied soil before cultivation are shown in Table (1).

**Table (1): Some physical and chemical properties of soil samples representing the studied location.**

Soil characteristics	Values
<b>Particle size distribution %</b>

Peanut and sesame were cultivated in a randomized split-split plot design, each treatment being replicated three times. The main plots were

either inoculated or un-inoculated with potassium dissolving bacteria (*Bacillus pasteurii*) as (Biopotash). The sub main plots were three nitrogen sources, including ammonium sulfate, calcium nitrate and ammonium nitrate, added at the rate of 30 kg N/fed. The sources of nitrogen were added in four equal split doses after sowing. The sub- sub plots represented the natural minerals (feldspar and bentonite), which were added individually or in combination (50% bentonite and 50% feldspar, as compared to mineral fertilizer (potassium sulfate)) at the rate of 50 kg K<sub>2</sub>O/ fed. Phosphorus fertilizer was added at the recommended dose (200 kg/fed.) for both peanut and sesame in the form of superphosphate 15.5 % P<sub>2</sub>O<sub>5</sub>. Both potassium and phosphorus fertilizers were completely added to soil before cultivation.

Plant and soil were sampled at 150 days and 120 days after sowing for peanut and sesame respectively, which represent the harvesting stage.

Surface soil samples (0-15 cm depth) were taken after harvesting stage to evaluate soil pH, EC and available nutrients (N and K) were determined according to Page et al. (1982).

Peanut and sesame plant samples were taken at harvesting stage to determine the nutrients status and yield components (straw and grain yield). Plant samples were oven dried at 70 °C for 48 hrs up to constant dry weight, then ground and wet digested using H<sub>2</sub>SO<sub>4</sub>:H<sub>2</sub>O<sub>2</sub> method described by Page et al. (1982). The digests were then subjected to the measurement of nutrients (N and K) according to procedures described by cottenie et al. (1982).

Obtained results were subjected to statistical analysis using STATISTICA 6.0 (statSoft, Inc, Tusla, USA) according to Hill and Lewicki (2007). Analysis of variance (ANOVA) was employed to examine the independent and interacted effects of inoculation with potassium dissolving bacteria, nitrogen and potassium sources. Also, treatments were compared by using L.S.D. at 0.05 level of probability according to Snedecor and Cochran (1980).

### **3. Results and Discussion:**

1- Influence of nitrogen fertilizer, natural mineral and inoculation with bacteria on some soil chemical characteristics.

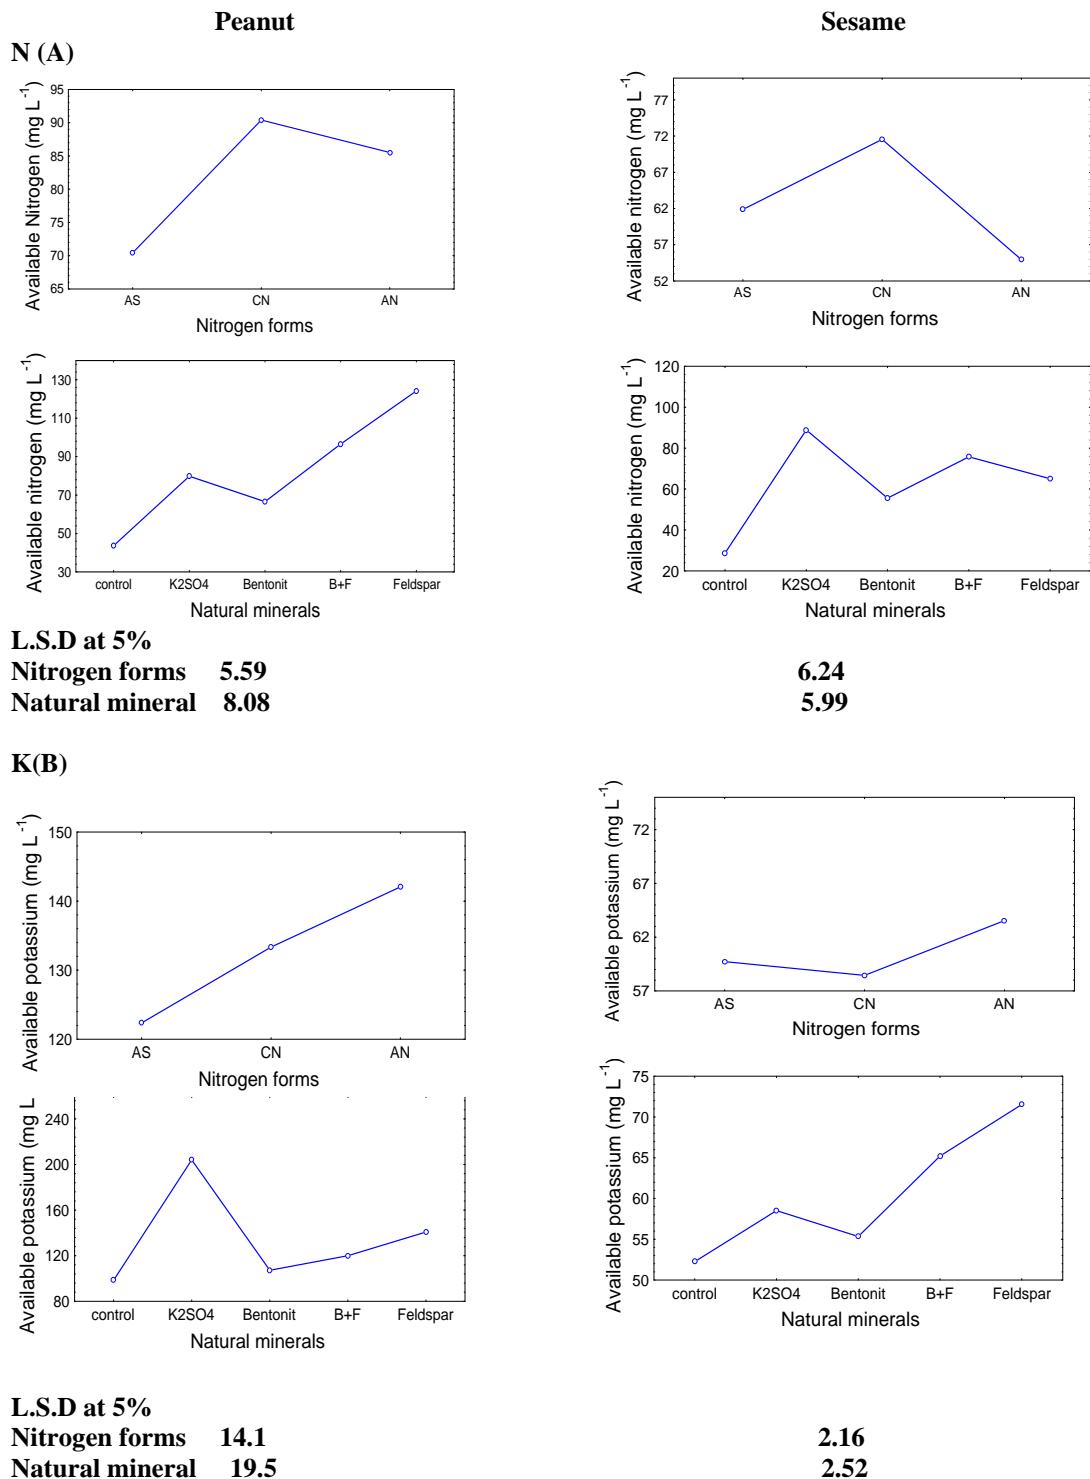

As for the effect of nitrogen forms and natural mineral on nitrogen and potassium availability, at the two studied seasons, results in Fig (1 A, B) reveal that calcium nitrate treatment was

superior at available N while ammonium nitrate being superior at available K.

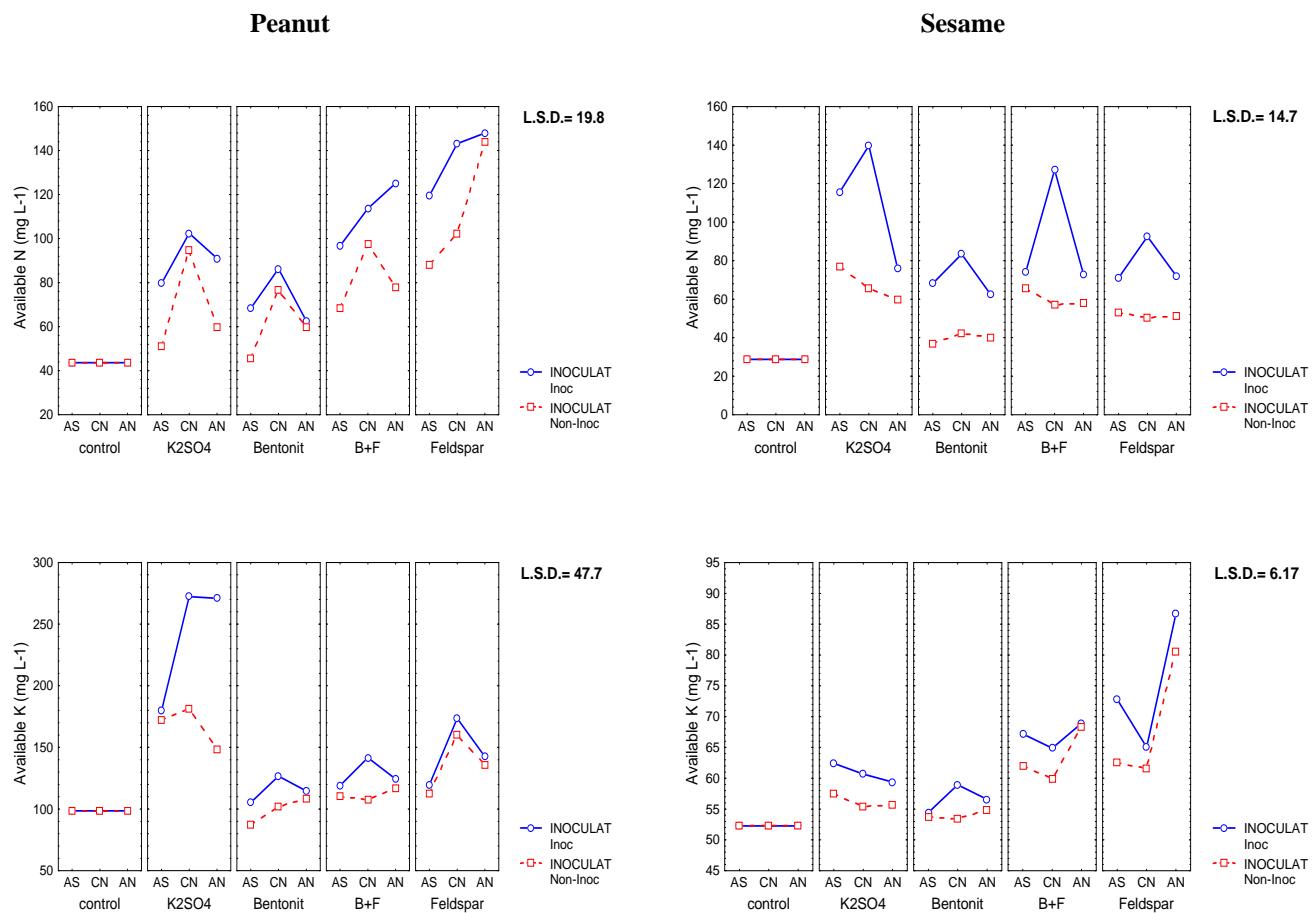

Furthermore, results showed that the highest values of available nitrogen and potassium exist in case of feldspar and potassium sulfate treatments, respectively at the first studied season. Such results are confirmed by Hagin and Shaviv (1990) who reported that the adequate supply of potassium enhances ammonium utilization and thus improves yields. An opposite trend was obtained at second season, which appeared to be highly significant with applied potassium sulfate for available nitrogen with feldspar being highly significant for available potassium. This obtained data could be due to the application of K solubilizing bacteria, which may produce bacterial acids, alkalies or chelates to enhance solubility and release of elements from potassium containing minerals in soil ( Lin Qi-mei , et al., 2002 and Seddik, 2006).

To make the picture clearer, it was thought usefully to express the obtained results as interactions between the influences of both natural mineral and nitrogen fertilizer forms; such interactions are shown in Fig (2). For available nutrients (N and K) in soil, at the two studied seasons, values were significantly increased as a consequence of applied natural mineral in the presence of nitrogen fertilizer and inoculation as compared to control. A previous study (Barker, et al., 1997 and Badr, et al., 2006) confirmed that this bacterial strain produces several organic acids such as acetate, butyric, pyruvic, lactic and formic acid during their biological activities. Such acids can increase mineral dissolution rates; carboxylic acid groups, which were shown to promote dissolution of silicate, are also common in extra cellular organic materials. Moreover, some microorganisms in the soil environment contain enzymes that function in ways analogous to chitinase and celluloses. i.e. they specifically break down mineral structures and extract elements required for metabolism or structure purposes (e.g., mineralization).

Also, data in Fig (2) show high significant increases in available N due to the application of ammonium nitrate in combination with feldspar, and calcium nitrate in combination with potassium sulfate in the presence of inoculation for peanut and sesame, respectively. However, application of calcium nitrate combined with potassium sulfate, and ammonium nitrate in combination with feldspar, in the presence of inoculation, led to significant increases in K available in soil for peanut and sesame, respectively.

**Fig (1): Effect of one factor either nitrogen fertilizer or natural mineral on both nitrogen (A) and potassium (B) availability for the tested soil after peanut and sesame harvesting.**

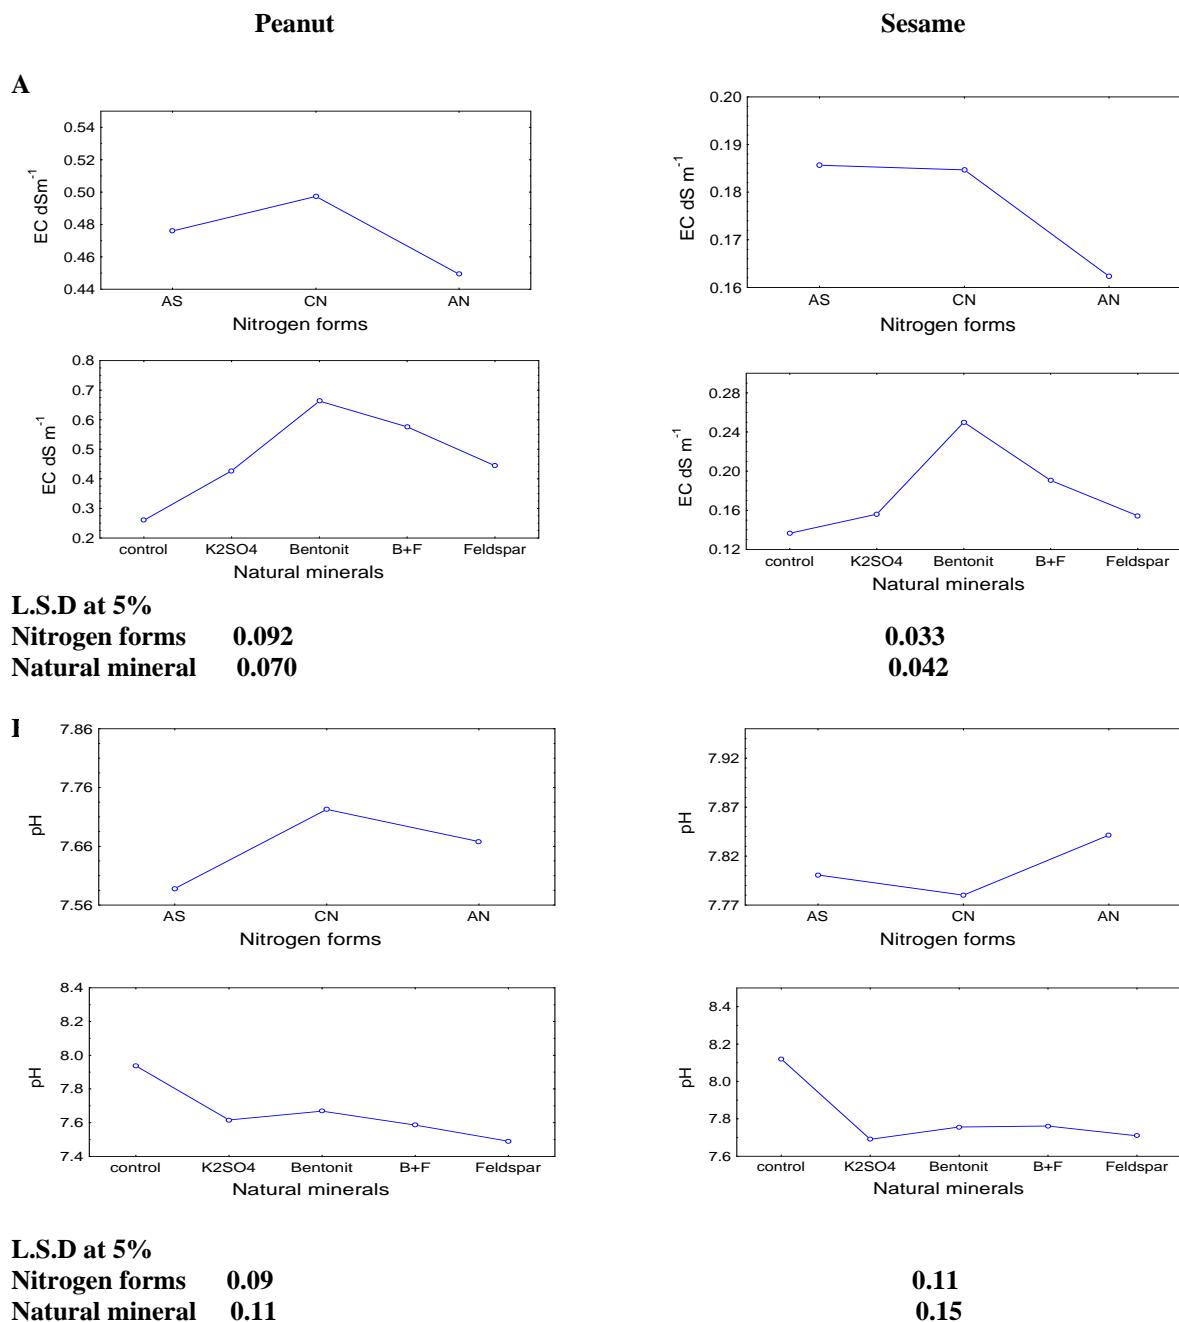

**Fig (2): Effect of different sources of natural mineral, nitrogen fertilizer and/ or inoculation with potassium dissolving bacteria on available nutrients (N and K) for the tested soil after peanut and sesame harvesting.**

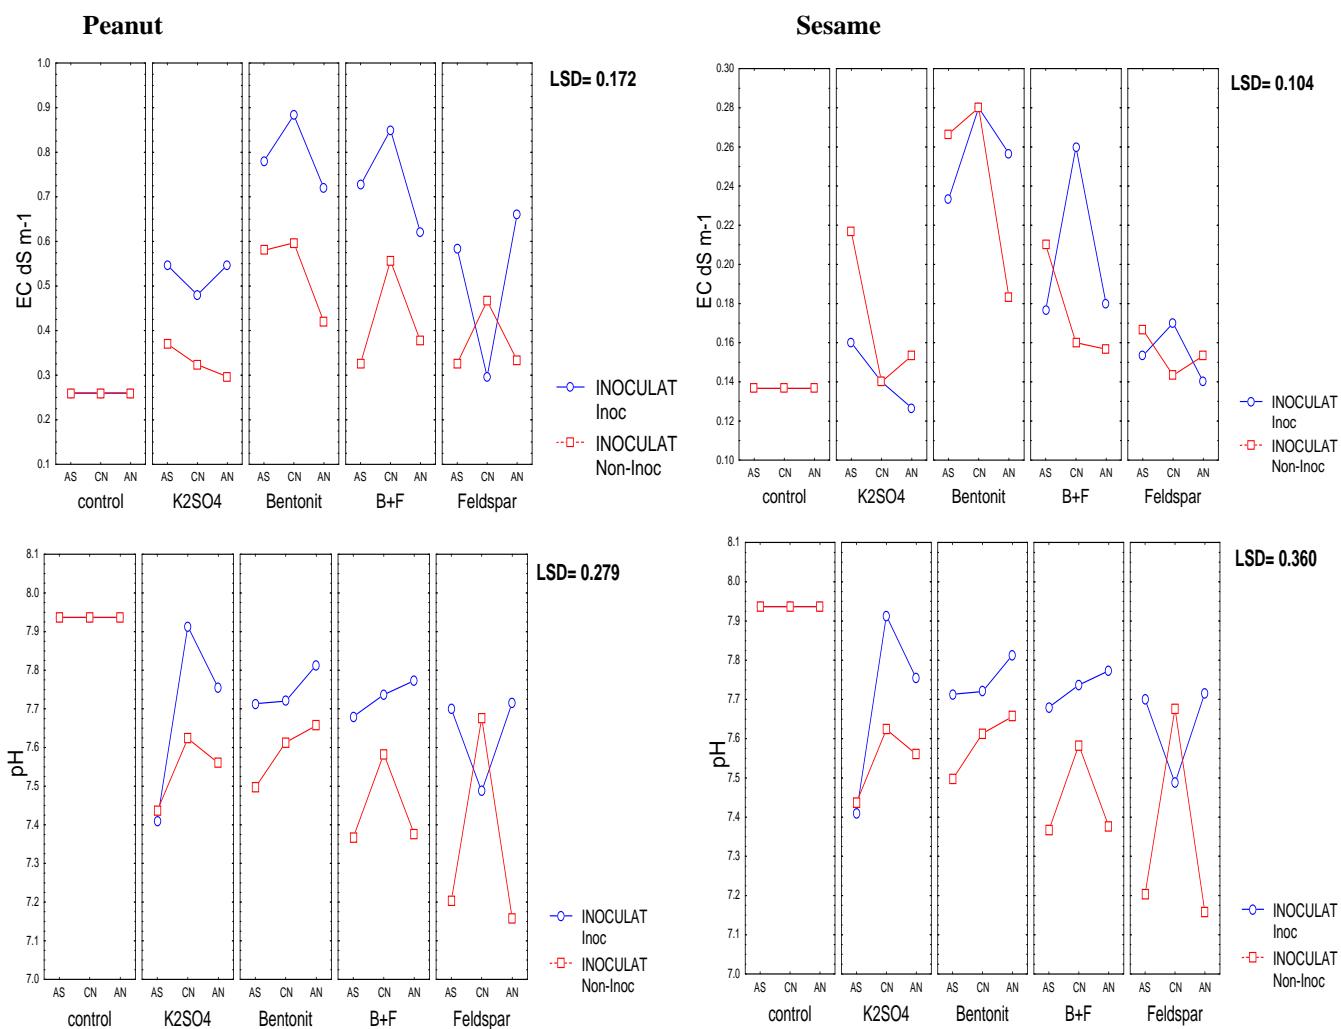

Concerning EC and pH values, the highest EC values in soil following the two studied seasons were reported for calcium nitrate fertilizer as well as bentonite mineral as a source of potassium fertilizer (Fig 3.A). With respect to pH values, the highest values in soil were reported for calcium nitrate at the first season (peanut) and for ammonium nitrate at the second season (sesame). An opposite trend was generally encountered with natural mineral, particularly for applied feldspar, which led to a decrease in pH values at the two seasons as compared to control (Fig 3.B).

Again, to make the picture clearer, it was thought useful to express the obtained results as

interactions between the influences of both natural mineral and nitrogen fertilizer forms; such interactions are shown in Fig (4). Data indicated that, for both studied seasons, application of different natural mineral significantly increased the EC values but decreased the pH values of the studied soil in the presence of nitrogen fertilizer forms as compared with control, whether inoculation or non-inoculation was performed. Moreover, the indicated values of EC and pH were higher in case of applying either bentonite or bentonite + feldspar ratio in the presence of all nitrogen fertilizer forms. Soil salinity increase could be due to the relatively high content of salts in bentonite (Gouda, 1984).

**Fig (3): Effect of either nitrogen fertilizer or natural mineral on both electrical conductivity (EC) (A) and soil reaction (pH) (B) for the tested soil after peanut and sesame harvesting.**

**Fig (4): Effect of different sources of natural mineral, nitrogen fertilizer and/ or inoculation with potassium dissolving bacteria on both electrical conductivity (EC) and soil reaction (pH) for the tested soil after peanut and sesame harvesting.**

2- Influence of nitrogen fertilizer, natural minerals and inoculation with bacteria on yield components at harvesting stage.

With respect to yield of straw and yield of grains or seeds for both peanut and sesame crops, data shown in Fig (5. A and B) revealed that the highest significant yield components of peanut and sesame crops were reported for ammonium nitrate fertilizer as compared to other treatments. Treatments of nitrogen fertilizer may be arranged as follows: ammonium nitrate > calcium nitrate > ammonium sulfate. Also, feldspar mineral gave the highest values of yield components. Treatments of natural mineral may be arranged as follows: feldspar > potassium sulfate > bentonite + feldspar > bentonite and feldspar > bentonite + feldspar > potassium

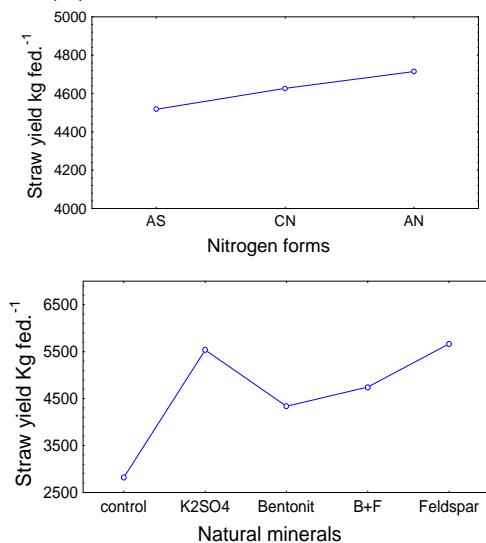

sulfate > bentonite for peanut and sesame yield, respectively.

In general, to make the picture clearer, it was thought usefully to express the obtained results as interactions between the influences of both natural mineral and nitrogen fertilizer forms; such interactions are shown in Fig (6). Data show that natural mineral was favorable to yields either in the presence of nitrogen fertilizer forms or inoculation with potassium dissolving bacteria as compared to control. Furthermore, results indicate that yield components of peanut and sesame increased in the presence of inoculation with potassium dissolving bacteria as compared to non-inoculation. Such results are confirmed by those of Han and lee (2005) who reported that the inoculation of potassium solubilizing bacteria synergistically solubilized the K

materials which were added into the soil and made them more available to the plant. This led to the promotion of their uptake and plant growth. Growth enhancement by *Bacillus* may be also related to its ability to produce hormones, especially IAA. In short,

**7.49**

**Fig (6): Response of yield components (Kg fed.<sup>-1</sup>) for both peanut and sesame at two seasons to application of different sources of natural mineral, nitrogen fertilizer and/ or inoculation with potassium dissolving bacteria at harvest stage.**

Feldspar treatment had recorded the highest values of yield components for either peanut or sesame, particularly in the presence of inoculation as compared to those given by other treatments. These increases in yield components of peanut crop, recorded 117 % and 46.2 % against 118 % and 39.4 % for sesame straw and grains or seeds as compared to control, respectively. These data agreed with the results reported by Badr (2006) who found that the better performance of feldspar-compost plus silicate dissolving bacteria could be attributed to better maintenance of soil nutrient status in the root zone, which in turn helped the plants to utilize nutrients more efficiently; release of potassium took place frequently, and thus favorably affects growth of the crop. Locascio and Hochmuth (1997) reported that potassium supply by the soil is an extremely important factor in yield production, and the high yield depends on the level of K available to the plants. Recently, Massoud et al. (2009) reported that AM-fungi inoculation combined to *B.circulans* is highly beneficial to the growth of plants. This combination optimizes the K solubilization from feldspar and increased microbial activity in the rhizosphere of plants. So, the weathering of feldspar by AM- mycorrhizal fungi and *B. circulans* bacteria enhance the release of K ions that led to encouragement for the growth and consequently, the diverse of rhizospheric microflora.

3- Influence of nitrogen fertilizer, natural mineral and inoculation with bacteria on nutrients uptake at harvesting stage.

#### A- Nitrogen uptake

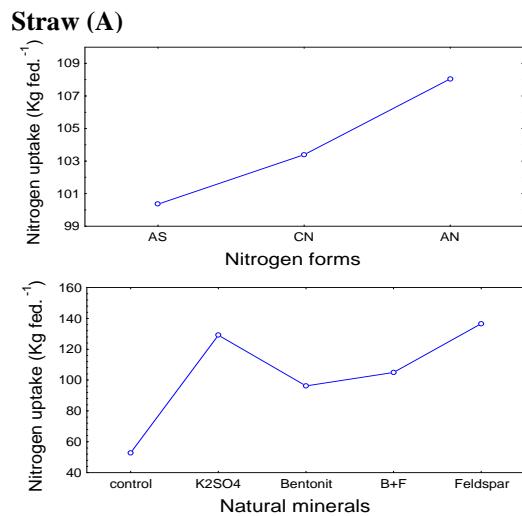

With respect to nitrogen uptake of peanut and sesame plants, generally, the highest significant increases for nitrogen uptake of straw and grain or seeds for either peanut or sesame yields were reported for ammonium nitrate fertilizer and feldspar mineral compared to other treatments (Fig 7., A and B). Treatments of nitrogen fertilizer may be generally arranged as follows: ammonium nitrate > calcium nitrate > ammonium sulfate for the two studied seasons. On the other hand, treatments of potassium fertilizer may be arranged as follows: feldspar > potassium sulfate > bentonite + feldspar > bentonite at the first season while arranged as follows: feldspar > bentonite + feldspar > potassium sulfate > bentonite for the second season. Also, behavior of nitrogen uptake followed the same trend of those obtained for yield components at the two studied seasons. In fact, Katai et al. (2010) indicated that the large bentonite doses reduced the nitrate- N content along with available phosphorus and potassium contents of soil, which reflected on nutrients uptake by plants.

To make the picture clearer, it was thought usefully to express the obtained results as interactions between the influences of both natural mineral and

nitrogen fertilizer forms; such interactions are shown in Fig (8). Data show that values at the two studied seasons were positively affected by application of natural mineral in the presence of nitrogen forms either of inoculation or non-inoculation compared to control.

Moreover, results showed that the nitrogen uptake was significantly increased with inoculation by potassium dissolving bacteria. These results are in agreement with those of Han et al. (2006) who reported that the soil inoculation with potassium solubilizing bacteria significantly increased nutrients uptake in pepper and cucumber plants, especially

Nitrogen forms 3.08

Natural mineral 4.03

when the respective rock potassium were added. Generally, pattern of nitrogen uptake followed the same trend of those obtained with yield components of both crops (peanut and sesame).

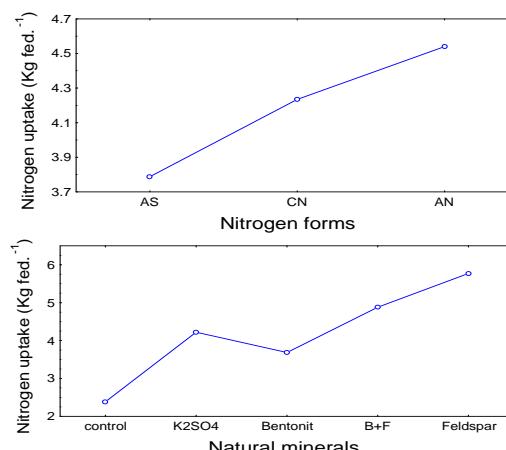

Application of feldspar with ammonium nitrate as a source of nitrogen fertilizer generally improved the uptake of nitrogen in plants, especially in the presence of inoculation compared to control. These increases in nitrogen uptake of peanut crop, recorded 214 % and 301 % against 219 % and 176 % for sesame straw and grains or seeds compared to control, respectively.

**Fig (8): Response of nitrogen uptake ( $\text{Kg fed}^{-1}$ ) for both peanut and sesame at two seasons to application of different sources of natural mineral, nitrogen fertilizer and/ or inoculation with potassium dissolving bacteria at harvest stage.**

#### B- Potassium uptake

However, the highest response for potassium uptake of straw and grains or seeds at the two studied seasons were recorded for ammonium nitrate fertilizer as a source of nitrogen fertilizer with potassium sulfate and feldspar mineral as sources of natural mineral for peanut and sesame yield, respectively. (Fig. 9, A and B).

Treatments of nitrogen fertilizer seemed to follow a trend for potassium uptake similar to those obtained for nitrogen uptake. Regarding to treatments of natural minerals, they could be arranged as follows: potassium sulfate > feldspar > bentonite + feldspar > bentonite for the peanut yield while arranged as follows: feldspar > bentonite + feldspar > potassium sulfate > bentonite for the sesame yield. The last behavior of potassium uptake, again, seemed to follow a trend similar to those obtained for nitrogen uptake for the two studied seasons. In the same concern, Badr (2006) found that the total uptake was greater when feldspar- compost plus silicate dissolving bacteria was applied followed by potassium sulfate while the lower was recorded for feldspar. This may indicate that a major portion of K present in feldspar mineral as well as in the organic

materials became available for uptake and contributed considerably towards the nutritional requirements of the crop. Further, loses due to drainage, leaching and percolation of potassium from feldspar charged compost are negligible as compared to soluble potassium salts. Hence, use of feldspar in a biological form should be, further, more economical than imported potash fertilizer.

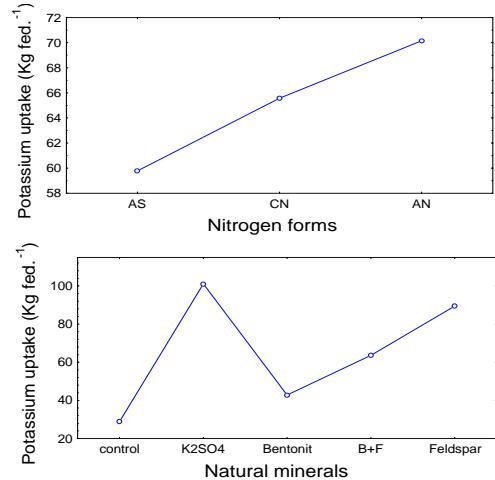

The obtained results as interactions between the influences of both natural mineral and nitrogen fertilizer forms (Fig 10) reveal positive responses for potassium uptake to application of natural mineral treatments in the presence of either nitrogen forms or inoculate as compared to control.

Application of ammonium nitrate with feldspar was generally superior, particularly in the presence of dissolving potassium bacteria. However, an exception being obtained in case of applying calcium nitrate with potassium sulfate for straw at first season compared to control. These increases in potassium uptake of peanut crop, recorded 336 % and 78.3 % against 352 % and 180 % for sesame straw and grains or seeds as compared to control, respectively.

From our obtained results, it could be concluded that, the feldspar mineral and ammonium nitrate as a source of potassium and nitrogen recorded the highest values of yield components as well as nutrient (N and K) uptake for either peanut or sesame particularly in the presence of inoculation. Moreover, the effects of both feldspar and feldspar + bentonite

## Clinical Perspective of Repeat Breeding Syndrome in Buffaloes

Ahmed W.M.<sup>\*</sup>, El-khadrawy H.H., Emtenan M. Hanafi , Amal H. Ali , Shalaby S.A.

Department of Animal Reproduction and Artificial Insemination, National Research Center Dokki,Cairo, Egypt.

<sup>\*</sup>[wahidmma@hotmail.com](mailto:wahidmma@hotmail.com)

**Abstract:** Local meat production in Egypt is in continuous decrease and can not meet the local market requirement. So this study was designed to throw light on true repeat breeding syndrome (RBS) as one of the reproductive disorders that hinders the buffalo meat and milk production. A field survey was carried out on 1358 female buffaloes which were subjected to clinical and gynecological examination , and blood samples were collected for carrying out some relevant analyses. Treatment trials were practiced using different ways to control the condition and the economic impact of this syndrome has been studied. Results revealed that the incidence of clinical repeat breeding (RB) in the examined buffalo cows was 4.34 %. Typical repeat breeders represented 7.25 % of total reproductive disorders in female buffaloes. Serum progesterone level was  $1.44 \pm 0.39$  and  $3.66 \pm 0.84$  in RB and normal buffaloes (NB), respectively. Oxidant/antioxidant markers in RB buffalo-cows showed increased malondialdehyde (MDA) and nitric oxide (NO) and decreased catalase (CAT), superoxide dismutase (SOD), ascorbic acid (ASCA), reduced glutathione (GSH-R) and total antioxidant capacity (TAC). Serum zinc, copper,iron and selenium values were lower in repeat breeder cows compared to normal animals. Repeat breeder buffalo-cows responded to the treatments with mineral mixture, GnRH and Lugol's solution with recovery rates; 63.64, 61.54 and 60.00%, respectively. The study concluded that special care should be paid for food additives to control this syndrome.

**Key words:** Repeat breeding buffaloes - progesterone - oxidant/antioxidants and trace elements

### 1. Introduction:

Currently, the incidence of infertility becomes relatively increased with consequent reduction of productivity of farm animals. According to global Agricultural Information Network report for 2010, the total number of Egyptian cattle and buffalo decreased from 6.256 million head in 2008 to 6.248 million in 2009 and it is expected to decline in 2010 to level lower than 2009 because of many problems that continue to limit the growth of the animal production industry [1]. The price of domestic beef increased dramatically and the imported frozen meat and liver are still important sources of protein in domestic market. The average per capita consumption of red meat including variety meats is estimated at 8.5 kilograms per year, which is quite low compared to consumption levels in other countries. The lower consumption is mainly due to limited local production combined with lower per capita income [1].

Although buffalo constitutes 49% of the above mentioned number, it is the source for high quality milk (65% of milk production), lean meat (33.9% of meat production) and preferred by most of Egyptians. However, in Egypt and most of developing countries having buffalo population, these animals are mostly raised in small holder farms under hard socioeconomic circumstances [2].

Reproductive disorders, poor nutrition, parasitic infection are the main constraints of buffalo development. Ovarian inactivity, silent heat, endometritis and repeat breeding are the main reproductive disorders in buffaloes in Egypt [3].

Typical repeat breeding (RB) is defined as the animal that did not conceive after three or more consecutive inseminations, despite, it comes normally in heat and shows clear estrous signs with no clinical detectable reproductive disorders [4].

The objective of this study was to throw light on typical repeat breeding syndrome in Egyptian buffaloes with emphasis on the oxidative status and application of some field treatment trials. Also, economic impact of this syndrome has been investigated.

### 2. Materials and Methods

#### Animals

The current study was conducted on 1358 mature polyparous buffalo cows randomly selected from small-scale holders at Al Sherkia governorate, lower Egypt during 2008-2010. These animals were fed on Barseem (*Trifolium alexandrinum*), wheat or rice straw and a few amount of concentrate mixture. Based on owner complains, case history, general health condition and the gynaecological examination, animals were categorized into two groups; the first group (G1) bred and conceived normally after no

more than 3 inseminations. The second group (G2) was those animals which did not conceive after three or more inseminations, despite no clinically detectable reproductive disorders were observed (Typical repeat breeders). Gynaecological examination was carried out through rectal palpation aided by ultrasonography machine (PiaMedical Falc e`Saote, Netherlands) with an endorectal linear array of 8.6 M hertz to register the reproductive status and/or disorders.

#### Sampling and Analysis:

Blood samples were drawn from the jugular vein of each animal, in tubes with and without EDTA. Serum was separated after centrifugation and stored at -20 °C until analysis. Serum progesterone level was assayed by ELISA microwell technique using kits from DIMA (Germany). The kit had a sensitivity of 2.0 pg/ml with inter- and intra- run precision coefficient of variations of 2.9 and 4.85, respectively [5]. The concentrations of malondialdehyde (MDA) [6], nitric oxide(NO) [7], catalase (CAT) [8], ascorbic acid (ASC) [9], superoxide dismutase (SOD) [10] and total antioxidants(TAC) [11] in the serum and glutathione reduced (GSH-R ) [12] in the whole blood were determined by colorimetric methods using chemical kits (Biomed Egypt) and Shimadzu UV 240 spectrophotometer. Zinc, copper, iron and selenium concentrations were determined using atomic absorption spectrophotometry (Perkin Elmer, 2380) as outlined by Varley et al.[13]

#### Treatment trials:

A total number of 34 repeat breeder buffalo cows was subjected to one of the following treatments:

- 1- No treatment at all and kept as the control group (n=5).
  - 2- Lugol's Iodine solution (0.5 – 2%) as a vaginal wash for 3 successive weeks (n=5).
  - 3- Receiving 20 g from a mixture of minerals, vitamins and Lasalocids® in their ration for 10 successive days. This mixture was prepared in the laboratory by through mixing of 20 g of zinc sulphate , 6.25 g of copper sulphate, 1.5 g potassium iodide, 30 mg sodium selenite, 200 g AD3E and 5 g Lasalocids®,(F-Hoffman-LaRoche,Basle, Switzerland) and sodium phosphate dibasic up to 1 kg [2] ( n=11)
  - 4- Receiving an intramuscular injection of GnRH (Receptal, Hoechst Roussel Vet GmbH) (n=13)
- Treatments were carried out according to the instruction of manufacturing companies. Animals were followed up during the next weeks for conception.

#### Economic evaluation:

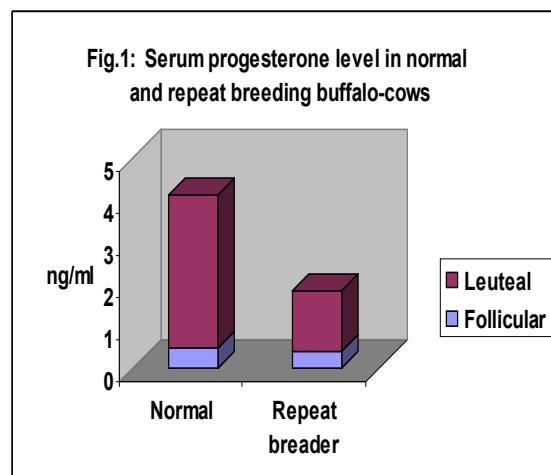

Economic losses were calculated on light of decreased calf crop, prolonged calving intervals, decreased milk production and veterinary intervention services, cost of the used drugs as well as cost of repeated AI.

#### Statistical analysis:

The data were computed and statistically analyzed using PSS-10.5 software package [14].

### 3. Results

The studied buffalo cows came normally in heat inseminated in the proper time with normal proven fertile bulls and came in heat again after 20 – 22 days during the breeding season of buffaloes (September– March). Ultrasonographic examination revealed that such animals showed no detectable clinical reproductive disorders with the corresponding normal physiological structure during the different stages of the estrous cycle. Serum progesterone level (Fig. 1) was significantly ( $P < 0.05$ ) low ( $1.44 \pm 0.39$  ng/ml) during the mid -luteal phase of the estrous cycle in repeat breeder animals compared to normal animals ( $3.66 \pm 0.84$  ng /ml).

#### 3.3. Oxidative status:

Table 1 show the oxidant/ antioxidant status of the investigated animals. It was found that MDA and NO values were significantly high ( $P < 0.01$ ) while, ASC, GSH-R, Zn, Cu, Fe and Se values were significantly( $P < 0.01$ ) low in repeat breeder buffaloes compared to normal animals.

**Table (1): Oxidant / antioxidants concentrations in repeat breeder buffalo- cows (Mean ± SE).**

Oxidant/antioxidant	Normal cows (N=10)	Repeat breeder buffalo-cows ( N=10)
MDA (mmol/ml)	1.98 ± 0.09	3.70 ± 0.48 **
NO (mmol/L)	15.55 ± 1.58	25.17 ± 0.85**
CAT ( U/ml)	2.28 ± 0.4	1.99 ± 0.10
ASC (µg/dl)	132.17 ± 5.12	95.16 ± 2.37**
SOD (U/ml)	338.16 ± 7.11	332.12 ± 16.14
GSH-R (mmol/L)	6.38 ± 0.11	2.66 ± 0.09**
TAC (mmol/L)	1.43 ± 0.08	0.46 ± 0.50
Zinc (µg/dl)	139.11 ± 2.17	120.21 ± 5.20**
Copper ( µg/dl)	78.65 ± 0.13	68.33 ± 2.05**
Iron (µg/dl)	168.40 ± 4.11	152.13 ± 2.05**
Selenium ( µg/L)	144.85 ± 0.34	130.12 ± 2.01**

\*\* P&lt; 0.01

### 3.4. Treatment trials:

Field trials to treat the typical repeat breeding syndrome using Lugol's solution, mineral mixture and GnRH indicated that 60 – 63 % of the treated animals get conceived as indicated by

gynecological examination in 40 – 60 days later, while no animal from the untreated group get conceived. It was found that mineral mixture- treated group gives the highest response.

**Table (2): Treatment trials for repeat breeder buffalo-cows (Mean ± SE).**

Treatment	Repeat breeder-cows	Recovered animals	Recovery (%)
No treatment	5	0	00
Lugol's solution	5	3	60
Mineral mixture	11	7	63.64
GnRH	13	8	61.54

### 3.5. Economic evaluation

In the present study, economic losses were estimated as 1588 LE =288\$ for every unsuccessful service. Moreover, such losses become greater if the animal did not get pregnant before the end of breeding season.

### 4- Discussion:

Repeat breeding is among reproductive disorders which hinder favorable productivity in buffaloes [15].

In the present study, the incidence of typical repeat breeders was 4.34% of the total examined animals and 7.25 % of all cases having reproductive disorders (813). The same result was found by Ahmed et al. [3]. Meanwhile, Cebra et al. and Bage et al [16 and 17] reported a range of 8.33 - 28% for this syndrome in bovines. Variations in incidences may be attributed to the heterogeneity or multifactorial causes of the repeat-breeder syndrome as well as the effect of locality and season [18].

The low progesterone level that was recorded in the current study in repeat breeder buffaloes during the luteal phase was similar to the result of Rizzo et al[19] that attributed the failure of conception in these

animals to their low progesterone level. Moreover, Sigh et al. [20] indicated that RB heifers revealed higher P4 concentrations during estrus and early metoestrus, and lower P4 concentrations during late metoestrus and onwards. In this respect, Binelli et al.[21] suggested that the supra basal level of P4 during estrus reduced tubal contractility and delayed sperm transport to the site of fertilization and early embryonic mortality. Also, Bage et al.[17] mentioned that the disturbed hormone level which prolonged standing estrus and delayed ovulation causes changes in the microenvironment of the preovulatory follicle, negatively affecting the final maturation of the oocyte leading to fertilization failure in those repeat-breeder heifers. In another study, he reported a negative correlation between conception rate and skim milk progesterone level in cows artificially inseminated [22].

It is well known that in a healthy body, reactive oxygen species (ROS) and antioxidants remain in balance. When the balance is disrupted towards an overabundance of ROS, oxidative stress (OS) occurs. Also, ROS have a role in pathological processes involving the female reproductive tract, whereas, it affect multiple physiological processes

from oocyte maturation to fertilization, embryo development and pregnancy [23]. This theory was confirmed in the current study where RB buffalocows showed increased MDA and NO and decreased CAT, SOD , ASCA, GSH-R and TAC. An endogenous NO system exists in the fallopian tubes [24].

NO has a relaxing effect on smooth muscles and it has similar effects on tubular contractility. Abnormal concentration of NO may lead to tubal motility dysfunction, resulting in retention of the ovum, delayed sperm transport and infertility. On the other hand, it was reported that increased NO levels in the fallopian tubes are cytotoxic to the invading microbes and also may be toxic to spermatozoa [24]. Moreover, Seino et al.[25] found that NO inhibits ovarian steroidogenesis. The presence of endothelial NO synthase in corpora lutea and its expression has been reported in the mid and early luteal phase and to a lesser extent in the late luteal phase Moreover, [26] and [27] added that NO inhibits steroidogenesis in the corpus luteum and has luteolytic action mediated through increased prostaglandins and by apoptosis.

SOD is present in the ovarian tissue and it was found that there is a correlation between SOD and Ad4BP which is a steroidogenic transcription factor that induces transcription of the steroidogenic P450 enzyme. Thus, it controls steroidogenesis in the ovaries. The correlation between Ad4BP and SOD expression suggests an association between OS and ovarian steroidogenesis [28]. The preovulatory follicle has a potent antioxidant defense, which is depleted by the intense peroxidation [29].

Glutathione peroxidase may also maintain low levels of hydroperoxides inside the follicle and thus play an important role in gametogenesis and fertilization [30]. Meanwhile, De Matos and Furnus [31] reported that glutathione is present in the oocyte and tubal fluid and has a role in improving the development of the zygote beyond the 2-cell block to the morula or the blastocyst stage

Vitamin C is a chain breaking antioxidant that stops the propagation of the peroxidative process and helps to recycle oxidized vitamin E and glutathione [32].

Increase in TAC was seen in follicular fluid of oocytes that later were successfully fertilized. Therefore, lower TAC is predictive of decreased fertilization potential [33].

The low concentrations of zinc, copper, iron and selenium traced in this study coincide with Das et al. and Ceylan et al. [34 and 35]who recorded that serum zinc and copper were significantly low in repeat breeders if compared to normal buffalo cows and added that when these animals were supplemented with 500 ppm zinc acetate in the

drinking water and sodium phosphate 40 g/head/day in the diet for 1 month, respectively , the conception rate improved by 80%.and this explains our findings where the treatment with mineral supplementation gave the best results for conception (63.64 %) . This is in agreement with Sah and Nakao [15] who reported that 64.6 % of repeat breeder buffaloes came to estrus and 58.4 % conceived within one month after supplementation with vitamin/mineral mixture for 3 weeks. Then, he added that the hormone treatment is more effective than 3 weeks supplementation with vitamin/ mineral mixture.

Use of hormonal treatments such as GnRH or hCG, have been used by many investigators to increase the rate of pregnancy for repeat breeder cows [36, 37, 38]. It is suggested that it has a role in the expression of SOD as it is found that the Cu-Zn SOD expression in the corpora lutea paralleled with levels of progesterone and these levels rose from early to the mid luteal phase and decreased during the regression of the corpus luteum. However, in the corpus luteum from pregnant cases, the mRNA expression for Cu-Zn superoxide dismutase was significantly higher than that in midcycle corpora lutea [28]. Other investigators reported that when 36.4- 50.0 % repeat breeder buffaloes washed by 1 liter of 1% Lugol's solution conceived within one month after treatment [15].

From the economic point of view, the repeat breeding syndrome impacts the buffalo industry as it causes increased culling, reduced milk production, and reduced value of breeding stock. On the other side, the indirect costs of sound diagnosis, treatment trials, repeated artificial insemination should also be considered. RBS return the animal to service, increased time to conception and thus increased calving interval in the long-term reduced milk production or permanent infertility. The profitability of milking buffalo-cow increases with age, and culling earlier than the fourth lactation may result in net cost.Also reduced fertility is the commonest reason for culling in the UK [39], so any disease or syndrome affects fertility will have an economic impact. RBS may negatively affect milk production. Whilst an increased calving interval would reduce the number of lactations within a period of years, an RB may increase or prolong the lactation in which it happens. Thus, the impact of RB on milk production is complex and has not been fully quantified. In twenty-two Michigan dairy herds, repeat-breeder syndrome was observed in 24% of 3,309 lactations. Cost components associated with unsuccessful inseminations included costs of delayed conception, extra inseminations, extra veterinary service and losses due to culling. Lactations with repeat-breeder syndrome were associated with a loss of

approximately \$385. An estimated extra cost of \$140 was associated with a second insemination, \$279 with three inseminations, \$429 with four inseminations and \$612 with five inseminations [40].

It was concluded that RB has economic impact on buffalo production and consequently, local meat and milk production in Egypt. Veterinary supervision should provide better animal health care and education to farmers regarding the risk factors that may lead to RB. Also, use of ultrasonography may help to get rapid and sound diagnosis. Great efforts should be done to catch up the breeding season not to lose the proposed new individual and lactation season. Also special care should be paid for minerals and food additive in animal's food stuff for animal welfare and breeder income.

## Biologically evaluation of pan bread supplemented with vital gluten, lupin, fenugreek and turmeric flour blends

Aly, M. H\*; El Nikeety, M. M\*; Saleh, M. A. M\*\*. and Abd El-Hak, N. A. M.\* \*\*

\*Cairo University, Faculty of Agric., Food Science & Technology Dept.

\*\* Food Technology Research Institute, Special Food & Nutrition Dept.

\*\*\*Food Technology Research Institute, Experimental Kitchen Unit.

**ABSTRACT:** The current study was carried out to utilize each of whole meal wheat flour (control), some legumes (lupin and fenugreek), turmeric and vital gluten flour in blends for preparation of pan bread more nutrients and healthy in order to enhance the dietary fiber and amino acids contents. The biological parameters of rats (non and induced diabetic) fed on such pan bread was also estimated. A significant higher amount of soluble, insoluble and total dietary fiber contents was found in the turmeric, fenugreek and lupin, pan bread compared to that found in control once( whole wheat flour). Normal rats (nondiabetic and fed on basal diet) exhibited an insignificant decrement in blood glucose. However, in the diabetic rats a significantly lowered blood glucose trend was found. The tested pan bread samples were more slightly effective in lowering liver and kidney function in the diabetic rats in a relation to diabetic rats, when compared with the positive control. Finally, it is recommended to utilize whole meal flour to prepare healthy diets to deal with diabetic status and control of some biological parameters.

**Key words:** Whole meal wheat, Vital gluten, Fenugreek seeds, Legumes, Turmeric, Diabetes.

### **INTRODUCTION**

Diabetes mellitus (DM), one of the major metabolic disorders, is characterized by high blood glucose levels due to the inability of body cells to utilize glucose properly. By the 2010 year, the total number of people worldwide with DM will be as high as 239 millions. Regions with greatest potential are Asia and Africa, where DM incidence could rise to 2-3-folds of the present incidence (Xue *et al.*, 2007). Recently, Vijayalakshmi *et al.* (2009) reported that diabetes is a disease of great concern to many all over the world and is known for its complications that include diabetic nephropathy, neuropathy, and retinopathy. In any form of management of diabetes, be it with insulin or drug, diet is a common factor. Some of the foods and their derivatives are recommended for better management of diabetes. In this direction, bitter gourd is one of the vegetables, which is advocated and well practiced in the control of diabetes.

Marques *et al.* (2007) reported that, more wheat -based products, including flour, bread, breakfast cereals, pasta and crackers, are available. It seems that such cereals products possess valuable nutritional and/or physiological properties, which

could help promoting the consumption of these products.

Wheat gluten is a readily available protein source that has been extensively used in baked products (Barber and Warthesen, 1982). Hemstad (2005) reported that vital gluten is a unique water-insoluble protein and carbohydrate complex that is extracted from wheat by wet processing.

Legumes play an important role in human nutrition since they are rich sources of protein, calories, certain minerals and vitamins. In African diets legumes are also, the major contributors of protein and calories for economic and cultural reasons (ELMaki *et al.*, 2007). Madhusudhan and Tharanathan (1995) found that, legumes have been shown to decrease blood glucose responses compared to other cereal based foods such as whole meal bread and are of very vital benefit in the diets of diabetes and hyperlipidemia patients. Moreover, Wolever *et al.* (2003) reported that the low-fat, high-carbohydrate diets are known to stimulate hepatic triglyceride production in diabetic subjects.

The turmeric is rich in dietary fibers and contains both soluble and insoluble dietary fibers. Dietary fibers are well established to play a beneficial role against various diseases like diabetes, colon cancer, heart disease.... etc, as reported by

Vijayalakshmi *et al.* (2009). Turmeric (*Curcuma longa L.*) is a medicinal plant extensively used in Ayurveda, Unani and Siddha medicine as a home remedy for various diseases (Ammon and Wahl, 1991). Turmeric is used as a food additive (spice), preservative and coloring agent in Asian countries, including China and South East Asia. It is also considered as an auspicious and is a part of religious rituals. In old Hindu medicine, it is extensively used for the treatment of sprains and swelling caused by injury (Kamal-Eldin *et al.*, 2000). Arun and Nalini (2002) reported that, both turmeric and curcumin decrease blood sugar level in alloxan-induced diabetes rats. Curcumin also decreases advanced glycation end products induced complications in diabetes mellitus.

On the other hand, Patil *et al.* (2009) reported that, during diabetes, a profound alteration in the concentration and composition of lipids occurs. Liver and kidney organs are important for glucose and lipid homeostasis, they participates in the uptake, oxidation and metabolic conversion of free fatty acids, synthesis of cholesterol, phospholipids and triglycerides. Basch *et al.* (2003) reported that, in human studies, fenugreek seeds reduced the area under the plasma glucose curve and increased the number of insulin receptors. Also, fenugreek seeds exert hypoglycemic effects by stimulating glucose-dependent insulin secretion from pancreatic beta cells as well as by inhibiting the activities of alpha-amylase and sucrase, two intestinal enzymes involved in carbohydrate metabolism.

Therefore, the objectives of the current study are to incorporate and utilization of whole wheat flour, vital gluten, fenugreek, lupin and Turmeric rhizome to prepare an edible and healthy. The objectives are extended also to *invitro* and *invivo* estimation of such products.

## MATERIALS AND METHODS

### Materials:-

Wheat grains (*Triticum aestivum*, Skha 69 variety) were obtained from the Wheat Research Department, Field Crops Research Institute, Agricultural Research Center, Giza, Egypt. The tested legumes lupin, *lupinus albus*, Giza 1variety and fenugreek seeds, *Trigonella foenung raecum*, Giza 30 variety were obtained from Legumes Research Department, Field Crops Research Institute, Agricultural Research Center, Giza, Egypt. Turmeric rhizome (*Curcuma longa*) was obtained from the local market at Giza, Egypt. Commercials wheat gluten which was purchased from Crestar Co. 7 Rue Du Marechal, Jaffre, BP 109, France, was obtained from Cairo Univ., Faculty of Agricultural, Special Baking Technology

Unit. Bread improver was obtained from Saint Paul Company Milk and Chocolate, Badr Industrial City, Cairo, Egypt. Commercial compressed yeast: The compressed Bakers yeast was purchased from the local market at Giza, Egypt. Alloxan (the diabetes mellitus inducer drug for rats) was obtained from Sigma Company, USA. Blood glucose, albumin, total protein, alkaline phosphatase, glutamic-oxalacetic transaminase(GOT), glutamic-pyruvic transaminase (GPT), creatinine, urea and uric acid kits were obtained from Biodagnostic Company, 29 El Tahrer street, Dokki, Giza, Egypt.

### **Methods:-**

#### **-Preparation of raw materials**

##### **-Germination and cooking of legumes**

Germination of fenugreek seeds were carried out according to the method of Marero *et al.* (1988). fenugreek seeds were cooked individually by boiling with sufficient amounts of water, till they became tender and well cooked. Lupin debittering processes, were carried out in the laboratory by washing and soaking the lupin in tap water for 24 h at room temperature, followed by germinating of whole seeds at 30 °C in the dark for 3 days, followed by warming using boiled water for 30 min and submerging the lupin seeds in a running tap water at room temperature for 4 days (Trugo *et al.*, 1993).

#### **Drying and milling of materials**

All such materials (legumes) were dried at 55° C for 12 h, in an air forced oven. Wheat grains, turmeric, dried germinated fenugreek and lupin seeds were milled with a laboratory mill (MLW, Type: Sk1, watt100, West Germany).

#### **Preparation of blends**

The optimum gluten scheme amount was 30%. Exactly 5, 5 and 1% of fenugreek, lupin and turmeric flour, respectively, were substituted (except the control blend) instead of a resemble amount of whole meal wheat flour to achieve the healthy impact.

#### **Baking procedures:**

A straight dough bread making process was performed according to Wang *et al.*, (2002). Basic dough formula of 500g flour basis was consisted of salt (5g), compressed yeast (10g), sugar (5g), bread improver (0.2g), oil (5g) and the required amount of water to reach 500 BU of consistency. The doughs were optimally mixed, fermented for 10min, and then dough pieces (450g) were divided, hand -moulded and sheeted. The dough was proofed for 55 min in a fermentation cabinet under controlled temperatures (30°C) and a relative humidity (78%) for 50 min and

then baked for 40 min at 180 °C in a baking oven. The pan bread attributes were evaluated after cooling for 1hr at room temperature.

### **Methods of analysis**

#### **Determination of amino acids**

All amino acids content, except tryptophan, of the cooked flour of each of lupin, fenugreek, as well as the flour of whole wheat meal, gluten and turmeric were determined using HPLC- PICO- TAG method according to the method described by Cohen *et al.* (1989). Tryptophan was calorimetrically determined in A.O.AC. (2000).

#### **Determination of total dietary fiber (TDF)**

Total dietary fiber (TDF) was determined in according to the method described by Prosky *et al.* (1984) and the modification by Vadivel and Janardhanan (2001).

#### **Determination of soluble and insoluble dietary fiber**

Soluble and insoluble dietary were determined according to the method described by Asp *et al.* (1983).

#### **Computation of protein efficiency ratio (PER).**

Protein efficiency ratio of pan bread was calculated using the equation suggested by Alsmeyer *et al.* (1974) as follows:

$$\text{PER} = -1.816 + 0.435 \text{ (methionine)} + 0.78 \text{ (leucine)} + 0.211 \text{ (histidine)} - 0.944 \text{ (tyrosine).}$$

#### **Biological assay:**

The experimental study was conducted on 45 adult male albino rats, 180-200 g weighed. Animals were housed at the animal house, Crops Technology Department, Food Technology Research Institute (FTRI). Before and during the experiment rats were fed on a basal diet containing 20% casein, 10% corn oil, 5% cellulose, 4% salt mixture and 1% vitamin and completed to 100% with corn starch (AOAC, 2000). After randomization to various groups and before initiation of experiment, the rats were acclimatized for a period of 7 days under standard environmental condition of temperature, relative humidity (55%), and dark/light cycle.

#### **The experimental design:**

All the animals were randomly divided in nine groups (five rats for each one group) and namely negative control (the normal group which fed on a

basal diet), positive (the diabetic group fed on basal diet), WWF (the diabetic group fed on whole meal wheat pan bread diet), WWG (the diabetic group fed on whole meal and gluten pan bread), WWGT (the diabetic fed on whole meal, gluten and turmeric pan bread), WWGL (the diabetic fed on whole meal, gluten and lupin pan bread), WWGF (the diabetic fed on whole meal, gluten and fenugreek pan bread), WWGLT (the diabetic fed on whole meal, gluten, lupin and turmeric pan bread), WWGFT (the diabetic fed on whole meal, gluten, fenugreek and turmeric pan bread) and WWGFLT (the diabetic fed on whole meal, gluten, fenugreek, lupin and turmeric pan bread). During the experiment, rats were separately kept in well aerated cages and the diet as well as water were *ad libitum* supplied.

#### **Induced diabetic animals:**

Rats were diabetic induced by a single intraperitoneal injection of alloxan monohydrate (150 mg/kg rat). Alloxan was first individually amount calculated for each animal according to the weight and the proper amount was solubilized with saline just prior to injection (Ahmed *et al.*, 2005) and the control group was saline injection only. Three days after alloxan injection, rats with plasma glucose levels of >140mg/dl were included in the study. Fasting blood glucose estimation was done at zero, 15, 30 and 45 day of the study. Urea, uric acid, creatinine, GOT, GPT, total protein, albumin and alkaline phosphatase estimation, as well as measurements were immediately carried out after the successful injection and at 45 day of the study start. At the end of the feeding period (after 45 days) rats were anaesthetized using diethyl ether and sacrificed. Insulin in plasma was also measured at the experiment end.

#### **Biochemical analysis:**

The blood samples were collected in tubes and centrifuged at 500 xg to obtain serum. It was kept in a deep-freezer until biological analysis was performed and subjected to the following biochemical analysis: fasting blood sugar (according to Trinder, 1969) in the separated serum samples. Serum insulin level (Temple *et al.*, 1992, at National Institute of the Diabetic and Endocrine Discos). Serum glutamic oxaloacetic transaminase (GOT) and glutamic- pyruvic transaminase (GPT) activities were calorimetrically measured according to the method described by Reitman and Frankel (1957). The protein content was determined using the method of Gornall *et al.* (1949). The alkaline phosphatase was determined using the method of Belfield and

Goldbery (1971). The albumin content was determined using the method of Doumes (1971).

### **Statistical analysis:**

Data analysis was performed using SAS (1987), software. All data were expressed as mean of three replicates. Analysis of variance was used to test for differences between the groups. Least Significant Differences (LSD) test was used to determine significant differences ranking among the mean values at  $P < 0.05$ .

## **RESULTS AND DISCUSSION**

### **Dietary fiber content of the tested materials**

Whole meal wheat, cooked lupin, cooked fenugreek, turmeric and vital gluten flour were analyzed for their total dietary fiber (TDF) contents and their soluble (SDF) as well as insoluble (IDF) fractions, the results are given in Table (1).

It is clear from data showed in Table (1) that fenugreek, lupin and turmeric flour were rich sources of dietary fibers and possessed the significant differences for TDF content (37.210, 23.150 and 20.20% on dry weight basis, respectively), of which the IDF represented the major fraction except turmeric flour (20.47 and 21.50 of TDF, respectively). While the highest amount of soluble form of dietary fiber (SDF) was found in turmeric

flour (19.80 %). Such results suggested that fenugreek, lupin and turmeric could be considered a good and inexpensive source of fiber content to be a suitable tool for flour and baked products enrichment. The fenugreek powder addition to the experimental diet in the form of dietary fiber, resulting in a higher fiber content in the experimental diet than that found in the control diet. The dietary fiber of fenugreek seeds is dispersed throughout the seed coat and is also found in the endosperm as reported by Madar and Stark (2002). The results of dietary fiber content of lupin flour (21.5 % and 2.45 % IDF and SDF, respectively) are in agreement with the results of Mohamed and Rayas-Durate (1995) who pointed out that lupin cotyledons contained 21.5 and 2.2% insoluble and soluble fiber, respectively. Therefore, while the hull contained 86.2 and 1% insoluble and soluble fiber, respectively, lupin could be used in existing or new products. Consequently, lupin can also be used in bread making, biscuits, pasta products, and a variety of other food products.

On the other hand, data presented in Table (1) showed that vital gluten contained the lowest amounts of total, soluble and insoluble dietary fiber compared to that found in whole meal wheat flour. Kahlon and Woodruff (2002) reported that the gluten is contained 1.90% of total dietary fiber 1.4 % insoluble dietary fiber and 0.5% of soluble dietary fiber (as dry matter basis).

**Table 1: Dietary fiber content of the tested materials (on dry weight basis).**

<b>Sample</b>	<b>Dietary fiber %</b>		
	<b>Insoluble(IDF)</b>	<b>Soluble(SDF)</b>	<b>Total(TDF)</b>
<b>Whole cooked lupin flour</b>	21.500 <sup>a</sup>	2.450 <sup>c</sup>	23.150 <sup>b</sup>

-Each value (an average of three replicates) within the same column, followed by the same letter is not significantly different at  $< 0.05$ .

### **Amino acids content of the tested materials and pan bread.**

The nutritive value of dietary protein is determined by the pattern and quantity of essential amino acids present of the tested materials. The presence of one or more specified of the essential amino acids in adequate amounts would increase the nutritive value of protein. The amino acid contents (g /100g protein) of the tested materials were determined and the results are shown in Table (2).

From the data in Table (2) it could be noticed that turmeric flour had lower quantities of isoleucine and lysine. Moreover, cooked lupin flour contained lower amounts of total sulfur amino acids while cooked fenugreek flour contained lower amounts of valine. On the other hand, gluten had lower quantities of lysine and threonine in relative

to the other tested materials. Whole meal wheat flour also, had lower amounts of lysine compared to the other tested materials. However, a significant variation was existed in the contents of some amino acids, particularly for valine and threonine.

The valine contents was varied from 2.72 gm / 100gm protein in turmeric flour to 4.50 gm /100 gm protein in gluten. Among the tested legumes, lysine, sulfur amino acids, serine, proline, glycine, arginine and glutamic acid were found to be rich in fenugreek, while isoleucine and lysine were found in appreciable amounts in turmeric among the different tested materials. Whole meal wheat and gluten were higher in total sulfur amino acids contents (methionine and cystine) than the other tested materials.

Glutamic acid was found to be the major non-essential amino acids in the tested samples, while maximum amount of proline was found in gluten. Total essential amino acids contents were the highest in gluten. On the other hand, legumes have been reported to contain adequate amounts of lysine, but are deficient in S-containing amino acids (methionine and cystine). However, Roccia *et al.* (2009) reported that the wheat flour is deficient in lysine. A common practice in breadmaking is to incorporate proteins in the product formulation to increase their nutritional value. Legume proteins are the major component of the diet of food producing animals and are increasingly important in human nutrition. Finally, the same data presented in Table (2) showed that the fenugreek flour contained highest amounts of tryptophan when compared to turmeric flour.

Data presented in Table (3) showed the mathematically amino acids content of 100gm of the tested pan bread. It could be concluded from such data that each mixture seemed to contain the same amount, with a slightly changes, of all the estimated amino acids. It was due to the variation of the ingredients in each mixture to prepare a complementary mixture containing the required amino acids with an adequate amount.

Data presented in Table (3) showed the amino acids content of manufactured pan bread of the suggested blends. The highest essential amino acids content was noticed in the tested blends pan bread, than that found in the control pan bread (prepared from whole meal wheat flour). Results in Table (3) showed that the amino acid contents of isoleucine, leucine, lysine and valine in WWG, WWGL, WWGT, WWGF, WWGFT, WWGLT and WWGFLT pan bread blends were higher than that found in pan bread from whole meal wheat flour. On the other hand, tryptophan content was higher in pan bread originated from whole meal wheat flour, vital gluten, turmeric and fenugreek flour than that found in all the other pan bread blends.

**Table 2: Amino acids content of the tested materials (calculated as g/100g protein).**

Amino acid	Whole meal wheat	Gluten	Lupin	Fenugreek	Turmeric
<b>Isoleucine</b>	3.28	3.40	5.15	3.64	1.12
<b>Leucine</b>	6.35	6.20	2.01	1.93	3.23
<b>Lysine</b>	0.44	0.31	3.4	4.90	1.35
<b>Methionine</b>	0.42	0.15	0.82	0.77	1.72

<b>Phenylalanine</b>	1.58	4.07	2.91	0.389	3.070
<b>Tyrosine</b>	2.85	3.49	3.95	5.280	6.340
<b>Threonine</b>	2.78	0.00	2.78	3.57	4.67
<b>Valine</b>	4.14	4.50	3.01	1.27	2.72
<b>Tryptophan</b>	0.72	0.75	0.60	1.25	0.35
<b>Total essential amino acids</b>	26.62	27.38	25.40	23.82	24.61
<b>Aspartic acid</b>	4.83	2.04	14.50	4.00	12.99
<b>Serine</b>	2.60	5.58	1.91	8.00	3.03
<b>Glutamic</b>	26.78	25.75	29.80	37.55	21.85
<b>Proline</b>	1.48	15.22	1.01	1.58	1.90
<b>Glycine</b>	4.88	3.32	4.02	6.12	3.67
<b>Alanine</b>	18.66	8.71	3.80	2.71	8.52
<b>Arginine</b>	3.09	9.44	6.095	9.66	7.66
<b>Histidine</b>	6.12	1.42	10.80	1.54	5.89
<b>Total amino acids</b>	95.06	97.86	97.33	94.98	90.12

Data presented in Table (3) showed also, that the calculated PER of manufactured pan bread could be divided into two groups. The first group included WWG, WWGT, WWGF and WWGL mixtures which had PER values less than 1.10. The second group included WWF, WWGFT, WWGLT and WWGFLT mixtures which had PER values more than 1.10. This variation in PER could be attributed to the variation of essential amino acids in the tested pan bread. However, WWGLT pan bread had the highest PER value when compared with other manufactured pan bread. Such results are due to its high amounts of lysine, phenylalanine and threonine. These results agreed with those of Doxastakis *et al.*, (2002) who reported that the lupin flours can be considered as an excellent choice for improving the nutritional value of bread.

**Table 3: Amino acids content of the pan bread (calculated as g/100g sample).**

#### Biological estimation of different tested blends.

It was of importance to estimate the impact of different tested diet types on some specific biological parameters (blood glucose, insulin levels, liver and kidney function). The values of blood glucose, GPT and GOT, alkaline phosphatase (ALP), total protein, albumin, serum uric acid, urea and creatinine of each rat group for zero time (initial period) and after adaptation period (where the rats fed on basal diet were nearly the same level).

#### - Effect of the different pan breads on blood glucose and insulin levels of nondiabetic and diabetic rats.

Blood glucose and insulin levels of the rat groups fed on the tested pan bread are presented in Table (4). The diabetic rats showed a range of 2.24-2.89 folds increment in the blood glucose after injection with alloxan. This increased of blood glucose after injection with alloxan may be due to that the alloxan may either increase the entrance rate of glucose into the blood stream from the liver (increased hepatic glycogenolysis or gluconeogenesis) or decrease the rate of glucose removal from the blood by tissues (decrease the storage and utilization). These influences might be due to the absence of an adequate amount of insulin. The blood glucose concentration was significantly higher in the diabetic rats fed on the basal diet (positive control) than of those diabetic rats fed on the tested pan bread (diabetic) as well as the nondiabetic rats fed on basal diet (negative control).

**Table4: Blood glucose level (mg/dl) and insulin level (mu/l) in serum of rat groups, fed on the tested diets.**

Groups*	After injection (3days)	Feeding period			Insulin level**
		15 day	30 day	45 day	
<b>Negative control</b>	95.0 <sup>h</sup>	97.0 <sup>j</sup>	95.0 <sup>j</sup>	93.0 <sup>l</sup>	0.525 <sup>b</sup>

\* Previously identified and listed in Materials and Methods of the current study.

\*\*At the end of experiment.

-Each value (an average of three replicate) within the same column, followed by the same letter are not significantly different at <0.05.

-Value of blood glucose was 84.0 and 95.0 at zero time and after adaptation period, respectively.

There were significant differences in serum blood glucose level in both negative control groups compared with the other diabetic rats groups. The decrease in blood glucose is due to the effect of dietary fiber from the tested materials. These results are agreed with Adam *et al.*, (2003) who reported that the dietary fiber intake, especially from whole grain sources, reduced the serum glucose level and lead to reduce the risk of coronary heart disease and diabetic. Such treatments containing fenugreek and turmeric flour reduced the serum blood glucose. These results agreed with Patil *et al.* (2009) who found that the mean fasting blood glucose in the diabetic untreated group (control positive) was  $280 \pm 8.33$  mg/dl after 21 days of diabetes induction. In the normal health group this value was  $76 \pm 2.59$  mg/dl. In comparison with the positive control group, the group which consumed fenugreek extract showed significantly lower mean fasting blood glucose  $141.83 \pm 9.04$  mg/dl ( $P < 0.05$ ) after 21 day of induced of diabetes. These results confirmed with Kumar *et al.* (2005) who reported that the beneficial effect of fenugreek seed mucilage is due to some of the bioactive compounds present in the mucilage, including 4-hydroxy isoleucine. 4-Hydroxy isoleucine is a novel amino acid known to facilitate insulin secretion. The effect of spent turmeric in rats may be mainly due to the high amount of dietary fiber, which would facilitate a slower absorption of glucose in the gastrointestinal tract. Results in Table (4) revealed that, within the diabetic rat groups, the whole meal possessed lower serum glucose content than that of positive control groups, respectively.

Kim *et al.*, (2006) reported that alloxan induces “chemical diabetes” in a wide variety of animal species by damaging the insulin secreting pancreatic  $\beta$ -cell, resulting in a decrease in endogenous insulin release. Therefore, Table (4) concerned the plasma insulin of the different groups at the end of the present study. It was found that the insulin level was significantly higher in diabetic rats fed on the WWGFLT and the negative control, while it was significantly lower in the positive control. The results showed that serum glucose level was increased, whereas serum insulin was decreased in the diabetic rats groups. It could finally concluded that the whole meal diet and the other blends containing fenugreek and turmeric flour could be used as a serum glucose controller via the lower sugar content either be decrease the glucose level or increase the insulin level in the serum. Such treatments contained fenugreek and turmeric flour may potentiate the insulin secretion by 4- hydroxyisocucine in fenugreek seed and this effect of turmeric could be done by antioxidant and dietary fiber influence. Also, demonstrated that the in vitro amino acid 4-hydroxyisocucine in fenugreek seeds, increased glucose-induced insulin release in human and rat pancreatic islet cells. This amino acid appeared to act only on pancreatic beta cells, since the levels of somatostatin and glucagon were not altered. Chattopadhyay *et al.*, (2004) reported that, both turmeric and curcumin decrease blood sugar level in alloxan-induced diabetes in rat. Curcumin also decreases advanced glycation end products

induced complications in diabetes mellitus. Srinivasan (2005) mentioned that, daily intake of curcumin (coloring principle of turmeric) not only reduced the fasting sugar level, but also lowered the dosage of insulin needed for normoglycemia. It was observed that the rhizome of turmeric showed blood glucose lowering activity in alloxan diabetic rats.

Vijayalakshmi *et al.*, (2009) reported that the role of spent turmeric in the management of diabetes could be mainly due to the presence of dietary fibers. Both soluble and insoluble dietary fibers contribute to the management of diabetes. Both of them not only serve in the slow absorption of glucose (in the gastrointestinal tract) but also are fermented by the microflora present in the colon, which release short chain fatty acids. In recent years, beneficial effect of short-chain fatty acids and that of butyric acid are receiving much attention in the improvement of disease conditions like cancer and diabetes.

\* Previously identified and listed in Materials and Methods of the current study.

-Each value (an average of three replicates) within the same column, followed by the same letter are not significantly different at <0.05.

Value of GOT was 25.0 and 30.0 at zero time and after adaptation, respectively.

Value of GPT was 40.0 and 39.0 at zero time and after adaptation, respectively.

Value of Alkaline phosphatase was 25.0 and 23.0 at zero time and after adaptation, respectively.

#### - Effect of the tested pan bread on liver functions of nondiabetic and diabetic rats

##### - Effect of the tested pan bread on GOT, GPT and ALP

The results in Table (5) showed that serum GOT, GPT and ALP activities were significantly increased in diabetic rats after injection with alloxan when compared with the nondiabetic rat. These results agreement with Eidi *et al.*, (2007) who reported that the serum GOT and GPT levels increased in diabetic control rats when compared with nondiabetic control rats. There was a decrement of liver function, serum GOT, GPT and ALP as a result of feeding the rats on the tested pan bread in the 45 days *in vivo* experimental assay, as shown in Table (5). Data presented in Table shows that there were significant changes in impact of all the tested diets under investigation on both of serum GOT, GPT and ALP tests either in diabetic control or healthy (normal rats). Serum GOT was the lowest in all diabetic rats fed on pan bread prepared from fenugreek, lupin and turmeric and pan bread from fenugreek and turmeric. GPT was lower in diabetic rats fed on WWG, WWGLT, WWGF and WWGT pan

bread blends compared with values of the other groups. There was an increment in liver function, serum GOT and GPT, as a result of feeding the rats on the basal diet (positive control). The decrement in GOT and GPT may be due to the decreased in serum glucose level which inhibited the glycogenesis (conversion of amino acids into sugars). These results are in agreement with Abbas (2008).

These findings confirmed, also, the healthy roles of legumes and whole meal in lowering the GOT and GPT activities as reported by Eidi *et al.*, (2007). It was found that, an increase in these enzyme activities reflects active liver damage. Inflammatory hepatocellular disorders result in extremely elevated transaminase levels. Administration of the fenugreek seeds extract (0.25 and 0.5 g/kg body wt) and glibenclamide (600 $\mu$ g/kg) similarly decreased GOT and GPT levels when compared with control diabetic rats. Data presented in (Table 5) showed that alkaline phosphatase activity in nondiabetic rats fed on basal diet and diabetic rats fed on WWGFLT pan bread blend was significantly lower than that found in the other rats groups fed on the suggested blends. The significant highest activity in ALP was noticed in case of diabetic rats fed on basal diet (positive control). There was, also, an improvement in ALP of in all groups relative to diabetic control. These results agreed with Mahmoud *et al.*, (2007) who reported that the feeding with legumes to alloxanized diabetic rats was characterized by a significant inhibition in ALP activity.

**Table 6. Albumin and total protein concentration and(g/dl) in rat groups fed on the tested diets.**

Groups*	Albumin concentration (g/dl)		Total protein (g/dl)	
	After Injection (3days)	45 days	After Injection (3days)	45 day
<b>Negative control</b>	2.31 <sup>a</sup>	4.93 <sup>a</sup>	4.93 <sup>a</sup>	7.53 <sup>f</sup>
<b>Positive control</b>	1.71 <sup>d</sup>	3.52 <sup>g</sup>	3.14 <sup>g</sup>	5.94 <sup>i</sup>
<b>WWF</b>	1.92 <sup>b</sup>	3.54 <sup>g</sup>	3.34 <sup>f</sup>	6.53 <sup>h</sup>
<b>WWG</b>	1.82 <sup>c</sup>	4.23 <sup>d</sup>	3.35 <sup>f</sup>	7.10 <sup>g</sup>

<b>WWGFLT</b>	1.85 <sup>c</sup>	4.97 <sup>a</sup>	3.65 <sup>d</sup>	8.75 <sup>a</sup>

\* Previously identified and listed in Materials and Methods of the current study.

-Each value (an average of three replicates) within the same column, followed by the same letter are not significantly different at <0.05.

Value of albumin concentration (g/dl) was 1.50 and 2.10 at zero time and after adaptation, respectively.

Value of total protein (g/dl) was 4.52 and 4.90 at zero time and after adaptation, respectively.

#### **- Effect of the tested pan bread on albumin and total protein concentration of nondiabetic and diabetic rats**

Data presented in Table (6) showed that a significant lower in total protein and albumin content was found among the rat groups serum after injection with alloxan. In this study, the decrease in serum protein may be due to increasing the excretion of nitrogen in urine and protein synthesis. The present results are in a good agreement with Venkateswamy *et al.*, (1993) who proved that there was a marked decrease in the serum protein content of alloxanized diabetic rats when compared with that of the normal control animals. These effect may be due to the increasing in the excretion of nitrogen in urine alloxanized diabetic rats and increased the activity of transaminases. After 45 days feeding, the protein level was significantly lower in the diabetic rats fed on the basal diet (positive

control) than those diabetic rats fed on the tested pan bread, nondiabetic fed on basal diet (negative control). There were significant differences in serum total protein among the diabetic rats fed on the WWGFLT, WWG, WWGT and WWF pan bread.

Table (6) showed that, after feeding the rats on the tested pan bread, it was found that there was a significant increment in serum albumin content in diabetic rats at the experimental feeding period end (45 days). It was also found that there were significant differences in serum albumin in normal rats and diabetic rats at each feeding stage(after and after adaptation) and within the tested period. The present results showed that serum albumin increased in diabetic rats fed on the tested pan bread when compared with diabetic control (positive control) rats. These results agreed with that found by Mahmoud *et al.*, (2007) who found that the feeding with legumes to alloxanized diabetic rats was characterized by improvement in protein and albumin.

#### - Effect of the tested pan bread on kidney function of nondiabeti and diabetic rats

It is of great importance to estimate the renal function which includes the determination of serum uric acid, urea and creatinine to evaluate disorders which may be occurred as a result of alloxan injection (El-Abd *et al.*, 2007).

The results in Table (7) indicated that alloxan injection caused a highly increase in serum uric acid, urea and creatinine values. The present results showed that serum urea, uric acid and creatinine increased in diabetic control rats when compared with nondiabetic control rats. This may be due to the protein glycation in diabetes may lead to muscle wasting and increased release of purine, the main source of uric acid, as well as increased activity of xanthine oxidase. These results confirmed by Eidi *et al.*, (2007) who showed that serum uric acid, urea, and creatinine levels were increased in diabetic rats. This may due to metabolic disturbance in diabetes reflected in high activities of xanthine oxidase, lipid peroxidation, and increased triacylglycerol and cholesterol levels. Data presented in Table (7) shows that there were significant changes in impact of all the tested diets under investigation serum uric acid, urea and creatinine amounts either in diabetic or healthy (normal rats). Serum uric acid was significantly decreased in diabetic rats fed on WWG, WWGF, WWGFT, WWGFLT and WWF followed by WWGLT and WWGT at the experimental period (45 days) end compared with that of diabetic (whole meal wheat and positive control) rat groups. Also, results in the same Table showed that, feeding on pan bread samples prepared from the tested materials flour led to a serum significantly decrement in urea amount in the diabetic rats group fed on the WWGFLT and nondiabetic rats group fed on the basal diet or whole meal wheat bread for 45 days compared with that of the positive control. These results agreed with Rubio *et al.*, (1998) who mentioned that, there is an inverse correlation between the biological value of foodstuff and blood urea concentration in rats. Because the urea is one of the main end products of protein catabolism in mammals, high plasma values are associated with disturbances in protein metabolism and increased protein degradation, which can finally result in a high loss of N through the urine.

However, data in Table (7) showed that the serum creatinine was significantly decreased in diabetic rats fed on WWGFLT and WWGFT followed by WWGLT for the experimental period (45 days) compared with that of diabetic (whole meal wheat, positive control) rat groups. These results agreed with Yadav *et al.*, (2004) who showed the presence of lipid deposits in the kidney of diabetic human and experimental animals and they have proposed that these deposits may play an important role in the pathogenesis of diabetic kidney disease.

From aforementioned results in Table (7) it could be concluded that fenugreek flour decreased the serum uric acid, urea, and creatinine levels in diabetic rats. These results are concurrent with Eidi *et al.*, (2007) who reported that the fenugreek seeds significantly decreased serum urea, uric acid, and creatinine when compared with control diabetic rats. Elevation of the serum urea and creatinine, as significant renal function markers, are related to renal dysfunction in diabetic hyperglycemia. However, Tharanathan and Mahadevamma (2003) showed that a high fiber diet seemed to lower the urinary phenol and cresol concentrations in humans. It has been suggested that the presence of undigested carbohydrates stimulates rapid growth of colonic bacteria, which can act as 'nitrogen sinks' for using remaining protein and protein metabolites for their metabolism and growth. Kumar *et al.*, (2005) also, mentioned that the water extract of fenugreek seeds is used in the management of diabetes and is known to improve kidney function during diabetes.

Finally, it is recommended to utilize whole meal flour, fenugreek, lupin and turmeric flour to prepare healthy diets to deal with diabetic status and control of some biological parameters.

**Table 7. Uric acid, urea and creatinine (mg/dl) in rats groups fed on the tested diets.**

Groups*	Uric acid (mg/dl)		Urea (mg/dl)		Creatinine level (mg/dl)	
	After injection (3days)	45 day	After injection (3days)	45 day	After injection (3days)	45 day
Negative control	3.47h	3.01h	35.23j	20.25j	0.76e	0.62g
Positive control	6.13a	5.70a	54.29a	40.14a	1.52b	1.4a
WWF	5.18d	3.91d	45.16i	34.18c	1.46c	1.38b
WWG	4.27g	3.14g	50.30f	32.51d	1.53b	1.37b
WWGL	5.87c	4.80b	51.32c	32.32e	1.51b	1.32d
WWGF	4.56f	3.16g	50.22h	31.48f	1.55a	1.30d
WWGT	5.19d	4.09c	50.28g	35.51b	1.50b	1.35c
WWGLT	4.83e	4.09c	50.78d	31.22g	1.42d	1.25e
WWGFT	5.92b	3.29f	50.63e	30.49h	1.48c	1.22e
WWGFLT	4.58f	3.82e	53.45b	26.21i	1.44d	1.19f

\* Previously identified and listed in Materials and Methods of the current study.

-Each value (an average of three replicates) within the same column, followed by the same letter are not significantly different at <0.05.

Value of uric acid (mg/dl) was 3.90 and 3.70 at zero time and after adaptation, respectively.

Value of urea (mg/dl) was 37.10 and 36.3 at zero time and after adaptation, respectively.

Value of creatinine(mg/dl) was 0.85 and 0.80 at zero time and after adaptation, respectively.

## Scleral Fixation Intraocular lenses

<sup>1</sup>Ayman Shouman, <sup>1</sup>Mohamed Marzouk, <sup>1</sup>Hesham Ali and <sup>1</sup>Ehab Zakzook

<sup>1</sup>Ophthalmology Department, Research Institute of Ophthalmology, Giza

[shoumannaes@yahoo.co.uk](mailto:shoumannaes@yahoo.co.uk)

**Abstract:** Background: The 1ry indication for scleral fixation of intraocular lenses (IOL) is dislocation as a principal complication of cataract surgery. Inadequate capsular support is the most common cause of IOL dislocation. Other indications include traumatic phakic lens dislocation (cataractous or clear), surgically aphakic eyes or anterior chamber IOL with complications (persistent hyphema, uveitis). Methods: 20 eyes of 20 patients were done, surgery was done only when the IOL was dislocated peripheral to the visual axis and was causing symptoms of visual loss sufficient to interfere with the patient's activities of daily living, or patients who were left aphakic for a 2ry implantation procedure. A modification of the technique was done which made the procedure faster and preserved the surrounding conjunctiva. Results: Best corrected visual acuity (BCVA) preoperatively ranged from 1/60 -6/60 and postoperatively between 6/60 – 6/6. Statistical analysis of the logarithm of the minimum angle of resolution (LogMAR) between the preoperative and postoperative visual acuity revealed significant improvement ( $p \leq 0.05$ ). Intraoperative complications included one case of accidental iris injury, two cases of mild vitreous hemorrhage, two cases of moderate vitreous hemorrhage. Early postoperative complications included pupillary block. Midterm post operative complications occurred in one case with the occurrence of cystoid macular edema. Conclusion: Scleral fixation of IOL is a safe procedure with minimal complications, but needs surgical skills to be managed optimally.

[Ayman Shouman, Mohamed Marzouk, Hesham Ali and Ehab Zakzook. **Scleral Fixation Intraocular lenses.** Journal of American Science 2010;6(11):680-687]. (ISSN: 1545-1003).

**Key words:** Scleral fixation, Intraocular lenses, Aphakia, IOL dislocation.

### Introduction

The indication for intraocular lens (IOL) scleral fixation is widely variable. The 1ry indication is IOL dislocation as a principal complication of cataract surgery, with early reports of 13% rate of IOL dislocation<sup>(1)</sup>. Inadequate capsular support is the most common cause of IOL dislocation and most commonly manifests in the early postoperative period<sup>(2)</sup>. Fixation of intraocular lenses in cases of insufficient or no capsular support is challenging and requires a large armamentarium of techniques to resolve different situations<sup>(3-24)</sup>. Other indications include traumatic phakic lens dislocation (cataractous or clear), surgically aphakic eyes or anterior chamber IOL with complications (persistent hyphema, uveitis). The reported incidence of dislocation of rigid posterior chamber IOLs (PCIOLs) is from 0.2% to 2%<sup>(25,26)</sup>. Management decisions are based on the clinical features of every individual case and surgeon preference. Management options described for dislocated PCIOLs include IOL repositioning with or without scleral fixation sutures (depending on residual capsular support) and IOL removal (with or without reimplantation of the same or alternative

IOL)<sup>(19,27,28)</sup>. IOL repositioning without scleral fixation suture is generally preferred technique if there is adequate capsular support. In the absence of adequate capsular support, the dislocated PCIOL may be sutured to the sclera or exchanged. The scleral suture fixation technique requires undamaged open-loop haptics. A PCIOL may be exchanged for a sutured PCIOL or an anterior chamber IOL (ACIOL)<sup>(29,30)</sup>. Dislocation of the phakic human lens is uncommon but serious complication, as it requires sophisticated techniques to remove safely, especially if it is dislocated in the vitreous cavity. Dislocation of a PCIOL into the vitreous cavity is another uncommon but serious complication with numerous techniques for its management<sup>(3,5,6,13,14,17,18,31-41)</sup>. During surgical intervention, an important consideration is whether to remove, reposition, or exchange the dislocated PCIOL after performing a pars plana vitrectomy. If adequate capsular support is found to be present, the same intraocular lens may be positioned into the ciliary sulcus. Alternatively, the dislocated PCIOL may be sutured to the sclera if capsular support seems inadequate. If the PCIOL is removed, the patient may be left aphakic if intraocular lens implantation is contraindicated for

any reason. However, when there is no contraindication to lens insertion, the patient may receive either a sutured PCIOL or an anterior chamber intraocular lens (ACIOL). Historically, ACIOLs, especially rigid and closed-loop lenses, have been associated with a higher rate of complications compared with PCIOLs<sup>(42)</sup>. These complications can lead to poor visual results and include bullous keratopathy, glaucoma, uveitis, hyphema, and cystoid macular edema. Newer, open-loop ACIOL designs, however, seem to have a lower rate of complications<sup>(43)</sup>. In case of ACIOL complications, exchange of the anterior chamber IOL to a sclerally fixated PCIOL is done. Previous studies describing the visual results in subjects who underwent intraocular lens exchange have reached conflicting conclusions. Some studies have found similar final visual results between eyes that received an ACIOL and those that received a PCIOL<sup>(44)</sup>, whereas other studies have found better postoperative visual results in eyes that received a PCIOL<sup>(45)</sup>.

### **Patients and Methods**

The study cohort included 20 eyes of 20 patients. Preoperative data included age, gender, type & duration of dislocation (surgery, trauma) or aphakia, coexisting ocular diseases, preoperative best-corrected visual acuity (BCVA), preoperative type of IOL, category of IOL dislocation (in the bag), and previous surgery including pars plana vitrectomy, sclera buckling procedure, or neodymium:yttrium-aluminium-garnet (Nd:YAG) capsulotomy. Surgery is recommended only when the IOL was dislocated peripheral to visual axis and was causing symptoms of visual loss sufficient to interfere with the patient's activities of daily living, or patients who were left aphakic for a 2ry implantation procedure. The scleral suture fixation technique for acrylic IOLs was previously reported<sup>(18, 46)</sup>. A modification of the technique was done which made the procedure faster and preserved surrounding conjunctiva (fig. 1). All surgeries were done by one surgeon (1<sup>st</sup> author A.S.).

### **Scleral fixation technique:**

We followed the technique reported by Richard Hoffmann (fig 1) where two limbal vertical incisions half corneal thickness 2.5 mm in length were done at 1:30 and 7:30 meridians. A 2.6 mm crescent knife was used to create a reversed sclera pocket 2.5mm backwards across the limbus into the sclera subconjunctivally. Polypropylene sutures (10-0) on a straight needle were introduced 1 mm

posterior to the limbus through the wall of the scleral pocket traversing the conjunctiva, sclera pocket and into the eye. The needle is passed across the eye behind the iris and delivered from the opposite side 1 mm behind the limbus through guidance by a 25 G needle introduced through the sclera pocket of the other side 180 degrees away. This needle is again introduced into the eye 1mm adjacent to its exit to pass to the opposite side in the same manner previously described. Finally, we have two 10/0 threads passing across the eye and 2 separate ends on either side of the limbus. A two step corneal incision 7mm is done. The two 10/0 threads are retrieved through the wound by a sinsky hook. Every two ends are tied to the hole on the haptic of sclera fixation PMMA 6.50 optic IOL, whenever the diopteric power was available or on the haptics if not. The two ends were pulled to centralize the IOL. The corneal wound is closed with 3 interrupted 10/0 nylon stitches. The 2 10/0 prolene threads on either side were retrieved from the corneal side of the scleral pocket and tied to one another on either side separately and buried in the sclera pocket.

In vitreous dislocated IOLs; 3 port 20 Gauge pars plana vitrectomy was done in the usual manner with perflurodecalin floatation of the dislocated IOL and retrieval with serrated vitrectomy forceps and into the anterior chamber above the iris, where it is removed through corneal incision. In cases where there was traumatic dislocation of the cataractous lens, the same former technique was done with removal of the lens by phacofragmatome. In cases where total vitrectomy was performed, peripheral retinal indentation was done with intraocular laser treatment to any suspicious peripheral tears and fluid air exchange was done with the eye left with air tamponade with no traction on the retina. In case of surgical aphakia, conjunctiva was not opened and anterior chamber vitrectomy was done either through two corneal side ports or through the main corneal wound. In cases of anterior chamber IOL subluxation, anterior vitrectomy was done through 2 corneal side ports and IOL was fixated with an anteriorly opened needle introducing the 10/0 prolene through the sclera pocket and retrieving it in the manner described earlier. The anterior chamber iris captured IOL was removed through corneal incision with anterior vitrectomy. All were followed by sclera fixation of a 6.5 optic Polymethylmethacrylate (PMMA) IOL. Visual acuity was converted to the logarithm of minimum angle of resolution for statistical analysis.

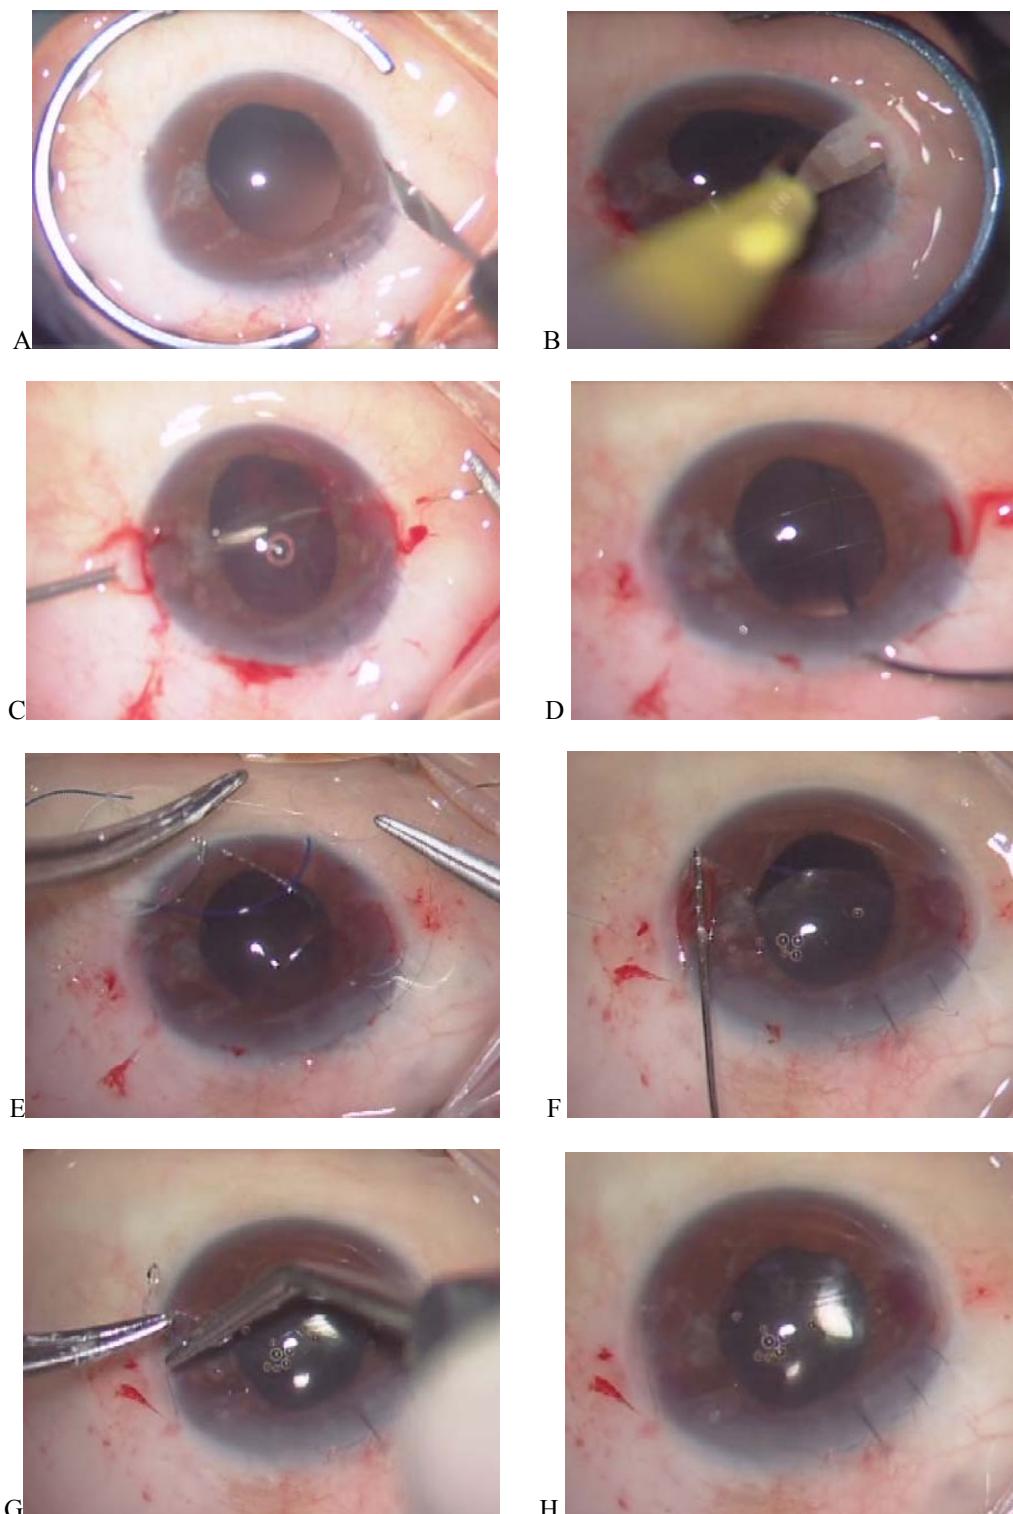

Figure1: Steps of scleral fixation: A- Limbal incision. B- Tunnel dissection. C- 10/0 prolene introduction and retrieval. D- 10/0 prolene thread retrieval. E-Haptic tying. F- 10/0 prolene pocket retrieval. G- 10/0 prolene tying and embedding in the sclera pocket. H- Final picture with no conjunctival opening.

### Statistical analysis:

The mean differences in paired designs were applied using paired t-test to analyze the differences in logMAR of visual acuity in the collected sample of this study at a confidence interval 95% and significance level 0.05.

### Results:

#### Preoperative Characteristics

The study cohort included 20 eyes of 20 patients (8 males, 12 females), with mean age of the patients was 52.9 years (range, 25-70 years; (Table 1). There were 11 (55%) right eyes. The median interval from 1<sup>ry</sup> procedure to the present procedure is 66 days (range, 14–120 days). The indications for scleral fixation were vitreous IOL dislocation during the 1<sup>ry</sup> procedure in 3(15%) eyes; surgical aphakia without enough capsular support for 1<sup>ry</sup> IOL implantation in 9 (45%) eyes; Traumatic cataractous phakic lens vitreal dislocation in 5 (25%) eyes; IOL subluxation with the optic bisecting the pupil and peripheral anterior synechiae and residual cortical matter in 2 (10%) eyes; Anterior chamber captured IOL suffering from chronic iritis in one (5%) eye. The preoperative mean BCVA logarithm of minimum angle of resolution was 1.67 (range of Snellen visual acuity, 1/60 – 6/60). There were 2 (10%) polymethyl methacrylate (PMMA) IOLs, 3 (15%) one piece acrylic IOLs, and 1 (5%) ACIOLs (Table 1).

Table 1. Baseline Characteristics

No. of patients	20
Eyes	20
Gender (%)	Female 12 eyes 60 %
Age (yrs)	Mean 52.9 Range 25–70
Right	11eyes 55 %
Types of dislocated IOL (n = 6)	
PMMA 1-piece	2 (10 %)
1-Piece acrylic IOL	3 (15 %)
ACIOL	1 (5 %)
Preoperative BCVA	
Mean logMAR	1.67
Range (Snellen)	1/60 – 6/60
Interval from IOL implantation to dislocation	Range 14 day to 120 days

ACIOL \_ anterior chamber intraocular lens; BCVA \_ best corrected visual acuity; IOL \_ intraocular lens; logMAR \_ logarithm of minimal angle resolution; PMMA \_ polymethylmethacrylate.

The median follow-up after dislocated IOL management or implantation was 18 months (range, 11months-24months). The postoperative mean BCVA logarithm of minimum angle of resolution was 0.24 (range of Snellen visual acuity, 6/60 – 6/6). Intraoperative complications included one case of accidental iris injury during anterior vitrectomy (Table 2). Two cases of mild vitreous hg which resolved after 2 weeks of bed rest (Fowler position). Two cases of moderate vitreous hg which mandated doing total vitrectomy during the procedure. Early postoperative complications included pupillary block with elevation of the IOP which resolved completely after a course of mydriatics. Mid term post operative complications occurred in one case with the occurrence of cystoid macular oedema (Irvine gass syndrome).

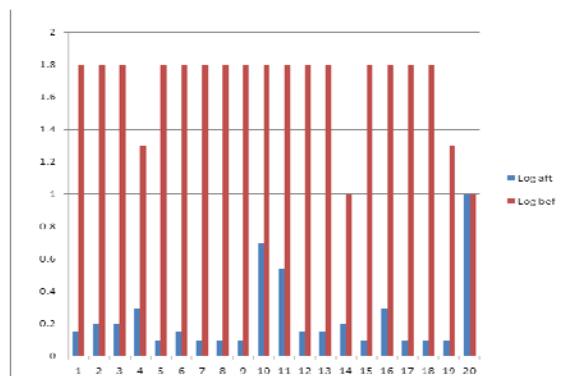

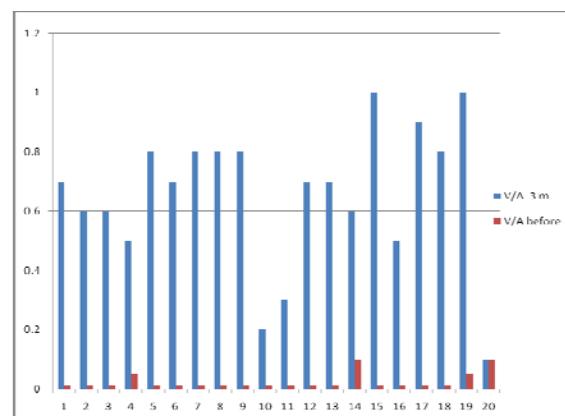

Figure2: graph of visual acuity pre and postoperative by 3 months, Figure3: graph of visual acuity LogMar conversion pre and postoperative by 3 months.

Best corrected visual acuity (BCVA) preoperatively ranged from 1/60 -6/60 and postoperatively between 6/60 – 6/6 (Figure 2, 3). Statistical analysis of the logarithm of the minimum angle of resolution (LogMAR) between the

preoperative and postoperative visual acuity revealed significant improvement ( $p \leq 0.05$ ).

Table 2: complications.

Complications	
Intraoperative	accidental iris injury (n:1)
	Mild vitreous hemorrhage (n:2)
	Moderate vitreous hemorrhage (n:2)
	Retinal tears (n:2)
Postoperative	
Early	Papillary block (n:1)
Midterm	Cystoid macular oedema (n:1)

### **Discussion:**

Previous studies have not definitively set surgical indications and optimal timing for management of dislocated IOLs; neither did this study. The management approach depends on surgeon preferences and individual case specifics, including integrity of capsule remnants, type of IOLs, and coexisting ocular pathology<sup>(47-50)</sup>. The surgical approach in this series was influenced by the specialty (vitreoretinal) and the preferences of the operating surgeon (AS), but standardization was established regarding the scleral fixation itself, while the remainder of the procedure was determined by the case pathology and operative circumstances. The stability and centralization of the sclerally fixated IOLs in this study were excellent during the follow up period with no rotation or subluxation. The visual acuity significantly improved postoperatively. Postoperative retinal detachment has been reported in 3%<sup>21</sup> to 14%<sup>10</sup> of cases. In the current study, postoperative retinal detachment didn't develop in any case postoperatively. In cases where total vitrectomy was performed, peripheral retinal indentation was done with intraocular laser treatment to any suspicious peripheral tears and fluid air exchange was done with the eye left with air tamponade with no traction on the retina. Knot exposure, intraocular hemorrhage, trans-scleral suture fistulas, and endophthalmitis have been reported with transscleral sutures, but none with the present technique. The scleral pocket technique done minimized this incidence. Intraoperative and postoperative intraocular hemorrhage is usually self-limited, with two cases resolved after 2 weeks but 2 (10%) patients received vitrectomy during the scleral fixation owing to moderate nature of the hemorrhage, which was related to the transscleral suture passes. Cystoid macular edema occurred in one case and was treated accordingly. Recent case studies of in-the-bag IOL dislocation have suggested predisposing factors

of pseudoexfoliation, uveitis, trauma, status after vitrectomy, and long axial length<sup>(27,33,48,51-59)</sup>. Postoperative retinal detachment occurred more commonly with in-the-bag IOL dislocation compared with extracapsular dislocation, but none in this study. Intraoperative retinal breaks were encountered in 2 eyes; 10% in this study during the course of vitrectomy and were treated with intraocular laser. Suturing of a dislocated PCIOL to the sclera could be technically demanding, potentially resulting in an increased number of intraoperative and postoperative complications such as intraocular hemorrhage, retinal tears, and retinal detachment, with a long-term risk of lens rotation, as well as endophthalmitis<sup>(36,48,60,61)</sup>. Repositioning a dislocated PCIOL into the ciliary sulcus is easier and less traumatic than suturing a lens into the sclera, however, there is the possibility of postoperative lens dislocation because of inadequate capsular support<sup>(35)</sup>. Finally, although technically easier to place, ACIOLs may be associated with a higher long term risk of corneal decompensation, glaucoma, and uveitis<sup>(42,43,62)</sup>. In contrast, PCIOLs have a long-term safety record in eyes with other ocular diseases such as glaucoma, uveitis, and diabetic retinopathy<sup>(63,64)</sup>. This series is rather few, but it adds to the belief of the safety and stability of sclerally fixated IOLs.

# Technological Properties of some Egyptian New Wheat Varieties

Ahmed M. S. Hussein, Mohie M. Kamil and Gamal H. Ragab

National Research Centre, Food Technology Department, Dokki, Cairo, Egypt  
email: [ResearchTeamMMK@yahoo.com](mailto:ResearchTeamMMK@yahoo.com)

**Abstract:** Whole meal and flour 72% of Gemmeiza 7, Gize 168, Sohage 3 and Sakha 93 wheat varieties were evaluated to produce pan bread, pasta and biscuits. Pan bread of whole meal wheat varieties had higher contents of moisture, protein, fat, ash and fiber than wheat flour 72% of the same varieties. Pan bread of Sakha 93 characterized with its higher baking quality (weight, volume and specific volume) than pan breads of other varieties. Crust color of pan bread slightly affected with whole-meal wheat varieties, where its color score maximized in Sakha 93 (7.7) and Sohage 3 (6.7). This result agreed with the obtained color parameter of Hunter, where lightness (L) maximized to 55.95 and 49.79 in pan bread crust of Sohage 3 and Sakha 93, respectively. Pasta characterized with its higher protein (13.12%), fat (2.59%) and crude fiber (2.82%) in case of using whole meal of Sohage 3, Giza 168 and Gemmeiza 7 varieties, respectively. Pasta cooking quality ranked first in case of using Sohage 3 whole meal, where its weight increase, volume increase and cooking loss reached to 265%, 305.3% and 8.3%, respectively. Pasta color parameter showed that, wheat flour 72% and whole meal of Sakha 93 characterized with its higher lightness (L). Sensory evaluation showed that, pasta of wheat flour 72% accepted slightly in appearance and color if compared with whole meal pasta of the same variety. In addition, there were no significant difference between pasta of wheat flour 72% and whole meal in flavor, tenderness and stickiness. Biscuit of whole meal characterized with its higher content of protein, fat, ash and crude fiber than wheat flour 72%. Whole meal biscuit of Sohage 3 characterized with its higher protein (12.13%), fat (31.0%) and ash (2.51%) contents; and lowest carbohydrate content (52.18%). Biscuit of Sakha 93 variety (whole meal or flour 72%) was higher in baking quality. Hunter color parameter and sensory evaluation showed that, biscuit of whole meal varieties was slightly darker than biscuit of wheat flour 72% varieties. In addition, biscuits flavor, taste, texture, appearance and overall acceptability of wheat flour 72% not affected significantly in case of using whole meal flour of the same variety.

[Ahmed M. S. Hussein, Mohie M. Kamil and Gamal H. Ragab. Technological Properties of some Egyptian New Wheat Varieties. Journal of American Science 2010;6(11):688-699]. (ISSN: 1545-1003).

**Keywords:** Egyptian wheat varieties – technological properties - Pan bread – Pasta – Biscuit - whole meal – wheat flour 72%.

## INTRODUCTION

In Egypt, there is a big gap between wheat production and consumption. Therefore, National Program for Wheat Research developed new wheat varieties characterized with its higher yield and persist pests, i.e. Gemmiza 7, Giza 168, Sohag 3 and Sakha 93 (**Anon., 2005**). The importance of wheat is mainly due to its nutritive value and the fact that its seed can be ground into flour, semolina, etc., which form the basic ingredients of bread and other bakery products, as well as pastas.

Milling of wheat has two important purposes, one is to remove the bran and the other is to reduce the endosperm to small and fine particles. Such process decrease the nutritive value of wheat, so several researchers (**Collins et al., 1983; Finney et al., 1985; Jenkins et al., 1988; Lai et al., 1989a; Mugford, 1993; Shouk, 1996 and Czerny and Schieberle, 2002**) studied the possibility of using whole meal grains (100%) in several products to

utilize from its bran and germ that contain several healthy and nutrient components, furthermore, maximize the yield of flour to reduce the big gape between wheat production and consumption in Egypt.

The differences usually occurred in the wheat flour products depend on the wheat variety (hard or soft wheat), rate of flour milling and particle size. On the other hand, whole meal flour contains the whole of the product derived from the milling of cleaned wheat. Bread can only legally be described as whole meal bread if the flour used in its manufacture is whole meal flour, and no other flour is added. Production of whole meal bread, which is produced from whole meal grains (100%) should reduce bread making cost.

This research aimed to evaluate processing quality of such new varieties to produce some important wheat products, i.e. bread, pasta and biscuit.

## Material and Methods

### Materials

Wheat grains varieties of Gemmeza 7, Giza168, Sohage 3and Sakha93 were obtained from Field Crops Department, Agricultural Research Centre, Ministry of Agriculture, Giza, Egypt. Shortening, sugar, salt and sodium bicarbonate were obtained from Egyptian local market.

### 1. Analytical methods

Moisture, ash, crude protein, fat and crude fiber contents of wheat products were determined according to the methods outlined in AOAC (2000), while carbohydrates were calculated by difference as mentioned by Tadrus (1989).

### 2. Statistical analysis

All results were evaluated statistically using analysis of variance as reported by McClave and Benson (1991).

### 3. Methods of Processing:

Wheat grains varieties were manually cleaned, tempered to 14% moisture content, then milled using Quadrumat Junior flour mill. The obtained flour represent whole flour mill (100% extraction), then sieved to obtain flours of 72% extraction.

#### 3.1 Preparation of Pan Bread

Pan bread baking carried out as described by Lazaridou *et al.* (2007) as follows: Firstly, yeast dissolved in warm water (35°C), then mixed and kneaded with flour, salt (1.5%) and sugar (1%). Then dough fermented at 30°C/30 min in a fermentation cabinet under 80-85% relative humidity. after which, dough was placed in the pan (150 g/piece) and kept under the same fermentation condition for 45 min. Bread dough loaves were baked at 240 °C for 20–25 min in an electric oven (Mondial Formi, 4T 40/60, Italy), then subjected to steam for 10 sec to enhance the browning process of bread. The obtained pan bread packed in a polyethylene bags and stored at room temperature for evaluation and analysis.

#### 3.2 Preparation of Biscuits

Tow type of biscuits were prepared, i.e. biscuit of whole meal flour (100%) and traditional biscuit of wheat flour 72% extraction. Biscuit were prepared according to the method of AACC (2000) by using the following formula: wheat flour 100% or 72% extraction (100 g), sugar (50 g), shortening (28 g), salt (0.93 g), sodium bicarbonate (1.11g), 14.66 ml of dextrose solution (5.93%).

#### 3.3 Preparation of Pasta:

Pasta samples were prepared in Food Technology Department, National Research Centre,

Cairo, Egypt, according to the method of AACC (2000) by using Pasta Matic 1000 Simac Machine Corporation, Milano, Italy. Pasta hydrated for 15 min under atmospheric air, dried in a cabinet dryer at 40°C for 14 hrs, then cooled at room temperature, packed in polyethylene bags and kept at room temperature for analysis.

### 4. Baking quality of Pan Bread and Biscuit:

Weight, volume and specific volume of manufactured pan bread were determined as described by AACC (1983).

Biscuits Diameter, volume and thickness were determined according to the standard method of AACC (2000). The spread ratio (Diameter/thickness) was calculated according to standard methods of AACC (2000).

### 5. Cooking quality of pasta

Cooking quality of pasta carried out by measuring the increases in weight, volume and cooking loss after cooking according the methods of AACC (2000).

### 6. Color quality of Processed Products:

The color of pan bread (crust and crumb), biscuit and pasta samples were evaluated using Hunter, Lab Scan XE, Reston VA., calibrated with a white standard tile of Hunter Lab color standard (LX No. 16379) x = 77.26, y = 81.94 and z = 88.14 (L\* = 92.43, a\* = -0.88, b\* = 0.21).

### 7. Freshness of pan Bread

Pane bread was packed in polyethylene bags and stored at room temperature. Loaves freshness of pan bread was tested at interval time (1, 3 and 5 days) using alkaline water retention capacity (AWRC) according to Kitterman and Rubenthaler (1971).

### 8. Sensory Evaluation of Processed Products:

Sensory evaluation of pan bread was performed by 10 trained panelists as described by Kulp *et al.* (1985) for symmetry of shape (5), crust color (10), break & shred (10), crumb texture (15), crumb color (10), aroma (20), taste (20) and mouth feel (10).

Cooked pasta organoleptically evaluated by ten panelists for its appearance (10), color (10), flavor (10), tenderness (10) and stickiness (10) as described by Hallabo *et al.* (1985).

Sensory characteristics of biscuits evaluated by ten trained panelist for its color (10), flavor (10), taste (10), texture (10), appearance (10) and overall acceptability (10) as mentioned by Zabic and Hoojjat (1984).

## Results and Discussion

### Technological properties of wheat varieties:

#### 1 Pan Bread

##### 1.1 Chemical composition:

Pan bread of whole meal or wheat flour 72% varieties were evaluated chemically and presented in Table (1). The obtained results showed that, pan bread of whole meal characterized with its higher moisture content if compared with wheat flour 72% of all the studied varieties. In addition, moisture content of whole meal pan bread increased significantly to the highest level (37.02%) in Sohage 3 variety and decreased to the lowest level (33.09%) in gemmiza 7. Sohage 3 also characterized with is higher protein content where it reached to 12.43% and 12.22% in pan bread of whole meal and wheat flour 72%, respectively. Fat content of whole meal ban bread decreased slightly in Giza 168, Sohage 3, Gemmiza 7 and Sakha 93 to reach 3.73, 3.42, 3.43 and 3.22%, respectively. The same trend also observed in ash content of pan bread for the same varieties. Crude fibre of whole meal pan bread reached to the highest level in Sakha 93 (3.07%) and lowest level in Sohage 3 (1.39%). Table (1) showed also that, all pan bread of wheat flour 72% varieties characterized only by its higher content of carbohydrate than whole meal, while whole meal had higher contents of moisture, protein, fat, ash and

fiber. This result agreed with those found by Kent-Jones and Amos (1967) and Shouk (1996).

##### 1.2 Baking quality:

The quality of pan bread depends on flour type, so baking quality of whole meal flour and wheat flour 72% of the studied wheat varieties evaluated. Data presented in Table (2) showed that, pan bread of whole meal varieties characterized with its higher weight (140-133.3 g) if compared with its wheat flour 72% varieties (134.8-131.0 g). In addition, the volume of pan bread whole meal increased and ranged between 312.5-265 cm<sup>3</sup>, while its wheat flour 72% decreased between 290-255 cm<sup>3</sup>. On other hand, pan bread of wheat flour 72% varieties characterized with its higher specific volume (2.16-1.91) if compared with its whole meal (2.25-1.94). The obtained results well agree with those found by He and Hoseny (1992) and shouk (1996). Also, Pommeranz et al (1977), stated that, as fiber content increase loaf volume and weight increase, also, Chen et al (1988) stated that, the effect could result from the interaction between gluten and fiber. It could concluded from Table (2) that, whole wheat meal and its flour 72% of Sakha 93 characterized with higher baking quality (weight, volume and specific volume) for pan bread than Gemmeiza 7, Giza 168 and Sohage 3 varieties.

### 1.3 Color quality:

Data presented in Table (3) represent color attributes of pan bread as affected by wheat varieties and its extraction rate (72%). The obtained results indicated that, the lightness color (L) of crust whole-wheat meal affected with wheat varieties, where it maximized in Sohage 3 to reach 55.95 and minimized to 44.18 in Giza 168. In addition, extraction rate (72%) and wheat variety increased lightness to 60.06, 57.01, 56.96 and 50.98 in Sohage, Giza 168, Gemmiza 7 and Sakha93, respectively. The obtained

results showed also that, the color parameter (a & b) of crust pan bread were affected with wheat varieties, but crumb not affected.

As expected, crumb color layer characterized with its higher whiteness than crust layer where lightness (L) score increased, and both redness and yellowness scores decreased. This result could explain as follows: the parameter L, a and b of crust color (wheat flour 72%) in Sohage 3 was 55.95, 11.72 and 31.11, respectively, while the same parameter color in crumb was 60.06, 6.09 and 25.28, respectively. This result could explained as stated by

**Kordonowy & Young (1985), Kim et al.(1997) and Ramy et al. (2002)** that darkness increased in whole-meal pan bread as a result of bran and germ that present in whole-meal.

#### 1.4 Sensory Properties:

Effect of wheat varieties on sensory properties of pan bread evaluated and presented in Table (4). The obtained results showed that, the symmetric shape of whole meal pan bread or its 72% extracted flour not affected significantly in case of using any one of the studied wheat varieties, where it ranged between 3.35 – 4.05. Crust color slightly affected with whole-meal wheat varieties, where its color score maximized in Sakha 93 (7.7) and Sohage 3 (6.7). This result agreed with the obtained color parameter of Hunter (Table 6), where lightness (L) maximized to 55.95 and 49.79 in pan bread crust of Sohage 3 and Sakha 93, respectively. In addition, sensory property and Hunter color parameter not affected significantly with wheat varieties flour (72%) of pan-bread crumb.

In case of comparing crust color pan bread of wheat flour (72%) with whole meal, it could state that, the crust color quality related to maillard reaction that affected by sugars content of flour. Therefore, wheat flour 72% had higher content of total and reducing sugars than whole meal, consequently crust color of wheat flour pan-bread was better than that of whole meal pan bread. This effect observed in all samples of the prepared pan-bread regardless of wheat variety. These findings are in agreement with those obtained by **Lai et al (1989b) and Shouk (1996)**. They proposed that, bran binds relatively large amount of water, changes the appearance and the handling properties of the dough. Therefore, the gluten not properly hydrated and developed at normal absorption levels.

Concerning break and shred, it's clear that pan bread of wheat flour 72% had better break and shred than that of whole meal pan bread. These findings observed in all tested samples regardless of wheat variety.

The same table showed that, crumb-texture, aroma, taste and mouth feel of pan bread wheat flour (72%) were better than whole meal pan bread regardless of wheat variety.

#### 1.5 Freshness:

Data in Table (5) show and compare the effect of whole meal, wheat flour (72%) and wheat varieties on the pan bread freshness that stored at room temperature for 1, 3 and 5 days. The obtained results showed that, pan bread wheat flour 72% had the lowest values of alkaline water retention capacity (AWRC) than that of whole meal pan-bread. Furthermore, all tested samples caused a noticeable

decrease in AWRC values at 1, 3 and 5 days storage. This could relate to whole meal pan-bread that contained more fiber and protein than wheat flour 72% bread, consequently could retain more water. **Mohamed et al. (2006)** reported that bread samples with higher wheat flour (higher amylase) and lower protein content showed higher firmness values. In addition, **Parker and Ring (2001)** stated that, bread staling is caused by amylose and to a lesser extent, amylopectin retrogradation. The high protein content altered the macromolecular content of the bread and thus the overall glass transition of the system. The change in the glass transition directly related to the molecular relaxation of the bread, which in turn affected the staling process as explained.

#### 2 Pasta:

Gemmeiza 7, Gize 168, Sohage 3 and Sakha 93 wheat varieties were evaluated also to produce pasta from its whole meal and flour 72%.

##### 2.1 Chemical composition of pasta:

Data presented in Table (6) showed that, moisture content of whole meal pasta was higher than pasta of wheat flour 72% in all studied varieties. This could attribute to higher content of crude fiber (ranged between 2.82 to 1.65) in pasta of whole meal than pasta of wheat flour 72% (ranged between 0.78-0.5). In addition, whole meal pasta of all wheat varieties characterized with its higher protein, fat and ash contents than wheat flour 72% pasta. In contrast, whole meal pasta was lower in carbohydrate than flour 72% pasta. This result agreed with those found by **Kent-Jones and Amos (1967) and Shouk (1996)** where they stated that, whole meal wheat bread was higher than wheat flour 72% bread in protein, fat, ash and fiber. Furthermore, whole meal pasta of Sohage 3, Giza 168 and Gemmeiza 7 characterized with its higher protein (13.12%), fat (2.59%) and crude fiber (2.82%) contents than other studied varieties, respectively.

##### 2.2 Cooking quality:

Table (7) showed that, cooked pasta of whole meal characterized with its higher increase in weight (ranged between 265-219.6%) and volume (ranged between 305.3-247.4%), while weight and volume of wheat flour 72% cooked pasta ranged between (230-175.8%) and (188-183.3%), respectively. Cooking loss (solids loss into cooking water) of wheat flour 72% pasta characterized with its lower cooking loss (ranged between 8.8-6%), while whole meal pasta ranged between 12.8-8.3%. Regarding to pasta cooking quality of four studied varieties, Sohage 3 ranked first in both whole meal and wheat flour 72% pasta, followed by Giza 168, Sakha 93, and Gemmeiza 7.

Weight increasing of whole meal pasta could due to its high fiber content (table 6), where fiber have a lower bulk density, more surface area, polar groups, and uronic acid groups leading to surrounding water, and increase in its swelling volume (**Lo et al, 1991 and Bao & Chang, 1991**).

The undesirable effect on cooking loss may be due to dilution of gluten, or the interaction between gluten and fiber that allows high starch to leach out from the pasta, consequently, resulting an increase in cooking losses.

**Table 4:** Effect of wheat varieties and extraction rate on sensory properties of pan bread.

### 2.3 Color quality:

Data presented in Table (8) showed the effect of wheat variety and extraction rate (whole meal and flour 72%) on the color quality of pasta. Regarding to pasta color parameter of four wheat varieties, Sakha 93 ranked first in lightness (L) in its flour 72% and whole meal, where L reached to 63.37 and 54.39, respectively. While, L value of pasta of other variety ranged between 59.05-57.76 and 52.12-49.90 in flour 72% and whole meal, respectively. Pasta of whole meal Gemmeiza 7 characterized with higher redness (a = 5.46) and yellowness (b = 20.62). In comparing pasta color of whole meal with flour 72%, pasta whole meal of studied varieties were darker, where its color parameter was lower in lightness (L) and higher in redness (a) and yellowness (b). This result could due to pasta of whole meal containing higher level of fiber if compared with pasta of wheat flour 72%.

**Table (8):** Effect of wheat varieties and extraction rate on color quality of pasta.

### 2.4 Sensory evaluation:

Pasta of studied wheat varieties (whole meal and wheat flour 72%) evaluated sensorially and presented in Table (9). The obtained results showed that, pasta of wheat flour 72% increased slightly in appearance and color if compared with whole meal pasta of the same variety. The obtained color score agreed with the obtained color parameter of Hunter (Table 8). In addition, **Kordonowy & Young (1985)** reported that flavor, texture and color of no bran spaghetti were rated significantly higher than those of other samples containing bran. Table (9) indicated also that, there were no significant difference between wheat flour 72% and whole meal in flavor, tenderness and stickiness.

**Table 9:** Effect of wheat varieties and extraction rate on sensory properties of pasta.

### 3 Biscuit

#### 3.1 Chemical composition of biscuit samples:

The effect of using some Egyptian new wheat variety (whole meal, flour 72%) on gross chemical composition of biscuit studied. Table (10) showed that, whole meal biscuit characterized with its higher content of protein, fat, ash and crude fiber than wheat flour 72%. While wheat flour 72% was higher than whole meal in total carbohydrate (TC). This result agreed with those found by **Kent-Jones and Amos (1967)** and **Shouk (1996)**, they stated that, whole meal wheat bread was higher than wheat flour 72% bread in protein, fat, ash and fiber. In addition, whole meal biscuit of Sohage 3 characterized with its higher protein (12.13%), fat (31.0%) and ash (2.51%) contents; and lowest carbohydrate content (52.18%), while whole meal biscuit of Sakha 93 characterized with its higher moisture (4.5%) and crude fiber contents (3.0%).

**Table 10:** Effect of wheat varieties and extraction rate on chemical composition of biscuit.

Total Carb.	Crude fiber	Ash	Fat	Protein	Moisture	Sample
<b>Gemmeiza 7:</b>

Total Carb. = Total carbohydrate.

#### 2.3.2 Baking quality:

Table (11) showed that, whole-meal biscuits were higher in weight and volume than biscuit of wheat flour 72%, where biscuit weight of whole meal and wheat flour 72% varieties ranged between (87.47-81.49g) and (81.51-74.38g), respectively; while biscuit volume of whole meal and wheat flour 72% varieties ranged between (160.0-135.0cc) and (143.30-123.3cc) respectively. Whole meal biscuits were also higher in height than wheat flour 72% biscuits, where biscuits height of whole meal varieties ranged between (1.15-0.95cm), while it decreased to be ranged between (1.01-0.87cm) in wheat flour 72% varieties. These results could due to increasing level of crude fiber in biscuit of whole meal (Table 10). In contrast, biscuits diameter and spread ratio of whole meal varieties were lower than biscuit of wheat flour 72% varieties, where diameter and spread ratio of biscuit of whole meal varieties ranged between (7.28-6.78cm) and (6.86-6.38diam/ht), while they increased to (7.62-7.13cm) and (8.73-7.08diam/ht) in wheat flour 72% varieties, respectively.

It could conclude from Table (11) that, the higher baking quality of whole meal biscuits or wheat flour 72% was obtained from Sakha 93 variety.

**Table 11:** Effect of wheat varieties and extraction rate on biscuits baking quality.

**2.3.3 Color quality:**

Biscuits color quality of whole meal and flour 72% for Gemmeiza 7, Giza 168, Sohage 3 and Sakha 93 varieties studied and presented in Table (12). As expected biscuits face or back of flour 72% varieties characterized with its higher lightness (L) than whole meal varieties. Where, (L) value of biscuits face and back of flour 72% varieties ranged between (75.16-68.58) and (63.46-45.12), respectively, while its whole meal ranged between (72.69-64.28) and (51.56-41.28), respectively. In addition, biscuits face or back of flour 72% varieties characterized with its higher redness (a) than whole meal varieties. In contrast, yellowness (b) of biscuits face or back of flour 72% varieties decreased if compared with biscuit of whole meal varieties. From the obtained result of Hunter color parameter (Table 12), it was found that biscuit of whole meal varieties was slightly darker than biscuit of wheat flour 72% varieties, where whole meal contain higher level of dietary fiber. This result agreed with those found by **Kim et al (1997)** who stated that adding dietary fiber to bread dough increase darkness.

**Table 12:** Effect of wheat varieties and extraction rate on biscuits color quality.

### 3.4 Sensory properties:

Biscuits quality of whole meal and flour 72% of studied wheat varieties evaluated sensorially and presented in Table (13). Biscuit color of wheat flour 72% varieties ranged between (8.17-7.7), while in case of whole meal varieties showed non-significant decrease (ranged between 8.16-6.66). This result agreed with the obtained Hunter color parameter (Table 12), where biscuit of whole meal varieties was slightly darker than biscuit of wheat flour 72% varieties. In addition, biscuits flavor, taste, texture, appearance and overall acceptability of wheat flour 72% showed non-significant increase if compared with whole meal of the same variety.

**Table 13:** Effect of wheat varieties and extraction rate on sensory properties of biscuits.

**ABSTRACT:** Premature atherosclerosis seen in systemic lupus erythematosus (SLE) patients is not explained by traditional risk factors. Circulating endothelial cells (CECs) have been shown to be a surrogate marker of endothelial dysfunction. The aim of this study was to assess the number of CECs in SLE patients and to determine any potential correlation between CEC count and endothelial function (FMD%), disease activity, organ involvement and therapy used. Also, to investigate VCAM-1 and ICAM-1 levels as markers of vascular inflammation and injury. This study was performed on 30 premenopausal female SLE patients and 20 age and sex matched healthy controls (HC). Patients were subjected to full history taking, complete clinical examination and assessment of disease activity using (SLAM) score. For both patients and controls, endothelial function (FMD%), laboratory estimation of CEC count, and serum level of VCAM-1 and ICAM-1 were performed. CEC count was significantly elevated in SLE patients comparing to HC ( $P<0.001$ ). CEC count was positively correlated with SLAM score, while negatively correlated with FMD%. Serum levels of VCAM-1 and ICAM-1 were significantly increased in SLE patients than controls. Moreover, VCAM-1 correlated significantly with disease activity and CEC count while ICAM-1 did not correlate with any of them. There was significant correlation between CEC count and skin vasculitis, renal involvement and anti-malarial medications. In conclusion, increased number of CEC may be a biomarker of disease activity and disseminated vasculopathy occurring in the course of SLE and may represent one of the first specific cellular markers to provide a direct link with the pathophysiology of cardiovascular disease (CVD). VCAM-1 is considered a marker of activation of endothelial cells. Taking together, this may predict patients at increased risk of CVD complications, lupus nephritis or vasculitic skin affection.

**Key words:** Circulating endothelial cells (CEC), SLE, adhesion molecules

## 1-INTRODUCTION:

It has been established that patients with systemic lupus erythematosus (SLE) are at increased risk of cardiovascular (CV) mortality and morbidity (Roman et al., 2003). However, the premature atherosclerosis and endothelial dysfunction in SLE are not solely attributed to traditional risk factors (Edile et al., 2001).

The risk of developing coronary heart disease remains increased 8-10 fold even after adjustment of risk factors identified in the Framingham Heart Study (Edile et al., 2001). This prompted us to investigate additional factors that might be related to disease process itself.

As we all know, the primary pathological findings in SLE patients are those of inflammation, immune complex deposition, altered angiogenesis and vacuities (Robak et al., 2009). Furthermore, the vascular endothelium in general is "primed" for injury by activated leucocytes (Belmont et al., 1997).

Circulating endothelial cells (CEC) are thought to be mature cells that have detached from the intimal

mono layer in response to endothelial injury (Boos et al., 2006). Several possibilities can be considered for the mechanism responsible for endothelial detachment. It might be due to apoptosis, mechanical dislodgment of cells, proteolysis of subendothelial matrix proteins, or a consequence of complement dependent injury (Hunting et al., 2005).

Endothelial cells (EC) are potential participant in the inflammatory processes that contribute to tissue damage. Furthermore, the activated phenotype of circulating endothelial cells suggests that they may be capable of vascular injury by producing prothrombotic mediators (Robak et al., 2009).

Although endothelial damage due to deposition of immune complexes is considered to be one of the main pathogenetic traits of SLE, other alternative mechanisms should also be taken into account when pondering the etiology of SLE microangiopathy - first and foremost inflammatory immune lesions of endothelial cells (Kluz et al., 2009).

Endothelial damage and dysfunction as well as increased leukocyte migration to loci of inflammation, mediated by adhesion molecules, are

believed to be key factors in the induction of vasculitis (Guillevin et al., 2007). Growing evidence, including increase in the expression of vascular cell adhesion molecule-1 (VCAM-1), intracellular adhesion molecule-1 (ICAM-1) on the endothelial cell surface, speaks for endothelial activation in SLE (Robak et al., 2007 and Constans et al., 2003).

The aim of this study was to assess the number of CECs in SLE patients and to determine any potential correlation between CEC count and endothelial function (FMD%), disease activity, organ involvement and therapy used. Also, to investigate VCAM-1 and ICAM-1 levels as markers of vascular inflammation and injury.

## 2-SUBJECTS AND METHODS

This study was conducted on 30 premenopausal SLE female patients and 20 age and sex-matched healthy controls (HC). They were recruited from the Internal Medicine and Rheumatology & Rehabilitation Departments, Tanta University Hospital, Egypt. All patients met the American College of Rheumatology (ACR) criteria for SLE (Tan et al., 1982). Assessment of disease activity was achieved by use of (SLAM) score (Liang et al., 1989). Clinical assessment included physical examination and laboratory investigations; also a complete medication history was obtained.

A written consent prior to participation in the study was taken from all patients and controls.

### Exclusion criteria:

- 1- Coronary artery disease, myocardial infarction and cardiac insufficiency which affect CEC count (Robak et al., 2009).
- 2- Patients received hemoperitoneal dialysis or had undergone kidney transplantation(de Groot et al., 2005)
- 3- Patients with clinical signs of infection or neoplastic disease(3 Robak et al., 2009 )
- 4- Diabetic patients(Deng et al., 2009)
- 5- Patients with evidence with other disease known to cause endothelial dysfunction.
- 6- Patients received other medications for at least 4 weeks before blood donation (Robak et al., 2009).

### Assessment of endothelial function by flow mediated dilatation (FMD %):

Endothelial function was assessed with high-resolution B-mode Doppler (ATL HDI 5000 with a 7.4 – MHz linear –array transducer) examination of the brachial artery using the protocol described by Rajagopalan et al. (2002). Briefly, the test was reformed in the morning in quiet, low light room; subjects had fasted and not smoked for at least the

preceding 12hs. The brachial artery was scanned 5–15 cm above cubital fossa. Resting diameter was measured. Then blood pressure cuff inflated to 300 mmHg around forearm and further scan was done 1 minute during occlusion then after occlusion (cuff release) by 1 minute.

FMD was calculated as follows:

$$\frac{[(\text{post deflation diameter} - \text{resting diameter}) / \text{resting diameter}]}{100}$$

### Sampling:

Venous blood samples (10 ml) were taken from each patient and controls and separated into two tubes: one tube (5ml) was collected into ethylene diaminetetra acetic acid (EDTA) and immediately transferred into citrate-theophylline-adenosine-dipyridamole (CTAD) anticoagulant, which recently has been shown to maximize antigen stabilization on leucocytes. Anticoagulated blood samples were kept at 4°C and analyzed by flow cytometry within 4 hr of venesection (Macey et al., 2003).

The remaining 5 ml were left to clot at room temperature for 30 min in the second tube then centrifuged at 1500 rpm for 15 min and serum was separated stored at -80°C till time of assay of serum ICAM-1, VCAM-1, anti-phospholipid antibodies, C3, C4, ANA, anti-dsDNA, urea, creatinine, lipid profile and blood glucose

24 hours urine was collected from patients for creatinine clearance, urinary protein and complete urinalysis.

### Study measurements:

- Complete blood count using Advia 60 Cell Counter (Bayer),
- Erythrocyte sedimentation rate by Westergren method.
- Serum ANA was assessed by indirect immunofluorescence using Hep-2 cells and anti-double-stranded DNA by indirect immunofluorescence on Crithidia luciliae (Sanofi Diagnostics Pasteur Inc, Minnesota, USA) (Fritzler 1992).
- Complement 3 (C3) and complement 4 (C4) were assayed by nephelometry (Behringwerke, Marburg, Germany)(Virella 1980). Antiphospholipid (APL) antibodies were measured by ELISA technique (HM007, Technoclone Diagnostics Ltd., UK).
- Quantitative sandwich ELISA technique was used to measure serum concentration of ICAM-1 (BMS201CE human sICAM-1, Bender Biosystem, Vienna, Austria, Europe) and VCAM-1 (BMS232CE human sVCAM-1, Bender Biosystem, Vienna, Austria, Europe). The standard range of sICAM-1

was 6.25 - 100 ng/ml and sVCAM-1 was 3.2 - 100 ng/ml (Robak et al., 2007 ).

- Serum creatinine, lipid profile, blood urea and glucose concentration were measured by using standard laboratory techniques on Synchron CX7 autoanalyzer (Beckman Instruments, CA, USA).
- Complete microscopic urine analysis for WBCs, RBCs, and casts, 24-hour urinary protein excretion (UPE) by the turbidimetric method using TP Kit supplied by Stanbio (Stanbio Laboratory Inc., San Antonio, USA) and creatinine clearance were measured for renal assessment.

#### **Immunophenotyping of CECs Flow cytometry (Goon et al., 2006):**

Freshly isolated peripheral blood mononuclear cells (PBMCs) were washed and separated from blood of patients and healthy control using 1X FACS lysis solution (BD) for erythrocytes lysis then PBMCs were resuspended in phosphate buffered saline (PBS, pH 7.4) containing 20 uL of the appropriate antibody and cells were double stained with mouse anti-human fluorescein isothiocyanate (FITC) conjugated CD45 antibody and mouse anti-human phycoerythrin conjugated CD 146 antibody (BD Biosciences) to identify CD45- and CD146+ respectively. The isotype control was used to determine nonspecific binding of the lymphocyte subset-specific antibodies and to set the cut-off between fluorescence-negative and fluorescence-positive staining. Stained cells were washed three times with 1% bovine serum albumin BSA-PBS, pH 7.2, and then 7AAD was added to stain dead cells. The cells were analyzed within 15 minutes after addition of 7AAD using a fluorescence-activated cell scanner and Cell Quest software [FACS Caliber, Becton-Dickinson (BD)]. Cells were plotted according to forward scatter (FSC) and side scatter profiles (SSC) and a region was drawn around the small, live cell population containing the lymphocyte. The cell population data obtained from the quadrant statistics (2- color staining) was standardized for the number of mature CEC using the sum of CD45-, CD146+ and 7-AAD negative (Live) cells within this region (i.e., CD45-, CD146+ and 7-AAD+ cells were not accounted). Normal CEC count by flow cytometry was < 20 cells/ml (Woywodt et al., 2006).

#### **Statistical analysis:**

Data were analyzed using SPSS version 11.5. Descriptive statistics were done by number and percent as well as mean, median and range. Unpaired student's t-test was used for comparison between groups. Correlation between variables was calculated

using Spearman's correlation coefficient.  $P < 0.05$  was considered statistically significant.

### **RESULTS:**

The cardiovascular (CV) risk profile regard to obesity, smoking, hypertension, hyper lipidaemia and diabetes mellitus did not differ significantly between patients and controls (Table 1).

#### **Circulating endothelial cells are elevated in SLE patients:**

Circulating endothelial cells (CEC) count in peripheral blood was significantly elevated in SLE patients than HC  $p<0.001\{39.1 (22.5 - 55.7) \text{ vs. } 7.8 (0.9 - 14.7)\}$  and in active than in non active disease  $p<0.001\{42.6 (29.5 - 55.7) \text{ vs. } 25.7 (22.5 - 28.9)\}$  (table 2, figure 1). CEC count from patients with vasculitic skin lesion and renal manifestations was significantly higher than patients without these manifestations ( $p<0.01$ ).

#### **Impaired endothelial function (FMD %) is linked to CEC count:**

FMD% was significantly reduced in SLE patients than HC [3.8(0.5-7.25)] versus [8.45(4.50-12.40)] respectively ( $P<0.05$ ), and in the active than in non active disease [2.55 (0.60 - 4.50)] versus [4.2 (1.20 - 7.20)] respectively ( $P<0.05$ ) (Table2).

There was a significant negative correlation between CEC count and FMD% ( $r=-0.942$ ,  $P<0.001$ ) (Table 3).

**VCAM-1 and ICAM-1**were significantly increased in SLE patients than HC [276.5(103-450)] and [149.5 (103-196)] versus [66 (37- 95)] and [69.5 (57- 82)]  $P<0.05$  respectively.

Moreover, VCAM-1 was significantly increased in the active than in non active disease, with a significant correlation with CEC count [ $r=0.917$ ,  $P<0.001$ ] (Table 2, 3), while there was no significant variation in ICAM-1 during SLE flare or any correlation with CEC count.

Analyzing the relationship between CEC count and the presence of particular clinical and laboratory parameters of the disease, organ involvement and therapy used, revealed significant positive correlation between CEC count and SLAM score, vasculitic skin lesion and renal involvement, but there was significant negative correlation between CEC count and low complement and antimalarial medications. On the other hand, we did not find any correlation between CEC count and joint involvement, CNS involvement or steroid medication.

**Table (1): Characteristics of SLE patients and controls**

	SLE (n=30)	HC(n=20)	P
<b>Demographics</b>

#### 4-DISCUSSION

Although premature atherosclerosis and endothelial dysfunction are well known comorbidities associated with SLE, their underlying cause is not fully explained by traditional risk factors (Lee et al., 2007).

Circulating endothelial cells (CECs) predict vascular function and serve as a surrogate marker of endothelial dysfunction and cumulative CV risk (Lee et al., 2007). CEC activation, described in patients with SLE, was suggested to be a potential inflammatory process mediator, able to induce progressive vascular damage on the vicious circle principle (Clancy et al., 2001).

Our results showed significant elevation in CEC count in SLE patients than healthy controls. This result was in agreement with those reported by Clancy et al. (2001) Woywodt et al.(2003) Robak et al.(2009) and Kluz et al. (2009). This suggests that increased number of CEC may be a marker of

disseminated vasculopathy occurring in the course of SLE (Robak et al.2009).

In the contrary to our data, however, two other reports showed significant deficiency of CEC count in their SLE patients (Lee et al., 2007 and Westerweel et al., 2007 ). The explanation of these discrepancies may be due to the fact that the population studied here comprised totally Egyptian, whereas the study of Lee et al. (2007) involved Africans, Americans, whites and others to nearly equal parts. In their study the ethnic distribution among controls was not matched to that among patients. Also those involved in Westerweel et al. (2007) study were in clinical remission but our patients include active and inactive disease.

Although elevated CEC count are observed mostly in conditions linked with endothelial damage, It seems that the dissociation of mature endothelial cells (ECs) from the vascular wall due to its damage is not the sole reason for increasing CEC numbers noted in those patients. It seems more probable that

extensive vascular involvement, resulting in the release of "desquamated" EC into peripheral blood, also mobilizes medullary endothelial progenitor cells (EPCs) reserves, as well as stimulates their differentiation into mature endothelial cells as a compensatory response to its damage (Kluz et al., 2009).

In our study, there was strong positive correlation between CEC count and disease activity. This observation matches with those reported by Elshal et al.(2009), Kluz et al.(2009), Sesin et al.,(2005) and Clancy et al.(2001), but, contrasting that reported by Robak et al. (2009).

Many previous studies concluded that endothelial function (estimated by FMD) serves as a better marker of vascular reactivity than traditional risk factors (Lee et al., 2007).Also, Moreover, endothelial dysfunction is the key point in both the development of vascular inflammation and atherosclerosis (Deng et al., 2009). In our study FMD% was significantly reduced in SLE patients than HC with significant negative correlation between CEC count and FMD. Soltecz et al. (2010) found that the endothelium dependent vasodilation (FMD) was significantly impaired in patients with MCTD, as compared to controls and concluded that FMD is a reliable sensitive marker of endothelial cell dysfunction in MCTD.

In analyzing the relationship between CEC count and organ involvement, we found that CEC count from patients with vasculitic skin lesion and renal manifestations was significantly higher than patients without these manifestations, a result which matches with that of Elshal et al. (Elshal et al., 2009). Also, we found a significant positive correlation between CEC count and both of skin vasculitis and renal involvement. This indicates that endothelial injury, as a part of immune mediated vascular damage, could play a crucial role in the pathogenesis of these manifestations. Sesin et al. (2005) showed that decreased expression of endothelial protein c receptor in CEC of SLE patients may predict and/or reflect vasculopathy and renal injury in SLE. Moreover, we found a significant correlation between CEC count and low complement, a finding which is in consistent with the previous study of Clancy et al. (2001).

Regarding the relationship between CEC and therapy used, we found a significant negative correlation between CEC count and antimarial medications, but no correlation with steroids. Jung et al. (2010) demonstrated that antimarial drugs are thromboprotective in SLE with a risk reduction of thrombovascular events of 68%. However, Lee et al.(2007) and Robak et al.(2009) concluded that

there was no correlation between CEC count and steroids, anti- malarials or cytotoxic agents.

It has been established that leukocyte stimulation due to complement activation (C3 and C4) is an important step in the development of endothelial dysfunction. Simultaneously, through the influence of numerous immune stimuli such as cytokines, immune complexes, antiendothelial or antiphospholipid antibodies, surface expression of adhesion molecules in endothelial cells is enhanced (Clancy et al., 2001 ).

In glomerulonephritis murine models, increased expression of VCAM-1 and ICAM-1 was found in renal tissue (McHal et al., 1999). Moreover, greater survival rates were observed in mice deprived of ICAM-1, suggesting that their enhanced expression may play a considerable role in SLE pathogenesis (Kevil et al., 2004). Furthermore, in numerous patients with active vasculitis, no circulating or deposited immune complexes are found. Similarly, in many instances, such a deposition within vessel wall does not lead to inflammatory infiltration or fibrotic necrosis development. Hence the suggestion that alternative mechanisms might be involved in the pathogenesis of inflammatory vascular lesions, such as interaction between VCAM-1 and very late activation antigen (VLA-4) as well as ICAM-1 and leukocyte function-associated antigen (LFA-1), determining the adhesion of leukocytes to endothelial cells and their subsequent damage linked with cytokines and neutrophils (Guillevin et al., 2007).

In this study, there was significant elevation of VCAM-1 and ICAM-1 in SLE patients than HC, but regarding their relations to disease activity and CEC count, VCAM-1 significantly increased with disease activity and correlate positively with CEC count, which led to the suggestion that increased expression of VCAM-1 plays a leading role in the pathogenesis of SLE and is a direct cause of enhancing activated leukocytes migration, responsible for inflammatory tissue lesions. A similar result was reported by Kluz et al. ( 2009), but opposite result was reported by Robak et al.(2009). Additionally, there was no interrelationship between ICAM-1 and CEC count or disease activity, implying that increased expression of this molecule seems to be primarily an indicator of a generalized EC dysfunction rather than a marker reflecting the degree of endothelial damage. This observation agrees with that reported by Kluz et al. (2009). However, the pathogenesis of SLE is complex, and it is based on several overlapping regulatory loops; so, further studies are needed to determine the relationship between CEC and angiogenic proteins and inflammatory cytokines.

**CONCLUSION:**

- \*Increased circulating endothelial cells number constitute a reliable marker of disease activity in SLE, reflecting endothelial damage and thus enabling the distinction of a patient group running a higher risk of vascular lesion development.
- \* Progressive increase in serum VCAM-1 concentration is linked with progression of SLE activity and development of lupus angiopathy.

**ABSTRACT:** Polycyclic aromatic hydrocarbons (PAHs) are a group of chemicals composed of two or more fused aromatic rings that are formed from the incomplete combustion or high-temperature pyrolysis of coal, oil, gas, wood, fossil fuel, garbage or other organic substances, such as tobacco, charbroiled meat and exhaust from automobile and trucks. They enter the environment and release to air, soil, water and food. Some PAHs have shown to have toxicological, carcinogenic and mutagenic effects on animals and humans. Biodegradation of PAHs in the presence of the three types of lactic acid bacteria (*Bifidobacterium bifidum*, *Streptococcus thermophilus* and *Lactobacillus bulgaricus*) were studied during the different incubation periods (2, 4, 6,8,10,12,24,48 and 72 h) at 37°C. The reduction of PAHs concentration proved that these compounds were affected by the previous lactic acid bacteria. At the end of incubation period (72 h), the reduction percent were 46.6, 87.7 and 91.5% with *Bifidobacterium bifidum*, *Streptococcus thermophilus* and *Lactobacillus bulgaricus*, respectively. These results could be explained as the bacterial cell is a high proteinous material and so may adsorbs PAHs which could interfere with cellular metabolism. Also, the variation of pH values during the incubation periods may control in the adsorbed PAHs on the cells. The biodegradation of PAHs by yoghurt starter during yoghurt manufacture were studied. Slightly reduction was observed during the incubation periods (1, 2 and 3 h). The reduction percent was 3.46 at the final product. It could be revealing that the persistence of PAHs depend on a number of factors such as the type of microorganism, the interaction between microorganisms, the microbial concentration, the composition of the medium, and the microbial growth conditions of temperature and pH. The foregoing information reveal that extra care must be taken when comparing the results since in-vitro studies are not always relevant to real situation in food products.

**Key words:** PAHs, Lactic acid bacteria, Degradation, MRS, Milk, Yoghurt.

### INTRODUCTION

Polycyclic aromatic hydrocarbons (PAHs) are a group of chemicals composed of two or more fused aromatic rings that are formed during the incomplete combustion or high-temperature pyrolysis of coal, oil, gas, wood, fossil fuels, garbage, or other substances, such as tobacco and charbroiled meat (*Mottier et al.,2000*). The quantity and composition of PAHs produced are closely related to the reaction conditions, temperature and amount of air and, therefore, may vary considerably (*Vaessen et al., 1988*). Over 100 PAHs have been identified and occur as complex mixtures, never as individual components.

PAHs comprise the largest class of known chemical carcinogens and have been detected in the environment especially in air, water, soil and foods. They enter the environment mostly as releases to air from volcanoes, forest fires, and residential wood burning, cigarette smoke, asphalt roads, coal, coal tar, agricultural burning, municipal, industrial waste incineration, hazardous waste sites and exhaust from automobiles and trucks.. They can also enter surface

water through discharges from industrial plants and waste water treatment plants. These compounds can be released to soils at hazardous waste sites if they escape from storage containers (*ATSDR 1995*). The populations may be exposed to PAHs in the soil at or near hazardous waste sites. The movement of PAHs in the environment depends on properties such as how easily they dissolve in water, and how easily they evaporate into the air. PAHs in general do not easily dissolve in water. They are present in air as vapors or stuck to the surfaces of small solid particles. They can travel long distances before they return to earth in rainfall or particle settling (*ATSDR 1995*). The PAHs content of plants and animals living on the land or in water can be many times higher than the content of PAHs in soil or water.

Polycyclic aromatic hydrocarbons (PAHs) are proven animal carcinogens; in humans they are suspected of causing cancer. Clinical studies have shown that exposure a mixture of highly concentrated PAHs may cause various cancers, in skin, lung, stomach and liver. It is generally convinced that PAHs

are responsible for the increasing cancer risks as PAHs are capable of damaging genetic materials and thus initiating the development of cancers (*Schneider et al., 2000*). Some of PAHs compounds such as benzo(a)pyrene and dibenzo (a,h) anthracene were reported to be the most carcinogenic (*Schneider et al., 2000*). So, the presence of these compounds in food has received considerable attention over the past three decades (*Maga, 1988*). Food quality and safety is a pertinent issue, consumers are concerned that their food should be both of high nutritional value and free from chemical residues.

As environment pollution in different countries is becoming a serious problem, it is possible that PAHs may be widely distributed in the environment and thus contaminates food. The occurrence of PAHs in food may result from their sorption from a contaminated environment or from food preparation. The variation in PAHs profile in food products also depends on the source of the contamination (*Vaessen et al., 1988*). PAHs have been detected in fresh vegetables, fruits, and cereals as a result of the deposition of airborne PAHs, particularly near industrial sources or in areas with high traffic (*Dennis, 1991*). They have also been found in mussels, snails, and fish from contaminated waters (*Speer et al., 1990*). *Kan et al.* (2003) reviewed the occurrence of PAHs in animal products. In France, PAHs have been found in milk at total levels of 37 and 27 ng/g fat (*Grova et al., 2001*). Concentrations up to 70 µg/kg were found in meat (SCF, 2002). PAHs are also present at elevated levels in some vegetable oils and margarine (*Thomson et al., 1996*), probably formed during processing. They are also formed during some methods of food preparation, such as charbroiling, grilling, roasting, frying, or baking (*Yabiku et al., 1993*).

PAHs can breakdown to longer-lasting products by reacting with sunlight and other chemicals in the air, generally over a period of days to weeks. Breakdown in soil and water generally takes weeks to months and is caused primarily by microorganisms (ATSDR 1995). Biodegradation of chemicals by living organisms is one of the most important mechanisms for the breakdown of organic compounds and the microorganisms are the most important agents for such degradation. However, degradation is a very specific process and the growth of some microorganisms can even be inhibited by a xenobiotic. If degradation does occur, it is likely to result from enzymatic activity and may either occur immediately or only after a period of adaptation to the chemicals (*Boethling, 1993*).

The study of degradation of such residues in these foodstuffs is very important because of their increasing rate of consumption world-wide. Therefore,

technological procedures in food production should be developed to reduce the content pollutants hazardous to public health in food products. Nowadays, in the food industry it is very common to use starter cultures to improve the characteristics of the food products, and the possibility that these microorganisms would degrade these contaminants is of great interest because the de-chlorinated products are generally less toxic to animals, less likely to bio-accumulate, and more susceptible to further microbial attack (*Bayarri et al., 1997*).

Report on microbial degradation of PAHs appear increasing numbers, but such investigation tend to be focused on soil or aquatic microorganisms (*Luning and Pritchard, 2002 and Story et al., 2004*), while the activity of microorganisms associated with food fermentation has been less will investigated.

With this in view, the present work was conducted to unveil and throw more light on the biodegradation of the target PAHs as affected by some types of lactic acid bacteria (dairy and fermented foods starter) in different media.

## MATERIALS AND METHODS

### 1. Polycyclic aromatic hydrocarbons (PAHs) reference standards

A mixture (16 compounds) of PAHs reference standards containing acetaphthene, acenaphthylene, anthracene, benzo (a) anthracene, benzo (a) pyrene, benzo (b) fluoranthene, benzo (g, h, i) perlylene, chrysene, dibenz (a,h) anthracene, fluoranthene, fluorene, indeno (1,2,3,-cd) pyrene, naphthalene, phenanthrene, pyrene and 2-bromonaphthalene was purchased from Supelco company (Supelco Park, Bellefonte, PA, U.S.A.).

### 2. Bacterial Strains

Strains of *Bifidobacterium bifidum* (*B. bifidum*), *Streptococcus thermophilus* (*S. thermophilus*) and *Lactobacillus bulgaricus* (*L. bulgaricus*) were obtained from Cairo Microbiological Research Center, Cairo MIRCEN, Faculty of Agriculture, Ain-Shams University, Egypt. The strains were stored at -18°C until utilized.

### 3. Degradation of polycyclic aromatic hydrocarbons(PAHs) by lactic acid bacteria

Sterilize liquid medium De Man-Rogosa-Sharpe (MRS) was prepared (300ml) according to *Man et al.* (1960) and spiked by PAHs mixture containing 16 compounds of acetaphthene, acenaphthylene, anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perlylene, chrysene, dibenz(a,h)anthracene, fluoranthene, fluorene, indeno(1,2,3,-cd)pyrene, naphthalene, phenanthrene,

pyrene and 2-bromonaphthalene 0.25 $\mu$ g of each/ml medium). The medium was divided into three portions. The first, second and third portions were inoculated by 1% *B. bifidum*, *S. thermophilus* and *L. bulgaricus*, respectively. All flasks incubated at 37°C for 2, 4, 6, 8, 10, 12, 24, 48 and 72 h .The collected samples (10 ml of each) were extracted according to the method of Hodgeson (1990) for PAHs residues. The extraction method was validated. The limit of detection (LOD) is equal to 3 times the standard deviation (SD) of the lowest standard concentration used for the calibration curve (Chandra and Sangchan, 2009). Minimum detectable concentrations of PAHs in the present investigation were ranged between 0.007 to 0.020  $\mu$ g/ml (Table 1). Recovery results refer to complete method with concentration of 0.25  $\mu$ g/ml of each compound PAHs (total compounds of 16 was 4 $\mu$ g/ml) used in this study ranged from 88 to 96 % (Table 1). The experiment was repeated by injecting a mixture of 16 PAHs standards 6 times.

**Table 1. Validation (detection limits and recovery) of PAHs**

Compound	LOD ( $\mu$ g/ml)	Recovery (%)
1-Naphthalene	0.010	88.0
2-Acenaphthylene	0.020	89.2
3-2.Bromonaphthalene	0.010	94.0
4-Acenaphthene	0.008	94.0
5-Fluorene	0.010	94.0
6-Anthracene	0.009	93.0
7-Phenanthrene	0.008	90.0
8-Pyrene	0.020	92.0
9-Fluoranthene	0.008	90.0
10-Chrysene	0.008	96.0
11-Benzo(a)anthracene	0.007	94.0
12-Benzo(k)fluoranthene	0.007	92.0
13-Benzo(a)pyrene	0.008	96.0
14-Benzo(ghi)perylene	0.009	94.0
15-Dibenz(a,h)anthracene	0.008	94.0
16-Indeno(1,2,3cd)pyrene	0.010	89.0

Measured volumes of the medium were serially extracted with dichloromethane. Sixty ml of dichloromethane was added to the sample in separating funnel with shaking for two minutes with periodic venting to release excess pressure. Then, the organic layer separated from the liquid phase and the dichloromethane extract collected in 250 ml Erlenmeyer flask. The extraction steps repeated by adding another 60 ml dichloromethane. A third extraction in the same manner was performed. The combined extracts of dichloromethane was dried through column containing about 10 cm of anhydrous sodium sulphate and the extracts were collected in Kuderna- Danish (K-D) concentrator and the K-D placed on a hot water bath (60-65°C), so that the concentrator tube is partially immersed in hot water, and the entire lower rounded surface of the flask was bathed with hot vapor. When the apparatus volume of

liquid reaches 0.5 ml, the K-D was removed and allowed it to drain and cool for at least 10 min. Then the synder column was removed. The flask and its lower joint into the concentrator tube were rinsed with 1-2 ml dichloromethane. The extract was evaporated with a gentle steam of N<sub>2</sub> flow to defined volume.

One micro-liter of each sample extract was injected into a Hewlett Packard 5890 gas chromatograph fitted with a HP-5 fused silica capillary column (50m x 0.2mm x 0.33 $\mu$ m film thickness) and connected to Hewlett Packard 5970 series mass selective detector. The carrier gas was helium, maintained at a flow rate of 1.0 ml/min. The injection port temperature was 275°C with electron energy of 70 eV. The quadrupole temperature was 280°C. The oven programmed was as follows: 70°C for 5 min, 3°C/min to 290°C for 30 min. The mass spectrometer is tuned by letting in a small amount of perfluorotributylamine (C<sub>12</sub>F<sub>27</sub>N) gas as a reference. The fragments of peak for m/z, 69, 219 and 502 were observed and tune results were recorded and the masses are calibrated. The mass spectrum for each of the peaks from the resulting chromatogram from analyzed samples was observed by the total ion count (TIC) mode. Calibration was carried out by external standards, mixture of 16 compounds (Fig.1). The mass spectrometer was operated in selective ion monitoring mode using separate ions to identify and confirm compounds. Acquired mass spectrum in samples was compared with the standard and library spectra for identification.

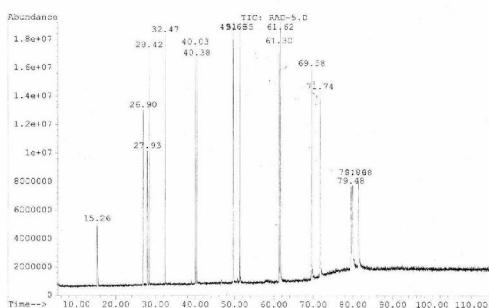

#### Degradation of PAHs by yoghurt starter

Mixture of buffalo's and cow's milk was heated at 80-82°C for 20 min and cooled to 40°C. The milk was polluted by polycyclic aromatic hydrocarbons (PAHs) mixture (16 compounds) to give concentration around 0.02  $\mu$ g/ml of each compound in the mixture and the PAHs concentration of the polluted mixture was determined.

Polluted milk was inoculated with 2% yoghurt starter (mixture of *S. thermophilus* and *L. bulgaricus*) and incubated at 40°C for 3.0 h as described by the Egyptian Organization for Standardization, EOS (1970). The samples were analyzed at zero time and after 1, 2 and 3 h (yoghurt product) intervals. The extracted samples were applied according to the method of Hodgeson (1990) as described before. The residues of PAHs were determined by GC/MS as described before.

#### Statistical analysis

The data were statistically analyzed by analysis of variance and least significant difference (L.S.D) at 0.05 levels according to the method described by Snedecor and Cochran (1980).

**Fig.1. Mixture of polycyclic aromatic hydrocarbons (PAHs) analyzed by GC/MS**

## RESULTS AND DISCUSSION

### RESULTS

#### Degradation of polycyclic aromatic hydrocarbons (PAHs) by lactic acid bacteria:

MRS media broth contaminated by PAHs (16 compounds, 0.25 µg of each/ml media) and inoculated with *B. bifidum*, *S. thermophilus* and *L. bulgaricus* and incubated at 37°C for 72 h, critical and significant role of lactic acid bacteria (LAB) in uptake and/or degrade PAHs was observed. It could be revealing that the persistence of PAHs depends on bacterial species and incubation period.

The obtained results revealed that PAHs was affected by *B. bifidum* strain during the incubation period (Table 2). After 2 to 48 h of incubation, naphthalene, acenaphthylene, 2-bromonaphthalene and acenaphthene weren't detected in the various samples. However, 2-bromonaphthalene and acenaphthene were appeared after 72 h of incubation and the reduction (%) was 74.8 and 87.6, in this order. Regarding to the other compounds in different samples, they were detected at

fluctuation levels and the sum of total mixture compounds was decreased during the incubation periods. The same pattern was detected in case of *S. thermophilus* (Table 3) except, the presence of residues of acenaphthylene, 2-bromonaphthalene and acenaphthene after 2 h incubation, beside presence of 0.017 µg/ml of 2-bromonaphthalene when incubation period was 72 h. Also, fluctuation levels were observed during the different period of incubation. The effect of *L. bulgaricus* (Table 4) on PAHs was similar to that detected with *B. bifidum*. It was observed that naphthalene, acenaphthylene, 2-bromonaphthalene and acenaphthene were disappeared during the incubation for 48 h. However, traces of either naphthalene (0.013 µg/ml) and acenaphthylene (0.003 µg/ml) were detected after 72 h and 48 h incubations, respectively. With the other compounds, the same sequence was detected as in other two strains.

Data presented in Table 5 proved the critical and significant role of LAB in uptake and/or degrade PAHs. During the incubation periods (2, 4, 6, 8, 10, 12, 24, 48 and 72 h), the reduction (%) relative to the initial concentration of PAHs (4 µg/ml) ranged from (46.6 to 92.9), (51.8 to 94.9) and (77.7 to 92.4), by *B. bifidum*, *S. thermophilus* and *L. bulgaricus*, respectively. It is worthy to mention that the highest reduction of PAHs by *B. bifidum* and *S. thermophilus* was observed after incubation for 10 and 12 h, and was found to be 92.6 and 96.0 %, respectively. However, the highest reduction by *L. bulgaricus* was recorded after 48 h and was found to be 92.4%. In a descending order, the strains tested could be arranged according to their ability to assimilate the PAHs at the end of incubation (72 h), to be as follows: *L. bulgaricus* (91.5%), *S. thermophilus* (87.7%) and *B. bifidum* (46.6%) as shown in Table 5.

### Degradation of polycyclic aromatic hydrocarbons (PAHs) by yoghurt starter

The purpose of this item, is to determine the role of yoghurt starter (*S. thermophilus* and *L. bulgaricus*) in degradation of PAHs compounds by in milk as complex medium . During the manufacture of yoghurt, data in Table 6 proved slightly significant role of yoghurt starter in degradation of PAHs (0.4044 µg/ml). The mean reduction (%) after 1 h of incubation at 40°C was 1.11%. However, after 2 h and 3 h, the reduction (%) increased to 2.15 and 3.46 % of sum PAHs compounds, respectively. These results indicate that the level of PAHs compounds were variable. The highest reduction were recorded with the compounds of indeno(1,2,3-cd)pyrene (5.81%), benzo (ghi) perylene (5.16%) followed by dibenz(a,h)anthracene (4.17%) at the end of incubation period (3 h). However, these reductions were slightly significant.

**Table 6. Concentrations (µg/g) of PAHs during incubation at 40°C as affected by Yoghurt starter**

### DISCUSSION

Biodegradation is defined as the biologically catalyzed reduction in complexity of chemical compounds (Wilson and Jones, 1992). It is based on two processes: growth and co- metabolism. In the case of growth, organic pollutants are used as a sole source of carbon and energy. This process results in a complete degradation (mineralization) of organic pollutants. Co-metabolism is defined as the metabolism of an organic compound in the presence of a growth substrate which is used as the primary carbon and energy source.

Enzymatic key reactions of aerobic biodegradation are oxidations catalyzed by oxygenases and peroxidases. Oxygenases are oxidoreductases that used O<sub>2</sub> to incorporate oxygen into the substrate. Degradative organisms need oxygen at two metabolic sites, at the initial attack of the substrate and at the end of the respiratory chain. Although the presence of PAHs in some types of food due to different treatments (FSA, 2002 and Falco *et al.*, 2003), no information available on the degradation of PAHs by LAB or by pure cultures of microorganisms isolated from food and dairy products. Most investigations studied the microbial degradation of PAHs in soil.

Factors that affect biodegradation include pollutant concentration and pure-exposure time. Microbial communities present in contaminated soil can metabolize PAHs at greater rates than soil microbial communities found in uncontaminated soils (Rathbone *et al.*, 1998). Greater population density and diversity of microorganisms often result in increased degradation rates of PAHs in soil (Rathbone *et al.*, 1998). However, organic matter did not appear to increase the population of known PAH-degrading microorganisms as much as general heterotrophic microorganisms (Carmichael and Pfaender, 1997). PAH degradation capabilities are associated with members of certain taxa such as *Pseudomonas*, *Sphingomonas*, and *Burkholderia*, independent of origin of the soil from which bacteria isolated (Mueller *et al.*, 1997). Moreover, genes responsible for PAH degradation are homologous and ordered (Dagher *et al.*, 1997). These genetic characteristics restrict enzymes diversity in microbial communities of pyrene and phenanthrene contaminated soils. Biodegradation of PAHs in the present study by LAB, *B. bifidum*, *S. thermophilus* and *L. bulgaricus* were similarly to that recorded with PAHs degradation in soils. The reduction of PAHs concentration in this investigation proved that the studied microorganisms

degraded the PAHs at different levels. The obtained results could be explained as the bacterial cell is a high proteinous material and so may adsorbs PAHs which could interfere with cellular metabolism. Also, the variations of PAHs levels detected during the incubation periods may be due to the lowering of PAHs values of the medium by the fermentation of their lactose contents. The variations of pH values during the incubation periods may determine whether PAHs could be adsorbed on the cells or became free in the MRS medium. The results of this study indicated that microbial communities exposed to PAHs contaminated media produced distinctive patterns of substrate utilization. The pattern indicated differences in community structure which resulted in a change in decomposition ability by the microorganisms. The PAHs have induced changes in type and amount of enzymes/or composition of the microbial population. The contaminants induced enzyme response from the microorganisms under their influence. The production of aromatic ring deoxygenase one of the PAH-degrading enzymes, was induced by the presence of PAH (*Dagher et al., 1997*). However, organic matter did not appear to increase the population of known PAH-degrading microorganism's as much as general heterotrophic microorganisms (*Carmichael and Pfaender, 1997*).

The slightly reduction of PAHs by yoghurt starter may be related to the pH effects of the culture medium after or during the incubation period. In this sense, several authors labeled the pH as a factor that influences the microbial degradation process (*Furukawa, 1982* and *Fewson, 1988*). On the other hand, the reduction of PAHs may be due to the protein affinity and/or adsorption ability of these compounds on the fat globule. Besides, bacterial cell is high proteinous material and may adsorb PAHs which could interfere with cellular metabolism.

The activity of microorganisms associated with food fermentation on the contaminants especially PAHs has been less will investigated. However, similar finding with pesticides (which represent the same group of PAHs, i.e. persistent organic pollutants) was recorded by *Hantke and Bradley (1972)* who found that adsorption of organochlorine pesticide residues was related to the interference with the cellular metabolism of organisms. Moreover, *Chacko and Lockwood (1967)* reported that bacterial cells can accumulate pesticide molecules. On the other hand, *Kim and Harmon (1970)* observed that amounts of dieldrin as pesticide are adsorbed or incorporated by the cells. In addition *Abou-Arab (1996, 1999 and 2002)* confirmed that the fermentation process in milk to produce dairy products (cheese) and meat products (fermented sausage) reduced pesticide residues and these reductions were due to the activity of milk or meat starter. Besides,

author reported that lactic acid bacteria decreased some types of pesticides (DDT, malathion and fenvalerate) during the incubation periods for 120 h.

Slight reduction of PAHs during yoghurt manufacturing was observed.. This result coincides with those reported by *Montourey and Muldon (1968)*, which explained the reduction in DDT content due to adsorption preferability by the milk protein , likewise, *Hugunin and Bradley (1971)* reported that significant amounts of dieldrin insecticide were associated with serum protein fraction in skimed milk . On the other hand, *Abou-Arab (1987, 1991and 2002)* reported significant role of lactic acid bacteria in degradation of some types of pesticides. The author reported that yoghurt starter reduced lindane, BHC and DDT by 77.3, 9.0 and 2.0 %, respectively. On the other hand, the reduction of DDT and lindane was (24.1-32.5) and (27.9-40.0%), respectively with *Micrococcus varians* as meat starter. Moreover, *Chacko et al. (1966)* reported that bacterial cells can accumulate pesticide molecules. However, *Kim and Harmon (1970)* observed that amount of dieldrin are adsorbed by the cells.

It could be concluded that, LAB may affected by PAHs during the first time of incubation. Nevertheless, the microorganisms rapidly adapted with presence of such PAHs and grow fast. Then critical and significant role of these strains in uptake and/or degrade PAHs was observed. But extra care must be taken when comparing the results since *invitro* studies are not always relevant to real situation in food products. This is due to the fact that the biodegradation process may be affected by a number of factors such as the type of microorganism (even the type of strain), the interaction between microorganisms, the microbial concentration, the composition of the medium, whether the medium is liquid or solid, and the microbial growth conditions of temperature and pH. However, more studies must be done on biodegradation of PAHs in food media.

**Abstract:** *Objectives:* To assess the level of expression of the antiapoptotic signal "Survivin" in Egyptian patients with acute leukemias and to delineate any significant correlation between the level of Survivin with the clinical and hematological findings in those patients. *Patients and Methods:* Survivin expression was quantitatively determined by a real-time PCR technique in 30 acute leukemia patients; ALL and AML in two age groups; pediatric group (<18 years) and adult group ( $\geq 18$  years) and in age and sex matched control healthy subjects. *Results:* Statistically significant higher expression was noted in both ALL and AML groups when compared to the control group (p-value = 0.0001). A statistically significant negative correlation was detected between Survivin expression and RBCs count, HB level and Platelet count with p-values = 0.01, 0.01 and 0.0001 respectively. Positive correlations were found with T.L.C, peripheral blood blasts, bone marrow malignant cells, LDH, ALP and uric acid levels with p-values = 0.0001, 0.0001, 0.03, 0.0001, 0.006 and 0.001 respectively. During the post-induction phase, Survivin expression showed a statistically insignificant difference between patients achieving complete remission and those showing unfavorable response with a p-value = 0.7. After follow up, the expression change between patients achieving complete remission and those showing unfavorable response was statistically insignificant with a p-value = 0.6. *In summary,* The previous data emphasized important correlations between Survivin expression and established risk factors in acute leukemia patients. Thus Survivin could be used as a marker for assessment of bone marrow infiltration that in future could be used to refine treatment stratification.

**Key words:** Survivin - Antiapoptosis function - Hematological malignancies

### Introduction

The balance between cell death and cell viability is important in tissue homeostasis. Abnormalities in the control of programmed cell death (apoptosis) play an important role in tumorigenesis (Tazzari et al. 2008). The evolutionarily conserved multi-step apoptosis cascade is regulated by proteins that promote or inhibit apoptotic cell death (Jakubowska et al. 2007). The inhibitor of apoptosis Survivin is a member of the inhibitor of apoptosis protein (IAP) family that suppresses apoptosis or programmed cell death and regulates cell division and thereby integrates apoptosis and cell division (Badran et al. 2004). Six human IAPs have been identified: XIAP, cIAP1, cIAP2, NAIP, livin, and survivin. Because of their important role in regulating apoptosis, IAPs are being investigated as a potential prognostic factor as well as a treatment target in cancer patients (Wrzesień-Kuś et al. 2004). The survivin protein shuttles between the nucleus and the cytoplasm, where it effectively inhibits apoptosis, most likely by binding to second mitochondrial activator of caspase (Smac) (Song et al. 2003).

One of the clinically significant features of survivin is its differential distribution in many cancers compared with its limited expression in normal terminally differentiated tissues (Johnson and Howerth 2004). Very high levels of survivin have been described in a number of different tumors (Ito et al. 2000, Kato et al. 2001, Kawasaki et al. 1998, Lu et al. 1998, Monzo et. 1999, Saitoh et al. 1999, Satoh et al. 2001, Swana et al. 1999, Tanaka et al. 2000 & Yoshida et al. 2001).

Overexpression of several IAPs has been detected in various hematological malignancies, including acute leukemias, myelodysplastic syndrome (MDS), chronic myeloid leukemia (CML), and many types of lymphoid malignancies, such as chronic lymphocytic leukemia (CLL) and diffuse large B-cell lymphoma (DLBCL). Many publications revealed significant correlation between a high level of IAPs, especially of XIAP and survivin, and tumor progression contributing to leukemogenesis due to deregulated apoptosis (Wrzesień-Kuś et al. 2004 & Troeger et al. 2007). The expression of survivin may be a general feature of cancer and survivin alone or with other antiapoptosis genes such as Bcl-2 may

extend the viability of transformed cells and regulate their susceptibility/resistance to apoptosis-based therapy. For this reason survivin may provide an ideal therapeutic target for its selective expression in neoplasia (Ambrosini et al. 1997). Various strategies have been developed to target IAPs for therapeutic purposes in leukemia and lymphoma cells, including small-molecule inhibitors and antisense oligonucleotides (Fulda 2009).

The aim of this study is to assess the level of expression of the antiapoptotic signal "Survivin" in Egyptian patients with acute leukemias and to delineate any significant correlation between the level of Survivin with the clinical and haematological findings in those patients. Hence we can throw some lights upon the prognostic impact of survivin

## **Patients and Methods**

Thirty patients with untreated de' novo acute leukemia were included in the analysis for survivin expression. Patients were selected from the out patient clinic of medical and pediatric oncology departments of the National Cancer Institute (NCI), Cairo University and followed up for one year. According to the French-American-British (FAB) standard there were 15 patients with acute myeloblastic leukemia (AML) and 15 patients with acute lymphoblastic leukemia (ALL) consisting of 25 males and 5 females. The leukemic patients were divided into two age groups; pediatric group (<18 years): 16 patients and adult group ( $\geq 18$  years): 14 patients. The control group included 20 age and sex matched normal healthy volunteers, they were 14 males and 6 females. All patients of this study were treated according to the institute ongoing induction and consolidation regimens. Patients were followed up for one year and outcome was designated either favorable or unfavorable. Favorable outcome was considered when complete remission (CR) was achieved; CR status was determined 4 weeks after induction chemotherapy, it is defined by neutrophil count at least ( $1.5 \times 10^3/\mu\text{L}$ ), platelet count ( $> 100 \times 10^3/\mu\text{L}$ ), BM aspiration and biopsy that demonstrate at least 20% cellularity, < 5% blasts and no auer rods as well as absence of extramedullary infiltration.

Unfavorable outcome was considered with failure of remission, occurrence of relapse or death.

An informed consent was obtained after complete description of the study from each adult participant and from parents or legal guardians of the children participants at the time of enrolment, according to guide line of the local ethical committee of the National Research Center.

Diagnosis of de novo' acute leukemias was made based on morphological and cytochemical assessment [Myeloperoxidase (MPO), Nonspecific esterase (NSE) and NSE with sodium fluoride inhibition] of peripheral blood and bone marrow smears. Complete Immunophenotyping was routinely performed using Flowcytometer Patec III DAKO cytometry for evaluation of acute leukemia. In addition, all patients were subjected to CSF examination, chest x-ray and pelvi-abdominal ultrasound for extramedullary involvement detection. Sera were analyzed for lactate dehydrogenase (LDH), alkaline phosphatase (ALP) and uric acid levels using Synchro CX9PRO.

*Survivin Gene expression* was quantitatively determined by real-time PCR technique. Extra peripheral blood samples were taken into tubes with K<sub>3</sub>EDTA from the patients (study group) and from healthy subjects (control group).

*RNA Extraction and complementary(c) DNA synthesis:* Total RNA was extracted from whole blood using QIAamp RNA Blood Mini kit supplied by QIAGEN worldwide companies (Cat No. 52304) according to manufacturer's protocol. The concentration and purity of RNA was determined by measuring its absorbance at 260 nm (A<sub>260</sub>) and 280 nm (A<sub>280</sub>) in a UV visible spectrophotometer. Total RNA (2  $\mu\text{g}$ ) was reverse-transcribed to complementary DNA (cDNA) according to manufacturing instructions using Thermal Cycler (Biometra, Germany) with kit provided from Applied Biosystems. cDNAs were stored at -20°C until real-time quantitative PCR was performed.

*Gene expression relative quantitation:* Polymerase chain reaction (PCR) amplification reaction mixtures (50  $\mu\text{L}$ ) contained cDNA, survivin forward primer (SF) 5'-ACCAAGGTGAGAAGTGAGGG-3' and Survivin Reverse Primer (SR) 5'-AACAGTAGAGGAGCCAGGG-3'. The Survivin RNA Genbank accession number is NM001168. The TaqMan Probe sequence was GCACCCCGGAGCGGAT. GAPDH primers were: GAPDH Forward Primer (GF) 5'-ACATCGCTCAGACACCATTG-3' and GAPDH Reverse Primer (GR) 5'-GTA GTTGAGGTCAATGAAGGG-3'. GAPDH RNA Genbank accession number is NM33197. The TaqMan Probe sequence CAAGCTTCCCCTCTCAGCC. All primers and probes were synthesized by Applied Biosystems-PerkinElmer.

Thermal cycle conditions included holding the reactions at 50°C for 2 minutes and at 95°C for

10 minutes and cycling for 40 cycles between 95°C for 15 seconds and 60°C for 1 minute. Results were collected and analyzed by Applied Biosystems Perkin Elmer 7300 sequence detection system. Relative quantitation using comparative threshold ( $C_t$ ) was used to determine the change in expression of a nucleic acid sequence (target) in the test and control samples. The  $C_t$  value for any sample was normalized to the endogenous housekeeping gene GAPDH. A negative control was included in each experiment. Survivin Gene expression levels were expressed as copy number per cell (c/cell).

### Statistical Methods:

All data were collected from the patient charts and entered into a computerized spreadsheet. The fit of the data to the normal distribution were tested with Kolmogorov-Smirnov Test. Data was statistically described in terms of range, mean, standard deviation (SD), frequencies (number of cases) and relative frequencies (percentages). Comparisons were made using Student's t-test, One-way ANOVA test and Pearson's correlation coefficients were calculated between the assessed variables. Statistical Package for Social Science SPSS Inc., Chicago, IL, U.S.A. version 9.0 was used for analysis of data. The null hypothesis was rejected with a two sided P value of  $< 0.05$ .

### Results

Frequency distribution of demographic and clinical data of ALL and AML patients are shown in Table 1. Median percentage of leukemic blast cells in peripheral blood was 80% in ALL patients and 53% in AML patients. Frequency distribution of FAB subtypes and therapy response data of AML and ALL patients included in the study are shown in Table 2.

Comparisons between hematological and biochemical data in the pediatric ALL patients, AML patients and control subjects are demonstrated in Table 3. Comparisons between hematological and biochemical data in the adult ALL patients, AML patients and control subjects are demonstrated in Table 4.

Survivin gene was expressed in 60.0% of ALL patients and in 73.3% of AML patients. Statistically significant higher expression was noted in both ALL and AML groups when compared to the control group (p-value = 0.0001) as shown in Figure 1 and Table 5. Survivin gene expression was significantly higher in pediatric groups of both ALL and AML patients than pediatric group of control subjects with a p-value = 0.004 (Figure 2). Also Survivin gene expression was significantly higher in adult groups of leukemia

patients than adult group of control subjects with a p-value = 0.0001 (Figure 3).

In the correlation studies, no statistically significant correlation was found between Survivin gene expression and demographic and clinical data of patients.

A statistically significant negative correlation was detected between Survivin gene expression and RBCs count, HB level and Platelet count with p-values = 0.01, 0.01 and 0.0001 respectively. Positive correlations were found with T.L.C, peripheral blood blasts, bone marrow malignant cells, LDH, ALP and uric acid levels with p-values = 0.0001, 0.0001, 0.03, 0.0001, 0.006 and 0.001 respectively (Table 6).

No statistically significant difference could be determined between L<sub>1</sub> and L<sub>2</sub> FAB subtypes (p-value = 1.0). Regarding immunophenotyping, Survivin expression level in C-ALLA patients showed a mean value of  $1.3 \pm 0.7$  c/cell, whereas Pro B and Pre B patients showed a mean Survivin expression level of  $0.6 \pm 0.8$  c/cell and  $0.8 \pm 0.7$  c/cell respectively with a p-value = 1.0 which is statistically insignificant.

In an attempt to correlate between Survivin expression and some prognostic factors of AML: AML patients with normal LDH level showed a mean Survivin level of  $0.4 \pm 0.3$  c/cell, whereas AML patients with elevated LDH level showed a mean Survivin level of  $1.6 \pm 0.6$  c/cell with a p-value = 0.003 which is statistically highly significant.

During the post-induction phase, Survivin gene expression showed a statistically insignificant difference between leukemic patients achieving complete remission and those showing unfavorable response with a p-value = 0.7. After the follow up period, the difference between mean Survivin gene expression in patients achieving complete remission and those showing unfavorable response was statistically insignificant with a p-value = 0.6 (Table 7).

### Discussion

Survivin has been identified as one of the top 4 transcripts among 3.5 million human transcriptomes uniformly up-regulated in cancer tissues but not in normal tissues (Sugahara et al. 2004). Therefore, we quantitatively determined the expression of survivin by a real-time polymerase chain reaction technique in 30 patients with acute leukemias; acute lymphoblastic leukemia (ALL), and acute myeloblastic leukemia (AML) in two age groups; pediatric group (<18 years) and adult group ( $\geq 18$  years) and in age and sex matched control healthy subjects. Age-related acute leukemia groups might be associated with distinct expression patterns of apoptosis-related molecules

leading to the distinct prognosis in adult and childhood acute leukemia.

In the present study statistically significant higher survivin expression was noted in both ALL and AML groups when compared to the control group. We found statistically insignificant change in Survivin expression level between ALL and AML groups.

Thus, the results of this study provide further evidence that survivin plays a role in the malignant process of acute leukemias. Survivin gene was expressed in 60.0% of ALL patients and in 73.3% of AML patients. This could be attributed to dysregulation of Survivin gene which is normally controlled by p53 and transcriptional factors as the Kruppel-like factor 5 (KLF5). Zhu et al. (2006) demonstrated that the transcription factor KLF5 is widely expressed in childhood ALL and is a positive regulator inducing the expression of the anti-apoptotic protein Survivin. Suppression of apoptosis contributes to leukemogenesis by different mechanisms, including prolonging cell life span, thus facilitating the accumulation of gene mutations, permitting growth factor-independent cell survival, promoting resistance to immune-based cytotoxicity, and allowing disobedience of cell cycle checkpoints which would normally induce apoptosis (Tamm et al. 2004). Carter et al. (2001) demonstrated that Survivin is highly expressed and is cytokine regulated in myeloid leukemias. In their study cytokine stimulation increased survivin expression in leukemic cell lines and in primary AML samples. In cultured primary samples, single-cytokine stimulation substantially increased survivin expression in comparison with control cells, and the combination of G-CSF, GM-CSF, and SCF increased survivin levels even further. Also Badran et al. (2003) reported that the analysis of Ph (+) blastic crisis CML patients (4 patients) revealed positive Survivin expression in all patients (100%). Data collected by Mori et al (2002) showed that Survivin was detected in 17 out of 31 AML patients (54.8%) and 5 out of 7 patients with CML blastic crisis (71.4%). The variation in the frequency of Survivin expression among different investigators is a consequence of variation in the procedures used and the number of cycles performed in PCR assays which may influence the sensitivity and specificity of the detection method. However Tamm et al. (2004) put few limitations and concluded that cryopreservation may alter protein expression in samples. Freezing and DMSO are proapoptotic stimuli potentially influencing expression levels of the proteins measured. Also the average leukocyte count could influence the expression level.

We did not find significant correlation between Survivin expression level and sex, organomegaly and

lymphadenopathy. Survivin expression level showed statistically significant negative correlations with RBCs count, HB level and platelets count. Significant positive correlations with T.L.C, peripheral blood blasts, bone marrow malignant cells, LDH, ALP and uric acid were identified. This could be explained by the antiapoptotic function of Survivin thus offering a survival advantage to malignant cells that dominate the bone marrow at expense of other hematological elements with high cell destruction. These results are in accordance with Oto et al (2007).

With respect to blast immaturity, a significant variation of Survivin expression level could not be identified in ALL patients. Also Troeger et al. (2007) showed that Survivin expression levels were comparable between the different immunophenotypes.

Concerning the outcome of our studied patients, difference in Survivin expression level during the postinduction period between patients who achieved CR and those who didn't was statistically insignificant.

After the follow up period of one year, the leukemic patients who achieved CR showed insignificant change of expression when compared to those with unfavourable response. Tamm et al. (2004) could not determine a prognostic role for survivin in adult AML. Survivin is a negative prognostic marker in a variety of solid tumors and diffuse large B-cell lymphomas (Adida et al. 2000a) For example, it has been reported that survivin expression in neuroblastomas correlates with clinically more aggressive, histologically unfavorable disease (Adida et al. 1998). Adida et al. (2000b) found no significant difference in remission rate or survival in adult AML patients expressing high versus low levels of survivin. Also difference in outcome correlations between investigators could be attributed to various treatment strategies and duration of follow up.

*In summary,* The previous data emphasized important correlations between Survivin expression level and established risk factors in acute leukemia patients. Thus Survivin could be used as a marker for assessment of bone marrow infiltration that in future could be used to refine treatment stratification. Elevated survivin levels could be cytokine regulated, thus explaining the controversy in its prognostic impact. In future Survivin may even serve as a therapeutic target itself. Patients should be assessed for a considerable period of follow up to compare between Survivin level before, during and after therapy and to correlate between patients' outcome and Survivin level on a larger scale.

[hanem\\_awad@yahoo.com](mailto:hanem_awad@yahoo.com)

**ABSTRACT:** Roselle (*Hibiscus sabdariffa* L.) is a plant which has a considerable industrial, pharmaceutical and economic values in Egypt and many other countries around the world, mainly for its pleasant sepals. There are many colored types of Roselle depends on sepals color. The biochemical and molecular characterization of three roselle types, green (G), light red (LR) and dark red (DR), were studied. RAPD-PCR patterns for their genomic-DNA were significantly different. The total protein electrophoretic profile of their seeds was similar except for some inter-individual variation in band density. Their total protein contents were 46.0, 66.5 and 68.1 mg/g seed, respectively. In addition to the water-soluble antioxidant capacity, the total polyphenolic-content and the antioxidant activity of 12 roselle extracts, three colored types in 2 solvent systems (aqueous, A and 30% ethanolic, E) and 2 extraction temperatures (hot, H and cold, C), were determined by Folin-Ciocalteu reagent and 1,1-diphenyl-2-picrylhydrazyl (DPPH) methods, respectively. The ability of these roselle extracts to inhibit the formation of nitrous acid-induced tyrosine nitration decreases in the order of LREC > DREC > LREH > GEC > DREH > GEH > GAC > DRAH > LRAC > GAH > LRAH > DRAC.

[Refaei M. Hussein, Yasser E. Shahein, Amr E. El Hakim and Hanem M. Awad. Biochemical and molecular characterization of three colored types of roselle (*Hibiscus sabdariffa* L.). Journal of American Science 2010;6(11):726-733]. (ISSN: 1545-1003).

**KEYWORDS:** Antioxidant activity; DPPH; HPLC; molecular characterization; polyphenol content; reactive nitrogen species (RNS); sepals, Roselle (*Hibiscus sabdariffa* L.).

### 1. Introduction

Roselle (*Hibiscus sabdariffa* L.) belongs to *Malvaceae* family and generally regarded as safe (GRAS) as foodstuff. It is commonly used to make jelly, jam, juice, wine, syrup, gelatin, pudding, cake, ice cream and flavors. The brilliant red color and unique flavor make it a valuable food product <sup>(1)</sup>. Many medicinal applications of this plant have been developed around the world. In China, it is used to treat hypertension, pyrexia, and liver damage <sup>(2)</sup>; and lately its sepal extract has been used as an effective treatment against leukemia, due to its high content in polyphenols, particularly protocatechic acid <sup>(3)</sup>. Roselle seeds, which until now do not have any commercial applications, are a source of a vegetable oil that is low-cholesterol and rich in other phytosterols and tocopherols, particularly  $\beta$ -sistosterol and  $\gamma$ -tocopherol. The global characteristics of roselle seed oil allow important industrial applications for this oil. These characteristics represent an added value for the culture of this plant <sup>(4)</sup>.

The fleshy calyces of roselle flowers (sepals) have a pleasant acid taste and very attractive red color, for which roselle is used as a beverage crop in many countries. The beverage drink is known in Egypt as Karkadi and recommended as a mild laxative in the form of acidulous drink. The anthocyanins (**Figure 1**) are responsible for the red color, while the acid taste is due to the presence of some organic acids. Sepals'

acidity may also contribute to their color variation. The dark red colored type has the highest content of anthocyanins followed by the light red colored type, while the green colored type has no or just traces of anthocyanins <sup>(5)</sup>.

Many chemical components present in roselle have potential health benefits and support the ethnomedicinal use of roselle in promoting cardiovascular health and preventing hypertension <sup>(2)</sup>. The red varieties of roselle had greater overall antioxidant and cyclooxygenase inhibitory activity than the white variety, and therefore they would potentially have greater health benefits. However, the white variety could also be used in antihypertensive applications, since its ethyl acetate extract had similar cyclooxygenase inhibitory activity as aspirin and Ibuprofen <sup>(6)</sup>. Nevertheless, further *in vivo* research is required to confirm the specific health benefits in biological systems, before increased consumption of any of the three varieties of roselle could be recommended.

There are few studies on roselle at the molecular level. In this study, we present a molecular characterization based on total protein and DNA level of three colored types of roselle [green (G), light red (LR) and dark red (DR)] (**Figure 2**). The variability of antioxidant capacity of these three colored types of roselle using different biochemical approaches was determined.

## 2. Materials and Methods

### 2.1. Plant Material

Seeds and sepals from three colored types of roselle were collected from previous experiments of our research group at the National Research Center, Egypt.

### 2.2. Chemicals

All chemicals were obtained from Sigma-Aldrich Chemical Co., USA. All reagents and other chemicals were of high analytical grade. The buffers were prepared according to Gomorri<sup>(7)</sup> and Blanchard<sup>(8)</sup> and the final pH was checked by pH meter (Hanna, pH 211 Microprocessor pH meter). *Taq* polymerase and PCR reagents were from Fermentas, Latvia.

### 2.3. DNA Extraction and PCR Amplification Conditions

Genomic DNA of *H. sabdariffa* was extracted from fresh young leaves using the CTAB (cetyltrimethylammonium bromide) extraction method<sup>(9)</sup>. PCR was carried out using a BioCycler TC-S thermal cycler from HVD, Austria. The PCR reactions were developed in a total volume of 50 µl with the following components: 5 µl of 10X reaction buffer (75 mM Tris-HCl, pH 9.0, 50 mM KCl, 20 mM (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> and 0.001 % bovine serum albumin), 2 µl of 25 mM MgCl<sub>2</sub>, 4 µl of 2.5 mM/each dNTP mix, 2.5 µl of 20 mM of each primer, 1 µl of *Taq* DNA polymerase (1 U/µl), and template DNA. The volume was completed to 50 µl with deionized, diethylpyrocarbonate (DEPC), water. The following PCR program was used: an initial denaturation of DNA was carried out at 94°C for 2 min followed by 40 cycles including denaturation at 94°C for 1 min, annealing at 37°C for 1 min, extension at 72°C for 2 min and a final extension at 72°C for 12 min. Template DNA was prepared from fresh young roselle leaves. The tubes containing PCR product were stored at -20°C till the next use. For RAPD analysis, the following random primers were used: B05 (5'-TGC GCC CTT C-3'), B08 (5'-GTCCACACGG-3'), B09 (5'-TGGGGGACTG-3'), B11 (5'-GTAGACCCGT-3'), B14 (5'-TCCGCTCTGG-3') and C15 (5'-GACGGATCAG-3').

## 2.4. Protein Determination

### 2.4.1. Protein Extraction

Protein extraction from *H. sabdariffa* seeds was carried out according to Rao and Pernollet<sup>(10)</sup> with minor modifications: 1 g of different types of seeds each was incubated overnight in 10 ml of 0.15 M phosphate-buffered saline (PBS) and 1 mM disodium EDTA, pH 7.2, containing cocktail protease inhibitors (1 mM ethylenediamine tetraacetic acid, ethylene glycol bis *N,N*, *N*, *N*-tetraacetic acid, *N*-ethylmaleimide and phenylmethylsulphonyl fluoride). The mixture was homogenized, filtered, sonicated and then centrifuged at 15,000 × g for 60 min. at 4°C. Supernatants were collected as roselle seed extracts.

### 2.4.2. SDS-Polyacrylamide Gel Electrophoresis (SDS-PAGE)

Electrophoretic analysis was performed in the Mini-Protean II Dual-Slab Cell (BioRad, USA). Preparation of

gels, samples and electrophoresis was performed according to Laemmli<sup>(11)</sup>.

### 2.4.3. Estimation of Protein Concentration

Protein concentration was determined according to Bradford<sup>(12)</sup>, using bovine serum albumin as standard protein.

## 2.5. Determination of Total Polyphenol Content (TPC)

The content of total phenolic compounds in each of the 12 extracts was determined according to the Folin-Ciocalteu method<sup>(13)</sup> with some modification to minimize the volume of the reactants used to microlitres. An aliquot of 10 µl of each extract (1 mg/ml) was mixed with 50 µl of Folin-Ciocalteu phenol reagent (10 × dilutions) and allowed to react for 5 min. Then 40 µl of 20% saturated Na<sub>2</sub>CO<sub>3</sub> solution was added and allowed to stand for 1 h in the dark before the absorbance of the reaction mixture was read at 725 nm using a microplate ELISA reader (BioRad). A gallic acid standard curve was obtained for the calculation of phenolic content. The total polyphenol content (TPC) of each extract was expressed as mg gallic acid equivalents per gram of plant material on a dry-weight basis.

## 2.6. Antioxidant Activity Determination

### 2.6.1. Determination of Water-Soluble Antioxidant Capacity (HACT)

Water-soluble antioxidants were extracted as follows: Plant sepals were frozen in liquid nitrogen and later, they were crushed in a hand mortar until obtaining a fine powder, to which a volume of distilled water was added (10 ml/3 g). The homogenized suspension was transferred to polypropylene tubes then shaken for 1 h at room temperature in the dark. The suspension was transferred to Eppendorf tubes and centrifuged at 6000 × g for 10 min; the supernatant was transferred to new Eppendorf tubes and filtered through a centricron (5 kDa cut-off) to eliminate proteins and other macromolecules from the water extract. Later, the resulting supernatant was kept at 4°C until analysis.

Samples of water extracts (5 to 200 µL) were supplemented with 1 ml phosphomolybdenum reagent, homogenized then incubated at 95°C for 90 min. Pure water was used in control reactions. Finally, absorbance at 695 nm was measured. HACT is expressed as equivalents of L-ascorbic acid. Standard curves were constructed with different amounts of L-ascorbic acid dissolved in water. An average extinction coefficient of 213 µM<sup>-1</sup> (*r*<sup>2</sup> = 0.9996) was used for quantitation. Total HACT per gram of wet plant material was obtained with the following formula:

$$\text{HACT} (\mu\text{mol L-ascorbic acid/g}) = A_{695} \times \epsilon^{-1} RV \times SV^{-1} \times EV \times M^{-1}$$

where A<sub>695</sub> is the absorbance at 695 nm, ε<sup>-1</sup> is the inverse of the extinction coefficient (213 µM<sup>-1</sup>), RV is the overall reaction volume, SV is the sample volume used in the reaction, EV is the volume of solvent used in the extraction of the plant material analyzed and M is the amount of fresh plant material extracted in grams. When the assays were performed at 37°C, the total antioxidant capacity was

obtained due to strong water-soluble antioxidants, HACT<sup>37</sup> (14). All determinations were done in triplicate.

#### 2.6.2. Preparation of the Extracts and Standard

A weighed quantities of three colored roselle sepals (G, LR and DR) were extracted with 30% aqueous ethanol (E) and distilled water (A) either at room temperature (C) or boiling temperature (H). This gave 12 samples to analyze: GEH, GEC, GAH and GAC; LREH, LREC, LRAH and LRAC; DREH, DREC, DRAH and DRAC (**Table 1**). A solution of ascorbic acid in water was used as a standard in this study. Serial dilutions of all these solutions were done with their respective solvents.

#### 2.6.3. DPPH Radical Scavenging Assay

The antioxidant activity of the 12 roselle extracts and standard were assessed on the basis of the radical scavenging effect of the stable DPPH free radical (15). 10 µl of each extract or standard (from 0.0 to 100 µg/ml) was added to 90 µl of a 100 µM methanolic solution of DPPH in a 96-well microtitre plate (Sigma-Aldrich Co., St. Louis, MO, US). After incubation in the dark at 37°C for 30 min, the decrease in absorbance of each solution was measured at 520 nm using an ELISA micro plate reader (Model 550, Bio-Rad Laboratories Inc., California, USA). Absorbance of blank sample containing the same amount of either water or 30% aqueous ethanol and DPPH solution was also prepared and measured. All experiments were carried out in triplicate. The scavenging potential was compared with a solvent control (0% radical scavenging) and ascorbic acid. Radical scavenging activity was calculated by the following formula:

$$\% \text{ Reduction of absorbance} = [(A_B - A_A) / A_B] \times 100, \text{ where: } A_B - \text{absorbance of blank sample and } A_A - \text{absorbance of tested extract solution (t = 30 min)}^{(16)}$$

#### 2.6.4. Reaction of Roselle Extracts with Reactive Nitrogen Species

The abilities of different roselle extracts to inhibit nitrous acid-mediated tyrosine nitration were investigated. Equimolar concentrations (400 µM) of tyrosine and NaNO<sub>2</sub> were co-incubated with each extract (0 to 300 µg) in 0.5 M HCl at 37°C for 4 h (17). Snap freezing reaction mixtures prior to HPLC analysis successfully terminated reactions. We monitored the formation of 3-nitrotyrosine (3-NT) from nitrous acid-mediated tyrosine nitration by HPLC analysis with photodiode array detection (see below). 3-NT formed was characterized and quantified by use of an authentic standard (retention time and unique spectral characteristics). Trolox was used as positive control. Artefactual formation of 3-NT during the preparation stage was found to be negligible.

#### 2.6.5. HPLC Analysis

Reaction mixtures were analyzed using reverse-phase HPLC. Analysis was performed on an Agilent 1100 system with a Zorbax ODS C18 column (150 × 4.6 mm i.d., 4 µm) and guard column (15 × 4.6 mm i.d., 4 µm). Mobile phase A consisted of methanol/water/5 N HCl (5/94.9/0.1, v/v/v) and mobile phase B of acetonitrile/water/5 N HCl (50/49.9/0.1, v/v/v). The following gradient system was

used (min/% acetonitrile): 0/0, 5/0, 40/50, 60/100, 65/100, and 65/10 with a flow rate of 0.7 ml/min. The eluent was monitored by photodiode array detection at 280 nm for 3-NT measurements with spectra of products obtained over the 220–600 nm range.

#### 2.7. Statistical Analysis

All experiments were conducted in triplicate (n=3). All the values were represented as mean ± SD. Significant differences between the means of parameters as well as IC<sub>50</sub> were determined by probit analysis using SPSS software program (SPSS Inc., Chicago, IL); with p values < 0.05 considered statistically significant.

Correlation coefficients (R) to determine the relationship between two variables (radical scavenging tests and content of total phenolic compounds) were calculated using MS Excel software (CORREL statistical function).

### 3. Results and Discussion

#### 3.1. RAPD Analysis of Roselle Types

PCR was used for genotypes analysis of roselle (**Figure 3**). The PCR products, which amplified using the random primer B05, were around 1 kb for genotypes green (G) and light red (LR) (**Figure 3A**) and dark red (DR) (**Figure 3B**). The primer B05 showed more specific and distinct bands in case of LR and DR genotypes. LR genotype showed a specific band with molecular size around 700 bp while the DR genotype showed a band around 1.5 kb and two faint amplification products at 800 and 700 bp, respectively. The other random primers B08, B09, B11, B14 and C15 used in this study, to differentiate between roselle genotypes, did not show any visible amplification products.

#### 3.2. Determination of Protein Content of Roselle Seed Extracts

The protein content of three colored roselle seeds revealed that the DR-colored type has the highest protein content (68.1 mg/g) followed by the LR-colored type (66.5 mg/g), while the G-colored type has the lowest protein content (46.0 mg/g).

#### 3.3. Characterization of Protein Content of Roselle Seed Extracts

Protein electrophoretic profiles of roselle seed extracts were very similar, except for some quantitative inter-individual variations. The SDS-PAGE analysis showed approximately 14–15 major protein bands, with relative molecular masses ranging from 14 to 100 kDa (**Figure 4**).

#### 3.4. Total Polyphenol Content (TPC)

As plant polyphenolics constitute one of the major groups of compounds acting as primary antioxidants or free radical terminators, the total amount of phenolic compounds in the 12 roselle extracts was determined using the Folin-Ciocalteu method. The Folin-Ciocalteu phenol reagent is used to obtain a crude estimate of the amount of phenolic compounds present in an extract. Phenolic compounds undergo a complex redox reaction with phosphotungstic and phosphomolybdic acids present in the

reagent. Phenolic compounds respond differently to the Folin-Ciocalteu reagent, depending on the number of phenolic groups they have<sup>(18)</sup>. As shown in **Table 1**, all extracts contain high amount of polyphenolics, to which their antioxidant activity may be ascribed. DREC, GEC, DREH, GEH and DRAC extracts which showed the highest antioxidant activities also had the highest amount of polyphenols. GAC, DRAH, LREH, LREC and GAH extracts which showed moderate antioxidant activities, had moderate TPC as well. LRAC and LRAH extracts showed the lowest TPC and the lowest antioxidant activities. Further studies are in progress to isolate and elucidate the structure of main components present in each extract.

### 3.5. Determination of Antioxidant Activity of Extracts

#### 3.5.1. Water-Soluble Antioxidant Capacity

Water-soluble antioxidant capacity was determined by the phosphomolybdenum method. HACT<sup>37</sup> and HACT represented strong water-soluble antioxidants and total water-soluble antioxidants, respectively<sup>(14)</sup>. It is known that roselle sepals are very rich in vitamin C, anthocyanins, polyphenols and other water-soluble antioxidants<sup>(19)</sup>. In Egypt, however, roselle farmers discard the roselle G-colored type plants, because roselle consumers prefer and demand the DR-colored type sepals<sup>(20, 21)</sup>. As shown in **Figure 5**, sepals of DR type showed the highest levels of total water-soluble antioxidant capacity followed by G type then LR type. These results are consistent with recent study on roselle sepals' water-soluble antioxidant capacity<sup>(4)</sup>.

On the contrary, G type showed the highest levels of strong water-soluble antioxidant capacity, followed by LR then DR types. These results are in agreement with the study of Rady et al.<sup>(22)</sup>. A high level of strong water-soluble antioxidant capacity in sepals of G type suggests that, there are abundant levels of vitamin C, and other strong water-soluble antioxidants, this fact would support the recommendation of consuming both DR- and G-colored types of roselle sepals.

#### 3.5.2. DPPH Radical Scavenging Activity

The stable DPPH radical has been used widely for the determination of primary antioxidant activity, that is, the free radical scavenging activities of pure antioxidant compounds, plant and fruit extracts and food materials. The assay is based on the reduction of DPPH radicals in methanol which causes an absorbance drop at 520 nm. Radical scavenging activities of the 12 roselle extracts were measured using model colorimetric test, DPPH radical scavenging test. The results are summarized in **Table 2**. GEH, DREH, DREC, GEC and DRAC showed the highest DPPH free radical scavenging activities. GAH, LREH, LREC, DRAH and GAC also showed relatively high DPPH free radical scavenging activities. Both LRAH and LRAC showed the lowest DPPH free radical activities. These results are in agreement with both HACT<sup>37</sup> and HACT results.

#### 3.5.3. Reaction of Different Roselle Extracts with Reactive Nitrogen Species (RNS) Derived from Nitrous Acid

Acidification of nitrite is known to generate a number of RNS, including N<sub>2</sub>O<sub>3</sub>, which is capable of nitrosating secondary amines and amides. The gastric formation of N-nitrosocompounds has been suggested to be a major source of human exposure to this class of environmental carcinogens<sup>(23)</sup>. It has been established that compounds such as  $\alpha$ -tocopherol and ascorbic acid react with nitrite, and hence are able to inhibit endogenous nitrosation<sup>(24)</sup>. More recently, the ability of certain polyphenols to inhibit tyrosine nitration mediated by nitrite in acid has been demonstrated *in vitro*<sup>(25)</sup>. This prompted our interest in studying the potential of 12 different roselle extracts as potential scavengers of RNS derived from nitrous acid. In order to monitor the potential of different extracts to react with RNS derived from nitrous acid, a model system was employed. In this study the ability of 12 different roselle extracts, to inhibit the formation of nitrous acid-induced tyrosine nitration, was investigated, for the first time, under conditions akin to those in the gastric milieu of humans. Exposure of tyrosine to nitrous acid in the presence of different extracts resulted in a significant inhibition of 3-NT formation in a dose-dependent manner (**Figure 6**). The IC<sub>50</sub>'s for the inhibition of 3-NT formation by different extracts are shown in **Table 2**. LREC, DREC, LREH and GEC extracts are very effective at a relatively low concentration. DREH, GEH, GAC and DRAH extracts showed moderate inhibition. However, LRAC, GAH, LRAH and DRAC extracts showed relatively low inhibition activities.

### 3.6. Statistical Analysis

With reference to Table 1, the correlations of TPC against the antioxidant activity based on the DPPH assay involving all 12 extracts were very high reflected by the high correlation coefficient (0.86), confirming that phenolic compounds contribute to the radical scavenging activity of these extracts. While, there were no correlations of TPC against IC<sub>50</sub> of 3NT-inhibition and DPPH against IC<sub>50</sub> of 3NT-inhibition reflected by their negative correlation coefficients (-0.49 and -0.42, respectively).

In Summary, the molecular studies on three colored types of roselle (*Hibiscus sabdariffa*) presented in this article suggested that the total protein electrophoretic profiles of these three types of roselle seeds were similar, while, their RAPD-PCR patterns were significantly different. The biochemical studies on these three roselle colored types revealed that, all three types could be used as a considerable source of strong antioxidants. The sepal extracts of these three types of roselle showed important abilities to react with the biologically relevant reactive nitrogen species (RNS) by inhibiting nitrous acid-mediated tyrosine nitration, using different solvents and extraction temperatures. The characteristics of the green sepals roselle type revealed that, it could not be less important than the other roselle colored types in the industrial and pharmaceutical applications. These characteristics support the ethnomedicinal use of roselle in Africa and the Caribbean and suggest that all the three types of roselle could potentially provide health benefits. In addition, our findings present helpful information to food markets and small farmers and may help increasing the roselle

marketability and profitability. Further studies are required to evaluate the contribution of these three types of roselle to the specific health benefits in biological systems, before

increased consumption of any of these three colored types could be recommended.

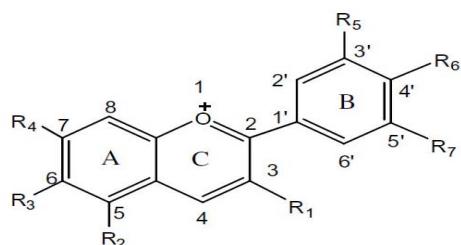

**Table 1. Full description of the abbreviations used in the text.**

Abbreviation	Description
DREH	Dark red roselle sepals (DR) extracted with 30% aqueous ethanol (E) at boiling temperature (H).
DREC	Dark red roselle sepals (DR) extracted with 30% aqueous ethanol (E) at room temperature (C).
DRAH	Dark red roselle sepals (DR) extracted with distilled water (A) at boiling temperature (H).
DRAC	Dark red roselle sepals (DR) extracted with distilled water (A) at room temperature (C).
LREH	Light red roselle sepals (LR) extracted with 30% aqueous ethanol (E) at boiling temperature (H).
LREC	Light red roselle sepals (LR) extracted with 30% aqueous ethanol (E) at room temperature (C).
LRAH	Light red roselle sepals (LR) extracted with distilled water (A) at boiling temperature (H).
LRAC	Light red roselle sepals (LR) extracted with distilled water (A) at room temperature (C).
GEH	Green roselle sepals (G) extracted with 30% aqueous ethanol (E) at boiling temperature (H).
GEC	Green roselle sepals (G) extracted with 30% aqueous ethanol (E) at room temperature (C).
GAH	Green roselle sepals (G) extracted with distilled water (A) at boiling temperature (H).
GAC	Green roselle sepals (G) extracted with distilled water (A) at room temperature (C).
HAECT	Hidrosoluble Antioxidant Capacity Total

**Table 2. Antioxidant activity, total polyphenol content and IC50 of roselle sepal extracts. Antioxidant activity was based on the ability to scavenge DPPH free radicals. Total phenolic content (TPC) was determined by the Folin-Ciocalteu method and IC50 was determined by the inhibition of nitrous acid-mediated 3-nitrotyrosine formation.**

### Abstract

**Statement of Problem:** Oral devices may be helpful in the management of obstructive sleep apnea by improving upper airway potency. **Purpose:** Management of obstructive sleep apnea using oral appliance with magnetic versus oral appliance with increased vertical dimension. **Material and Methods:** 12 patients with mild to moderate obstructive sleep apnea were evaluated in this study before and after wearing devices for six months. The patients randomly divided into two equal groups(A and B ). Group A used oral appliances with magnetic for six month Patients in group B wear oral appliances with increased vertical dimension, Evaluation was done by Polysomnograph, clinical findings and cephalometric x-rays. **Results:** The results of this study revealed that improvement of clinical finding, symptoms and apnea index for patients wearing two types of oral appliance. **Conclusions:** It can be concluded that oral appliance, with magnetic and increase vertical dimension, make improvement for OSA patients oral appliances with magnets are more effective in management of mild and moderate obstructive sleep apnea in comparison to appliances with increased vertical dimension.

**Keywords:** Management; obstructive; sleep; apnea; oral appliance; magnetic; dimension

### Introduction

Obstructive sleep apnea (OSA) is repetitive episodes of upper air way obstruction during sleep, arterial oxygen desaturation, daytime hypersomnolence and snoring.<sup>(1)</sup> In addition, these patients are at increased risk for hypertension, heart failure myocardial infarction and stroke and road and traffic accidents when compared with general population.<sup>(2,3)</sup> The site of sleep dependent obstruction in OSA is usually in the retro palatal or the retroglossal region or both, the upper air way lumen.

Several studies demonstrate that oral appliances can be a useful alternative to positive air way pressure with mild to moderate sleep apnea .<sup>(4,5)</sup> There is also robust evidence of the efficacy of oral appliances for improving polysomnographic indices and modifying the health risk associated with OSA.<sup>(6)</sup>

Oral device may be helpful in the management of OSA by; improving upper air way potency, increasing the cross sectional area or decreasing the upper air way collapsibility by increasing the muscle tone .<sup>(7)</sup>

Orthodontists who get involved in this form of therapy are often surprised at how grateful their

patients are after only a few nights of sleep without interruption and the subsequent restoration of adequate rapid eye movement (REM) sleep.<sup>(8)</sup>

The main advantages of oral devices are their relative simplicity of the treatment, reversibility , cost effectiveness and providing a genuine non surgical alternative to patients who can't tolerate continuous positive airway pressure devices ( CPAP) or who represent a poor surgical risk . Also, they enhance craniofacial growth.<sup>(9)</sup>

The US FDA approved 16 devices for use in sleep apnea oral appliances as an alternative to CPAP therapy. They are designed to keep upper air way open.<sup>(10)</sup>

Although Mandibular Advancement Device (MAD) has positive effect in treatment of OSAS, it has multiple complications. These may include craniofacial change in maxillomandibular relationship and bony dimensions, overbite alteration, tooth pain and TMJ problems.<sup>(11)</sup>

In 2003, Iranhoe<sup>(12)</sup> suggested other devices claimed to increase vertical jaw separation. Frantz, 2001<sup>(13)</sup> mentioned that the effectiveness of such appliance improved when increasing vertical opening exceeding the rest position up to 5mm opening and

had comparable success to MADS. A magnetic appliance were used for treatment of obstructive sleep apnea.<sup>(14)</sup>

The aim of this study was to evaluate the effect of magnetic appliance versus increase vertical dimension on management of obstructive sleep apnea

#### **Material and methods:-**

This study was carried out on 12 patients selected from E.N.T clinic, Faculty of Medicine, Mansoura university. The patients suffered from mild or moderate OSA as evaluated by polysomnographic (PSG).

The following steps were done for each patient:

- 1) Apnea hypopnea index (AHI) (average number of apnea events per hour of sleep) was evaluated by PSG, clinical findings and symptoms were recorded. Any caries and perioral infection were also treated.
- 2) Lateral cephalogram was taken for each patient in centric occlusion, then traced and examined.
- 3) Upper and lower primary and secondary impression were made to obtain master cast. The patients were then classified into 2 groups; including 6 patients each, according to the appliance used:

#### **Group A:**

For this group, oral appliance with magnets was constructed as follows:

- 1) Mounting upper cast by using face bow and lower cast by centric occlusion record was done, undercuts and large diastema were blocked out with a thin mix of plaster.
- 2) The upper & lower teeth were waxed up occlusally, buccally and lingually to the height of contour of teeth then packing, curing and finishing to obtain upper and lower acrylic appliance device.
- 3) Fixation of magnets, in each splint two parylene coated (poly-para-xylene 250 $\mu$ m) neodymium-iron-boron magnets (Size 6.4mmØ x 2mm) (Ortho Organizers-Hanover- Germany) of the same pole in area of premolar & molar using self cure acrylic resin (to obtain repulsion force and prevent mouth closing) was done. Fig 1
- 4) A polysomnograph evaluation for one night and recording clinical findings and symptoms during insertion and after 4, 8 months of device insertion were done. Cephalometric radiograph was also taken after insertion, then after 8 months of appliance wear.

#### **Group B:**

For this group, oral appliance with increased vertical dimension of occlusion (about 5mm exceeding the rest dimension) was done as follows.<sup>(15)</sup>

1) After adapting one layer of warm modeling wax over standing teeth, it was converted into clear acrylic resin templates.

2) Accurate adaptation of acrylic template inside the patient mouth after determining the vertical dimension of rest was done.

3) While the patient was closing, the upper and lower acrylic templates were sealed in his mouth at the vertical dimension of rest using soft compound.

4) Converting the modeling compound into chemical cured acrylic resin by using Heaper duplicate was followed.

5) After finishing and polishing, insertion in patient's mouth (Fig 2) and checking adaptation, instructions were given to the patient to use appliance during sleep and to have good home care.

A polysomnograph evaluation for one night, cephalometric radiograph and clinical finding and symptoms were recorded.

6) After one month from appliance insertion, upper and lower templates were separated and reinserted into patient mouth with softened compound for recording the new increased vertical dimension (5mm from rest).

8) The modeling compound was again converted into chemical cured acrylic resin and steps 5 and 6 were made, then follow up after 2, 4, 8 months as in group A.

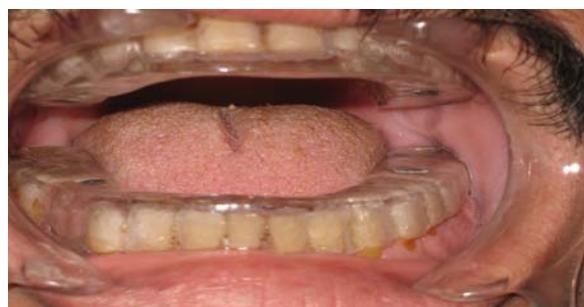

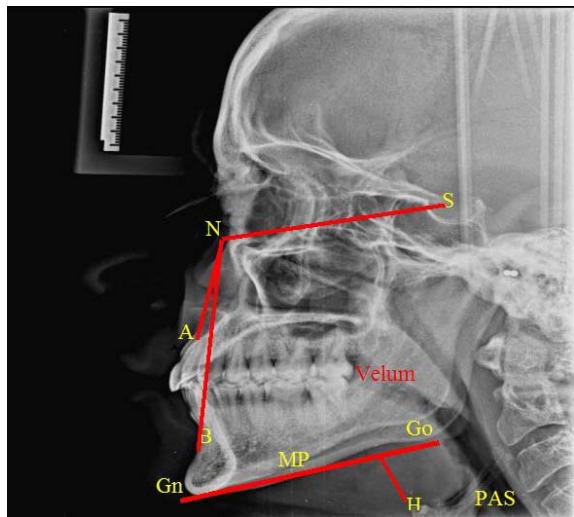

Fig 1: Oral appliance of group A with magnets.

Fig 2: Oral appliance with increased vertical dimension of group B.

### Evaluation of patients:-

**Figure 3:** Lateral cephalometric radiograph showing the Cervico-craniofacial skeletal reference points and lines used for linear and angular measurements. (A: subspinale : the most posterior midline point in the concavity between the anterior nasal spine and the lowest point on the alveolar bone overlying the maxillary incisors, B: Supramentale : the most posterior midline point on the anterior concavity of the mandibular symphysis, N: Nasion : the most anterior point of the frontonasal suture in the median plane, SNA: Maxilla protrusion angle, SNB: mandibular protrusion angle, ANB: maxilomandibular discrepancy, ANS-PNS: sagittal length of maxilla, GN-GO: length of the body of the mandible , MP-H: mandibular plane hyoid distance , P: The most lower point of soft palate, PAS: posterior airway space retroglossal).

OSA is heterogeneous disorder rather than a single disease, therefore, evaluation by multi parametric procedure successively including a clinical findings items, resolution of symptoms and the course of a simple indicator of the quality of breathing sleep were done.

#### a) Cephalometric evaluations:

Lateral cephalometric radiographs with the teeth in occlusion were obtained for all subjects before the start of treatment and after 8 months. All cephalometric films were traced.

According to De Almeida et al.<sup>(16)</sup>, Cervico-craniofacial skeletal reference points and lines were used for linear and angular measurements as follow:

SNA angle measures the projection, anterior or posterior, of the maxilla. The reference range value is  $82 \pm 2^\circ$ . SNB angle measures the position of the mandible. The reference range value is  $80 \pm 2^\circ$ . Less than this is considered retrognathia. ANB angle measures the position of the maxilla with the mandible. The reference range value is  $2^\circ$ . This measures prognathism. PAS or retroglossal space; the reference range is 10-16 mm. MP-H is the distance between the mandibular plane (MP) and the hyoid bone (H). The reference range is 11-19 mm. The longer the distance, the higher the possibility of the patient having OSA (Fig. 3).

b) Clinical findings which help in the subjective assessments of OSA. Patients with high risk of sleep apnea were those who met two of the following three criteria :- Snoring(S), persistent day time sleepiness or drowsiness while driving(P) and obesity or hypertension(H)<sup>(17)</sup>.

c) Frequency of sleep apnea- hypopnea index before and after treatment using polysomnograph. (AHI) Apnea hypopnea index: (the number of apnea and hypopneas average per hour of sleep; which is the total number of apnea during sleep divided by the total number of hours of sleep). This index measures the severity of the apnea.

Traditionally an AHI of 5 or more has been used to define the presence of OSA by dividing the sum of hours.

The American academy of sleep medicine<sup>(18)</sup> classified the severity of sleep apnea as follow :

Mild: RDI score between 5 and 15 apneas or hypopneas per hour of sleep.

Moderate: RDI score between 16 and 30.

Severe: RDI score higher than 30.

### Results:

#### Clinical finding & symptoms:-

The score of clinical finding ranged from 0 to 3: Score: 0= never, 1=slight chance, 2 = moderate chance, 3=high chance of clinical finding symptoms. The patients were evaluated during insertion of the devices, after 4months and after 8 months.

1-after appliance insertion.

2-after 8 months from appliance wear.

Table 1 Shows clinical findings and symptoms for group A,B during insertion. There were 3 patients with high chance of snoring and persistent sleep. 3 patients had moderate chance of snoring and persistent sleep. 2 patients had high chance of hypertension and 4 patients had moderate chance of hypertension.

Table 2 demonstrates also the result of apnea hypopnea index . It was found that for group A : during insertion 4 patients had moderate OSA, 2 patient had mild OSA. After 4 months, 2 patients had moderate OSA and 4 patients suffered from mild OSA. After 8 months, 3 patients had moderate OSA and 3 patients had no apnea. For group B: during insertion 3 patients had moderate OSA and 3 patients had mild OSA. After 4 months, 2 patients had moderate OSA and 4 patients had mild OSA. After 8 month, only one patient did not suffer from OSA while the other 5 patients had mild OSA.

Table 2: Clinical findings and symptoms: Snoring (S), persistent day time sleepiness or drowsiness while driving (P), hypertension (H) and Apnea hypopnea index (AHI), for group A, B during insertion, after 4 months and after 8 months:

The statistical analysis of data obtained in the present study was done by using excel program and spss program statistical package for Social Sciences version 10.<sup>(19)</sup> For all statistical analyses, the significance level was set at  $P < .05$ .

By using Mann Whitney U test, the polysomnographic findings revealed that the mean percent changes in AHI values for the 2 groups before and after 4 and 8 months following the insertion of oral appliances. There was a significant ( $P=.041$ ) in H04p in group A patients in comparison to group B patients. Also, P08 was significantly higher in group A patients in comparison to group B patients. Ah08 was significantly higher in group A patients compared to group B patients. On the other hand, SNA<sub>b</sub> was significantly higher in group B patients in comparison to group A patients.

Fig 4 shows improvement Apnea hypopnea index for group A more than group B.

### Discussion:

OSA has been described as a public health problem comparable to smoking in its effect upon society.<sup>(20)</sup>

Patients awareness regarding the problem is low especially in mild and moderate cases. An outline of the diagnostic approach to OSA is very important

The diagnosis of OSA is completed by two main:

- 1) Subjective assessments which involved focus sleep questioner clinical finding and classic symptoms
- 2) Objective assessment as physical examination sleep test polysomnograph and portable recording device.<sup>(21)</sup>

Chan A. et al.<sup>(22)</sup> mentioned that major advances in the field of oral appliances have provided a solid evidence for the use of oral appliances in the clinical management of OSA. OA are preferred by the patients; this has the potential of translating into better patient compliance and an equivalent health outcome.

Cephalometric studies have shown subtle retro positioning and shortening of the mandible and maxilla, even in the absence of distinct craniofacial abnormalities. In OSA patients compared with normal subjects<sup>(23,24,25)</sup> shorter and more posteriorly displaced mandible have been confirmed in up to two third of OSA patients and correlated with decreased pharyngeal size.<sup>(26)</sup>

Neodymium-iron-boron alloy was selected as the magnetic material of choice because of its high energy product value (260 kJ/m<sup>3</sup> as compared with 190 kJ/m<sup>3</sup> for the often used samarium-cobalt alloy, Sm<sub>2</sub>Co<sub>17</sub>), and because the neodymium-iron-boron alloy shows even better biocompatibility than samarium-cobalt magnets. The high energy product implies a possibility of stronger attractive forces in the rest position for the same size and shape of magnetic units. In this study, two magnets were inserted in each splint, producing an inter jaw force of 2.5 to 3.0 N (250 to 3250g). One shortcoming of the rare earth magnets, particularly the neodymium-iron-boron alloy, is that the alloy is very susceptible to corrosion assault by the saliva. When a magnet corrodes, there is considerable risk of destroyed magnetic properties and loss of force. Furthermore, there is a risk of liberation of cytotoxic components. To avoid inter oral corrosion, the paryene coated magnets have to, as in this study, be further embedded in acrylic.<sup>(27,28)</sup>

Interestingly, in the present investigation, improvements in clinical, cephalometric and Apnea index record by polysomnographic parameters were observed for most patients of the two groups included. Consequently this could confirm that OA should be a satisfactory and an alternative treatment modality in large proportions of patients with mild and moderate OSA who could not get benefit from other treatment options. This observation appears to be in agreement with the findings of Hoffstein.<sup>(29)</sup> and Jayan et al.<sup>(30)</sup> who supported OA therapy for OSA patients.

This study can firms that OA can be a satisfactory treatment in a large proportion of patients with slight to moderate OSAS as this response consists of a reduction in AHI(<15 events per hour) combined improvement with clinical finding together with improvement in the quality of sleep.<sup>(31)</sup>

Also psychology behavior relative had improved. Another finding in the present work showed statistically significant decrease in daytime sleepiness. There was also an overall subjective improvement after the initial use of OAs.

This may be due to for group A and B made minimum upper air way space. This agree with george zoal.<sup>(32)</sup> who suggest that bite opening should

be kept to minimum for improve at upper air way potency by stretching the palatoglossus and superior pharyngeal constrictor muscle.

An effective appliance for sleep apnea treatment should be able to move lower jaw horizontally to attempt to open the air way and rotate the lower jaw clock wise with a resultant further closing of pharyngeal space.

But more improvement for group A (magnetic appliance) than group B in spite of non significance occur. This can be explained by the fact that continuous repelling force from inherent magnetic forces which lead to improve at upper air way potency and allows freedom of function and, consequently, patient compliance is improved these agree with Bernhold M. et al.<sup>(14)</sup> who concluded that obstructive sleep apnea responded well to treatment with intra-oral magnetic appliance.

The most interesting point is decreased snoring, this may be due to the return of patients to normal state with continuous airflow; thus no vibration of soft Tissue occurred. This agrees with Jayan et al<sup>(30)</sup>, who found that as a result of OSA, a reduction of the air flow occurs, so the patient increase the speed of the air flow in an attempt to maintain the required oxygen to the lungs. The increase in the air flow velocity causes vibration of soft tissues which is the sound of snoring.

### Conclusion:

Oral appliance, with magnetic and increase vertical dimension, make improvement for OSA patients.

Oral appliance with magnetic more effective and help the management of patient with mild or moderate OSA patient in comparing with increase vertical separation of jaws

**Abstract** –Pregnancy is the more prevalent stress in under feeding small ruminant with multiple bearing. Fifty Ossimi ewes of two years old and their body weight ranging between 35 and 50 kg were allotted into three groups; Group I: contains ten non pregnant non lactating ewes were used as control group. Group II: contains twenty single pregnant ewes\* and Group III: contains twenty twin pregnant ewes used as experimental animals. Our study focused on the comparison between single and twin bearing ossimi ewes in the last three weeks of pregnancy and the day of parturition by measurement of reduced glutathione (GSH) level and the activities glutathione peroxidase (GSH-Px); glutathione reductase (GR-ase); glutathione-S-transferase (GST) and total superoxide dismutase (t-SOD) in erythrocytic haemolysate. In addition, glucose, non esterified fatty acid (NEFA), Beta hydroxyl butyric acid (BHBA), cortisol, insulin and protein electrophoretic patterns were measured in serum. Our results concluded that, In erythrocytic haemolysate the mean values of GSH-Px and GST in group II and III during the period of 2<sup>nd</sup> and one week before parturition and at the day of parturition were high significantly increased. While, GSH and t-SOD were high significantly decreased ( $P<0.01$ ) and GR-ase activities were significantly decreased. While serum insulin level decreased while serum NEFA, BHBA and cortisol were increased in single and twin but in twin the values is more significant. The data showed that twin bearing ewes are more susceptible to pregnancy toxemia than single bearing that may be decrease the productivity and performance of those animals.

## 1. INTRODUCTION

Pregnancy, parturition, and lactation represent a physiological load to the female body. Where pregnancy toxemia (gestational ketosis) caused by negative energy balance in late gestation is commonly observed in ewes and does (Kulcsar et al., 2006), in beef cows (Rook, 2000), and also in monogastric species as rabbits, guinea pigs, dogs and in ferrets (Bell, 1997; O'Rourke, 1997; Dalrymple, 2004 and Lewington, 2007). The background of the disease is the result of the fetal carbohydrate- or energy-demand exceeding maternal supply during the last trimester of pregnancy.

In ruminants, dietary carbohydrates provide well over one half of the energy needs for maintenance, growth, and production. Glucose is a primary energy source for certain animal tissues and a precursor for lactose synthesis in the mammary gland. Consequently, understanding carbohydrate digestion and absorption, dietary glucose availability, and the involvement of gluconeogenesis in the regulation of glucose homeostasis is essential for the manipulation of the production and quality of agricultural foods (Rafael and Donald, 2007). Lipid

digestion in ruminants is unique in that after ingestion feed lipids are placed into a hydrolytic and reductive environment. The result is that glycerol from triacylglycerols and phospholipids are fermented to VFA and those unsaturated fatty acids which are hydrogenated to mostly saturated fatty acids before absorption (Jenkins and Palmquist, 1984 and Van Saun, 2000). In ewes, number of fetuses plays role in keeping the homeostasis. The last trimester of pregnancy is very demanding for that homeostasis, because fetuses gain over half of their weight in this period (Seidal et al., 2006). Pregnancy toxemia is a metabolic disease that commonly affects pregnant ewes with multiple fetuses and does during late gestation. It is characterized by hypoglycemia, increased concentrations of ketone bodies in the blood and elevated plasma concentrations of free fatty acids is the result of energy demand exceeding maternal supply during last trimester of pregnancy (Kabakci et al., 2003 and Kulcsar et al., 2006).

The endocrine system especially the pancreas probably is involved in the development of ruminant ketosis. Insulin inhibits ketogenesis when free fatty acids levels are high, as well as growth hormone

secretions inhibited by cortisol and free fatty acids. Insulin also appears to be important in regulating the utilization of ketone bodies as the uptake of  $\beta$ -hydroxybutyrate and acetate (**Abd-Elghany et al., 2010**).

Cortisol is a regulator of glucose in ruminants, which acts to increase gluconeogenesis from amino acids. In starving ruminants the gluconeogenesis is maintained by elevated levels of glucocorticoids (**Azab and Abdel-Maksoud, 1999**). In lactating ruminants the rate of hepatic gluconeogenesis and the relative concentrations of glycogenic precursors regulate the level of milk production (**Huntington, 1990**).

Ketone bodies serve as an alternative fuel for many tissues, but they probably do not or only to a minor extent contribute to the energy supply of the fetus (**Battaglia and Meschia, 1988**). Glucose remains the most important metabolite for fetal and placental growth. The ability of the ewe to provide a sufficient amount of glucose to the fetus from dietary sources is limited because about 70 to 75% of the dietary carbohydrate is converted in the rumen into nonglycogenic products. The remaining fraction of digestible carbohydrate provides 40 to 60% of the circulating glucose through propionate. During periods of a negative energy balance and increased demand for glucose, up to 23% of the glucose may be synthesized from liberated glycerol from the adipose tissue. Along with this glycogenic precursor, a larger amount of fatty acids is released into the circulation that may give rise to an increased rate of ketone body formation (**Weekes, 1979 and Schlumbohm and Harmeyer, 2004**). Our study aimed to investigate carbohydrate and fat metabolic changes in single and twin bearing ossimi sheep.

## 2. Material and methods

### *A. Experimental design*

The present study was carried out in field farm of Veterinary medicine, Moshtohor, Banha University. Fifty apparently healthy, multiparous Ossimi sheep, of two years old and their body weight ranging between 35 and 50 kg. All animals were kept at the same environmental and nutritional conditions. All over the experimental period, the ewes were allotted into three groups as following:

*Group I:* included ten ewes (non pregnant non lactating) were used as control group.

*Group II:* included twenty single pregnant ewes used as experimental animals.

*Group III:* included twenty twin pregnant ewes used as experimental animals.

Animals were fed free in feedlot. Concentrate feed mixtures were adjusted to the changing of body weight every two weeks. Concentrate mixtures were

given twice daily at 10 a.m. and 2 p.m. while wheat straw was offered (*ad lib.*).

Table (1) Chemical and cell wall constituents of feed concentrate mixture and corn stalks (on DM basis)

Items	Feed concentrate mixture <sup>a</sup>	Wheat straw
<b>Chemical composition</b>		
<b>DM</b>	91.51	93.48
<b>OM</b>	89.64	89.58
<b>CP</b>	14.34	3.26
<b>CF</b>	8.47	40.23
<b>EE</b>	2.24	1.32
<b>NFE</b>	64.59	44.77
<b>ASH</b>	10.36	10.42
<b>Cell wall constituents</b>		
<b>NDF</b>	34.62	78.24
<b>ADF</b>	16.24	54.13
<b>Hemicellulose</b>	18.38	24.11
<b>NFC<sup>b</sup></b>	8.47	6.76

\*NFC: Non fibrous carbohydrates= 100 - % (CP+ NDF + EE + ASH) (Calsamiglia et al., 1995).

<sup>a</sup> Feed concentrate mixture consists of 18% undecorticated cotton seed meal, 4% soybean meal, 36% yellow corn, 36% wheat bran, 3% Vinass, 1.5 % limestone, 1.4% NaCl and 0.1% common salts.

### *B. Blood samples*

The blood samples were collected from jugular vein of all animals in the examined groups in the early morning with one week interval during the last month of pregnancy and the day of parturition. Blood samples were divided into two portions; The first portion was collected in heparinized tube contained 20 I.U. heparin for one mL blood for preparation of haemolysate by using digitonin and washing by physiological saline according to (**Kornburg and Korecker 1955**). This was used for estimation of erythrocytic GSH (**Sedlak and Lindsay, 1968**); t-SOD (**Misra and Fridovich, 1972**); GSH-Px (EC: 1.11.1.9) (**Chiu et al., 1976**); GR-ase (EC: 1.6.4.2) (**Bergmayer, 1983**); GST (EC: 2.5.1.18) (**Vessey and Boyer, 1984**). The second one was collected without anticoagulant for obtaining a clear non-hemolyzed serum by centrifugation of the blood sample at 3000 r.p.m for 5 minutes. The clear sera were freshly used for determining of blood glucose (**Trinder, 1969**), non esterified fatty acid (NEFA) and Beta hydroxyl butyric acid (BHBA) (**Duncombe, 1964**). Commercial radioimmunoassay kits were used to measure concentration of cortisol and insulin (**Tietz, 1968 and Wilson and Miles, (1977)**).

*C. Electrophoretic pattern of serum protein by SDS-PAGE* which performed according to the method of (**Laemmli, 1970**).

*D-Statistical analysis* was done by (**SAS, 1996**).

### 3. RESULTS

The data presented in (Table 2) revealed a high significant increase ( $P<0.01$ ) in the mean values of GSH-Px and GST in group II and III during the period of 2<sup>nd</sup> and one week before parturition and at the day of parturition. In contrast, GSH and t-SOD were high significantly decreased ( $P<0.01$ ) and GR-ase activities were significantly decreased at the same period of experiment.

Serum glucose level (Table 3) of single pregnant ewes showed significant ( $P<0.05$ ) decrease than control during the last 3 weeks of pregnancy. But of twin pregnant ewes was decreased significantly ( $P<0.05$ ) during the last 4 weeks of pregnancy.

Concentration of serum non esterified fatty acid (Table 3) of single pregnant ewe showed significant ( $P<0.05$ ) increase than the control during the last 3 weeks of pregnancy as well as at the day of parturition. But of twin pregnant ewes showed significant ( $P<0.05$ ) increase during the last 4 weeks of pregnancy.

Serum BHBA level (Table 3) of single pregnant ewes showed significant ( $P<0.05$ ) increase

than the control during the last 3 weeks of pregnancy and the day of parturition. And twin pregnant ewes showed significant ( $P<0.05$ ) decrease than the control during the last 4 weeks of pregnancy and the day of parturition.

Serum insulin level (Table 3) of single and twin pregnant ewes showed significant ( $P<0.05$ ) decrease than the control during the last 4 weeks of pregnancy and the day of parturition.

Serum cortisol level (Table 3) of single and twin pregnant ewes showed significant ( $P<0.05$ ) increase than the control during the last 2 weeks of pregnancy as well as the day of parturition.

The electrophoretic pattern of serum protein revealed that albumin, alpha ( $\alpha$ )-1-globulin, alpha ( $\alpha$ )-2-globulin and gamma ( $\gamma$ ) globulin of single pregnant ewes (Table, 4 and Figure, 1) were significantly decreased during the last week of pregnancy and the day of parturition. But, the concentration of serum beta ( $\beta$ ) globulin showed significant ( $P<0.05$ ) decrease during the last week of pregnancy as well as the day of parturition.

#### 4. Discussion

Our study revealed a high significant increase in the mean values of GSH-Px and GST in group II and III during the period of 2<sup>nd</sup> and one week before parturition and at the day of parturition. And showed high significantly decreased in GSH and t-SOD and a significant decrease in GR-ase. This result indicated that t-SOD activity decreased as it is a first line in antioxidant enzymes defense. In the second line, GSH-Px and GST were consuming GSH as a reductant cofactor. For that reason GSH-Px and GST activities were increased and GSH level was decreased. In addition, GR-ase activities were decreased because of GR-ase enzyme generates GSH (**Mandour and Abou-El-Ela, 1999 and Abdel-Maksoud et al., 2000**). As the glutathione assumes pivotal roles in bioreduction, protection against oxidative stress, detoxification of xenobiotics and endogenous toxic metabolites, transport, enzyme activity, and sulfur and nitrogen metabolism. Its biological significance comes from the free sulfhydryl moiety of the cysteine residue and nucleophilic properties. In cells, glutathione mainly exists in the reduced form (GSH), as the oxidized form (GSSG) (**Taisuke et al., 2009**). Erythrocytes are permanently in contact with potentially damaging levels of oxygen, but their metabolic activity is capable of reversing this injury under normal conditions. Erythrocytes are equipped by many defence systems representing their antioxidant capacity. This protective system includes superoxide dismutase (SOD), catalase (CAT), reduced glutathione, glutathione peroxidase (GPx), glutathione-S-transferase, and glutathione reductase (GR). However, the cellular antioxidant action is reinforced by the presence of dietary antioxidants (**Nakbi et al., 2010**).

The present study showed that a significant decrease in the mean values of glucose of single and twin that lower plasma glucose levels came in accordance with (**Balikci et al., 2007 and Seidal et al., 2006**). The observed decrease in serum glucose level may be due to the, negative energy balance increases lipid mobilization, which results in hepatic lipidoses with subsequent impairment of hepatocellular function, glucose deficiency with intermittent hypoglycemia and accumulation of ketone bodies. The hypothesis that cows suffering from stress and/or painful diseases have elevated blood glucose levels due to an increase in serum cortisol (**Forslund et al., 2010**).

NEFA and BHBA concentrations in single and twin pregnant ewes were significantly increased than control but in twin were more significantly increased; these results were proved by (**Nazifi et al., 2002 and Moghaddam and Hassanpour, 2008**).

Serum cholesterol level of single and twin pregnant ewes showed significant increase than the control during the last 2 weeks of pregnancy as well as at the day of parturition. The high cortisol level inhibits the growth of the axial skeleton in the sheep fetus during the late pregnancy which enhances the parturition process (**Fowden et al., 1996**).

Serum insulin level of single and twin pregnant ewes showed significant decrease than the control during the last 4 weeks of pregnancy as well as at the day of parturition. The decrease of insulin level may be attributed to negative energy balance which leads to decrease in glucose level and increase the lipolysis (**Faulkner and Pollock, 1990**). The shift of energy metabolism in a catabolic direction is characterized by a wide range of endocrine changes, such as insufficient pancreatic β-cell function with a coinciding increase in insulin resistance.

The data illustrated in table (3) showed significant increase in cortisol level than the control during the last 2 weeks of pregnancy as well as the day of parturition in Single and twin pregnant ewes. This observation may be due to a hypothesis that the known relation between stress and/or painful diseases in high yielding dairy cows and pregnant ewes may be mediated through a concurrent increased cortisol secretion leading to hyperglycaemia (**Rohrbach et al., 1999**). On the other hand, **Forslund et al., (2010)** reported significantly low levels of cortisol in Cows with ketonemia (BHBA > 1.5 mmol/l). The significant increase in cortisol and presence of significant negative correlation between plasma glucose concentration and cortisol level and the significant positive relationship with β-hydroxybutyrate may be due to increased adrenal output or to impaired ability of the fatty liver, which was a consistent finding in pregnancy toxemia, to mobilize and excrete the hormone (**Ford et al., 1990 and Abd-Elghany et al., 2010**).

The concentrations of serum albumin, alpha-1-globulin, alpha-2- globulin, beta globulin and gamma globulin of single pregnant ewes showed significant decrease than the control during the last week of pregnancy as well as the day of parturition. These results may attributed to consequence increase in the mother's basal metabolic rate, the maximal nutrient requirements of the placenta and the growing fetus, together with the transfer of serum albumin, immune globulins, and amino acids from the blood stream to the mammary gland for synthesis of colostrums (**Batavani et al., 2006**).

#### 5. CONCLUSION

Late pregnancy in ewes is a very stressful period specially the late period in which in erythrocytic haemolysate the mean values of GSH-Px

and GST were high significantly increased; GSH and t-SOD were high significantly decreased ( $P<0.01$ ) and GR-ase activities were significantly decreased. While, serum glucose, total protein, albumin, globulin and insulin were decreased while serum NEFA, BHBA and cortisol were increased in single and twin but in twin the values are more significant. Our research results recommended that twin bearing ewes need a special care during pregnancy and after parturition by supplementation of ewes by a demands of appositive energy balance.

# Study the Efficiency of Investment and its Determinants in the Agricultural Sector

Khairy Hamed Eleshmawy, Enaam Abd elFattah Mohamed, Laila Mustafa ELShrif, Haitham Bauomy Hassan

Department of Agricultural Economics - National Research Center

**Abstract:** The promotion of increased rates of the investment growth is the main priority of the economic development, where there can be no development without adequate levels of investment. The problem has been narrowed to study in lower volume of investment goes to agriculture in spite of the importance of this sector to increase the rate of economic growth, the study aims to identify the relative importance of the investment total agricultural and agricultural domestic and foreign farm, as well as identify the most important factors affecting each. In addition to, identify the efficiency of agricultural investment. The results indicated that, overall agricultural investment and agricultural domestic and foreign farm represented about 9.38%, 7.98%, 1.4% of the total investments, and investments amounted to local agriculture, and foreign to 84.88%, 15.12% of the total agricultural investment. Estimating the efficiency indicators of agricultural investments shows that, there is efficiency in agricultural investment despite lower Kimpalastmarat directed to the agriculture sector during the study period. The results showed that, the agriculture sector capital intensive, in addition to increasing the coverage of agricultural savings to agricultural investment as much as about 46% in 2008. While the share of one acre of agricultural investment from 283.65 pounds in 1999 to about 194 pounds in 2008. The results showed that, the most important factors affecting the local agricultural investments are in value-added farm income and saving agricultural and domestic liquidity and interest rate on farm loans. While the GDP and the budget deficit and non-agricultural investments, the most important factors affecting foreign investments in agriculture. Therefore, the study recommends the need to increase investments directed to the agricultural sector given the importance of this sector and its contribution to economic growth. You need to follow monetary policies that reduce the interest rate on agricultural loans to encourage investment in agricultural projects, in addition to the need to reduce taxes on agricultural projects as a means to stimulate the agricultural investor.

**Keywords:** Agricultural. Investments, Domestic Agricultural. Investments, Foreign Agr. Investments. Gross Investments.

## Introduction:

Investment is the primary focus of economic growth on the national level. Agricultural investment is also one of the tools essential to the success of agricultural development, which is the basic foundation to increase production and income and create new jobs. Increasing investment means the addition of productive projects and contributes to increasing production and thereby increase exports and reduce imports, thereby improving the trade balance, and increase national income and the individual and which is reflected in increased savings which in turn results in the creation of new investments, and therefore the investment is considered a variable stream has an effective role in finding solutions to the problems of the Egyptian economy as well as to absorb as much of the manpower is not working as well as reducing the unemployment rate of about 8% in 2008 (7).

Agriculture also contributes about 25% of GDP, has targeted the state would increase the rate of

growth in the agriculture sector to around 5% annually, which requires increased investments aimed at this sector to about 14% (9).

This investment has reached about 104.65 billion national pounds, which represents investments in agriculture by about 6.7% during the period (2002-2008).

**Study Problem:** The problem with the study in the low volume of investment goes to agriculture relative to the investment to other sectors of non-agricultural despite the importance of that sector to increase the rate of economic growth through increased agricultural output and boost agricultural development, and also reduced the relative importance of agricultural investment in general and agricultural investments domestic and foreign, in particular.

**The Aim of the Research Subject:** The study aims to identify the efficiency of agricultural investment

through some of the economic indicators, as well as identifying the size of the total agricultural investment and agricultural investment, foreign and domestic the most important factors influencing them.

**Methodology and Source of Data:** The study relied on methods of descriptive statistics and quantitative data analysis to achieve the objective of research, as well as some measures of efficiency and methods of time trend in the public and multiple regression and gradual. The study was based on data published and unpublished, which have been collected from various sources such as the National Bank of Egypt, Ministry of Economic Development, and the device center for Public Mobilization and Statistics.

### Research results and discussion

#### The relative importance of agricultural investment

Table (1), shows the relative importance of agricultural investment fluctuates from year to year, ranging between a maximum of about 14.2% in 2001 and a minimum of about 4.8% in 2006 and an average of about 9.38% of the total investments of national, which indicates a decline in importance relative to agricultural investments.

As seen from Table (2), the agricultural investments increased annually by 20.4 million pounds and with an annual increase of statistically

significant estimated 0.28% of average, amounting to around 7.21 million pounds during the period (1995-2008).

With regards to, the investments of domestic agriculture, ranged from a maximum of about 8.07 billion pounds in 2001, a relative importance of about 11.9%, 84.2% of the total national and agricultural investments, respectively, a minimum of about 3.8 billion pounds in 1995 represented about 7.01%, 84.8% of the national and agricultural investments, respectively, representing an annual average of about 7.98%, 84.9% of the national investment, agricultural, respectively, during the study period. The data in Table (2), shows that the local agricultural investments increased annually by 6.5 million pounds and an annual increase of about statistically significant 0.11% from an average of about 6.121 billion pounds.

With regards to, the agricultural investments in foreign, data in Table (1) indicates that, it reaches a maximum of 1.52 billion pound in 2001, representing about 2.3%, 18.8% national and agricultural investments, respectively, as a minimum to 0.69 billion pounds in 1995 representing about 0.8%, 11.5% of the national and agricultural investment, respectively, representing an annual average of 1.4%, 15.12% of the national and agricultural investment, during the period (1995-2008).

Table (1): Relative Importance of Agricultural (total, domestic and Foreign Investments) (1995-2008)

year	Gross Investments	Agr. Investments		Domestic Agr. Investments			Foreign Agr. Investments		
		Value	% of Gross Investments	Value	% of Gross Investments	% of total Agr. Inv.	Value	% of Gross Investments	% of total Agr. Inv.
1995	54.9	4.48	8.2	3.8	7.01	84.8	0.69	1.2	15.2

Average	75.24	7.21	9.38	6.12	7.98	84.88	1.095	1.4	15.12

**Source:** Compiled and calculated from:

1 – Egyptian National Bank: varians bullitins.

2 – CAPMAS- Statistical Data Base.

As it turns out that, foreign investments in agriculture increased annually by about 13.84 million pounds, with an annual rate estimated statistically significant 1.27% on average, amounting to around 1.092 billion pounds during the study period, Table (2).

Estimating the coefficient of variation to the relative variation for each of the national and agricultural investments of local and foreign during the study period, which means differ from year to year.

Above it is a clear decline in the relative importance of agricultural investment, despite the importance of agriculture to increase production and farm income and create jobs and reduce unemployment, and then push the wheel of development.

Table (2): Statistical Estimation of National, Agricultural, Agricultural domestic and Agricultural foreign investments (1995-2008).

Variable		Average	Change rate %	F TEST	R <sup>2</sup>	Variation coefficient
Gross Investments	20.36	132.63	1.54	30.7**	0.53	11.5
Agr. Investments	20.4	7.21	0.28	12.9**	0.62	19.8
Domestic Agr. Investments	6.5	6.121	0.11	15.3**	0.69	19.8
Foreign Agr. Investments	13.84	1.092	1.27	17.2**	0.72	24.6

(\*\*) Significant at 0.01; **Source:** Compiled and calculated from data Table (1)

**Efficiency of investment in the agricultural sector:** The process of allocating investments to the agricultural sector and optimize the distribution is the main determinant for long-term stability and make economic growth of this sector, with the consequent increase in productivity of factors of production and the growth rate of agricultural GDP. There are various standards and indicators used to measure the efficiency of investment it takes up in this part of the research together.

**1 - The investment rate:** expresses the amount of investment spending necessary to add one unit of agricultural output and is calculated from the following formula:

$$\text{Investment rate} = \text{Agriculture Investment} / \text{Agricultural local output}$$

**Reflects the decline in the rate of one right on the efficiency of agricultural investment and vice versa.**

It is clear from Table (3) that, the investment rate fluctuates from year to year, the maximum is reached about 0.714 million pounds in 1997, the minimum was about 0.332 million pounds in 2008, an average of about 0.554 million pounds during the period (1995-2008), which has already seen that the rate of agricultural investment decreased from the correct one during the study period, which indicates the efficiency of agricultural investment in order to lower the value of the investments needed to increase GDP by one unit.

**2 - Return on Investment:** This indicator reflects the units of the GDP generated from one unit of expenditure Alastmary, and is calculated from the following equation:

**Return on Investment**=Agricultural local output/ total Agriculture Investment

It reflects the high value of the index for the right one on the efficiency of agricultural investment and estimating the return on agricultural investment during the period (1995-2008), shown in table (3)

that ranges from a low of around 1.4 million pounds in 1997, the ceiling was about 3.013 million pounds in 2008 and an estimated annual average of 1.89 million pounds, Which has already seen efficiency in agricultural investment because of the high unit value of GDP generated from investment spending.

### 3 - per acre of agricultural investment:

Calculated by dividing the investment of the agricultural cultivated area. Data in table (3), show that, the high per acre of agricultural investments ranging from a low of around 127.72 L.E in 1995, the ceiling was about 283.65 L.E in 1999, an average of an estimated 204 L.E during the study period (1995 - 2008), which has already seen the success of the investment policy in the mobilization of investment in the agriculture sector.

**4 - Coefficient of Endemism:** Indicates the coefficient of endemism to the contribution of the agriculture sector in generating gross domestic product, according to the investment of this sector and is calculated dividing the proportion of agricultural investment from the National Investment on the percentage of agricultural gross domestic product of the national gross domestic product, as in the following equation:

**Coefficient of Endemism** = (agricultural investment/ National Investment) ÷ (agricultural gross domestic product/ national gross domestic product)

Low this standard for the right one means that the agricultural sector has attracted investments of less than its contribution to GDP of the agricultural sector. The data in Table (3) that the minimum coefficient of endemism was about 0.24% in 1998, while the upper limit of about 0.87% in 2003, and an average annual estimated 0.58%. Notes from the table that the coefficient of endemism at least one order for each year of the study. This indicates the importance of directing more investments to the agricultural sector because of its importance in increasing gross domestic product.

Table (3): Criteria of agricultural investment efficiency (1995-2008)

year	Agr. Invest. coeff	Agr. Invest. returns	Agr. Invest. Per feddan (L.E)	Coefficient of Endemism	Capital intensification coeff.	Agr.savings /investment	Average propensity to save in agrionltwe%	Agr. Investment productivity
1995	0.474	2.108	127.72	0.31	0.963	32	9.6	3.28

Source: Compiled and calculated from data

1 - Ministry of Economic Development, a plan of economic and social development issues separate.

**5-"Capital Condensation Coefficient (Coefficient of Employment):** Capital intensity factor shows the ratio between agricultural investment and the number of agricultural workers is calculated as follow:

**Capital intensification factor** = agricultural investment/ agricultural workers

The lower the coefficient of employment indicates the number of workers increased by more than increased investment, which requires increasing the volume of investments to recruit more and contribute to solve the problem of unemployment. Coefficient reflects the employment component of the condensation of the capital or the condensation of the work item and thus reflects the contribution of the sector in employment. The data in Table (3) that the coefficient of employment ranges from a low of about 0.963 thousand pounds in 1995, an upper limit of about 1.929 thousand pounds in 2001, and estimated an annual average of 1.43 thousand pounds. Above clearly that employment factor greater than one indicating that the agriculture sector capital intensive except for 1995. This may reflect the tendency for farmers to use modern machinery and modern technologies in agriculture due to the high wages for agricultural labor.

**6 - The coverage rate of saving schemes of agricultural of agricultural investment:** shown in table No. (3) that the coverage rate of saving agricultural to agricultural investment ranging between a minimum of about 23% in 1997, an upper limit of about 46% in 2008, an average year an

estimated 33% during the study period. It is a clear already high rate of savings to cover the agricultural investment during the study period which may be due to higher savings and lower agricultural investments in agriculture, which means an imbalance in the relationship between equilibrium indicates to pass some savings to agricultural investment of non-agricultural.

**7 - The tendency of the average agricultural Savings:** reflects the change in the amount of average propensity to save agriculture and agricultural savings is calculated by dividing the farm income.

**Average propensity to save agriculture I=** save agriculture/agricultural income

Data from Table (3) that the tendency of the average savings ranging from a minimum at about 9.6% in 1995, an upper limit of about 14.4% in 2000, an average year an estimated 11.7% during the study period. Clear from the above average decline in the trend of saving during the study period. This may be due to low savings and increase agricultural income and, which means a relative imbalance in the equilibrium relationship between them.

**8 - Factor productivity of agricultural investment:** This measure reflects the profitability of a unit of money invested in the agricultural sector, calculated by dividing the agricultural income to agricultural investment:

Factor productivity of agricultural investment = agricultural income / agricultural investment

The data table (3) The coefficient of the agricultural productivity of investment between a low of about 2.02 in 2001, and a maximum 4.84 in 2008, and the average annual estimated 3.10 during the study period.

#### **Economic variables affecting the agricultural investment in Egypt:**

**1 - Agricultural GDP Total:** shown in table No. (4) that the total agricultural output fluctuates from year to year from a low of about 11.4 billion pounds, and a maximum of about 17.21 billion pounds, with an average annual rate of about 12.5 billion pounds during the period ( 1995-2008), The amount of annual change by about 0.52 billion pounds, an annual rate of statistically significant estimated 3.98% of the average of the period, reflecting the relative coefficient of variation (\*) variation during the study period, where an estimated 19.9%.

**2 - General deficit:** Data from the previous table that the General deficit in fluctuates from year to year between the lower limit of about 9.6 billion pounds and a maximum of about 89.6 billion pounds, an average annual rate of about 37 billion pounds this, the amount of annual change about 7.16 billion pounds per year statistically significant change is estimated at 19.3%, and a coefficient of variation relative to 85.3 reflecting the differences in the General deficit during the study period.

**3 - Agricultural income:** it is clear from Table (4) that the real agricultural income ranges from a minimum of about 16.71 billion pounds and a maximum of about 27.67 billion pounds, an average annual rate of around 20 billion pounds. This may show that the income of agricultural growing annually by about 0.89 billion pounds and statistically significant annual rate of around 4.5% and the relative difference by a factor is reflecting the variation in per capita income of about 19.6% during the period (1995-2008).

**4 - Evolution of value added:** examine the development of value-added of the agricultural sector in real terms shows that they fluctuate from year to year between a minimum of about 12.8 billion pounds and a maximum of about 20 billion pounds, an average annual rate of about 14.7 billion pounds, this has increased in real value added annually by about 0.63 billion pounds, a statistically significant annual increase of about 4.3% and coefficient of variation reflects the relative differences in real value added of about 19.2% during the period (1995-2008).

**5- Saving agriculture:** Data from the Table No. (4) that saving agricultural real terms ranged from a minimum of about 1.46 billion pounds and a maximum of about 2.7 billion pounds, an average annual rate of around 2.46 billion pounds, this has increased saving agriculture at an annual rate significantly statistically is about a factor of 3.5% and the difference reflects the differences in agricultural savings of about 19.2% during the study period.

**6 - agricultural loans:** Data from the previous table to the relative stability of the value of agricultural loans, ranging from a minimum of about 2.1 billion pounds and a maximum of about 2.7 billion pounds and an average annual rate of around 2.55 billion pounds, this has increased agricultural loans during the study period at a rate statistically significant year of about 1.9% and the relative difference by a factor reflecting the variation in the value of agricultural loans of around 13.6%.

**7 - agricultural workers:** study of the evolution of agricultural employment during the period (1995-2008) shown in Table (4) to range between a minimum of about 4.75 million workers and a maximum of about 5.38 million workers by an average of about 4.58 million workers have taken this trend increased general statistically significant annual rate of change is about a factor of 1.44% and the difference reflects the relative convergence in a number of agricultural labor as an estimated 6.1% during the period of study.

**8 - the interest rate on loans:** The interest rate of the most important determinants of investment if the interest rates have risen, this is the decline of investments, while low interest rates lead to stimulate further investment, it is clear from Table (4) to range from a low of about 11.9% and a maximum of about 17% average annual rate of about 14.5%, this has increased at an annual rate of about statistically significant 3.7% relative difference by a factor reflecting the variation in interest rates on loans of around 11.6% during the period (1995-2008).

**9 - Evolution of the dollar exchange rate of the pound:** reflects the strength of the pound against the dollar and the data indicate the table number (4) that the exchange rate of the dollar is about 3.4 pounds, at a minimum, and about 6.2 pounds with an average maximum of about 4.62 pounds during the study period, and is growing annually by about 0.24 pounds, a statistically significant annual change of about 5.22% and a difference of a factor of about 24.2%, which reflects the differences in the exchange rate.

Table No. (4): Statistical analysis description of the most important Economic Variables affecting the Agricultural: total, domestic and Foreign Investments (1995-2008)

variable	Lower limit	Upper limit	The Average	Change rate %	R <sup>2</sup>	F TEST	Variation coefficient

1 - Central Agency for Public Mobilization and Statistics - Statistical Database, unpublished data.

2 - National Bank of Egypt, Economic Bulletin numbers sporadic.

3 - Ministry of Economic Development, reports of annual follow-up of the plan the number of sporadic.

**10 - Evolution of the wage of agricultural real:** between a minimum of about 1.14 thousand pounds at a minimum and about 6.84 thousand pounds, a maximum annual average is estimated at 2.5 thousand pounds, this has increased at an annual rate statistically significant estimated 15.8% and a factor of difference relative reflecting the variation in agricultural real wage of the worker is estimated at 75.9%.

**11 - Evolution of investments for non-agricultural:** Data from the table (4) shows, that the investments for non-agricultural fluctuate from year to year, ranging from a minimum of about 53.2 billion pounds and a maximum of about 147.8 billion pounds, an average annual rate of about 80.2 billion pounds during the period (1995 -2008), this has increased at an annual rate of about statistically significant 6.9%, which indicates that the non-agricultural sectors will attract investment, and the relative coefficient of variation was about 36.8, which reflects the differences in non-agricultural investments.

**12 - domestic liquidity:** As indicated in table (4) that, the local fluidity ranging from a minimum of about 0.053 billion pounds and a maximum of about 0.115 billion pounds, an average annual rate of around 0.078 billion pounds, this has increased domestic liquidity during the study period at an annual rate significantly statistically estimated by a factor of 6.74% and the relative difference amounted to about 29.8% reflecting the variation in the value of local liquidity.

**Determinants of agricultural investment:** It has been made several attempts to include various combinations of independent variables of the previous study to measure the impact on total agricultural investment and agricultural investment both domestic and foreign, to the possibility of obtaining estimates on the degree of efficiency using the method of regression staging in different images and select the best images that conform to signals with economic logic.

The most important factors affecting the total agricultural investments: show Equation (1) Schedule No. (5) that changes the equation explain about 86% of the changes in the value of total agricultural investment, as an increase in variables of value added agricultural income, savings and agricultural and domestic liquidity by one million pounds each of them individually leads to increase agricultural investment by 1.9, 2.54, 3.1 0.101400000 pounds, respectively. The effect was a negative interest rate on loans means that the high interest rates on agricultural loans lead to a decrease in agricultural loans and investments in agriculture and about 574 million pounds. The most important factors affecting the local agricultural investments:

Show equation (2) Schedule (5) that, the variables within the model explains about 85% of the changes in investment by local agriculture, and due to the value-added farm income and savings and agricultural domestic liquidity and interest rates on farm loans. As an increase in value-added farm income and saving agricultural and domestic liquidity

by one million pounds each of them individually lead to increased investment by local agricultural 1.54, 2.12, 2.65 0.2670000 pounds, respectively. The effect was negative for a variable interest rate on loans means that the high interest rates lead to decreased agricultural loans, agricultural and domestic investment by about 464 million pounds.

#### The most important factors affecting foreign investments in agriculture:

Show the equation (3) table (5) that the factors affecting foreign investments in agriculture are in the GDP and the budget deficit and non-agricultural investments. Also show a positive

correlation between GDP on foreign investments in agriculture since the increased One million pounds lead to increase foreign investments in agriculture by £ 7.673 million. While showing an inverse relation between the budget deficit and non-agricultural investments on foreign investments in agriculture as enhancing them one million pounds lead to a decrease in foreign investments in agriculture by about 0.024 0.0075000 pounds, respectively. The coefficient of determination shows that 78% of the changes in foreign investments in agriculture due to the previous variables.

**Abstract:** The concept of family economic has become important around the world. It has been realized that communities based family economic can play a fundamental role in poverty alleviation. Measuring of family economic status is an important step in developing family economic strategies to achieve poverty reduction. This paper used qualitative approaches to illustrated family economic status. The purpose of this study is to explore the concept and indicators of family economic. The literature derived from my study in family economic management.

[Mehdi Yadollahi & Laily Hj Paim. Measurement of Family Economic Status. Journal of American Science 2010;6(11):756-760]. (ISSN: 1545-1003).

**Key Words:** Family Economic, Income, Physical Assets, Expenditure

## 1. Introduction

Family Economy used to denote the basic structure of production and consumption in the preindustrial Europe. In the family economy there were regional variations, which were how different places were different in family economy (Wikipedia, 2010). Economic status represents the economic capacity of families to meet their material and non-material needs. Income and ownership of physical assets are means that can use to acquire suitable economic status of families. According to Friedman (1957) families with low income levels are disproportionately represented by a provisional reduction in the current income that will usually suggest a high ratio of consumption to income. Expenditure also largely depends on income and assets. It represents an even more direct means to achieve human well-being. Families' perception on availability of money to make ends meet are not uniform, however, it is even closer to indicating overall family economic status. In otherwise, families with high-income levels are representing by those with temporary increases in income and will demonstrate low ratios of consumption to income.

## 2. Indicators of Family Economic Status

The word family raises powerful pervasive images. The institution of the family can be seen as the foundation within our society, the most powerful emotional system to which

we will ever belong. However, the meaning of the world family can vary significantly depending on how it is used and by whom. Bindon and Vitzhum (2003) in their studies have reported a number of significant factors affecting family economic resources. These included education, occupation, and economic behaviour including number of household members involved in family production activities. Some researchers have categorized the family economic status into three categories, poor, average and rich (Dao et al., 2006).

Quality of life is another construct related to family economic status. Several indicators were used by Xavier et al., (2003) to measure quality of life. These indicators were included level of satisfaction and well-being of health, activity, income, social life, and relationship with family members (Xavier et al., 2003). The search for these indicators is an effort to achieve new information that will be valuable to assess the past, direct the activities of the present, and plan for future.

Family economic status also can categorize into two levels. The first is 'not enough to live', and the second is 'enough to live' (Xavier et al., 2008). Conventionally, indicators of socio economic status is measured financially using income or consumption expenditure, based on the proposition that material living standards reflects well-being (Falkingham & Namazie, 2002). The empirical measures of different

levels of family economic status used by different researchers are aimed at the recognition of strengths and weaknesses of the family economic dimensions (Lundberg & Pollak, 2007). There is a long-standing debate about whether income or expenditure is a superior measure of socio economic status. Income is commonly more obtainable than consumption. According to Friedman (1957) permanent income hypothesis confirmed that families are likely to base their consumption on times of income fluctuation, for example, by borrowing or drawing on savings during times of low income (Friedman, 1957). Consequently, it broadly asserted that consumption expenditure is a superior indicator of the long-term socio-economic status than income. This argument holds true in low-income countries, where income maybe derived from a diversity of sources and may vary significantly across seasons. The long-term aspects of the socio economic status take a while before being related to various health outcomes, adding to the reasons for choosing consumption expenditure over income (Laura et al., 2008). Within low-income countries, the measure of consumption expenditure is fraught with problems. There is the inconvenience concerning recall and an unwillingness to reveal information (Deaton & Zaidi, 1999). In addition, collecting consumption expenditure data requires an extended questionnaire that must be done by skilful and experienced interviewers (Laura et al., 2008).

Other indicator to measure family socio economic status is an asset-based approach. It is an option to income and consumption expenditure. In the case of data on income or consumption expenditure lacking, information on possession of a range of durable property can be used (Falkingham & Namazie, 2002; Rutstein & Johnson, 2004). Gathering of data concerning assets has claimed to be more consistent than income or consumption expenditure. This is because, it uses uncomplicated questions or straight observation by the interviewer and, therefore, should suffer less from recall or social desirability related problems (Sahn & Stifel, 2003).

Educational level, occupational status and income are the most widely used indicators of socio-economic status (SES). Though moderately correlated, each of these indicators can capture distinctive aspects of social position, and they are

not interchangeable. Income has employed broadly as an indicator of SES, with the majority of typical income-based measures being a family's total cash income, measured over some period such as a monthly, or yearly preceding measurement. Some researchers suggest that income is perhaps the strongest and most robust predictor of health (Lantz et al., 1998; McDonough et al., 1997), because, to some degree, the impact of other SES variables are mediated through it (House & Williams, 2000). Others would disagree, since a strong case can be made that education alters health-related behaviour as well as some psychosocial factors, and these influence health independently of education's effect on income (John et al., 2002).

In assessing socio-economic status, particularly economic status, measuring variables other than family income may be useful, for example, assets such as inherited wealth, savings, employment benefits, or ownership of homes or motor vehicles (Berkman & Macintyre, 1997). While income represents a flow of resources over some period, wealth captures the stock of assets at a given point in time, and, thus, economic reserves. Wealth is a source of economic security providing an index of a family's ability to meet emergencies or absorb economic shocks such as unemployment. However, the importance of wealth as a source of economic security may vary among societies. Income and wealth are completely correlated, but they are not exchangeable, as revealed by the example of an elderly person with a modest fixed income but substantial accumulated wealth (John et al., 2002).

Socio-economic status typically is divided into three categories – high SES, middle SES, and low SES. When placing a family into one of these categories some or all of the three variables (income, education, and occupation) can be assessed (Werner et al., Goode, 1999; Marmot, 2004; 2007). Other studies have attempted to explain family economic status using two categories –high and low family economic status (Ahmed et al., 2000, 2003). Chuma and Molyneux measured family economic status by using expenditure and assets. They determined that household economic status categorized in rural and urban areas (Chuma & Molyneux, 2009).

Many Americans consider that there are three straight forward class models of family or society that separate the better off, the middle class, and the poor based on economic status (Eichar, 1989). Mainly, definitions of class differentiate people according to wealth, income, education, type of occupation and association in a particular social system. Several explanations of class merely look at

numerical measures such as wealth or income. Additional factors taken into account include qualitative factors, such as education, culture, and social status (Gilbert, 1998).

Salsberry and Reagan (2009) in their research comparing the influence of childhood and adult economic status on midlife obesity used three income categories. An income variable was then used to categorize the sample into three categories (i) below the 33.3 percentile of sample, (ii) between the 33.33 percentile and the 66.7 percentile, and (iii) above the 66.7 percentile (Salsberry & Reagan, 2009). Frederic (2007) also in his research about the anatomy of increasing income inequality of US family used five income categories based on percentile. These categories were from the first income level (0-20), (20.1-40), (40.1-60), (60.1-80) and the last one was (80.1-100) percent (Frederic, 2007; Meyrick & Yusuf, 2006). World Bank (1998) also used five categories of income to investigate world annual consumption. In these categories, per capita income for the first level was less than \$1,000, second level \$1,001 to \$4,000, third category \$4,001 to \$10,000, fourth level \$10,000 to \$20,000, and the last level \$20,000 and above (World Bank, 1998).

## 2.1 Income

Income is the most important indicator of family economic status, as it provides a direct means to acquire goods and services that are considered fundamental to sustaining a healthy lifestyle. Income can be used as a quantitative variable and can be grouped into categories. The categorical approach is more common since individuals tend to be reticent about providing exact income information or they are uninformed. Thus, they are more willing to indicate their placement in categories. Despite the use of the categorical approach to income responses, refusal rates are higher than for the other two commonly used indicators (i.e., education and occupation). Categories often determined by the expected range of income of participants. This fact reduces comparability across studies since the ranges of income levels are affected by the geographic area, characteristics of the respondents, and the time of study. For purposes of analysis, income categories are usually recoded to their midpoints and are often transformed to logarithms (John et al., 2002). An important consideration in the construction of survey questions is the scope of the income sources the respondent should consider when determining "household income". According to John et al., (2002) Questions about income received from jobs, social security, retirement

annuities, unemployment benefits, and public assistance. The income sources such as interest dividends, income from rental properties, child support and alimony also might be considered in a calculation of family income. In addition, family income may also include income earned from the "informal economy" (e.g., jobs that pay cash but have no benefits or job security), particularly in communities of immigrants and minorities, as well as informal transfers (e.g., of goods and services) (John et al., 2002).

Family incomes cannot be compared without knowledge of the family size. The impact of a given income is significantly dependent on family size and composition. A total family income of \$30,000 would mean something quite different to a family of two and a family of eight. It also means something different depending on whether one breadwinner earns all or most of the income while the other is able to attend to other household responsibilities in comparison to two adults having to work full-time to earn an equivalent income. While some researchers ignore the issue of family size and composition, others divide the total household income by the number of household members to produce a per capita income. This tends to overcompensate because the costs of maintaining a given standard of living do not increase proportionately. Other researchers suggested an intermediate adjustment, dividing the family income by the square root of the family size. This approach suggests that a family of four needs about double the income of a single person to have a comparable standard of living (Buhmann et al., 1998). There are a number of limitations in using income as an indicator of FES. Firstly, analysis of income is likely to be open to reverse causation arguments. Secondly, income is a more unstable measure of FES than education or occupation, and is sensitive to changes in life circumstances (thus, the advantage of using, for example, 5-year income). Income information is especially sensitive for some people, resulting in greater errors in reporting and non-response for income questions than for some other FES indicators. In other ways, measuring income can be costly and time consuming.

## 2.2 Ownership of Physical Assets

Historically, property and ownership of physical assets carry an interesting connotation in Iran, since they are mostly immovable as land and buildings and transferred through generations.

Physical assets can classify according to household assets such as whether the family home are owned or rented, and whether there is a car or garden. Wealth in the form of assets maybe offset by accumulated debt, thus, suggesting that getting a sense of the balance of assets to debt is important. Some people's wealth derives from their ability to borrow, or find investors for very large sums of money to invest; and in these less frequent cases they may be "making a living" off borrowed wealth. The distributions of income are related to the division and concentration of wealth – although the two bear no similarity. Wealth is a much broader concept than income, and contains ownership of both monetary (income, savings, investments, stocks and bonds, etc.) and other assets (real estate, home ownership, buildings, land, art, etc.). Assets maybe more strongly linked to social class than earned income. Assets also associated with health independent of other SES indicators. There are some limitations to measure of assets. These limitations are associated with the indexing of income. Given the multiple categories that may contribute to assets, assessment can be difficult for some respondents. The information also is sensitive for some people than for other FES indicators. Lastly, the measuring of assets can be costly and time consuming.

### 2.3 Expenditure

Expenditure includes consumption and non-consumption items such as education and taxes. Usually, to a certain degree, the household expenditure depends on family size; however, some families tend to spend more than others, even with the same size. Therefore, family expenditure also is used to examine the inequality in distribution of expenses. Any consumption estimate largely depends on what items are counted as consumption. It will be the aggregation of family expenditure on food, house rental, utilities, health, clothing, transportation, entertainment, furniture and appliances. The largest component of expenditure for all consumer units in Iran until 2001 has been housing, with compare other expenditures (Ministry of housing and urban, 2010). Magrabi, et al (1992) also confirmed that the housing is the largest expenditure for most of families (Magrabi et al., 1992). In developed countries, family economic status dose not directly affected to the household consumption. Studies on well-being and economic variables have dealt with the relation between income and

assets rather than with consumption. Even though income and assets are not strongly relate to well-being, but the goods and services that families buy with their money affect their satisfaction with consumption.

### 3. Conclusion

The literature review revealed the importance relevance of family economic for poverty reduction in households' communities. This study showed dimensions of family economic status that are involved in processes of family economic development. The findings of this study contribute to family economic literature. The outcome of this study also assists researchers in the field of family management and family economic.

[foda302002@yahoo.com](mailto:foda302002@yahoo.com)

**Abstract:** Eighty six cultures were isolated from soil of different Egyptian Governorates including Quina, El-Menofaya, El-Gharbia, El-Sharkia, El-Behera and Kafr EL-Sheikh Governorates. Investigations of the mosquitocidal Egyptian isolates have revealed that isolate No.1 have the ability to form more toxin than the international reference strain *Bs*2362. The selected isolate No.1 exhibited a lower LC<sub>50</sub> and LC<sub>90</sub>values than the International strain *B. sphaericus* 2362 upon bioassay against secondinstars' larvae of *Culex pipiens*. The Egyptian isolate No.1 was identified morphologically and biochemically as *Bacillus sphaericus*. Physiological factors affecting growth and toxin formation in *B. sphaericus*No 1 in comparison to *B.s* 2362 were carried out. THE organism grown on modified Nutrient broth medium yielded the highest larval toxicity against the second instars' of *Culex pipiens* for both *Bacillus sphaericus*isolate No 1 and the international strain *Bacillus sphaericus*. The Optimum air : medium ratio were 9:1 and 4:1 of the flask volume for 4 and 3 days incubation periods using 2%and 3% sizes of inocula for *B. sphaericus* 2362 and the Egyptian isolate *B. sphaericus*No.1, respectively. Sodium acetate was the suitable carbon source for the isolate *B. sphaericus* No.1, while *B. sphaericus* 2362 was capable to utilize both sodium acetate and sodium succinate as carbon sources. The Egyptian isolate *B. sphaericus* No.1exhibited the highest mosquitocidal activity upon growth on kidney beans seeds and sesame meal as nutrient substrates at 3% final concentration, while *B. sphaericus*2362 exhibited the highest mosquitocidal activity by utilizing soy beans, lentils and sesame meal as complete media for growth and mosquitocidal toxin production.

## Introduction

The mosquito acts as a vector for many of the world's most serious diseases, both parasitic e.g. malaria (*Anopheles*), lymphatic filariasis (*Anopheles*, *Aedes*, *Culex* and *Mansonia*) and viral e.g. yellow fever, dengue (both *Aedes*) and encephalitis (*Culex*). (Baumann *et al.*, 1991).

*Bacillus sphaericus* has been successfully used for the the biological control of numerous of disease -transmitting mosquitoesmosquito and black fly species (Lacey and Undeen, 1986). The prime advantage of the *B. sphaericus* strain lies in their ability to persist for longer periods in the environment than *Bacillus thuringiensis*var. *israelensis*. This may be due to recycling and amplification of spores in larval cadavers under certain aquatic situations or

may be simply due to the long-term persistence of sufficient and accessible toxin in the environment or a combination of both of the above (Singer, 1990; Correa & Yousten, 1995). Major advantage of these bacterial insecticides are thir safety, biodegradability, and low environmental impact (Maramorosch,1987)

Opotaet *et al.* (2008) reported that the binary toxin (Bin) from *Bacillus sphaericus* exhibits a high insecticidal activity against *Culex* and *Anopheles* mosquitoes. The cytotoxicity of Bin requires an interaction with a specific receptor present on the membrane of midgut epithelial cells in larvae, a direct correlation exists between binding affinity and toxicity. The toxin binds with high affinity to its receptor in its primary target namely, *Culex pipiens*.

The present work paper aims for isolation of new *Bacillus sphaericus* strain with mosquitocidal activity that exceeds the existing international strains e.g. *B. sphaericus* 2362. In the hope to reduce Production costs of mosquitocidal toxin used for biological control of disease-transmitting mosquitoes in the developing countries production physiology of the bacterial toxin was studied on synthetic agroindustrial byproducts.

## MATERIALS AND METHODS

### Microorganisms

The International strain *Bacillus sphaericus* 2362 was kindly obtained from prof. F.G. Priest, school of life sciences, Heriot watt university, UK

A new *Bacillus sphaericus* isolate namely No.1 was isolated from soils of Quina Governorate, Egypt.

### Media used for growth, sporulation and mosquitocidal toxin production in shake cultures.

#### a-Media based on Agroindustrial by-products:

These media included offal's meal, feather meal and cotton seed meal. Most of these agroindustrialby-products are currently used in animals feed and available in Egyptian market.

**b-Media based on cheap, locally available plant proteins:** Certain legume seeds that are locally available in Egypt were examined as protein sources for growth, sporogenesis and mosquitocidaltoxin production. These legumes seeds such as soy beans, kidney bean, black eyed bean, yellow split pea, and lentils were finely grinded and used in conjunction with the standard mineral salt solution at appropriate concentration.

#### Bioassay of bacterial toxins against Mosquitoes larvae.

Bioassay of locally isolated *Bacillus* cultures including *B. thuringiensis* and *B. sphaericus* were carried out as described by **Priest and Youstine (1991)**. Toxicity was determined with laboratory reared *Culex pipiens*. Serial dilutions in distilled water were tested in a preliminary toxicity screen. The range of concentration of full grown whole culture (FWC) which killed 50% and 90% of the larvae were identified. Then further toxicity tests were done in the range recorded to evaluate precisely the LC<sub>50</sub> and LC<sub>90</sub> values for each highly promising bacterial culture.

The corrected mortality was then plotted against culture dilution of cells/ml on log paper to

determine LC<sub>50</sub> and LC<sub>90</sub> values for each highly promising bacterial cultures.

The bacterial dilutions were placed in small cups in duplicates along with 10 second instar larvae. Appropriate controls were run simultaneously using distilled water instead of cultures. The cups kept at room temperature 27±2°C. The mortality percentage was recorded by counting the number of living larvae and corrected by using appropriate control and applying Abbott's formula (**Abbott, 1925**). The medium lethal concentrations LC<sub>50</sub> of potent isolates was computed through probit analysis within 95% confidence limits using propan program.

#### Abbott's formula:

$$\text{Corrected mortality \%} =$$

$$\frac{\text{Observed mortality \%} - \text{Control mortality \%}}{100 - \text{Control mortality \%}} \times 100$$

## RESULTS

### 3.1. Isolation, Identification and Mosquitocidal Toxin Production by *Bacilli* isolated from the Egyptian environments

Eighty six isolates were obtained from soils and mud samples of six different Egyptian Governorates including Quina, El-Menofaya, El-Gharbia, El-Sharkia, El-Behera and Kafr EL-Sheikh. Among these isolates, isolate No.1 obtained from Quina Governorate was the only isolate giving 100% mortality up to culture dilution 10<sup>-5</sup>. Accordingly this isolate obtained from Quina Governorate was selected for further investigation.

### 3.2. Determination of LC<sub>50</sub> and LC<sub>90</sub> values of the Egyptian isolate No.1 obtained from Quina Governorate soils.

LC<sub>50</sub> and LC<sub>90</sub> of isolate No.1 and *B. sphaericus* 2362 bioassayed against second instar larvae of *Culex pipiens* revealed that the Egyptian isolate No.1 is more toxic than the reference strain 2362. **Table (1)**.

### 3.3. Identification of the Egyptian isolate No.1 isolated from Quina Governorate.

The colonies exhibited beige color with medium size colonies, The texture is smooth semi-glistening

with round margin; The appearance of colonies is shiny with little elevation and flat.

Examination of the cells with the electron microscope revealed the rod-shaped of the vegetative cells as shown in Fig (1); sporulated cells (sporangia) with subterminal spores that are round in shape giving the sporangia club shaped appearance as shown in Fig (2). Also it was observed that isolate No.1 produced a spherical spore and round crystals when examined under the electron microscope as shown in Fig (3).

Some biochemical tests for the identification of the Egyptiaisolate No.1 obtained from QuinaGovernoratewere carried out Table (2).

### **3.4. Comparative Physiological studies on factors affecting growth, sporulation, and toxin production of the Egyptian isolate *B. sphaericus*No.1 and the International *B. sphaericus* 2362 strain under submerged fermentation conditions**

#### **3.4.1. Effect of types of media on growth parameters, sporulation titer and mosquitocidal toxicity under submerged conditions.**

Four types of media were used in this study namely Nutrient yeast salt medium, Luria –Bertani medium, Nutrient broth (NB), and modified Nutrient broth (NB+ 0.5% yeast extract)The obtained results showed that modified Nutrient broth medium yielded the highest larval toxicity against the second instars' larvae of *Culex pipiens*for both *Bacillus sphaericus*isolate No 1and the international strain *Bacillus sphaericus*2362(Data not shown).

#### **3.4.2 Effect of aeration level on growth and toxicity of *B. sphaericus***

In this experiment the extent of aeration was altered by varying the air : medium ratio (amount of medium in the culture flask). The effect of aeration extent on growth parameters and toxicity of the mosquitocidal agent produced by the organisms under study are shown in Figures (4,5). It was noted that the viable count and toxicity increased with increasing the air : medium ratio. Furthermore, The sporulation and toxin production gave the highest titers when the medium volume occupied 10% and 20%, i.e. corresponding to air: medium ratio 9:1 and 4:1 of the flask volume for *B. sphaericus* 2362 and the Egyptian isolate *B. sphaericus*No.1, respectively.

#### **3.4.3. Effect of different carbon sources utilized by *B.sphaericus*on growth parameters and mosquitocidal toxin formation.**

It is known that *B. sphaericus*can not utilize carbohydrates for growth due to the lack of many of the enzymes of Embden Meyerhof and hexose monophosphate path ways (**Russelet et al., 1989**).In this experiment different carbon sources were used for testing the ability of the tested organisms*B. sphaericus* No.1 and *B. sphaericus* 2362 to utilize this carbon sources. The results revealed that sod. acetate was utilized by the isolate *B. sphaericus* No.1, at which the sporulation and toxin production yielded the highest titers. On the other hand, *B. sphaericus* 2362 was capable to utilize sod. acetate and sod. succinate, as shown in Figures (6,7).

#### **3.4.5.. Effect of inoculum size on growth parameters and mosquitocidal toxin formation of *B. sphaericus*.**

Different volumes of overnight growing culture were used as inocula for a set of 250 ml conical flasks each containing 25ml of modified nutrient liquid medium . The results of growth parameters and toxin production of tested organisms are illustrated by Figures (8,9).

The increase of inoculum size has led to the increase of sporulation titer and toxin production up to 3% inoculum size, and then decreased with the increasing of inoculums size in case of the Egyptian *B. sphaericus* No.1. However the sporulation and toxin production of *B. sphaericus* 2362 showed a little effect by changing the inoculum size. The highest toxicity were achieved using 3% inoculums size and 2% by isolate *B. sphaericus* No.1 and *B. sphaericus* 2362, respectively.

#### **3.4.6. Effect of incubation period on growth parameters and mosquitocidal toxin formation of *B. sphaericus*.**

This experiment was carried out under standard conditions by using a set of 250 ml conical flasks containing 25ml of modified nutrient liquid medium, then the extent of growth, sporulation titer and toxin production were followed and determined by harvesting after 2, 3, 4 and 7 days of incubation at 28 ± 2°C on a rotary shaker.

The results are shown in Figures (10,11). The mortality increased with increasing the incubation period until 3 days incubation period in case of *B. sphaericus* No.1 and 4 days for*B. sphaericus* 2362.

**Table(1):** Values of LC<sub>50</sub> and LC<sub>90</sub> for mosquitocidal toxins of the Egyptian isolate No.1 in comparison with those of the International strain of *Bacillus sphaericus* 2362 at confidence limits(95%). The bioassay were carried out against second instar larvae of *Culex pipiens*.

**3.4.7. Effect of different by-products and grinded legumes seeds used as complete media on growth, sporulation and toxin production of *Bacillus sphaericus*.**

Isolate	LC <sub>50</sub> (Confidence limits at 95 %) by $\mu$ l	LC <sub>90</sub> (Confidence limits at 95 %) by $\mu$ l
The Egyptian isolate <i>B. sphaericus</i> No.1 from Quina. Egypt	264.4 (155.3-365.8)	725.9 (517.3-1351.7)
The International strain <i>B. sphaericus</i> 2362	359.2 (228.5-479.3)	932.4 (674.3-1818.9)

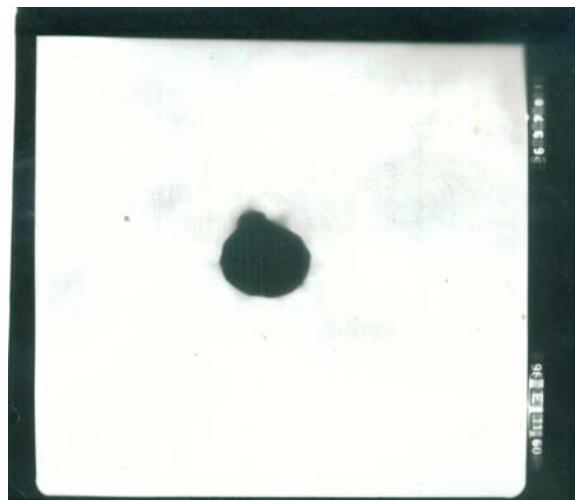

Ten agroindustrial byproducts that are available in Egypt were examined as a complete cost effective media for toxin production. The data in Figures(12,13) illustrated that the Egyptian isolate *B. sphaericus* No.1 exhibited the highest mosquitocidal activity by utilizing kidney beans and sesame meal as nutrient substrate at 3% final concentration, while *B. sphaericus* 2362 exhibited the highest mosquitocidal activity by utilizing soy beans, lentils and sesame meal as growth media for growth and mosquitocidal toxin production.

## DISCUSSION

The mosquito acts as a vector for many of the world's mostserious diseases, both parasitic e.g. malaria (*Anopheles*), lymphaticfilariasis (*Anopheles*, *Aedes*, *Culex* and *Mansonia*) and viral e.g. yellow fever, dengue (*Aedes*) and encephalitis (*Culex*). The present work aims to isolate some local isolates of *B. sphaericus*pathogenic to mosquito larvaefrom the Egyptian environment. Itwas also devoted to investigate the growth physiology and various factors that are affecting growth, sporulation and toxins formation. On the other hand, special attention was given to search for suitable media that are low-priced and locally available in Egypt for *B. sphaericus* production on a large scale. The goal stemmed from the fact that the feasibility of economic production of spores and toxin crystals of *B. sphaericus* is dependant to a large extent on production costs and availability of raw materials under the local conditions. Physiological factors affecting growth and toxin formation in *B. sphaericus* revealed that modified Nutrient broth medium yielded the highest larval toxicity against the second instars' of *Culexpipiens*for both *Bacillus sphaericus*isolate No 1 and the international strain *Bacillus sphaericus*2362. The requirements of individual bacterial strain for nutrients may vary for different strains and also of different isolates within the same strain within the same species. Thus optimal concentration of nutrients for one isolate may not necessarily be suitable for another. Therefore, it is impossible to recommend a fermentation medium that will be best for all isolates of the same species (**Fodaet al. 2000**).

It is established that *B. sphaericus* is an obligate aerobe and adequate air supply is needed for growth, initiation of sporulation and toxin synthesis (**Yousten and Wallis, 1987**).

In our studies, it was found that the maximum sporulation and toxicity were acheived when the medium volume to air ratio was 1:4 for the Egyptian isolate *B. sphaericus*No.1 and 1:9 for the International strain *B. sphaericus* 2362 that was used for comparative purposes. The increase in medium volume to air ratio has lead to the decrease in sporulation and toxicity. This result agrees with what reported by **Yousten and Wallis (1987)**. They found that oxygen was required for toxin production by *B. sphaericus* strain 2362. However, they reported that increasing the level of dissolved oxygen (DO) in the medium by use of pure oxygen in the gas stream lowered toxin production, while in case of strain 1593, (another *B. sphaericus*International strain), increased

(DO) produced a block in sporulation, but toxin synthesis was normal (**Youstenet al., 1984**).

The result of growth parameters of tested organisms indicated that *B. sphaericus* isolate No.1 gave high sporulation titer and toxicity at inoculum size 3% and a decrease in toxicity was recorded by increasing the inoculum size, However the highest sporulation and toxin production levels of strain 2362 were achieved by inoculum size 2%. This result agrees with that reported by **Fodaet al. (2000)**, they reported that the sporulation of the Egyptian isolate No. 69 increased by decrease in the inoculum size to reach  $7.5 \times 10^6$ /ml viable count whereas the sporulation of strain *B. sphaericus*2362 exhibited a little effect by changing the inoculum size.

*B. sphaericus*can not use carbohydrates for growth due to the lack of many of the enzymes of Embden Meyerhof and hexose monophosphate pathways(**Russelet et al., 1989**).

In the present study, it has been found that the Egyptian isolate *B. sphaericus* No.1 grew well using acetate as sole carbon source. On the other hand the International strain *B. sphaericus*2362 grew with acetate or succinate as sole carbon source. This result agrees with what reported by (**Gordon et al., 1973; De BarJacet et al., 1980; Klein et al., 1989; Widjayaet al., 1992 and Ahmed et al., 1993 and 1996**). They reported that numerous strains of *B. sphaericus*grew with acetate, Pyruvate, lactose, glutamate, succinate, histidine and arginine, as sole major carbon and energy sources.

In the present study, ten leguminous seeds and agroindustrial by-products were used as nutrient substances at concentration 3% and the result indicated that soy beans, kidney beans and sesame seed meal could be used efficiently as nutrientssources to support growth, sporulation and toxin production of the Egyptian isolate *B. sphaericus*No.1. High levels of toxicity were obtained even at low concentration of diluted culture ( $3 \times 10^6$ ), as inocula. On the other hand, *B. sphaericus* 2362 grew well on a medium contained soy beans, lentils and sesame seed meal and the growth, sporulation and high levels of toxin production were achieved at the same culture dilution. Uses of such various by-products as well as legume seeds have shown that local production from inexpensive ingredients available in different regions is possible. Such studies may pave the way for mass production on industrial scales.**Dulmageet al. (1970)**culturd*B. sphaericus*1593 and 2362 separately in a fermentor on peptonized milk medium with yeast

extract and mineral supplements. The fermentor beer was centrifuged and then resuspended in lactose solution and precipitated with acetone. These powders were highly insecticidal to *Culex quinquefasciatus* larvae producing LC<sub>50</sub> values in the range of 10<sup>-2</sup> µg/ml. **Obeta and Okafor (1983)** formulated five media from dried cow blood, mineral salts and seeds from four species of legumes (ground nut cake, cowpea, mambara beans and soy beans) for production of *B. sphaericus* 1593. Good growth, sporulation and toxin activity of *B. sphaericus* 1593 were obtained with all tested media. **Dharmsthiti et al. (1985)** grew *B. sphaericus* on a medium containing 7% hydrolyzed liquor by-product from a monosodium glutamate factory. **Klein et al. (1989)** used hydrolyzed industrial peptones (waste product of industry) for constructing seven media for production of *B. sphaericus* larvicides. These media contained 5 g/l industrial peptone in 50 mM phosphate buffer (pH 7.0) in combination with other carbon and nitrogen sources. Industrial peptone medium supplemented with glycerol was the most efficient medium for growth and larvicides production by *B. sphaericus* 2362. The local availability of proteinaceous materials is vitally important for *B. sphaericus* fermentation. For example, one of the most useful nitrogen sources is cotton seed flour (**Dulmageet et al. 1990b**). They reported that several nitrogen sources are used in *Bt* fermentation, including soybean flour, cotton seed flour and fish meal. The soy flour and cotton seed flour were both very good sources of nutrients for both *Bt* and *B. sphaericus* production. **Gangurde and Shethna (1995)** concluded that mustard seed meal (MSM) contains 40% protein, with glutamic acid and arginine as a major amino acids. Therefore, growth and larvicidal activity of *B. sphaericus* 2362 and 1593 produced in MSM can be attributed in part to the presence of these amino acids. **Ampofo (1995)** used some local raw-materials for production of *Bs* insecticides in Ghana. He tested anchovy, spent grain from breweries, bambara beans and sprout maize as media for production of *B. sphaericus* IAB 881. He reported that larvicidal activity of *Bs* IAB 881 grown in anchovy, spent grain, bambara beans and sprout maize, was similar to that obtained in synthetic medium with LC<sub>50</sub> ranging from 0.3×10<sup>-5</sup> to 0.68×10<sup>-6</sup> (dilution). Cell counts were in the range of 11×10<sup>8</sup> – 36×10<sup>8</sup> CFU/ml and spore counts were between 29×10<sup>7</sup> and 61×10<sup>7</sup> CFU/ml. **El-Bendary (1999)** used ground agroindustrial by-products and leguminous seeds at 2% final concentration as media for production of *B. sphaericus* in distilled water with or without addition of NYSM salts. The obtained results indicated that most of the tested substances supported

formation of highly efficient media for *Bs* toxin production of appreciably high sporulation yield and toxicity. She also reported that the most efficient media for *B. sphaericustoxin* production were soy flour, cotton seed flour, corn steep solids and offals meal. Furthermore, it was observed that addition of NYSM salts to these substances increased the *B. sphaericus* toxicity. Moreover, the toxicity of *B. sphaericus* increased about 1.5-4.5 times when these agroindustrial by-products were partially hydrolyzed by nuclease or alkalase enzymes before using as media. **El-Bendary et al. (2008)**, used whey permeate (WP) for production of mosquitocidal toxin by *B. sphaericus* 2362 and the Egyptian isolate, *B. sphaericus* 14N1 under both submerged and solid state fermentation conditions. Under submerged fermentation, high mosquitocidal activity was produced by *B. sphaericus* 2362 and *B. sphaericus* 14N1 at 50% -100% and 25% -70% whey permeate, respectively.

# Global Analysis of an Epidemic Model with General Incidence Rate.

**M. M. A. El-Sheikh and S. A. A. El-Marouf**

Department of Mathematics, Faculty of Science, Taibah University, Kingdom of Saudi Arabia  
 Permanent Address: Department of Mathematics, Faculty of Science, Menoufia University,  
 Shebin El Koom, Egypt.

**Abstract:** A general four-dimensional SIQR epidemic model is considered. Threshold, equilibria and their stability are established. The dynamics of the system is discussed in the case of this general form of incidence rate. The global stability of both free-disease and endemic equilibria are deduced. Hopf bifurcation , boundedness, dissipativity and persistence are studied.

Journal of American Science 2010;6(11):770-783]. (ISSN: 1545-1003).

**Keywords:** Epidemic model; Nonlinear incidence rate; quarantine; uniformaly persistence; global stability; Hopf bifurcation.

## 1. Introduction:

The technique of introducing quarantine in standard *SIS* and *SIR* epidemic models has received great interest in the last two decades (see for example [1], [5], [6], [7], and [21]). Over the centuries quarantine, which means forced isolation or stoppage of interactions with others, succeeded to reduce the transmission of human and animal diseases. In their recent paper Feng and Thieme [5] considered an *SIQR* model with a quarantine class and showed that the quarantine can lead to periodic solutions. They considered in [6] a more general endemic model that includes *SEIQR* models with arbitrary distributed periods of infection including quarantine. They proved extinction and persistence results. In [12], Hethcote et al discussed six endemic models with quarantined class. In this paper we consider an *SIQR* model with an incidence term more general than those used by [3], [10] , [11], [12], [14], and [16]. Following [12],we assume that the total host population is partitioned into susceptible, infectious, quarantine and recovered which

densities denoted respectively by  $S(t), I(t), Q(t)$  and  $R(t)$ . The natural birth rate denoted by  $A$ . Assume that infectious confers permanent immunity, so that, individuals can move from the  $I$  and  $Q$  classes to the  $R$  class, where  $R(t)$  is the number of individuals with permanent immunity and  $N(t) = S(t) + I(t) + Q(t) + R(t)$ . In this paper we assume that the general incidence rate term  $H(I, S)$  is differentiable, with  $\frac{\partial H}{\partial I}$  and  $\frac{\partial H}{\partial S}$  are nonnegative and finite for all  $I$  and  $S$ . More precisely we consider the 4-dimensional system of differential equations,

$$\begin{aligned}
 S' &= A - \beta IH(I, S) - dS, \\
 I' &= \beta IH(I, S) - (\gamma + \delta + d + \alpha_1)I, \\
 Q' &= \delta I - (d + \alpha_2 + \varepsilon)Q, \\
 R' &= \gamma I + \varepsilon Q - dR,
 \end{aligned} \tag{1.1}$$

where  $A$  and  $d$  are positive constants and  $\gamma, \delta, \varepsilon, \alpha_1$  and  $\alpha_2$  are non-negative

constants. The constant  $A$  is the recruitment rate of susceptible corresponding to birth and immigration,  $\beta$  is the average number of adequate contact,  $d$  is the per capita natural mortality rate,  $\delta$  is the rate constant for individuals leaving the infective compartment  $I$  for the quarantine compartment  $Q$ ,  $\gamma$  and  $\varepsilon$  are the rates at which individuals recover and return to susceptible compartment  $S$  from compartment  $I$  and  $Q$ , respectively, and  $\alpha_1$  and  $\alpha_2$  represent the extra disease-related death rate constants in classes  $I$  and  $Q$ , respectively. The total population size  $N(t)$  satisfies  $N'(t) = A - dN - \alpha_1 I - \alpha_2 Q$ , so that the population size  $N(t)$  approached the carrying capacity  $\frac{A}{d}$  when there is no disease. The differential equation for  $N$  implies that the solutions of (1.1) starting in the positive orthant  $R_+^3$  either approach, enter, or remain in the subset

$$D = \left\{ (S, I, Q, R) : S \geq 0, I \geq 0, Q \geq 0, R \geq 0, S + I + Q + R \leq \frac{A}{d} \right\}.$$

The model (1.1) is more general epidemiological model than those discussed in ([11],[14],[16], and [17]). It is known (see [11]) that the system (1.1) always has the disease-free equilibrium  $P_0 = (\frac{A}{d}, 0, 0, 0)$ .

We define the quarantine reproduction

$$\text{number in the form } R_q = \frac{\beta(\frac{A}{d})}{(\gamma + \delta + d + \alpha_1)}$$

where if  $R_q > 1$ , the region  $D$  contains also the endemic equilibrium  $P^* = (S^*, I^*, Q^*, R^*)$ , where

$$\begin{aligned} S^* &= \frac{A}{d} - \frac{(\gamma + \delta + d + \alpha_1)}{d} I^*, Q^* = \frac{\delta I^*}{d + \alpha_2 + \varepsilon}, \\ H(I^*, \frac{A}{d} - \frac{(\gamma + \delta + d + \alpha_1)}{d} I^*) &= \frac{(\gamma + \delta + d + \alpha_1)}{\beta}. \end{aligned} \quad (1.2)$$

The aim of this paper is to study the dynamic of (1.1) by different techniques with a generalized incidence term. We show that some of our obtained results may be applied for many special forms of  $H(I, S)$ . The organization of this paper is as follows. In section 2, we discuss the stability properties of the reduced 3-dimensional  $SIQ$  epidemic model. In section 3, we study the boundedness, dissipativity, persistence, global stability and Hopf bifurcation of solutions of the 4-dimensional model (1.1). Our technique in this section depends on [20]. The paper ends with numerical justifications and brief discussion in section 4.

## 2. A reduced $SIQ$ epidemic model

Since the last equation in (1.1) is independent of the other equations ( see[10], [11], [12] and [13]), we may start by discussing the 3-dimensional system,

$$S' = A - \beta I H(I, S) - dS,$$

$$I' = \beta I H(I, S) - (\gamma + \delta + d + \alpha_1) I,$$

$$Q' = \delta I - (d + \alpha_2 + \varepsilon) Q.$$

The dynamic of (1.1) in  $D$  is equivalent to that of (2.1) in the feasible region

$$\Gamma = \{(S, I, Q) \in R_+^3 : S + I + Q \leq \frac{A}{d}\}, \quad (2.2)$$

which can shown to be closed and positively invariant set with respect to (2.1) (see [14]). Letting  $\partial\Gamma$  denotes the boundary of  $\Gamma$  and  $\Gamma^0$  its interior , the system (2.1) always has

disease-free equilibrium point  
 $P_0 = \left(\frac{A}{d}, 0, 0\right) \in \partial\Gamma$ .

**Lemma 2.1.** If  $R_q \leq 1$ , then there exists a unique equilibrium point  $P_0 = \left(\frac{A}{d}, 0, 0\right)$ .

If  $R_q > 1$ , then there exists an endemic nontrivial equilibrium point  $P^* = (S^*, I^*, Q^*)$  in  $\Gamma^0$ .

**Proof.** The uniqueness of the endemic nontrivial equilibrium point can be guaranteed by [25]. From the isocline equations, it is clear that the coordinates of the endemic equilibrium  $P^* = (S^*, I^*, Q^*)$  satisfy (1.2). Hence since  $S^*$  exists, then  $H$  must be less than  $\frac{A}{d}$ , i.e. when  $R_q > 1$ ,

$S^*$  does not exist and the only equilibrium point is  $P_0 = \left(\frac{A}{d}, 0, 0\right)$ . Now the local stability of  $P_0$  can easily deduced by inspection of the eigenvalues of the following Jacobian matrix at  $P_0$

$$M_{P_0} = \begin{pmatrix} -d & -\beta H(0, \frac{A}{d}) & 0 \\ 0 & \beta H(0, \frac{A}{d}) - (\gamma + \delta + d + \alpha_1) & 0 \\ 0 & \delta & -(d + \alpha_2 + \varepsilon) \end{pmatrix}$$

which has the eigenvalues  $\lambda_1 = -d$ ,  $\lambda_2 = (\gamma + \delta + d + \alpha_1) - \beta H(0, \frac{A}{d})$ ,

and  $\lambda_3 = -(d + \alpha_2 + \varepsilon)$ . This completes the proof.  $\square$

**Lemma 2.2.** The disease-free equilibrium point  $P_0 = \left(\frac{A}{d}, 0, 0\right)$  is globally

asymptotically stable in  $\Gamma$  if  $R_q \geq 1$ , while it is an unstable saddle point if  $R_q \leq 1$ .

**Proof.** Constructing the Liapunov function  $V = I$ ,

then

$$\begin{aligned} V' &= [\beta H(I, S) - (\gamma + \delta + d + \alpha_1)]I \\ &< [\beta(\frac{A}{d}) - (\gamma + \delta + d + \alpha_1)]I, \end{aligned}$$

since  $H < \frac{A}{d}$ . Thus

$$V' \leq I\{R_q - 1\}.$$

Consequently, if  $R_q \leq 1$ , then

$$V' \leq 0.$$

Moreover

$$V' = 0 \text{ iff } V = 0.$$

Thus the largest compact invariant set in  $\{(S, I, Q) \in \Gamma : I = 0\}$  in the case of  $R_q \leq 1$  is the singleton  $\{P_0\}$ . Consequently by La salle's invariance principle, it follows that the disease-free point  $P_0 = \left(\frac{A}{d}, 0, 0\right)$  is

globally asymptotically stable in  $\Gamma$  ( see [23]). Now in the case  $R_q > 1$ ,  $P_0 = \left(\frac{A}{d}, 0, 0\right)$  is an unstable saddle point because as stated in Lemma 2.1 the eigenvalues will be  $\lambda_1 = -d < 0$ ,  $\lambda_2 = (\gamma + \delta + d + \alpha_1) - \beta H(0, \frac{A}{d}) > 0$

and  $\lambda_3 = -(d + \alpha_2 + \varepsilon) < 0$  i.e. if  $R_q > 1$ , the nontrivial equilibrium emerges, two roots have negative real parts and one is positive, so  $P_0$  is an unstable saddle point.  $\square$

Now we may note that the case when  $R_q = 1$  cannot be discussed here by linear analysis. However the above Lyapunov

technique covered this case in the case  $R_q \leq 1$ .

**Remark 2.1.**

(1) heorem 2.1 completely determines the local dynamics of (2.1) in  $\Gamma$  depending on the reproduction rate  $R_q$ . Its epidemiological implication is that the infected population (the sum of the latent and infectious population) vanish in time so the disease dies out.

(2)The quarantine reproduction number

$$R_q = \frac{\beta \frac{A}{d}}{(\gamma + \delta + d + \alpha_1)} \quad \text{represents the}$$

product of  $\beta H(0, \frac{A}{d})$ , and the average

residence time  $\frac{1}{(\gamma + \delta + d + \alpha_1)}$  in infective

class  $I$ . i.e.  $R_q$  is the average number of secondary infectious in a completely susceptible population when one infectious entries the population in the situation where the average infectious period decreased by the quarantining of some infectives.

It was stated in Lemma 2.1 that the system (2.1) has a unique endemic nontrivial equilibrium  $P^* = (S^*, I^*, Q^*)$ . Now we discuss the global asymptotic stability of this unique endemic equilibrium  $P^* = (S^*, I^*, Q^*)$  using the method of higher-order generalization of the Bendixon criterion (see [16],[17],and [23]).The main theorem of the method depends on the use of Lozinski Logarithmic norm. For a general  $3 \times 3$  matrix  $J = (J_{ij})$ . Following [23],we consider the Lozinskii measure  $\mu$  of  $B = P_f P^{-1} + P J^{[2]} P^{-1}$  with respect to a vector norm  $\|\cdot\|$  in  $R^N$ ,  $N = \binom{n}{2}$ ,

$$\mu(B) = \lim \frac{|I + hB| - 1}{h}.$$

The following auxiliary result is a basis for most of the work of global stability for an autonomous system

$$Y' = f(Y).$$

**Lemma 2.3.** Assume that

(I<sub>1</sub>)  $\Gamma$  is simply connected,

(I<sub>2</sub>) There exists a compact absorbing set  $\Omega \subset \Gamma$ ,

(I<sub>3</sub>) The system  $Y' = f(Y)$  has a unique equilibrium  $Y^*$  in  $\Gamma$ .

Then  $Y^*$  is globally asymptotically stable in  $\Gamma$  provided that a function  $B(x)$  and a Lozinski measure  $\mu$  exists such that

$$\limsup_{t \rightarrow \infty} \frac{1}{t} \int_0^t \mu(B(x(s, r_0))) ds < 0.$$

**Theorem 2.4.** If  $R_q > 1$ , then the unique endemic equilibrium  $P^* = (S^*, I^*, Q^*)$  is globally asymptotically stable in  $\Gamma^0$ .

**Proof.** Setting the diagonal matrix

$$p(S, I, Q) = \text{diag}\left(1, \frac{I}{Q}, \frac{I}{Q}\right),$$

then  $P$  is  $C^1$  and nonsingular in  $\Gamma^0$ . Letting  $f$  to represent the vector field of (2.1). Then

$$p_f p^{-1} = \text{diag}\left(0, \frac{I'}{I} - \frac{Q'}{Q}, \frac{I'}{I} - \frac{Q'}{Q}\right), \text{ where}$$

the matrix  $p_f$  is

$$(p_{ij}(x))_f = \left( \frac{\partial p_{ij}(x)}{\partial x} \right)^T \cdot f(x) = \nabla p_{ij} \cdot f(x).$$

(2.3)

Setting  $k_1 = \gamma + \delta + d + \alpha_1$  and  $k_2 = k_1 + d + \alpha_2 + \varepsilon$  the Jacobian matrix  $J$  at  $p^*(S, I, Q)$  is

$$J_{p^*} = \begin{pmatrix} (-\beta I \frac{\partial H}{\partial s} - d) & (-\beta H - \beta I \frac{\partial H}{\partial I}) & 0 \\ \beta I \frac{\partial H}{\partial s} & \beta I \frac{\partial H}{\partial I} & 0 \\ 0 & \delta & k_2 \end{pmatrix}$$

Now it is known (see [17], [19], [22]) that its second additive compound is

$$J_{p^*}^{[2]} = \begin{pmatrix} -\beta \left( \frac{\partial H}{\partial I} + \frac{\partial H}{\partial s} \right) - d & 0 & 0 \\ \delta & k_2 - d - \beta I \frac{\partial H}{\partial s} & -k_1 - \beta I \frac{\partial H}{\partial I} \\ 0 & \beta I \frac{\partial H}{\partial s} & k_2 + \beta I \frac{\partial H}{\partial I} \end{pmatrix}$$

Moreover

$$p^* J_{p^*}^{[2]} p^{-1} = \begin{pmatrix} -\beta \left( \frac{\partial H}{\partial I} + \frac{\partial H}{\partial s} \right) - k_1 - d & 0 & \frac{Q}{I} \left( k_2 + \beta I \frac{\partial H}{\partial I} \right) \\ \frac{\partial I}{Q} & \left( k_2 - d - \beta I \frac{\partial H}{\partial s} \right) \left( -k_1 - \beta I \frac{\partial H}{\partial I} \right) & 0 \\ 0 & \beta I \frac{\partial H}{\partial s} & k_2 + \beta I \frac{\partial H}{\partial I} \end{pmatrix}$$

Consider the matrix  $B = p_f p^{-1} + p^* J_{p^*}^{[2]} p^{-1}$

where the matrix  $p_f$  is as in (3.1) can be written in the matrix form

$$B = \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix},$$

where

$$B_{11} = -\beta I \left( \frac{\partial H}{\partial I} + \frac{\partial H}{\partial s} \right) - k_1 - d,$$

$$B_{12} = (0, 0), \quad B_{21} = \begin{pmatrix} \frac{\partial I}{Q} \\ 0 \end{pmatrix},$$

and

$$B_{22} = \begin{pmatrix} \frac{I'}{I} - \frac{Q'}{Q} + \left[ k_2 - d - \beta I \frac{\partial H}{\partial s} \right] & -k_1 - \beta I \frac{\partial H}{\partial I} \\ \beta I \frac{\partial H}{\partial s} & \frac{I'}{I} - \frac{Q'}{Q} - k_2 + \beta I \frac{\partial H}{\partial I} \end{pmatrix}.$$

Choosing a vector norm

$$\|(u, v, \omega)\| = \max\{|u|, |v| + |\omega|\},$$

where  $(u, v, \omega)$  be a vector in  $R^3$ . Let  $\mu$  be

the Lozinski measure with

$$\mu(B) \leq \max\{\mu_1(B_{11}) + |B_{12}|, |B_{21}| + \mu_1(B_{22})\}, \quad (2.4)$$

where  $|B_{12}|$  and  $|B_{21}|$  are matrix norm with

respect to the  $L^1$  vector norm ,and  $\mu_1$

denotes the Lozinski measure with respect to

the  $L^1$  norm. Here  $\mu_1$  is given by

$$\mu_1(B_{11}) = -\beta I \left( \frac{\partial H}{\partial I} + \frac{\partial H}{\partial s} \right) - k_1 - d,$$

$$|B_{12}| = 0, \quad |B_{21}| = \frac{\delta I}{Q},$$

$$\mu_1(B_{22}) = \frac{I'}{I} - \frac{Q'}{Q} + k_2 - d.$$

$$\text{Thus } g_1 = -\beta I \left( \frac{\partial H}{\partial I} + \frac{\partial H}{\partial s} \right) - d, \quad \text{and}$$

$$g_2 = \frac{\delta I}{Q} + \frac{I'}{I} - \frac{Q'}{Q} + k_2 - d. \quad \text{But since by}$$

(2.1)

$$\frac{I'}{I} = \beta H(I, S) + k_1 \quad \text{and} \quad \frac{Q'}{Q} = \frac{\delta I}{Q} + k_2.$$

(2.6)

Then by (2.3), (2.4) and (2.5), we get

$$g_1 = -\frac{I'}{I} \left( \frac{\partial H}{\partial I} + \frac{\partial H}{\partial s} \right) \frac{I}{H} - \frac{k_1}{H} - d, \quad \text{and}$$

$$g_2 = \frac{I'}{I} - d.$$

Since by assumptions  $\frac{\partial H}{\partial I}, \frac{\partial H}{\partial S}$  and  $k_1$  are

all nonnegative ,then  $\mu(B) \leq \frac{I'}{I} - d$ .

Thus along each solution  $(S(t), I(t), Q(t))$  of (2.1) such that  $\begin{pmatrix} S \\ (0), I(0), Q(0) \end{pmatrix} \in \Gamma$ , the absorbing set, we have

$$\lim_{t \rightarrow \infty} \frac{1}{t} \int_0^t \mu(B) ds < \lim_{t \rightarrow \infty} \frac{1}{t} \int_0^t \left( \frac{I'}{I} - d \right) ds = \frac{1}{t} \ln \frac{I(t)}{I(0)} - d,$$

$$\text{Then } \limsup_{t \rightarrow \infty} \frac{1}{t} \int_0^t \mu(B(x(s, r_0))) ds < 0.$$

Thus by Theorem 2.1 the unique endemic equilibrium  $P^*$  is globally asymptotically stable in  $\Gamma^0$ . This completes the proof.  $\square$

Now we consider the nontrivial equilibrium  $P^* = (S^*, I^*, Q^*)$  of the system (2.1) where

$$S^* = \frac{A}{d} - \frac{A}{d} I^* (\gamma + \delta + d + \alpha_1), \text{ and } Q^* = \frac{\delta}{(d + \alpha_2 + \varepsilon)} I^*.$$

The Jacobian matrix at  $P^*$  is

$$M_{P^*} = \begin{pmatrix} -\beta^* H_{S^*} - d & -\beta^* - \beta^* H_{I^*} & 0 \\ \beta^* H_{S^*} & \beta^* H_{I^*} & 0 \\ 0 & \delta & -(d + \alpha_2 + \varepsilon) \end{pmatrix}, \quad (2.8)$$

where  $H_{S^*} = \frac{\partial H}{\partial S}|_{S=S^*}$ ,  $H_{I^*} = \frac{\partial H}{\partial I}|_{I=I^*}$  and

$H^* = H(I^*, S^*)$ . Assume that  $H_{S^*}$ ,  $H_{I^*}$

and  $H^*$  are positive. The characteristic equation at  $P^* = (S^*, I^*, Q^*)$  is given by

$$(\lambda + a_0)[\lambda^2 + a_1 \lambda + a_2] = 0, \quad (2.9)$$

where

$$a_0 = d + \alpha_2 + \varepsilon,$$

$$a_1 = (\beta^* H_{S^*} + d) + \beta^* H + H^* H_{I^*} (1 - \beta^* H_{S^*}) - (\gamma + \delta + d + \alpha_1), \quad (2.10)$$

$$a_2 = -(\beta^* H_{S^*} + d)(\beta^* H + H^* H_{I^*}) (1 - \beta^* H_{S^*}) - (\gamma + \delta + d + \alpha_1).$$

Since by the Routh-Hurwitz criterion (see [9]) it is known that  $P^* = (S^*, I^*, Q^*)$  is locally asymptotically stable if the roots of the characteristic equation (2.9) lie strictly in the left half-plane, then we have the following theorem.

**Theorem 2.5.** Suppose that the conditions

$$(A_1) \quad \beta^* H_{S^*} \neq 1, \quad (A_2)$$

$$H^* H_{I^*} < H^*.$$

be satisfied. Then the equilibrium point  $P^* = (S^*, I^*, Q^*)$  is locally asymptotically stable.

**Proof.** The proof is similar to the proof of Theorem 2.1, so it is omitted.  $\square$

### 3. The SIQR epidemic model

In this section we show that the system (2.7) is bounded, positively invariant, and dissipative.

**Definition 3.1.** ([10], pp. 394) A differential equation  $X' = f(X)$  is said to be dissipative if there is a bounded subset  $B$  of  $R^2$  such that for any  $X^* \in R^2$  there is a time  $t_*$ , which depends on  $X^*$  and  $B$ , so that the solution  $\phi(t, X^*)$  through  $X^*$  satisfies  $\phi(t, X^*) \in B$  for  $t \geq t_*$ .

**Theorem 3.1.** Let  $\Gamma$  be the region defined by

$$\Gamma = \left\{ (S, I, Q, R) \in R_+^4 : S + I + Q + R \leq \frac{A}{d} \right\}. \quad (3.1)$$

Then

- (i)  $\Gamma$  is positively invariant,
- (ii) All solutions of the system (1.1) are uniformly bounded,
- (iii) System (1.1) is dissipative.

**Proof.** Let  $S(t_0) = \bar{S}_0 > 0$ . Since

$$\dot{S} = A - \beta IH(I, S) - dS,$$

$$< A - dS - S \min_{S \in \Gamma} \overline{H}(I, S),$$

where  $IH(I, S) = S\overline{H}(I, S)$ . Letting

$$\mu = -(d + \min_{S \in \Gamma} \overline{H}(I, S)), \text{ then}$$

$$\dot{S} < A + \mu S, \quad \mu < 0. \quad (3.3)$$

Thus

$$S \leq \frac{-A}{\mu} + \bar{S}_0 e^{\mu t}, \quad (3.4)$$

so that

$$S \leq \max\left(\frac{-A}{\mu} + \bar{S}_0\right). \quad (3.5)$$

Thus

$$\limsup_{t \rightarrow \infty} S \leq \frac{-A}{\mu}, \quad \mu < 0, \quad \bar{S}_0 \geq 0. \quad (3.6)$$

Hence  $S(t)$  is uniformly bounded. Since  $S(t) = N(t) - I(t) - Q(t) - R(t)$ , and  $S(t)$  is uniformly bounded, then the solutions of (1.1) are uniformly bounded. Dissipativity of the system (1.1) follows by Definition 3.1. Thus the proof is completed.  $\square$

Now, we discuss the existence and global stability of the equilibria of (1.1). By solving the system of isocline equations  $A - \beta IH(I, S) - dS = 0$ ,

$$\beta IH(I, S) - (\gamma + \delta + d + \alpha_1)I = 0,$$

$$\delta I - (d + \alpha_2 + \varepsilon)Q = 0,$$

$$\gamma I + \varepsilon Q - dR = 0,$$

thus the possible equilibrium points of (1.1)

$$\text{are } P_0 = \left(\frac{A}{d}, 0, 0, 0\right), \text{ and } \bar{P} = (\bar{S}, \bar{I}, \bar{Q}, \bar{R}).$$

The Jacobian matrix due to linearizing (1.1)

at the equilibrium point  $P_0 = \left(\frac{A}{d}, 0, 0, 0\right)$  is

$$J_{P_0 = \left(\frac{A}{d}, 0, 0, 0\right)} = \begin{pmatrix} -d & \beta H(0, \frac{A}{d}) & 0 & 0 \\ 0 & \beta H(0, \frac{A}{d}) - (\gamma + \delta + d + \alpha_1) & 0 & 0 \\ 0 & \delta & -(d + \alpha_2 + \varepsilon) & 0 \\ 0 & \gamma & \varepsilon & -d \end{pmatrix} \quad (3.2)$$

The eigenvalues of  $P_0 = \left(\frac{A}{d}, 0, 0, 0\right)$  are given by

$$\lambda_1 = \lambda_2 = -d < 0, \quad \lambda_3 = -(d + \alpha_2 + \varepsilon) < 0 \text{ and } \lambda_4 = \beta H(0, \frac{A}{d}) - (\gamma + \delta + d + \alpha_1) \quad (3.8)$$

The above discussion leads to the following results.

**Theorem 3.2.**

(i) If  $R_q \leq 1$ , then the disease-free equilibrium point  $P_0 = \left(\frac{A}{d}, 0, 0, 0\right)$  is locally asymptotically stable.

(ii) If  $R_q > 1$ , then the equilibrium point  $P_0 = \left(\frac{A}{d}, 0, 0, 0\right)$  is a hyperbolic saddle and is repelling in the both directions of  $Q$  and  $R$ . In particular, the dimensions of the stable manifold  $W^+$  and unstable manifold  $W^-$  are given by

$$\text{Dim } W(P_0) = \left(\frac{A}{d}, 0, 0, 0\right) \nparallel 1, \quad \text{Dim } W(P_0) = \left(\frac{A}{d}, 0, 0, 0\right) \nparallel 3, \quad (3.9)$$

respectively.

**Proof.** The proof of(i) follows by Lemma 2.1 and the Routh-Hurwitz theorem [ 9], so it is omitted. The proof of (ii) follows directly from inspection of the eigenvalues of the

Jacobian matrix at  $P_0 = \left(\frac{A}{d}, 0, 0, 0\right)$  and

examples from Freedman and Mathsen [8].

□

Now to give sufficient conditions for existence of a positive interior equilibrium  $\bar{P} = (\bar{S}, \bar{I}, \bar{Q}, \bar{R})$ , we discuss the uniform persistent of (1.1). To show a uniform persistence in the set

$$R_{SIQR}^+ = \left\{ (S, I, Q, R) : S > 0, I > 0, Q > 0, R > 0, S + I + Q + R \leq \frac{A}{d} \right\}$$

(3.10)

we assume the following hypotheses for system (1.1).

( $A_3$ ) All dynamics are trivial on  $\partial R_{SIQR}^+$  (the boundary of the set  $R_{SIQR}^+$ ).

( $A_4$ ) All invariant sets (equilibrium points) are hyperbolic and isolated.

( $A_5$ ) No invariant sets on  $R_{SIQR}^+$  are asymptotic stable.

( $A_6$ ) If an equilibrium point exists in the interior of any 3-dimensional subspace of  $R_{SIQR}^+$  it must be globally asymptotically stable with respect to orbits initiating in that interior.

( $A_7$ ) If  $M$  is an invariant set on  $\partial R_{SIQR}^+$  and  $W^+(M)$  and it is strong stable manifold, then  $W^+(M) \cap \partial R_{SIQR}^+ = \emptyset$ .

( $A_8$ ) All invariant sets are cyclic.

Here, we drive criteria for the global stability hypothesis ( $A_7$ ) to be valid.

Now, we discuss the global stability of  $\bar{P}_* = (\frac{A}{d}, 0, 0)$ . In  $R_+^4$  consider the Liapunov function

$$V = I. \quad (3.11)$$

Thus

$$\begin{aligned} \frac{dV}{dt} &= [\beta H(I, S) - (\gamma + \delta + d + \alpha_1)]I \\ &= (\gamma + \delta + d + \alpha_1) \left[ \frac{\beta H(I, S)}{(\gamma + \delta + d + \alpha_1)} - 1 \right] I. \\ &\leq 0. \end{aligned}$$

Now we give the following result.

**Theorem 3.3.** If

$$\frac{\beta H(I, S)}{(\gamma + \delta + d + \alpha_1)} \leq 1, \quad (3.13)$$

then the disease-free equilibrium point

$\bar{P}_* = (\frac{A}{d}, 0, 0)$  is globally asymptotically stable with respect to solution trajectories initiating from  $\text{int } R_S^+$  (the interior of the set  $R_S^+$ ).

**Proof.** The proof is similar to the proof of Theorem 3.1 in ([19], p. 197) so it is omitted.

□

Now, to discuss the global stability of the point  $\bar{P} = (\bar{S}, \bar{I}, \bar{Q})$ , choose the Liapunov function

$$V = \frac{1}{2} k_1 (S - \bar{S})^2 + \frac{1}{2} k_2 (I - \bar{I})^2 + Q - \bar{Q} - \bar{Q} \ln \frac{Q}{\bar{Q}}$$

(3.14)

where  $k_i \in R^+, i = 1, 2$ .

The derivative of (3.14) along the solutions curve (2.1) in  $R_{SIQ}^+$  is given by,

$$\frac{dV}{dt} = k_1 (S - \bar{S}) [(A - IH(I, S) - dS]$$

$$+ k_2 [\beta IH(I, S) - (\gamma + \delta + d + \alpha_1)]]$$

(3.15) (3.15)

$$+ \left(1 - \frac{Q}{\bar{Q}}\right) [\delta I - (d + \alpha_2 + \varepsilon) Q]$$

where

$$A = \beta \bar{I} H(\bar{I}, \bar{S}) + d \bar{S}, \quad (3.16)$$

$$\beta H(\bar{I}, \bar{S}) = (\gamma + \delta + d + \alpha_1),$$

$$\delta \frac{\bar{I}}{Q} = d + \alpha_2 + \varepsilon.$$

Hence

$$\frac{dV}{dt} = -k_1 d(S - \bar{S}) + k_1 [\bar{I} H(\bar{I}, \bar{S}) - I H(I, S)] \quad (3.17)$$

$$+ \beta k_2 (I - \bar{I}) [I H(I, S) - \bar{I} H(\bar{I}, \bar{S})] + \delta [\bar{I} Q - I \bar{Q}]$$

$$\text{Let } X = \begin{pmatrix} v_1 \\ v_2 \\ v_3 \end{pmatrix} \text{ such that } v_1 = (S - \bar{S}), \quad v_2 = (I - \bar{I}), \quad v_3 = (Q - \bar{Q})$$

set

$$a_{11} = -k_1 d,$$

$$a_{12} = a_{21} = k_1 \frac{\beta [\bar{I} H(\bar{I}, \bar{S}) - I H(I, S)]}{(I - \bar{I})} + k_2 \frac{\beta [\bar{I} H(\bar{I}, \bar{S}) - I H(I, S)]}{(S - \bar{S})} \quad \text{number, where } x_* \text{ is the equilibrium point.}$$

$$a_{22} = k_2 \frac{\beta [I H(I, S) - \bar{I} H(\bar{I}, \bar{S})]}{(I - \bar{I})}, \quad a_{13} = a_{31} = 0, \quad a_{33} = \delta \frac{[\bar{I} Q - I \bar{Q}]}{(\bar{Q} - Q)} \quad \text{(iii) } a_{ij} \text{ are bounded for all } i, j = 1, 2, 3.$$

The characteristic roots of the matrix  $A$  are given by

$$\det(A - \lambda I_{3 \times 3}) = 0 \quad (3.21)$$

$$(\bar{Q} - Q)^3 \lambda^3 + m_1 \lambda^2 + m_2 \lambda + m_3 = 0,$$

where

(3.19)

Thus

$$m_1 = -\text{trace} A = -(a_{11} + a_{22} + a_{33}),$$

$$\frac{dV}{dt} = a_{11} v_1^2 + a_{22} v_2^2 + a_{33} v_3^2 \quad (3.19)$$

$$= a_{11} v_1^2 + \frac{1}{2} a_{12} v_1 v_2 + \frac{1}{2} a_{13} v_1 v_3 + \frac{1}{2} a_{12} v_1 v_2 + \frac{1}{2} a_{23} v_2 v_3$$

$$+ a_{22} v_2^2 + \frac{1}{2} a_{23} v_2 v_3 + \frac{1}{2} a_{13} v_1 v_3 + a_{33} v_3^2, \quad \text{where } a_{ij} = a_{ji} \quad \text{with}$$

$$a_{13} = a_{23} = 0, \quad i, j = 1, 2, 3. \quad \text{But}$$

$$\frac{dV}{dt} = X^T A X = X A X^T = \langle A X, X \rangle$$

(quadratic form), where  $A$  is an  $3 \times 3$  real symmetric matrix such that  $A = \frac{1}{2}(A + A^T)$

and given by

$$A = \begin{pmatrix} a_{11} & \frac{1}{2} a_{12} & \frac{1}{2} a_{13} \\ \frac{1}{2} a_{12} & a_{22} & \frac{1}{2} a_{23} \\ \frac{1}{2} a_{13} & \frac{1}{2} a_{23} & a_{33} \end{pmatrix}. \quad (3.20)$$

Let  $a_{ij}, i, j = 1, 2, 3$  are such that

$$(i) a_{ij} \in C^1(R^+ \times R^+ \times R^+, R),$$

$$(ii) \lim_{x \rightarrow x_*^-} a_{ij} \text{ exists as a finite}$$

$$a_{12} = a_{21} = k_1 \frac{\beta [\bar{I} H(\bar{I}, \bar{S}) - I H(I, S)]}{(I - \bar{I})} + k_2 \frac{\beta [\bar{I} H(\bar{I}, \bar{S}) - I H(I, S)]}{(S - \bar{S})} \quad \text{(iii) } a_{ij} \text{ are bounded for all } i, j = 1, 2, 3.$$

The characteristic roots of the matrix  $A$  are given by

$$\det(A - \lambda I_{3 \times 3}) = 0 \quad (3.21)$$

$$(\bar{Q} - Q)^3 \lambda^3 + m_1 \lambda^2 + m_2 \lambda + m_3 = 0,$$

where

(3.19)

Thus

$$m_1 = -\text{trace} A = -(a_{11} + a_{22} + a_{33}),$$

$$\frac{dV}{dt} = a_{11} v_1^2 + a_{22} v_2^2 + a_{33} v_3^2 \quad (3.19)$$

$$m_2 = \det \begin{vmatrix} a_{11} & \frac{1}{2}a_{12} \\ 1 & a_{22} \\ \frac{1}{2}a_{12} & a_{22} \end{vmatrix} + \det \begin{vmatrix} a_{11} & \frac{1}{2}a_{13} \\ 1 & a_{33} \\ \frac{1}{2}a_{13} & a_{33} \end{vmatrix} + \det \begin{vmatrix} a_{22} & \frac{1}{2}a_{23} \\ 1 & a_{33} \\ \frac{1}{2}a_{23} & a_{33} \end{vmatrix},$$

$$m_3 = -\det A.$$

But since  $a_{13} = a_{23} = 0$ , then

$$m_1 = -(a_{11} + a_{22} + a_{33}), \quad (3.22)$$

$$m_2 = a_{11}(a_{22} + a_{33}) - \frac{1}{4}a_{12}^2,$$

$$m_3 = a_{33}\left(\frac{1}{4}a_{12}^2 - a_{11}a_{22}\right)$$

Hence by the Routh-Hurwitz criteria and Lemma 6.1 of ([15], pp. 177), it follows that  $A$  is negative definite if

$$m_1 < 0, m_3 < 0, \text{ and } m_1m_2 > m_3. \quad (3.23)$$

Thus we have the following theorem.

**Theorem 3.5.** Suppose that the two conditions,

$$(i) a_{ii} < 0, i = 1, 2, 3,$$

$$(ii) a_{11}a_{22} - \frac{1}{4}a_{12}^2 < 0,$$

hold, then the equilibrium point  $\bar{P} = (\bar{S}, \bar{I}, \bar{Q}) \in R_{SIQ}^+$  is globally asymptotically stable with respect to solution trajectories initiating from  $\text{int } R_{SIQ}^+$

**Proof.** The proof follows the lines of those of Nani et al[20, Lemma 6.1] and Frobenius Theorem.  $\square$

The following Lemma due to Butler-McGehee (cf. [20]) be needed for our later results.

**Lemma 3.6.** Let  $P$  be an isolated hyperbolic equilibrium in the omega limit set  $\Omega(X)$  of an orbit  $\mathcal{O}(X)$ . Then either  $\Omega(X) = P$  or there exist points  $Q^+, Q^-$  in  $\Omega(X)$  with  $Q^+ \in M^+(P)$  and  $Q^- \in M^-(P)$ .

Now, we discuss persistence, uniformly persistence and give sufficient conditions for the existence of a positive interior equilibrium point  $\bar{P} = (\bar{S}, \bar{I}, \bar{Q}, \bar{R})$ .

**Theorem 3.7.** Assume that,

(i)  $P_\circ = (\frac{A}{d}, 0, 0, 0)$  is a hyperbolic saddle point and is repelling in both  $Q$  and  $R$  direction (see Theorem 3.4).

(ii) System (1.1) is dissipative and solutions initiating in  $\text{int } R_{SIQR}^+$  are eventually uniformly bounded.

(iii) The equilibrium points  $\bar{P} = (\frac{A}{d}, 0, 0)$

and  $\bar{P} = (\bar{S}, \bar{I}, \bar{Q})$  are globally asymptotically stable. Then the system (1.1) is uniformly persistence.

**Proof.** The proof depends on Lemma 3.6. Let

$$\Gamma = \{(S, I, Q, R) \in R_{SIQR}^4 : S + I + Q + R = 1\} \subset R_+^4.$$

We have shown in Theorem 3.2 that  $\Gamma$  is positively invariant, and any solution of system (1.1) initiating at a point in  $\Gamma \in R^4$  is eventually uniformly bounded. However

$\bar{P}_\circ = (\frac{A}{d}, 0, 0)$  is the only compact

invariant set on  $\partial R_+^4$ . Let

$M = \bar{P} = (\bar{S}, \bar{I}, \bar{Q}, \bar{R})$  be such that

$M \in \text{int } \partial R_+^4$ . The proof will be completed by showing that no points  $Q_i \in \partial R_+^4$  belongs to

$\Omega(M)$ . Suppose the contrary that  $P_\circ \in \Omega(M)$ .

Since  $P_\circ$  is a hyperbolic,  $P_\circ \notin \Omega(M)$ . By Lemma 3.6, there exists a point

$Q_0^+ \in W^+(P_\circ) \setminus \{P_\circ\}$  such that

$Q_0^+ \in \Omega(M)$ . But since

$W^+(P_\circ) \cap (R_+^4 \setminus \{P_\circ\}) = \emptyset$ , this contradicts

the positive invariance property of  $\Gamma$ . Thus

$P_\circ \notin \Omega(M)$ . We also show that

$P_1 = (\bar{S}, \bar{I}, \bar{Q}, 0) \notin \Omega(M)$ . If  $P_1 = (\bar{S}, \bar{I}, \bar{Q}, 0) \in \Omega(M)$ , then there exists a point  $Q_1^+ \in W^+((P_1) \setminus \{P_1\})$  such that  $Q_1^+ \in \Omega(M)$ . But  $W^+(P_1) \cap (R_+^4) = \emptyset$  and  $P_1 = (\bar{S}, \bar{I}, \bar{Q}, 0)$  is globally asymptotically stable with respect to  $R_{SIQ}^+$ . This implies that the closure of the orbit  $\vartheta(Q_1^+)$  through  $Q_1^+$  either contains  $P_1$  or be unbounded. This is a contradiction. Hence

$P_1 = (\bar{S}, \bar{I}, \bar{Q}, 0) \notin \Omega(M)$ . Thus we see that if  $P_1$  is unstable, then  $W^+(P_1) \cap (R_+^4 \setminus \{P_1\}) = \emptyset$ . Also, we deduce that if  $P_1$  is unstable, then

$$W^+(P_1) \cap (Int R_+^4) = \emptyset, \text{ and}$$

$$W^-(P_1) \cap (R^4 \setminus R_+^4) = \emptyset.$$

Now, we show that  $\partial R_+^4 \cap \Omega(M) = \emptyset$ . Let  $E \in \partial R_+^4$  and  $E \in \Omega(M)$ . Then the closure of the orbit through  $E$ ,  $\vartheta(E)$  either contains  $P_1$  and  $P_1$  or be unbounded, and the uniformly persistence result follows since  $\Omega(M)$  must be in  $int R_+^4$ . This completes the proof.  $\square$

Now, we discuss Hopf bifurcation for the system of equations (1.1) with bifurcation parameter  $\delta$ . The system (1.1) can be recast into the form

$$\dot{X} = F(X, \delta),$$

where  $X \in R^4 = \begin{pmatrix} S \\ I \\ Q \\ R \end{pmatrix}$  and  $\delta$  is the bifurcation parameter.  $F(X, \delta)$  is a  $C^r$  ( $r \leq 5$ ) function on an open set in  $R^4 \times R^1$ . Let

$B_\delta = \left\{ P_\circ = \left(\frac{A}{d}, 0, 0, 0\right), \bar{P} = (\bar{S}, \bar{I}, \bar{Q}, \bar{R}) \right\}$  be the set of equilibrium points of (1.1) such that  $F(B_\delta) = 0$ , for some  $\delta \in R^1$  on a sufficiently large open set  $G$  containing each member of  $B_\delta$ . The linearized problem corresponding to (1.1) about any  $\delta$  is give by

$$\dot{y} = J_\delta(F(B_\delta))y, \quad y \in R^4.$$

(3.24)

Here, we are interested in studying how the orbit structure near  $B_\delta$  changes as  $\delta$  is varied.

**Theorem 3.8.** If

$$\beta H\left(\frac{A}{d}, 0\right) > (\gamma + \delta + d + \alpha_1),$$

then the Hopf bifurcation can not occur at

$$P_\circ = \left(\frac{A}{d}, 0, 0, 0\right).$$

### Examples.

1- Consider the special case of incidence rate  $\beta I^P S^q$  considered by [18], and [19] for  $q = 1$ , with the choices  $\gamma = 0.8$ ,  $\mu = 0.3$ ,  $A = d = 0.00027473$  and  $\beta = 0.3$ , then a simple calculations , leads to the  $R_q$  is very close to 0.3 i.e. the condition  $R_q \leq 1$  be satisfied .Moreover in this case the condition  $(A_1)$  be satisfied .This because in this case  $IH_s = I^P$ , where  $q = 1$  may only equal one in two uncosiderable cases,  $p = o$  or  $I = 1$ . In the special case of incidence rate  $\beta IS$  considered by [ 23 ], the conditions of Theorem 3.10 are not satisfied in this special case of the incidence rate. This is consistent with the conclusion of [12].

### 4. Discussion

In this paper, we discussed a generalized *SIQR* epidemic system with vertical transmission for the dynamics of an infectious disease. The generalized incidence term of the form  $\beta IH(I, S)$  is of nonlinear form and the immunity is assumed to be permanent. It has endemic equilibrium that are asymptotically stable so that no periodic solutions arise by Hopf bifurcation. We established local asymptotic stability of the disease free-equilibrium  $\bar{P}_o = (\frac{A}{d}, 0, 0)$  and

$P_o = (\frac{A}{d}, 0, 0, 0)$  for the systems (2.1) and (1.1), respectively. Our results are consistent with those obtained by Korobeinikov et al [13], when conditions  $(A_1)$  and  $(A_2)$  of Theorem 2.1 be satisfied. We have shown that if the condition  $(A_1)$  of Theorem 2.1 is satisfied, then the disease free-equilibrium point  $\bar{P}_o = (\frac{A}{d}, 0, 0)$  is locally asymptotically stable in the interior of the feasible region and the disease always dies out. The main theorem of the method depends on Lozinski Logarithmic norm. We have shown that if the two conditions  $(A_2)$  and  $(A_3)$  of Theorem 2.2 hold, then a unique endemic equilibrium point  $P^* = (S^*, E^*, I^*)$  exists and is locally asymptotically stable in the interior of the feasible region. Moreover, once the disease appears, it eventually persists at the unique endemic equilibrium level. The local stability of  $\bar{P}_o = (\frac{A}{d}, 0, 0), P = (\frac{A}{d}, 0, 0, 0)$ , and  $P = (S^*, E^*, I^*)$  are obtained using the Routh-Hurwitz criteria, which has been widely used in the literature ([2] and [9]). The global stability of  $\bar{P}_o = (\frac{A}{d}, 0, 0)$  and

$P = (S^*, E^*, I^*)$  in Theorem 3.4 and Theorem 3.5 are established using Liapunov functions a similar approach to those in Li ([14], [15]) and Freedman [20]. We employ the mathematical tools of differential analysis, persistence theory and a technique similar to that used by Nani and Freedman [20]. We discuss uniform persistent and Hopf bifurcation of system (1.1) at  $P_o = (\frac{A}{d}, 0, 0, 0)$ . We give some numerical examples that ensure our results. Our obtained results improve and partially generalize those obtained in [3], [4], [11] [13] and [24].

**Abstract:** The purpose of this study is to identify the effect of the combination of herbal mixture and conventional chemotherapy on minimizing the incidence of chemotherapeutic side effects for 2<sup>nd</sup> stage breast cancer. Forty adult female patients aging 20 to 65 years old diagnosed with breast cancer stage (II), receiving chemotherapy for at least one month and will continue to receive it for 3 months- were selected randomly and divided equally into study and control groups. They were free from any associated co-morbid diseases as diabetes, renal, cardiac. The patients were interviewed in the oncology outpatient clinic. Study group patients were instructed about the importance of taking herbal capsules regularly with chemotherapeutic cycles, on a scheduled dose of 1 capsule three times per day for 3months. Complete assessment for both groups as baseline data to assess the chemotherapeutic side effects, laboratory investigations and the nutritional status of the patients were done, and then after 45days and after 3 months. The results revealed that (45%) of cancer breast women were in age group 49-65 years. The greater proportion of the sample (62.5%) breast fed and lactated for three times and more through their life. The least affected systems with chemotherapeutic side effects and the most affected systems when combined herbal to conventional therapy were: liver functions and endocrine studies, renal functions, reproductive system, urinary system, and weight changes. While psychological status, nervous system, and skin, hair, and nails were the most affected systems with the side effects of chemotherapy, and they were the least affected systems when combined herbal to conventional chemotherapy. Also it was found that there was significant difference between the study and control groups in relation to second and third assessments related to all body systems. It is recommended that herbal education should be introduced in nursing and medical curriculum. Further researches related to these herbal components to measure its efficacy on minimizing the side effects of chemotherapy for breast cancer and/ or other types of cancer. Further researches are also needed on larger number of sample. Clinical studies should be done to identify the effect of these herbs on different cancer therapies, different chemotherapeutic protocols, specifically pre or post mastectomy.

[Nagla Hamdi Kamal Khalil, Sanaa Alaa El- Din, Maha Adel Salem. The Effect of Combining Herbal Therapy with Conventional Chemotherapy on the Incidence of Chemotherapy Side Effects in 2nd Stage Breast Cancer Patients. Journal of American Science 2010;6(11):784-801]. (ISSN: 1545-1003).

## Introduction

Breast cancer is the second most common type of cancer after lung cancer, and the fifth most common cause of cancer death. Egyptian National Cancer Institute (NCI)<sup>(9)</sup>, reported that breast cancer is the most common cancer among women, representing 18.9% of total cancer cases (35.1% in women and 2.2% in men) among series of 10556 patients during the year 2001, with an age-adjusted rate of 49.6 per 100 000 population. Breast cancer in Egyptian patients has a younger age distribution with the majority of patients occurring at 30–60 years of age. In Alexandria over the year 2006, 1183 patients

diagnosed with breast cancer (1132 patients were females and 51 patients were males)<sup>(10)</sup>.

The type of treatment for breast cancer varies with the location, type and severity of the tumor. Therapy options for breast cancer include surgery, chemotherapy, radiation therapy, biological therapy and hormonal therapy<sup>(63)</sup>. The treatment can be physically exhausting for the patient. Current chemotherapeutic techniques have a range of side effects mainly affecting the fast-dividing cells of the body. Important common side-effects include: Bone marrow suppression, digestive system changes as nausea and vomiting, appetite loss and weight

changes, taste changes, constipation, diarrhea, hair loss, fatigue, heart damage and nervous system changes<sup>(14, 15)</sup>. Recently, there is a call for returning to the nature by using herbals with proven efficacy in prevention, treating, and minimizing the consequences of many diseases. Health care in the twenty-first century requires that nurses recognize the shift of thinking toward the incorporation of alternative and complementary approaches to care. Nurses at all levels and in every area of practice are answering the call to use new methods to care for the ill patients and to enhance the health of those who are well<sup>(7)</sup>.

Complementary and alternative medicine (CAM) is widely embraced by cancer patients due to largely patients' demands for integration of herbal therapies into their cancer treatment. Integrated medicine is a holistic approach to cancer care, with some herbal medicines showing proven efficacy as adjuvant to conventional medical treatments. At the present time there is little evidence of a systematic process of evaluation or dialogue between mainstream medicine and herbal medicine practitioners<sup>(16)</sup>. Herbal Medicine is one of the oldest types of medicine which is dating back to the ancient cultures of Egypt, China, and India, and possibly even pre-historic times for healing purposes<sup>(17)</sup>. It encompasses the use of natural sources as plants and natural products for healing or therapeutic purposes<sup>(16, 17)</sup>.

In Egypt, there is a lack in clinical researches investigating the real effect of herbals as a complementary and / or alternative medicine, despite of its safety and benefits in curing chronic diseases or conditions. So the approach today is to use herbals in dealing with these chronic disabilities with other conventional or traditional therapy for managing these disorders<sup>(22)</sup>.

This study emphasizes on identifying the effect of a herbal mixture in a capsule form containing a blend of 5 herbals used in culinary edible purposes. The herbal mixture composed of Ginger rhizome, Nigella Sativa seeds, Boswellia, Curcuma rhizome, Cardamom seeds. This study aims to identify the effect of the combination of herbal mixture to conventional chemotherapy on minimizing the incidence of chemotherapeutic side effects for 2nd stage breast cancer. When patients integrate these complementary therapies as herbals into their medical and surgical care, they are creating a more comprehensive treatment plan and helping their own bodies to regain health and vitality<sup>(22)</sup>.

David (2008), reported that, *nigella sativa* (Black Cumin) helps treat a broad array of diseases,

including some immune and inflammatory disorders, anticancer activity in prostate and colon cancers, as well as antioxidant. Much of the biological activities of its seeds have been reported to provide protection against nephrotoxicity and Hepatotoxicity induced by either disease or chemicals<sup>(90)</sup>.

Ginger is the rhizome of *Zingiber officinale* (*Zingiberaceae*) contains effective compounds known as gingerols, and volatile oils with antimicrobial effects. The root has antiemetic effects from its carminative and digestive properties which has the ability to enhance GI motility and it reduces the severity and duration of nausea during chemotherapy<sup>(94,95)</sup>. Ginger has anti-inflammatory effects; by inhibit prostaglandins and thromboxane, antimigraine effects; which inhibit platelet aggregation, antithrombotic effects. Ginger is used most commonly to treat colic, flatulence, and indigestion<sup>(95)</sup>. It is claimed to treat hypercholesterolemia, burns, ulcers, depression, impotence, and liver toxicity and as an anti-inflammatory for those with arthritis and as an antispasmodic.

*Boswellia* is a natural oleo-gum resin which consists of resinous portion contains about 60% of Boswellic Acids (BA) (alpha-and beta) which are the active constituents in boswellia<sup>(97)</sup>. Studies have shown that boswellic acids have an anti-inflammatory action by having an antimicrobial activity and inhibit the complementary system. This acts much like the conventional nonsteroidal anti-inflammatory drugs (NSAIDS). *Boswellia* inhibits pro-inflammatory mediators in the body, such as leukotrienes and also prevents the breakdown of connective tissue. The mechanism is similar to the action of non-steroidal groups of anti-arthritis drugs. Long-term use of *boswellia* does not lead to irritation or ulceration of the stomach<sup>(98)</sup>.

*Curcuma* is a dried rhizome of *Curcuma longa*, family *Zingiberaceae*. The main active constituent of which is known as curcumin. It protects against free radical damage because it is a strong antioxidant. It also reduces inflammation by reducing histamine levels and possibly by increasing production of natural cortisone by the adrenal glands. It protects the liver from a number of toxic compounds and, it reduce platelets from clumping together, which in turn, improves circulation and helps protect against atherosclerosis (figure 15)<sup>(100)</sup>. Numerous studies have also shown cancer-preventing effects of curcumin. This may be due to its powerful antioxidant activity in the body. A symbol of prosperity, it was considered as a cleansing herb for the whole body<sup>(101)</sup>. Medically, it was used as a digestive aid and treatment for fever,

infections, dysentery, arthritis, jaundice and other liver problems.. Curcumin is used for the treatment of anorexia, liver disorders, cough, diabetic wounds, rheumatism, and sinusitis. It has been evaluated for its anticarcinogenic and antimutagenic properties<sup>(102)</sup>.

Cardamoms are used to sooth the stomach and treat dyspepsia for its antispasmodic, antiflatulent, and motility- enhancing effects<sup>(105)</sup>. It is also used for respiratory disorders, asthma, common cold, cough, bronchitis, headache, hoarseness, indigestion, diarrhea, nausea, vomiting and stomach complaints<sup>(105, 106)</sup>. Cardamom seeds, with their sweet and spicy aroma, are used in aromatherapy to stimulate energy. A few drops of the oil in the bath help fight fatigue. The standardized dose of cardamom is 400 mg-600mg three times per day<sup>(106)</sup>.

The nurse has an important role in assessing and managing many of the problems experienced by the patient undergoing chemotherapy. Therefore, nursing assessment and care focus on identifying and modifying factors that further increase the patient's risk. Suppression of the bone marrow and immune system increase the risk for anemia, infection, and bleeding disorders. Aseptic technique and gentle handling are indicated to prevent infection and trauma. Laboratory test results, particularly blood cell counts, are monitored closely. Any changes in blood test results and signs of infection and bleeding must be reported promptly. The patient and family members are instructed about measures to prevent these problems at home<sup>(107)</sup>.

**Aim of the study:** The aim of the present work is to identify the effect of the combination of herbal mixture to conventional chemotherapy on minimizing the incidence of chemotherapeutic side effects for 2<sup>nd</sup> stage breast cancer.

#### **Keywords:**

**Herbal Mixture:** in form of capsules containing 5 natural herbals (Nigella Sativa–Cardamom m–Ginger–Curcuma–Boswellia serrata gum ).

#### **Material & Methods**

##### **Materials:**

**Research design:** A Quasi experimental research design was utilized in this study.

##### **Settings:**

**Oncology out-patient clinics of Alexandria Main University Hospital.**

#### **Sample :**

Forty adult female patients who were diagnosed with breast cancer and were receiving chemotherapy for at least one month and will continue to receive it for 3 months were included in the study. The subjects were selected randomly and divided equally into study and control groups, 20 patients in each group. Patients age ranged from above 21 to below 65 years , they were diagnosed with breast cancer of the same type, stage II, on chemotherapy for at least 4 months basis. The subjects included were one month post 1st chemotherapeutic cycle of the same protocol. Either pre-or post operative and they were free from any associated co-morbid diseases as diabetes, renal, cardiac, hypertension.

**Tools:** Two tools were used:

#### **Tool: Breast cancer women's assessment questionnaire sheet:**

This questionnaire was developed by the researchers based on literature review and specialist opinion. It was divided into three parts.

**(A). Chemotherapeutic side effects schedule sheet;** it was adopted from Sitizia, (1999)<sup>(116)</sup>.This part includes a list of chemotherapeutic side effects. Its grade of severity ranged from one to four (not present, mild, moderate, and severe). These side effects were divided according to body parts and systems.

**Facio-maxillary, integumentary system, gastrointestinal system, musculoskeletal system, neurological system, cardiovascular system, respiratory system, urinary system, reproductive system, psychological status**

**(B). Laboratory investigations:** Complete blood count (CBC), renal and liver functions tests, and fasting blood glucose level.

**(C). Quality of life standard scale:** This part includes two questions which assess the standard of life for all patients -control and study groups- over the three months of the study. For study group they assess the standard of life pre and post administering the herbal capsules. These two questions are part of The European Organization for Research and Treatment of Cancer quality of life questionnaire version 3,0 (EORTC QLQ-C30 Version 3.0): it is the most recent version, composed of 30 questions, for assessing the health related quality of life (QOL) of cancer patients participating in international clinical trials research, developed by The European Organization for Research and Treatment of Cancer (EORTC) in Arabic language in 1995.these two questions (likert

scale) are scored positively (i.e. 7 indicated excellent is the best and 1 indicated very poor is the worst)<sup>(47), (117)</sup>.

\***In addition to:** Patient's Sociodemographic data as:

Name ,age, educational level, occupation, marital status, number of children, type and number of child's feeding, date and type of first dose of chemotherapy.

Chemotherapeutic protocol prescribed by oncologist for both groups, for each cycle, includes:

- Endoxane with 500 cc glucose 5%.
- Adriamycin with 100 cc saline 9%.
- Fluorouracil with 500 cc saline 9%.

\* The doses of these drugs are calculated according to the patient's weight and height.

\* Before starting these drugs, there was a starting bottle contains 100 cc saline 9% with one ampoule of Zantac, one ampoule Decadron and another one of Emax

#### **Tool II: Nutritional assessment check list:**

It was developed to detect nutritional health status of the breast cancer patients which includes:

\* **Anthropometric measures:** anthropometric measurements provide an objective assessment of nutritional status it includes patient's body weight, height, triceps skin fold (TSF) mid – upper arm circumference. (MAC) and mid upper arm muscle circumference (MAMC) as well as body mass index (BMI). Each of these measurements was taken according to the standard procedures recommended by Jelliffe (1998)<sup>(118)</sup>.

**1- Body weight:** - it should be recorded on admission and monitored regularly. Weight was taken by asking every patient to stand on the center of a bath spring scale without moving or touching any thing. The reading was recorded to the nearest 1 kilogram<sup>(119)</sup>.

**2- Standing height:** - Height was measured by asking the patients to stand on the floor bare head and feet .she stands erect with shoulders and back of the head in the upright position and looking straight ahead, both heels and scapula are in contact with the wall. The measurement was taken by a measuring tape. The reading was recorded to the nearest 0.1 cm<sup>(112)</sup>.

**3- Body mass index (BMI):** - calculation of body mass index, is a way of classifying weight. It was estimated by the following equation:  $BMI \text{ (kg/m}^2\text{)} = \{\text{weight (kg)}/\text{height (meter)}^2\}$ <sup>(119)</sup>.

**4- Triceps skin fold thickness (TSF):**-it is an index of total body fat, the assessment of subcutaneous body fat by skin fold measurements is accurate. The measurement was done using the skin fold calipers. The site of measurement selected is the same mid point used to measure mid – upper arm circumference<sup>(112)</sup>.

**5- Mid-upper arm circumference (MAC):-**mid – arm circumferences measures muscle mass and subcutaneous fat, although it is not a useful measurement by it self, it is used as a part of the procedure for calculating arm muscle circumference (MAMC).<sup>(119)</sup>.

**6- Mid arm muscle circumference (MAMC):-** it was calculated from the MAC and TSF measurements by the following equation:  
 $MAMC \text{ (cm)} = MAC \text{ (cm)} - \{3.14 \times TSF \text{ (cm)}\}$ .

The value is recorded and compared with standard reference value<sup>(119)</sup>.

#### **II-METHODS:**

**1. Permission to conduct** the study was obtained from responsible authorities of the general director of the Alexandria University Hospital and the head of oncology department in the Main University hospital.

**2. An ethical approval** was taken from the ethical committee of the Faculty of Nursing Alexandria University for carrying out this study.

**3. The researchers have undergone a special training** about the route for preparing and fixing the herbal capsules about one month, under the supervision of a specialist trainer in the pharmacognosy department who was one of the supervisors of the thesis, the herbal mixture was mixed then prepared in the form of capsules. The dose was adjusted to be 1 capsule three times per day for 3 months for the study group in conjunction with chemotherapy protocol .Control group will be on chemotherapy protocol only.

**4. Aflatoxins study:** The mixture was subjected to aflatoxins test to insure its safety and puerility.

**5. Herbal materials:** The dose of herbal calculated and fixed according to the reference's recommended doses as *nigella sativa* seeds is 500 mg /three times per day, curcumin is 500 mg /three times per day, cardamom is 500 mg /three times per day, boswellia is 300 mg /three times per day, ginger is 2 gm /three times per day.

**6. Research Tools** The tools were developed based on the recent relevant literature. Tool I was developed by the investigators. Content validity was tested by ten experts in the filed of nursing and oncology field. Tool II was taken according to the standard procedures recommended by jelliffe (1998)<sup>(118)</sup>. Reliability for Tool I and Tool II were done by using test- re test.

**7. Pilot study** A pilot study was carried out before starting the data collection. It was applied on 10 patients with breast cancer who fulfill the study criteria to test feasibility and applicability of both tools and necessary modification were done.

**9. Patient's consent** Patient's written consent to participate in the study was then obtained. Every patient was informed that confidentiality will be assured, and she had the right to discontinue from the study at any time she wants.

The researchers interviewed every patient from the first day of the second cycle of receiving chemotherapy. Each patient was interviewed individually and each interview took approximately one hour. For the study group patient and her family were instructed about the importance of taking herbal capsules regularly, and illustrate the aim of the study as well as the scheduled dose which is 1 capsule three times per day for 3months on an individual basis. Numbers of sessions were adopted according to chemotherapeutic protocol till 3 months.

**11. Assessment phase (for both groups)** firstly General data about the patient has been collected as name, age, address, marital status, level of education, occupation, and date of first dose of chemotherapy.

**12. Implementation Phase (for both groups)** two tools (I&II) were used for both groups as baseline

## **II. The standard ranges that used for laboratory investigations are<sup>(66)</sup>:**

RBC (4.2 – 6.1) x 10<sup>6</sup> cells /ul  
HCT (37 -52) %  
MCH (27 – 31) pg  
WBC (5.2 – 12.4) x 10<sup>3</sup>cells/ul  
Lympho (19- 48) %  
Eso (0 – 7) %  
Platelets count (150 – 450) x 10<sup>6</sup> cells /ul  
Blood urea Nitrogen (7 – 18) mg/dl  
Total Bilirubin (.3-1.9)mg/dl  
SGOT (30 – 65) u/l  
Fasting Blood Glucose (70 -110).

data to assess the chemotherapeutic side effects, laboratory investigations as well as the nutritional status of the patients. Then these two tools were also applied for both groups after 45days then after 3 months of administering the herbal capsules to detect their effect on chemotherapeutic side effects and the nutritional status of the patients. Laboratory investigations data was obtained from the patient's hospital sheet at the scheduled times. Nutritional assessment weight has been measured at the first assessment then at the second and third one; percent of weight changes is calculated using the following formula. {(first weight – current weight) / first weight} x 100 =% weight change.

## **13. Evaluation Phase (for both groups):**

**I. Side effects of chemotherapy** in relation to all body systems were evaluated by using tool I & II after 45 days and then repeated after 3 months.

HGB (12- 18) g/dl  
MCV (80-99) fL  
MCHC (33- 37) g/dl  
Neutro (40 -74) %  
Mono (3.4 – 9) %  
  
Baso (0.5 -1.5) %  
Creatinine (0.6- 1.3) mg/dl  
SGPT (15 – 37) u/l

## **IV. Interpretation and evaluation of anthropometric measurements:**

### **(1) Evaluation of Body Mass Index:<sup>(125)</sup>**

Under weight	<19
Normal weight	19 - < 25
Over weight	25 - < 30
Mild obesity	30 - < 35
Moderate obesity	35 - < 40
Severe obesity	40

### **(2) Evaluation of MAC, TSF, and MAMC:<sup>(119)</sup>**

Measurement	Standard
MAC (cm)	29.0

TSF (mm)	16.5
MAMC (cm)	23.5

#### 14. Statistical analysis:

Data was analyzed using PC with statistical Package for Social Sciences version 13.0. The 0.05 level was used as the cut off value for statistical significance and the following statistical measures were used.

#### A. Descriptive statistics:*Count and percentage and Minimum, Maximum, Arithmetic mean ( $\bar{X}$ ), Standard deviation (SD):*

Analytical statistics:the following were used:

##### 1. Chi square: ( $\chi^2$ ):

Fisher Exact Test:

Monte Carlo Exact Test:

##### 2. Student t-test:

a. The pooled variance t-test: If the variances of the two groups are equal.

b. The separate variance t-test: If the variances of the two groups are not equal.

**Levene test** is used to test the hypothesis that the two population variances are equal.

##### 3. One way Analysis Of Variance (ANOVA):

It is used for testing the difference between more than 2 groups mean. In case of significant ANOVA f test the Post Hoc Sheffe test was used for multiple comparison of each of couple of groups.

## RESULTS

Table (I): Distribution of the study and control groups regarding to biosociodemographic characteristics.

Item	Study		Control		Total		Test of significant
	n	%	n	%	n	%	
<b>Age:</b>							
27-	6	30%	2	10%	8	20%

**Table (I):** shows distribution of the patients among the study and control groups regarding to biosociodemographic characteristics. It was observed that the majority of patient's age (45%) were in the age group of (49 – 65) years, while (20%) only were in the age group of (27 – 38) years. Regarding to educational level, it is evident that illiterate patients formed the greatest proportion of the sample (65%). There was no statistically significant difference among the study and control groups in relation to age and educational level. P= (0.274 and 0.443), respectively.

As regard the occupation the majority of the patients (80%) were found to be non - working, while (20%) were working. There was a statistically significant difference among the two groups in relation to occupation P= (0.044). In relation to marital status, it was observed that the majority of patients (75%) were married, while (10%) were single. there was a statistically significant difference among the two groups in relation to marital status P= (0.025). Concerning the type and frequency of breast feeding. It was found that the majorities of the sample (62, 5%) were breast fed and lactated their children for three times and more through their life. There was no statistically significant difference among the study and control groups in relation to type and frequency of breast feeding where, P= (0.744).

**Table (II):** shows the effect of herbal and conventional therapy on the side effects of chemotherapy regarding to all body systems among the study and control groups. This table illustrated that, the side effects of chemotherapy regarding to all body systems for the study group shows a decrease on the second and third assessments ( $30.9 \pm 4.4$ , and  $23.2 \pm 3.4$ ), respectively compared with the first assessment ( $43.0 \pm 5.6$ ). In contrast for the control group, it was observed that these side effects showed an increase of its severity on the second and third assessments ( $43.9 \pm 5.3$ , and  $54.3 \pm 3.6$ ), respectively compared with the first assessment ( $37.4 \pm 4.9$ ). It was found that there was a significant difference between study and control groups in relation to first, second and third assessments related to all body systems. P = (0.002, 0.000, 0.000), respectively.

**Table (III):** shows the ranking of all body systems that affected with the chemotherapeutic side effects post herbal and conventional therapies (3<sup>rd</sup> assessment) among two groups. This table illustrated the actual effect of herbal therapy in relation to the third assessment, it was found that, liver functions and endocrine studies, renal functions studies, reproductive, urinary system, and weight changes were the least affected systems with the side effects

of chemotherapy, and they were the most affected systems with combining herbal to conventional chemotherapy ( $6.3 \pm 11.1$ ), ( $10.0 \pm 22.5$ ), ( $13.5 \pm 5.9$ ), ( $15.6 \pm 6.6$ ), and ( $16.9 \pm 6.1$ ), respectively. Gastro intestinal, respiratory, musclo skeletal system, hematological tests, and eye, ear, mucous membranes were moderately affected systems with the side effects of chemotherapy, and they were also moderately affected systems with combining herbal to conventional chemotherapy ( $17.3 \pm 3.4$ ), ( $23.5 \pm 4.9$ ), ( $24.4 \pm 8.3$ ), ( $25.8 \pm 15.6$ ), and ( $28.0 \pm 6.7$ ), respectively. It was also found that, psychological status, nervous system, and skin , hair, and nails were the most affected systems with the side effects of chemotherapy, and they were the least affected systems with combining herbal to conventional chemotherapy ( $30.3 \pm 6.5$ ), ( $32.5 \pm 10.3$ ), and ( $33.1 \pm 8.9$ ), respectively. On the other hand, for control group, it was also found that, weight changes, reproductive system, liver functions studies , urinary system, and gastro intestinal were the least affected systems with the side effects of chemotherapy, ( $18.1 \pm 12.5$ ), ( $27.9 \pm 5.3$ ), ( $45.0 \pm 15.4$ ), ( $48.3 \pm 6.3$ ) and ( $53.3 \pm 7.1$ ), respectively. Nervous system , hematological tests, Skin, hair, and nails, eye, ear, mucous membranes and psychological status were moderately affected systems with the side effects of chemotherapy, ( $53.8 \pm 7.1$ ), ( $57.3 \pm 12.3$ ), ( $62.8 \pm 6.9$ ), ( $64.5 \pm 5.6$ ) and ( $65.0 \pm 9.2$ ), respectively. Concerning, respiratory systems, musclo skeletal and renal functions studies were the most affected systems with the side effects of chemotherapy, ( $65.8 \pm 4.8$ ), ( $68.1 \pm 6.0$ ) and ( $92.5 \pm 18.3$ ), respectively.

**Table (IV):** reveals the effect of herbal and conventional therapy on the side effects of chemotherapy regarding to Health and Life style grades among the study and control groups. Concerning, health grades and life style of the patients, the table revealed that, all the study group have bad and accepted degrees of health grade and life style grades, and all the control group have bad and moderate degrees of health grade and life style grades on the first assessment. In relation to the third assessment post herbal and conventional therapy it was found that the entire study group has good and very good degrees, while all of the control groups have bad and accepted degrees.

In relation to significant difference between the three assessments among the study and control groups in relation to health and life style grades. It was found that there was a significant difference between study and control groups in relation to first, second and third assessments P = (0.000).

**Table (V):** Reveals the effect of herbal and conventional therapy on the side effects of chemotherapy regarding to anthropometric measurements among the study and control groups. Concerning patient's weight, there was an increase in patient's weight of the study group on the third assessment ( $76.9 \pm 11.1$ ), compared with the first assessment of weight ( $73.6 \pm 11.0$ ). While there was a decrease in patient's weight of the control group on the third assessment ( $71.1 \pm 7.8$ ), compared with the first assessment of weight ( $74.6 \pm 8.9$ ). There was no statistical significant difference between both groups in relation to assessment of weight in first, second and third assessment  $P= (0.753, 0.610, 0.063)$ , respectively. The table revealed that, there was statistical significant difference between both groups in relation to assessment of height in first, second and third assessments.  $P=0.006$ .

In relation to mid arm circumference, the mean of mid arm circumference in study group was increased in the 2<sup>nd</sup> and 3<sup>rd</sup> assessments ( $31.5 \pm 2.7$ ,  $32.1 \pm 2.7$ ), respectively, compared with the first assessment of mid arm circumference ( $31.0 \pm 2.6$ ). While in the control group there was a slightly decrease on the 2<sup>nd</sup> and 3<sup>rd</sup> assessments ( $28.0 \pm 1.8$ ,  $27.6 \pm 1.8$ ), respectively, compared with the first assessment of mid arm circumference  $28.6 \pm 2.0$ . There was statistical significant difference between both groups in relation to assessment of mid arm circumference on first, second and third assessments  $P= (0.002, 0.000, 0.000)$ , respectively.

Moreover, the mean of triceps skin fold in study group was increased on the 2<sup>nd</sup> and 3<sup>rd</sup> assessments ( $17.8 \pm 2.1$ ,  $18.4 \pm 2.2$ ), respectively, compared with the first assessment of triceps skin fold ( $17.5 \pm 1.9$ ). While in the control group there was a decrease on the 2<sup>nd</sup> and 3<sup>rd</sup> assessments ( $16.5 \pm 1.0$ ,  $16.2 \pm 1.0$ ), respectively, compared with the first assessment of mid arm circumference ( $16.8 \pm 1.1$ ). There was no statistical significant difference between both groups in relation to first assessment of triceps skin fold  $P= (0.137)$ . While on the second and third assessments There was statistical significant difference between both groups  $P= (0.016, 0.000)$ , respectively.

Finally the table shows that, there was an increase in study group in relation to body mass index on the 2<sup>nd</sup> and 3<sup>rd</sup> assessments ( $27.8 \pm 3.0$ ,  $28.6 \pm 3.0$ ), respectively, compared with the first assessment of body mass index ( $27.3 \pm 3.0$ ). While in the control group there was a decrease on the 2<sup>nd</sup> and 3<sup>rd</sup> assessments ( $25.6 \pm 2.5$ ,  $25.0 \pm 2.3$ ), respectively, compared with the first assessment of body mass

index ( $26.2 \pm 2.7$ ). There was no statistical significant difference between both groups in relation to first assessment of body mass index  $P= (0.199)$ . While in the second and third assessments There was statistical significant difference between both groups  $P= (0.020, 0.000)$ , respectively.

**Table (VI):** shows the relation between age and chemotherapeutic side effects of all body systems among breast cancer women post herbal and conventional therapy. This table revealed that, the chemotherapeutic side effects of all body systems for the study group by its age categories were decreased on the 2<sup>nd</sup> and 3<sup>rd</sup> assessment ( $29.3 \pm 4.3$ ,  $22.8 \pm 3.6$ ), respectively, compared with the first assessment ( $42.8 \pm 2.7$ ) for the age group 27-38.while for the control the side effects of chemotherapy were increased on the 2<sup>nd</sup> and 3<sup>rd</sup> assessments ( $42.4 \pm 11.4$ ,  $53.3 \pm 6.2$ ), respectively, compared with the first assessment ( $36.9 \pm 10.3$ ) for the same age group. There was no significant difference between age and all the side effects of chemotherapy among the three assessments of the study group  $P= (0.700, 0.573, 0.790)$  respectively. And also for the control group  $P= (0.443, 0.422, 0.425)$ , respectively.

**Table (VII):** shows the relation between occupation and chemotherapeutic side effects of all body systems among breast cancer women post herbal and conventional therapy. It was found that, the chemotherapeutic side effects of all body systems of the study group was slightly increased between the working group (43.2),compared with the non - working group (43.0) on their first assessment. This result was changed on the third assessment, working group (22.9) and non - working (23.2), while in the control group it was a decrease between the working groups (34.0) compared with the non - working group (39.2) on their first assessment. This result wasn't changed on the third assessment, working group (34.0) and non - working (55.5).The table also revealed that, for non- working group of the study group, the chemotherapeutic side effects of all body systems were decreased on the second and third assessments ( $30.8 \pm 4.4$ ), ( $23.2 \pm 3.5$ ), respectively, compared with the first assessment ( $43.0 \pm 5.7$ ). While for the control group, there was an increasing in the chemotherapeutic side effects of all body systems on the second, and third assessments ( $45.7 \pm 4.6$ ), ( $55.5 \pm 2.9$ ), respectively, compared with first the assessment ( $39.2 \pm 4.6$ ).

There was no significant difference between occupation and all the side effects of chemotherapy among the three assessments of the study group  $P= (0.971, 0.977, 0.935)$ , respectively. While for the

control group there was a significant difference between occupation and all the side effects of chemotherapy among the three assessments of the control group  $P= (0.021, 0.026, 0.030)$ , respectively.

**Table(VIII):** shows the relation between type and frequency of breast feeding and chemotherapeutic side effects of all body systems among breast cancer women post herbal and conventional therapy. This table illustrated that, the chemotherapeutic side effects of all body systems of the study group was slightly increased between the patients have a history of natural breast feeding for three times and more ( $43.2 \pm 6.9$ ), ( $43.2 \pm 6.8$ ), respectively, compared with patients who have history of bottle feeding for less than three times ( $42.6 \pm 2.7$ ), ( $42.7 \pm 3.0$ ), respectively on their first assessment. This result was changed on the third assessment; patients have a history of natural breast feeding for three times and more ( $22.8 \pm 3.5$ ), ( $23.1 \pm 3.3$ ), respectively and patients who have history of bottle feeding for less than three times ( $23.7 \pm 3.3$ ), ( $23.3 \pm 3.7$ ), respectively.

Concerning, the relation between the type of breast feeding it was found that, the chemotherapeutic side effects of all body systems was decreased on the second , and third assessment ( $t=0.37$ ), ( $t=0.58$ ), respectively, compared with the first assessment ( $t=0.24$ ). While for the control group, there was an increasing in the chemotherapeutic side effects of all body systems on the second, and third assessment ( $t=0.38$ ), ( $t=0.43$ ), respectively, compared with first the assessment ( $t=0.39$ ). On the other hand, for the control group, there was an increasing in the chemotherapeutic side effects of all body systems on the second, and third assessment ( $t=0.38$ ), ( $t=0.43$ ), respectively, compared with the first assessment ( $t=0.39$ ).There was no significant difference between type of breast feeding and all the side effects of chemotherapy among the three assessment of the study group  $P= (0.812, 0.714, 0.567)$ , respectively. Also for the control group  $P= (0.705, 0.705, 0.669)$ , respectively.

Regarding, significant difference between frequency of breast feeding and all the side effects of chemotherapy, it was found that, there was no significant difference among the three assessment of the study group  $P= (0.84, 0.28, 0.96)$ , respectively. Also for the control group  $P= (0, 41, 0.77, 0.31)$ , respectively.

## DISCUSSION:

The use of complementary and alternative medicine using herbals and their natural products for

the prophylaxis, protection, and treatment of various diseases has become more popular in recent years than ever before. Surveys indicate that 64% of cancer patients use alternative medicine, either for treating cancer or relieving symptoms that are associated with different cancer treatments<sup>(123)</sup>.

This study was carried out to show the effect of the combination of herbal mixture to conventional chemotherapy on minimizing the incidence of chemotherapeutic side effects for 2<sup>nd</sup> stage breast cancer.

Geoff, (2006) illustrated that; integrated medicine is a holistic approach to cancer care. Some herbals showed proven effectiveness as adjuvant to conventional medical treatments<sup>(124)</sup>. Janelle et al, (2007) mentioned that, complementary and alternative medicine is widely used by cancer patients due to largely patient's demands for integration of herbal therapies into cancer treatment<sup>(83)</sup>. This was congruent with the findings of the present study which revealed that, patients with herbal and conventional therapies experienced less chemotherapeutic side effects of all body systems than patients with only conventional therapy.

In the present study, as regards to age, it was found that, the majority of patient's age was ranged from 49-65 years old. This was congruent with the American Cancer Society, (2008), which reported that about 80% of all breast cancers arise in women over age 50<sup>(125)</sup>. In addition, Winsock (2004) stated that the most important risk factor for development of breast cancer is increasing age. As any woman ages, her risk of breast cancer increases, especially over 50 years<sup>(58)</sup>.Also this is in line with Thom et al, (2006) who indicated that people over the age of 50 years old are more risky for developing breast cancers<sup>(126)</sup>. DeMichele et al, (2007) reported that, Breast cancer occurs more often in women over 50 and is less common in premenopausal women. Nearly 80 percent of all newly diagnosed invasive breast cancer cases occur in women aged 50 and older<sup>(127)</sup>.

Regarding to educational level, the study illustrated that, the majority of the patients were illiterate this result is similar to Ebrahim's findings, (1999) on his study to identify the preoperative stressors among surgical patients, emphasized that, the majority of the studied subjects were illiterate; he stated that the overwhelming majority of the Egyptian population are illiterate or does not have any formal education<sup>(128)</sup>. The present findings may be due to the setting of the study is a free governmental hospital and the majority of patients have a low education and

economical standards. This result is not in agreement with Jan and Sundquist, (2007) who mentioned that, highly educated women run a greater risk of developing breast cancer especially noninvasive breast cancer than women with less education. At the same time, highly educated women have better chances of surviving in various types of cancer than those with a low level of education<sup>(129)</sup>. They said that; it is naturally not education itself that causes breast cancer. It is most likely that highly educated women attend mammography in greater numbers. Such screening is the most reliable way to find the earliest stages of breast cancer<sup>(129)</sup>. Furthermore, the present study revealed that the non working patients formed the greatest proportion of the sample. This may be due to their lower educational level and being females which decrease their chance of getting a job, they were house wives which are the greatest proportions of the Egyptian's females<sup>(131)</sup>, also it may be due to the setting of the study does not provide health insurance services and there is other hospital for working patients. This result disagree with Ali and Hussain, (2003) who reported that occupations are increasing the risk of getting cancer especially some types of occupations as , teachers who had the highest rates of having breast cancer, and other three occupational groups had statistically significant for cancer of the ovary as printing machine, launderers, and dry cleaners<sup>(132)</sup>.

In relation to marital status the present study showed that, married represented higher percentage than single and widowed, this is opposite to Hayes, (2005) who concluded that, the risk for breast cancer, treatment recommendations and follow-up should not be altered based on a woman's marital status<sup>(133)</sup>.

In agreement with the present study, Frank (2005) mentioned that, current chemotherapeutic techniques have a range of side effects mainly affecting the fast-dividing cells of the body. These side-effects can be reduced by several agents and therapeutic modalities<sup>(138)</sup>. One of these managements which reduce these side effects is the using of herbal medicine as a complementary therapy to eliminate the side effects of cancer therapy<sup>(138)</sup>. This is in line with the present findings, that the herbal components of the study are composed of *nigella sativa*, ginger curcuma, boswella gum, and cardamom. These components have different actions and properties, the commonest actions of these components are; anti-inflammatory, immunomodulator, anti-oxidant, anti- emetic, anti-arthritics, analgesic. Therefore, the aim of this study is decreasing the side effects of the chemotherapy by

using these effects and actions of the herbal components to minimizing these side effects.

Braun and Cohen, (2007) stated that, long term side effects of chemotherapeutic drugs, are due to the formation of free radicals that lead to oxidative organ damage<sup>(139)</sup>. Herbal and its ingredients antioxidants have been investigated in humans and several studies have shown improvement or prevention of some side effects and possibly increased treatment effectiveness<sup>(140, 141)</sup>.

Altman and Marcussen, (2001) high lights the study findings regard to musclo skeletal system, which is a moderately affected system by the combining herbal to conventional therapy, the result illustrated that, there was no significant difference between study and control groups in relation to first assessment. While, in the second and third assessments there was a statistically significant difference between the two groups. This may be attributed by the effect of ginger inhibits the production of immune-system components called cytokines. These chemicals are believed to create a long-term tendency toward inflammation. Stated that, Ginger stimulates blood circulation. These effects of ginger are taken advantage in treating a number of disorders marked by swelling and pain, such as arthritis<sup>(95)</sup>. The finding is congruent with Cassiani et al, (2002) who reported that, studies have also shown that ginger can relieve pain without the side effects typically found when using nonsteroidal anti-inflammatory drugs (NSAIDs) and steroids<sup>(145)</sup>.

This view is also supported with Goldberg et al, (2000) who mentioned that ginger can decrease inflammation. In fact, many health care professionals today use ginger to help treat health problems associated with inflammation, such as arthritis and muscle stiffness. In a study of 261 people with osteoarthritis of the knee, those who received a ginger extract twice daily experienced less pain and required fewer pain-killing medications compared to those who received placebo<sup>(146)</sup>. Davis et al, (2007) reported that, Boswella can reduce painful symptoms of arthritis on dozens of patients, who received the herb and showed better movement and less pain and stiffness<sup>(98)</sup>.

Moreover, the study also revealed that, there was a significant difference between study and control groups in relation to first, second and third assessments of the nervous system, This result were supported by Fahs and Kinny, (2005) who reported that the main effect of curcuma, in which curcumin is the main constituent, is to protect against free radical damage because it is a strong antioxidant, and reduces inflammation. It accomplishes this by reducing histamine levels and

possibly by increasing production of natural cortisone by the adrenal glands by these mechanisms curcumin can inhibits headache, and suppress the unpleasant effects of the nervous system<sup>(147,148)</sup>.

As regard to respiratory systems it was found that, there is no significant difference between study and control groups in relation to first assessment. While in the second and third assessments there was a significant difference between the two groups. This result was supported by Vanbree et al (2002). Who noted that boswellia was believed to support the respiratory and immune systems during respiratory attacks as flu, bronchitis, coughs and decreasing restlessness<sup>(149)</sup>. It is also in line with Hadid et al, (2003) who noted that Cardamom used to sooth the respiratory tract, and it is used also for asthma, cold, cough, bronchitis<sup>(150)</sup>.

Recent studies as indicated by Ashraf and Ali, (2005) who support the action of fixed and essential oils of the *nigella sativa* seeds which has anti-inflammatory, an immunomodular activity, and analgesic effects<sup>(151)</sup>. So; the present findings is due to the combined effects of boswellia and cardamom as well as *nigella sativa* seeds.

Furthermore, the current study also revealed that , there is a significant difference between study and control groups in relation to first , second and third assessments of the reproductive and psychological status. This result is congruent with Basil, (2007) who reported that, due to the analgesic effect and / or the pain reliving properties of ginger; it can reduce discomfort associated with breast cancer. Also added that, ginger also helps control inflammation, due to the presence of gingerols, which is the main constant of ginger, which work like the older anti-inflammatory drugs, such as aspirin. Ginger unlike aspirin, has a calming effect on the intestinal tract<sup>(152)</sup>. Gingerols prevent the aggregation of platelets, as well as reducing inflammation; they can help to minimizing platelets aggregation.<sup>(152)</sup>.

This was congruent with the present findings, especially related to a menorrhea and decreasing breast and vaginal discharge which may be due to inflammatory effects. Ahmed et al, (2003) added that, in addition to these benefits; Ginger can decrease the risk of heart disease by "platelet inhibition" and by lowering cholesterol. It is a strong antioxidant and can inhibit certain bowel infections (*Salmonella*) and it can be effective against vaginal Trichomonas infections, which is the commonest cause of vaginal discharge<sup>(153)</sup>.

Jane et al, (2004) mentioned that, ginger has a long history of use for treating anxiety and depression<sup>(154)</sup>. Heller et al, (2001) recommended the use of ginger as anti depressant and for managing or treating insomnia, especially before the bed time<sup>(155)</sup>. Emphasized that, ginger works in a similar way to some prescription antidepressants by increasing the brain chemical serotonin, involved in controlling mood.

Adesson, (2007) patients are more concerned about the occurrence and management of side effects than the actions of particular chemotherapeutic agents. Identifying the side effects or patient's problems, will assist in achieving the desired outcome. As well as the time sequence in which side effects generally occur may allay patient anxiety and will assist nurses in selecting the appropriate interventions<sup>(156)</sup>.

Related to the hematological studies, renal, and liver and endocrine studies, the study illustrated that, these systems are the latest affected systems with the side effects of chemotherapy. And they are the most affected systems by the combining herbal to conventional chemotherapy as well as there is a significant difference between the study and control groups in relation to first assessment except for renal functions. While in relation to second and third assessment there was a significant difference between the tow groups. This result was congruent with Elassafy, (2001) who mentioned that; cancer patient should continue the intake of *nigella sativa* during chemotherapy. This can be effective way of limiting the side effects of chemotherapy, because *nigella sativa* supports maintenance of trileanial erythropoiesis (red blood cells, white blood cells and platelets). The guiding principles is the adherence to 6 sessions of chemotherapy which usually are the hemoglobin level, the white cell count, the platelet count with administering of *nigella sativa* help in maintaining these normal levels during chemotherapy<sup>(157)</sup>.

Nagi et al, (2008) concluded that, *nigella sativa* seeds are effective in protecting against hypertension and renal damage especially serum creatinine level possibly via its antioxidant activity of thymoquinone (TQ), the main constituent of the volatile oil of *nigella sativa* seeds<sup>(158)</sup> . Also it is in line with Elkahtany et al, (2007) who added that, ginger has been used to reduce the toxic side effects of some chemotherapeutic drugs, as showed in protective effects against nephrotoxicity induced by chemotherapeutic agents<sup>(159)</sup>. Ahmed et al, (2006) reported that, there is a significantly reduction in the elevated levels of blood glucose, lipids, plasma insulin

and improved altered levels of lipid peroxidation products and antioxidant enzymes which minimizing the harmful effects of the liver and kidney<sup>(160)</sup>. These results confirm the antidiabetic activity of *nigella sativa* seeds extract and suggest that because of its antioxidant effects its administration may be useful in controlling the diabetic complications<sup>(160)</sup>.

Block & Mead, (2003) added that, curcumin and boswellia, combination have been used in cancer therapy, not only to reduce the associated side effects but also to enhance the effectiveness of chemotherapy<sup>(161)</sup>. On a systematic review of these herbals for chemotherapy induced side-effects in cancer patients, Taixiang et al, (2005), analyzed the results of four trials that used a formulation containing Curcumin can stimulate immuno-competent cells and decrease side effects in patients treated with chemotherapy.<sup>(162)</sup>

One of the more problematic side effects of chemotherapy is the incidental damage to normal tissues and all body systems. This damage to normal tissues of the body systems, in some patients, can be sufficiently severe to stop chemotherapy. Ginger and *nigella sativa* have a powerful anti inflammatory effects and immunomodulatory effects; so they can reduce these side effects<sup>(93, 95)</sup>.

It is imperative to assess accurately the patient's physical and emotional status before therapy is initiated. This information assists the health-care team to identify risk factors that could contribute to the occurrence or severity of side effects. Other factors that may affect the patient's response to therapy are age, general condition, coexisting illnesses, and nutritional status<sup>(163)</sup>.

Concerning to health and life style grades, it was found that there was a significant difference between study and control groups in relation to first, second and third assessments. This result is opposite to Ganz, (2004) who mentioned that, patients survivors older than the age of 65, less educated individuals and people living in urban areas were less likely to make or maintain healthy lifestyle changes after awarning they had cancer<sup>(164)</sup>. While it is in line with Petter, (2006) who concluded that, being diagnosed with cancer can be a "teachable moment," when people are very open to suggestions about eating better, exercising and other healthy habits. So, in the present study, when the patients had low chemotherapeutic side effects of all body systems, they became more healthy and their life style became better<sup>(165)</sup>.

In relation to body mass index (BMI), there was no statistical significant difference between study and control groups in relation to first assessment. While in the second and third assessment there was significant difference between both groups. This result is congruent with Massimo, (2005) who indicated that, when nausea and vomiting decreased; body weight and body mass index eventually can be also increased. He also added that, high BMI has been considered as a prognostic indicator for managing cancer patients<sup>(166)</sup>. This findings are not in agreement with Kifeli, (2005) who mentioned that, high BMI is known as an important risk factor for development of breast cancer this is at the pre diseased period<sup>(167)</sup>. But, in the present study, the patients are already cancer patients so; high BMI has considered as a prognostic indicator for managing cancer.

Concerning to the relation between age and all the side effects of chemotherapy, there is no significant difference among the three assessments of the study and also for the control group. It is observed that, breast cancer's women of the study group at the age of (49-65) experienced minimal side effects than other age groups. This result is congruent with Lancet, (2001) who reported that, the effects of chemotherapy are more pronounced in younger women than elders, emphasized this by younger women who are likely to need chemotherapy because their cancer often has a worse prognosis, and she experienced a severe degree of the chemotherapeutic side effects<sup>(168)</sup>.
