2.2 ***Gamma-ray Detection system***

The experimental set-up is a stand-alone high-resolution spectroscopic system used for the in-situ measurement of the energy spectrum of the emitted gamma rays in the energy range between 50 keV and 3000 keV. The system consist of a high-purity germanium (HPGe) detector EG & G ORTEC® coaxial cylinder of crystal length of 46.8 mm and diameter 55.0 mm, with an efficiency of 23.5% 27 relative to a 7.6 x 7.6 cm^2 NaI(Tl) crystal. In addition, energy resolution (FWHM) of 2.0 keV was achieved, all for a ^{60}Co emission point source at 25 cm for 1.33 MeV. This type of detector can sustain warm up when not in use, which is a convenient feature during extended field trips. The detector was mounted on a portable (hand-held) 10 litres liquid nitrogen Dewar that features an all attitude capability. Liquid nitrogen was used for cooling the detector during operation. After filling the portable Dewar with liquid nitrogen, it requires a 6 hour cool-down time before becoming operational with 24 hours nominal holding time. The detector assembly was mounted on a 1 m tripod with the crystal end cap facing down towards the ground and the Dewar above. This orientation maximizes the flux that will be intercepted and registered by the detector (Kelvin, 1997). The detector unit was connected to a battery powered EG & G ORTEC® "Normad Plus" portable computer based spectroscopy system. High voltage and preamplifier power were supplied to the detector by the system. An advanced multi-channel analyzer (MCA) emulsion software (MAEASTRO-32) was used for data acquisition, storage display and analysis, of the acquired gamma-spectra.

Figure 1: Typical *in situ* g-ray detection system at one of the monitoring points (MP)

2.3 In-situ measurement and analysis

The current study was conducted in the months of May and June 2005. The field measurement of terrestrial gamma radiation was based on the assumption that there exist laterally uniform distribution of natural Radionuclides in the environment and that the vertical contribution from the soil is limited to the first horizon (≈ 10cm to 30cm). Measurements were performed over flat terrain; that allow source geometry to be represented as an infinite half-space; that is 2π geometry in terms of solid angle subtended by the source.

The source measured was soil sample and counting statistics for a given spectral absorption peak were obtained in a fraction of the time required for counting a small collected sample. Measurements of spectra in the field were made for a period of 5000 s. However, series of random short readings of about 600 sec were first taken, to ensure that, there is approximate uniformity, consequently, the desired counting statistics. The measuring system was routinely checked with ^{137}Cs and ^{60}Co standard sources.

A computer based multi-channel analyzer system with emulsion software (MAESTRO–32) was used for spectra acquisition. Based on two-point energy calibration as set for the operation, prominent peaks were identified in a benchmark spectrum (fig.1d) and the appropriate regions of interest were set up. These peaks, which are characteristics of typical environmental spectra, are:

- the 295, 352, 609, 1120 and 1765 keV peaks in the ^{238}U series,
- the 238, 510, 583, 911, 965 and 2615 keV peaks in the ^{232}Th series,
- the 1460 keV peak of ^{40}K.

The set energy bands define the peaks where the left and right channel markers are representative of the Compton continuum. Detector's specific calibration factors (measured efficiency) determined in an earlier experiment (Auwal, 2005), were applied to convert from net peak count rate to activity concentration. Only peaks with reasonable gamma-ray emission probabilities were considered.

3. Results and discussion

The activity concentrations for ^{232}Th, ^{238}U and ^{40}K with standard error of the measured locations are presented in table 2, while table 3, show the statistical analysis of the results and percentage contribution is shown in figure 3. The activity concentrations were calculated by the net peak areas of 511 keV (^{208}Tl) and 911 keV (^{208}Ac) for ^{232}Th, 609 keV (^{214}Bi) and 352 keV (^{214}Pb) for ^{238}U, and 1460 keV for^{40}K. The concentrations range from 15.5 ± 4.3 to 46.4 ± 3.5 Bq kg^{-1}(34.3 ± 3.4) for ^{232}Th, 4.8 ± 3 to 11.9± 2 Bq kg^{-1} (8.3 ± 2.6) for ^{238}U and 317.2 ± 8.4 to 985.3 ± 7 Bq kg^{-1} (684 ± 7.3) for ^{40}K with mean values enclosed in the brackets. The relative contribution of the different natural gamma emitters (Thorium series, Uranium series, and ^{40}K) to the total activity concentration vary among the monitoring point. This range from

3.3% to 8.3% for ^{232}Th, 0.7% to 1.7% for ^{238}U and 90.2% to 95.5% for ^{40}K .Of all the locations MP004 and MP011 appear to have the highest concentration of ^{232}Th, also MP004 exhibits the highest concentration of ^{238}U. MP012 appear to have much higher concentration of ^{40}K when compared with the concentrations at other locations, with value of 985.3 ± 7 Bq kg^{-1}. In addition, the ^{232}Th/^{238}U ratios for the locations range from 2.8 to 6.4. This shows uranium is less than thorium by a factor of three.

Comparing the activity concentrations of the present work with the Ibeanu *et al*., (2002), in which a laboratory based NaI(Tl) detector was employed to measure the radionuclide concentrations in dry soil samples from the same measurement points, the *in situ* measurement results for ^{232}Th and ^{238}U were generally significantly lower than the laboratory data, except for some of the ^{238}U that were reported as below detection limit. On the other hand, ^{40}K has exhibited certain degree agreement between the two results, with a variation of approximately ±5% at some points.

Table 2Activity concentration of ^{232}Th, ^{238}U and ^{40}K

Concentration ±Stat. Error (Bq kg^{-1})								
Site ID	**^{232}Th**	**Contr. (%)**	**^{238}U**	**Contr. (%)**	**^{40}K**	**Contr. (%)**	**^{232}Th/^{238}U**	**Total**
MP001	21.1±2.5	3.3	7.5±2.8	1.2	609.6±5.7	95.5	2.8	638.2±9.6
MP002	45±3.5	5.5	11.9±2.0	1.5	759.9±10	93.0	3.8	816.8±15.5
MP003	37.5±2.4	4.1	10±1.8	1.1	868.4±6	94.8	3.8	915.8±10.2
MP004	46.4±3.5	5.3	11.9±2.0	1.4	809.9±10	93.2	3.9	868.1±15.5

MP011	46.2±2.9	6.8	10.5±2.5	1.5	626.2±9.1	91.7	4.4	682.9±14.5
MP012	45.9±3.6	4.4	7.2±1.8	0.7	985.3±7	94.9	6.4	1038.5±12.4
MP013	32.1±5.3	6.1	7.2±3.8	1.4	487.9±5.5	92.6	4.5	527.1±14.6
MP014	30.9±3.3	5.9	6.4±2.5	1.2	487.9±4.1	92.9	4.8	525.2±9.9
MP111	31.1±3.1	6.5	8.34±2.9	1.7	442±7.1	91.8	3.7	481.5±13.1
MP112	36.8±2.9	4.4	9.6±2.4	1.2	783.5±9.9	94.4	3.8	829.9±16.2
MP113	15.5±4.3	4.6	4.8±3.0	1.4	317±8.4	94.0	3.2	337.2±15.7
MP114	41±3.5	8.3	7.5±2.9	1.5	444±9.1	90.2	5.5	492±14.5

The reason for the difference may be mostly coming from the type of detector used in each case, the accuracy of the response at the energies used in the analyses, and the method of calibration. Moreover, soil moisture variation or actual variation in the dry concentration of radionuclides with depth is among the limiting factors for establishing comparability between in-*situ* and soil sample measurement.

Table 3Statistical data for activity concentration (Bq kg^{-1})

Nuclide	**Mean**	**Confid. ±95.000%**		**Median**	**Range**		**Std.Dev.**	**Standard error**
^{232}Th	34.3	26.8	41.9	34.5	15.5	46.4	10.5	3.3
^{238}U	8.3	6.8	9.9	7.9	4.8	11.9	2.1	0.7
^{40}K	641.8	488.8	794.8	617.9	317.0	985.3	213.9	67.6
^{232}Th/^{238}U	4.1	3.4	4.8	3.9	2.8	6.4	1.0	0.3
Total	684.4	524.9	844.0	660.6	337.2	1038.5	223.1	70.5

It may be noted that in the *in-situ* measurement, the detector samples the photon flux from a volume of soil out to a radius of approximately 10 m and down to a depth of about 30 cm, depending upon the photon energy (Kelvin, 1997). Fig. 1.c shows a pictorial representation of the relative ground area contributions to the primary (uncollided) flux at a height of 1m for a medium energy (662keV) source with typical exponential depth profile in the soil. Thus, the activity that was closer to the soil surface tends to produce a wider field of view. In effect, a field spectrum samples an area of several hundred square metres: averaging out the local inhomogenities in the distribution of the Radionuclides.

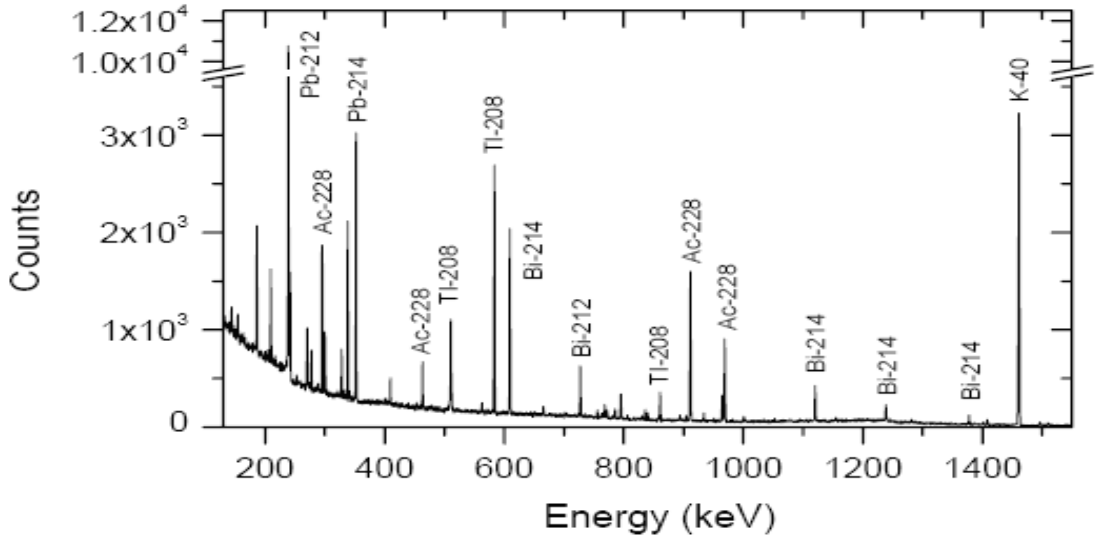

Figure 2: A typical gamma-ray spectrum showing important identified photo-peaks and their associated Radionuclides

The calculated activity mean values from the locations were 34.3, 8.3 and 641.8 Bq kg^{-1} for ^{232}Th, ^{238}U and ^{40}K respectively. Correspondingly the revised median values worldwide (UNSCEAR, 2000) are 30, 35, and 400 Bq kq^{-1} respectively. This reveals that the mean concentration level measured in the selected areas of Zaria for ^{232}Th is slightly higher than the world median value while that of ^{238}U is lower than the corresponding world value; thus ^{238}U is less than the world value by a factor of three. However, ^{40}K concentration appeared to be higher than the world median value at all the points, except MP113 with value of 317 ± 8.4 Bq kg^{-1}.

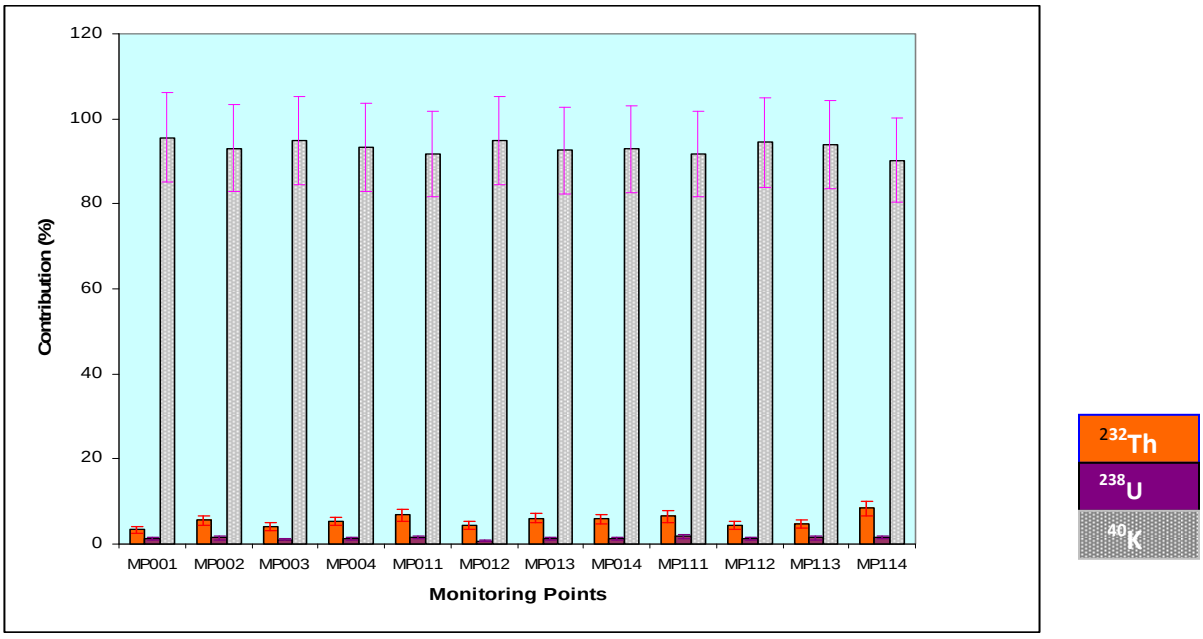

Figure 3: Percentage contribution of activity concentration

4 Conclusion

High-resolution gamma ray spectrometry was exploited to determine distribution of gamma emitting Radionuclides in soils around the Centre for Energy Research and Training, Ahmadu Bello University, Zaria. Natural radionuclide concentrations determined for ^{232}Th, and ^{238}U were significantly lower when compared with those determined by laboratory based NaI(Tl) detector system but in general agreement for ^{40}K by both techniques. The mean activity concentrations were higher than the revised world median values for ^{232}Th, and ^{40}K and lower for ^{238}U. This technique is useful for operational and post operational monitoring for the Centre, which will serve as reference for present and future assessment. The assessment of the radionuclide level of the area did not detect the presence of any artificial radionuclide and thus no significant impact of the extensive usage of radioactive materials within and around the Centre the on the radiation burden of the environment.

Acknowledgement

The authors wish to express their gratitude to the Centre for Energy Research and Training, Ahmadu Bello University, Zaria for the support given to the entire project.

Abstract: Background Assessment of clinical competence is of great importance when evaluating the expected learning outcomes of nursing education. Increasing number of students enrolled at Egyptian nursing faculties might increase the chances of malpractice that compromise patients' conditions. Therefore it is challenging to have such an objective assessment tool to comprehensively assess students' clinical competencies especially with increased students' number. Aims of the current project are building capacity of nursing faculties and staff members for OSCE; establishing simulated learning experiences (OSCE) in nursing practice; comparing the feasibility, utility, and effectiveness of using OSCE versus traditional clinical assessment; examining faculty and students perspectives for OSCE; and evaluating the effectiveness of OSCE versus traditional clinical assessment. Method: To achieve aims of this study needs' assessment of faculty members were carried out during conduction of raising awareness seminar about OSCE which attended by 72 faculty and staff members from both Cairo and Ain Shams Universities. A total of 7 workshops were held to build up their capacities on the scheme of OSCE and clinical scenario writings .One-hundred and forty faculty and staff members were attended and pre-post tests a were administered. Out of the 140, 31 were trained as data collectors. . Implementation of the OSCE was carried out on 400 second and third year students at the areas of critical care units. Comparison of students' achievements at traditional and OSCE methods were carried out. Faculty's and students' perspectives were investigated. Results: Needs' assessment revealed that 57% of faculty members knew nothing about OSCE and 98.6% of them had no experience in using OSCE; also a high statistical significant differences between OSCE and traditional assessment groups in the first and second trial ($t = 2.423$, $p= 0.016$), and ($t= 6.23$, $p= 0.000$) respectively. The students' achievements were better with OSCE. Faculty staff members indicated that, OSCE saves time (76.3%), prepares highly qualified competent students (62.5%) and improve students' performance (62.5%). Conclusion OSCE examination offers an attractive option for assessment of students' competency. It provided particular strengths in terms of faculty staff objectivity and reliability of the assessment process for all students, especially when compared with other methods of assessing practice.

Key Words: Assessment, OSCE, traditional method, Faculty capacity building, students' perspectives.

1. Introduction:

Assessment plays a major role in the process of nursing education, in the lives of nursing students and in society by certifying competent practitioner who can take care of the people. The objective Structured Clinical Examination (OSCE) is an approach to students' assessment in which aspects of clinical competence are evaluated in a comprehensive, consistent and structured manner, with close attention to the objectivity of the process (Byrne & Smyth, 2007). Objective Structured Clinical Examination" (OSCE) evolved from medical education in Scotland, and has been used extensively in nursing worldwide. It is now widely accepted as a fit-for-purpose instrument for measuring clinical reasoning skills with a high degree of technical fidelity (Ahmad, Ahmad & Abu Bakar, 2009).

Steady increase in number of students enrolled at Egyptian nursing faculties might increase the chances of malpractice that compromise patient's conditions, in addition to limited resources from clinical sites that might hinder the opportunity of student to practice on patient. Traditional clinical nursing examinations are not standardized to assess clinical competency, and clinical reasoning skills. Acquisition of critical thinking and problem solving skills among nursing students are difficult to manage with large groups of students. Furthermore, in traditional assessment method, teachers carrying out the assessment of student performance tend to give summative scores. Therefore it is challenging to have

such an objective assessment tool to comprehensively assess students' clinical competencies especially with increased students' number.

OSCE is now an established part of the repertoire of clinical assessment skills in many nursing schools around the world. Nursing faculties in Egypt use a range of assessment techniques that are appropriate for testing students' outcome. However, in Egypt, there is no available evidence for using OSCE in nursing education. OSCE is a new issue that needs capacity building for Egyptian nursing faculties. A baseline survey in the assessment of competency resulting from medical and nursing education in Egypt (2006) reported that skills assessed are poorly performed by four learner groups (medical & nursing undergraduates, nurse intern and house officers) in both medical and nursing faculties Furthermore, clinical training as it is currently organized and implemented for the competencies assessed is inadequate for all learner groups of all regions in Egypt (Health Workforce Development, 2006).

Assessment should measure cognitive learning, mastery of essential practice skills, and the ability to communicate effectively while using data in both critical thinking and problem solving processes (Elzubeir, & Rizk, 2003). Moreover, assessment of student's clinical competence is of paramount importance (Byrne & Smyth, 2007).

Effective and accurate clinical evaluation should be of concern to all nursing faculties and clinical instructors. There is a reasonable expectation for evaluation to be objective, fair, specific, and documented. In addition, students need to know, very clearly delineated, the specific objectives by which they are being evaluated. One type of assessment which meets these criteria is a performance based assessment. An example of a performance-based assessment is the "OSCE" (Ahmad, Ahmad & Abu Bakar, 2009).

OSCE has been widely and increasingly used since it was developed. Researches have shown that it is an effective evaluation tool to assess practical skills. In many instances the OSCE process has been adapted to test trainees from different healthcare related disciplines. In nursing education principles of OSCE can also be used in a formative way to enhance skills acquisition through simulation (Alinier, 2009).

Schoening, Sittner & Todd (2006) indicated that acquisition of critical thinking and problem solving skills among nursing students were unwieldy and difficult to manage with large groups of students; also, the nurse teachers carried out the assessment of student performance giving summative scores in traditional assessment method. While in OSCE simulation, the students find learning such skills are more beneficial because there is an immediate formative feedback following an event. Simulation-based training is superior to problem based learning for the acquisition of critical assessment and management skills. A framework for the development of clinical competence has been described by Miller (1990) who outlines four levels at which a learner can be assessed: *knows, knows how, shows how* and *does*. The OSCE conforms to the third *shows how* level of Miller's pyramid which focuses on assessment of performance of specific skills in a controlled setting (Ahmad, Ahmad & Abu Bakar, 2009). This makes it particularly relevant for the early stages of undergraduate curricula, where assessment comprises compartmentalized exercises (Miller, 2009).

Furthermore, simulated clinical learning offers significant advantages over traditional educational methods. Benefits include the provision of a safe environment for both patient and student during training in high risk procedures, unlimited exposure to rare but complicated clinical events, the ability to manipulate training opportunities rather than wait for a suitable situation to arise, the ability to provide immediate feedback, the opportunity to standardize and evaluate performance and the opportunity to repeat performance. Currently, the ability of simulation to meet the needs of practice education remains limited (Pierre, Wierenga, Barton, Branday & Christie, 2004). In addition, (Ahmad, Ahmad & Abu Bakar, 2009) added that OSCE is developed to reduce bias in the assessment of clinical competence; it is not now without the pitfalls of other assessment methods. In particular, the need for more rigorous evaluation of OSCEs in nursing education programs has been highlighted (Brosnan, Evans, Brosnan, & Brown 2006); (Miller, 2009) as these assessments are directed towards assurances that passing students can practice safely in the clinical setting with patients.

Bartfay, Rombough, Howse, & LeBlance (2004) concluded that OSCEs can be used most effectively in nurse undergraduate curricula to assess safe practice in terms of performance of psychomotor skills, as well as the declarative and schematic knowledge associated with their application. OSCEs should be integrated within a curriculum in conjunction with other relevant student evaluation methods Furthermore, as a method of clinical skills assessment; the OSCE possesses a number of intrinsic advantages. Firstly, it can include both summative and formative components, in which a judgment or evaluation of an individual's performance is made (summative) followed by the provision of feedback, from which the student can

learn (formative). Secondly, because each student is required to demonstrate specific behaviors in a simulated work environment, strict control over the clinical context is possible, while at the same time, reflecting real-life professional tasks. This control eliminates the 'luck of the draw' problem that arises when students are assessed within the 'real-world' clinical environment with actual patients as well as the risk of harm occurring to a patient. The underlying premise is that such standardized procedures ensure objectivity and maximize reliability in assessment (Bartfay et al 2004; Major 2005).

OSCE also provides an innovative learning experience for students. It offers a valid means to evaluate students' clinical performance in a holistic manner (Ahmad et al., 2009). Harden (1988) emphasized that the real power of OSCE lies in its ability to evaluate a wide rang of knowledge and skills which improves the reliability of the examination. Within OSCE reliability is based upon the interaction among students, standardized patients and assessors (Ahmad, Ahmad & Abu Bakar, 2009). These advantages made OSCE to be extensively used in nursing (Alinier, 2003; Ahmad, Ahmad & Abu Bakar, 2009).

Feedback from nursing students suggests that OSCE is an objective tool for evaluating clinical skills. Students perceived OSCE scores as a true measure for essential clinical skills being evaluated, standardized, and not affected by student's personality or social relations. The objectivity of OSCE was highlighted in the literature by many authors (Ahuja, 2009; Harden, 1988). The evaluation of OSCE by nursing students highlighted some areas that need to be enhanced in future, such a s the inadequate time of some of the stations, and the limited period of orientation about OSCE. The insufficient time at OSCE stations was one of students' complaints in some of the studies which investigated students' perspective of OSCE (Pierre et al., 2004).

OSCE generated a considerable uncertainty among students regard in g aspects of OSCE attributes, performance, scoring and objectivity. Students' uncertainty about OSCE was also reported in other studies (Pierre et al., 2004). Such uncertainty may reflect inadequate knowledge about the nature of OSCE and insufficient training on OSCE procedure. It appeared that the train in g session that students received on OSCE before the final exam was not enough for providing them with a comprehensive view of the OSCE. Brewin & Cantwell (1997) suggested that students' uncertainty about OSCE may be due to the fact that the OSCE was a new experience for all of them. From our experience, the implementation of OSCE is time consuming, and requires huge effort and extensive resources. This was also reported in other studies which implemented OSCE (Munoz, Byrne, Pugsley, & Austin 2005). It also requires a large number of qualified personnel to observe and evaluate students during OSCE (Alinier, 2003).

The measurement of clinical skills performance continues to pose a challenge for nurse educators. Experience suggests that the OSCE may be a powerful tool in the evaluation of clinical competence in nursing and that it may also be an effective facilitator for learning to perform clinical skills in nursing. Although there are a few drawbacks in using OSCEs they should not be neglected. The running cost of the OSCE is outweighed by the educational benefits (Ahmad, Ahmad & Abu Bakar, 2009) as well as the students' satisfaction to have learned something useful. The potential of OSCE as a flexible teaching method has been recognized by many lecturers from the University of Hertfordshire and might be used more regularly in several nursing curricula. This provides opportunities for students to use a number of medical pieces of equipment in a safe environment and to become more familiar with them.

Using problem-based learning scenarios, students have to employ critical thinking skills related to both the practice and theory of the task they are expected to perform. OSCE can be set up to integrate IT, communication, and critical thinking using simulation. From this it can be suggested that OSCE provide an integrated way of measuring learning outcomes in skills based learning. This has implications for work-based learning. OSCEs encourage a deep approach to learning because higher cognitive functions are tested. The OSCE sessions not only help students determining their own weaknesses, but also enable examiners or lecturers to realize what the current students' are. If required additional teaching sessions can be organized to address skills that caused problems to the students during the OSCE. The use of such sessions may well be a key element to the training of better-prepared healthcare professionals. The widespread of hybrid OSCE to other disciplines to teach and assess students on basic skills specific to the different subject of study may well occur in the near future (Alinier, 2009).

Aims of the study:

a. Capacity Building of nursing faculties and staff members for using OSCE.
b. Establish simulated learning experiences (OSCE) in nursing practice.

c. Compare the feasibility, utility, and effectiveness of using simulated learning experiences (OSCE) versus traditional clinical assessment.
d. Examine Faculty and students perspectives for OSCE.
e. Evaluate the effectiveness of OSCE Versus traditional clinical assessment.

2. Subjects and Methods

Research Design:

A time serial research design was used to accomplish aims of this study.

Sample and Setting:

A total sample of 400 second and third year students were selected randomly from Faculty of Nursing - Cairo and Ain Shams Universities. Both faculties have integrated the same curriculum of second year (Medical Surgical Nursing) and third year of (Pediatric and Maternity & New Born Health Nursing). The nursing students of both faculties' universities attended the training program of high risk and critical care nursing units.

As well, 140 faculty staff members from Faculty of Nursing - Cairo and Ain Shams Universities were participated in the current study through attending preparatory workshops. Among this group 31 faculty staff members were selected randomly for implementation of the OSCE. The involved faculty staff members at both faculties were committed and dedicated for training of nursing students at skills laboratories. Selected students were assessed by both traditional and OSCE assessment methods. Data collection was done twice: firstly through assessment of 190 students in different nursing specialties, however, the second trial was done through assessment of 210 students.

Tools of Data collection:

These tools were developed by the investigators. They were Faculty member needs assessment sheet; students' assessment and evaluation (Achievements) sheets; and student and staff perspective sheets.

a. Faculty member needs assessment sheet it was developed, used and analyzed to plan accurately TOT program.
b. Students' assessment and evaluation (Achievements) sheet covered the three domains to give an accurate judgment on student adequacy regarding the specified course knowledge, skills and attitudes.
c. Students' and staff perspective sheets that was used to assess and analyze the information about student and staff feedback, opinion as regard OSCE used as well as their recommendation to improve the newly introduced system.

Procedure:

To accomplish the aims of the study two approaches were utilized. The first approach was training of trainers for OSCE and implementing OSCE scheme on students and examined its impact on students' achievements. The second approach was assessing and analyzing the students' and faculty staff members' feedback and perspectives in regard to the newly introduced system (OSCE) as well as their recommendation to improve it. Ethical review of the study project was obtained, developing data collection tools, holding seminar for faculty staff members at both faculties to raise the awareness of OSCE. A total 72 of faculty staff members attended the seminar where needs assessments were carried out.

After reviewing related literature to fulfill the aims of the study, three different tools were designed by the research team and revised by the consultants, also content validity and expert's opinion were taken into consideration and the needed modifications were carried out., and

Face Validity of the tools was examined through a jury of three experts.

Regarding the planning phase it lasted for one month where 7 TOT - OSCE training workshops were conducted for faculty staff at Cairo and Ain Shams Nursing faculties, each for 3 days/week (approximately 20-30 trainers) at Cairo and Ain Shams Universities. Four workshops were held at faculty of nursing Cairo University and 3 workshops at Ain -Shams University. A pre-post test was administered to examine the impact of workshops in gaining knowledge about OSCE. In addition, training for putting the scheme as well as clinical scenarios was carried out; an expert for each nursing specialties attended the training workshop and was assigned to review the scenarios related to the specialties.

The implementation and data collection phase (lasted six months) where data collection was carried out using the designed tools. Training of data collectors was done where a total of 31 clinical instructors and faculty members were trained for implementing the OSCE and collecting data. through 3 workshops were carried out. OSCE were carried out at critical care units at medical-surgical, maternal-newborn health nursing and pediatric health nursing on total of 400 students at second and third year at both faculties during academic year 2008-2009 second semester as a first trial. Students were evaluated at their clinical training areas using the OSCE method Students and faculty perspectives sheets were distributed to be fulfilled at their own

pace. An oral feed back was obtained through interviewing of a focal group of students.

The second trial was conducted at the academic year 2009-2010 first semester at critical care units at maternal-newborn health nursing and pediatric health nursing at both faculties; the students were evaluated in their clinical training areas using the traditional method of evaluation in one area and the other one is evaluated using the OSCE method.

3. Results

Findings of the current study are presented in two main sections: The first one represents faculty staff members' capacity building, and the second one is concerned with students' academic achievements.

Section I: Faculty staff members' Capacity Building and Perspectives

A- Needs Assessment

This section represents findings related to description of faculty staff members according to their academic rank, computer skills, needs' assessment, pre-post test findings and their faculty perspectives about application of OSCE. Table (1) shows that more than two thirds of the study group (70.8%) was clinical instructors and assistant lecturers, while the other one third (29.5%) was faculty staff members. Their mean age was 32.31 ± SD = 8.391 years old.

Table (1): Distribution of Academic Rank and Age among Staff Members who Attended the Raising Awareness Seminar (n=72).

Academic rank	No.	%
1- Clinical instructor	33	45.8
2- Assistant lecture	18	25
3- Lectures	14	19.4
4- Assistant professor	4	5.5
5- Professor	3	4.2
Total	72	100
Mean age = 32.31±8.3 Age range: 23 : 62		

As shown in table (2) more than half (55.6%) of staff members (Cairo & Ain Shams Universities) indicated that the disadvantages of traditional clinical evaluation were being time and effort consuming, in addition to subjectivity, and shortage of resources in clinical areas AS indicated by 26.38%, and 20.83% respectively.

In relation to knowledge about OSCE; table (3), and table (4), show that 43.1% of the staff members had knowledge, most of them (73.3%) obtained their knowledge from workshops, and (n = 24 = 77.4%), and indicated that OSCE is used to evaluate knowledge, intellectual and practical objectives. The entire study group (100%) who had knowledge about OSCE reported that OSCE saves time and efforts. However, inspite of having knowledge about OSCE 98.6% of the faculty staff members who attended the raising awareness seminar did not have previous experience in utilizing OSCE. In addition, 77.45% indicated that it is a valid and reliable method of evaluation. As regard steps of developing OSCE; the great majority of those who knew OSCE (96.7%) indicated that it should start with training of the staff members, (64.5 %) indicated that it requires establishing OSCE laboratories with simulators at first, while more than half (51.6%) revealed that it should start with setting the objectives and competencies.

Table (2): Disadvantages of Traditional Clinical Evaluation as Mentioned by the Staff members who attended the raising awareness seminar (n=72).

Item	N	%
Disadvantages of traditional clinical evaluation*		
1- Time and effort consuming	40	55.6
2- Ineffective with large numbers	12	16.6
3- Subjectivity and low reliability	19	26.38
4- Shortage of resources in clinical areas	15	20.83
5- Lack of standardized cases	3	4.16

***** Responses are not mutually exclusive

Table (5) shows the distribution of the Staff Members as Regards their Knowledge about the Requirements to Establish OSCE training 58.33%,%, and skills in using OSCE as a method of evaluation in different specialties indicated by 36.15% of them.

Regarding the benefits of using OSCE as indicated by the staff members; table (6) shows that using OSCE, saves time for performing another activity in the institution (76.3%), and prepares highly qualified, competent graduates, and improves students' performance (62.5%). However, the obstacles of using OSCE were concerned with lack of maintenance, high costs, and shortage of staff (69.4%, 69.4%, and 65.2%) respectively.

B- Faculty Pre/Post test scores

Regarding to the findings of the pre/ post test about OSCE among the staff members who

attended the workshops, table (7) shows that the proportion of those who provided correct answers related to OSCE system increased significantly in the post test as compared to pretest. In addition, there was a significant improvement in the post test responses / answers regarding characteristics of OSCE, with higher mean post test scores as compared to the pre test scores, indicating high significant statistical differences.

Table (3): Frequency Distribution of the Faculty Staff Members who Attended the Raising Awareness Seminar as regards Their Knowledge about OSCE (N=72).

Items	No.	%
a-What is OSCE?

Mean + SD	28.6± 10.9					

Staff members' opinion total mean scores = 43.06 ± SD =16.08

The advantages of using OSCE at the academic institution as indicated by faculty staff members, figure (1) revealed that, OSCE saves time (76.3%) prepare highly qualified competent students (62.5%) and improve students' performance (62.5%).

Figure (1): Advantages of Using OSCE at the Academic Institution as Indicated by Faculty Staff Members Who Attended the Preparatory Workshops (n=140).

Section II: Students' Achievements and Perspectives.

A- Students' Achievements

Regarding the effectiveness of OSCE, the current study indicated that, the third year students obtained higher mean scores in OSCE pediatrics exams (22.03+SD=2.56) as compared to their mean scores of the traditional method of evaluation (24.68+ SD=2.96) with a highly statistically significant differences (t= 2.015, at p≤0.046). However, the opposite picture was observed in the other two specialties (Medical-Surgical Nursing & Obstetrics) where the mean scores of the traditional method of evaluation were higher than those of OSCE. However, global comparison between the two groups of OSCE versus traditional method of evaluation revealed higher mean OSCE scores with a high significant statistical difference between the two groups in first trial (table 9).

Table (10) shows comparison of means among the students who underwent OSCE in the second trial. It is clear from the table that high statistical significance differences was found between the two groups who undergone OSCE as compared to the non OSCE groups. The same

picture was noticed regarding the total mean scores of the groups who undergone OSCE as compared to non OSCE group, indicating a high statistical significant difference in second trial (t= 6.23, at p≤ 0.000).

Table (9): Comparison of Students' OSCE versus Traditional Evaluation System Mean Scores: First Trial (N=190).

Specialties	OSCE	Traditional Evaluation	t	P-value
	Mean ± SD			
Medical-Surgical Nursing	22.03+ 2.56	24.68+ 2.96	-5.071	0.00**

* Significance at p≤0.05 ** Significance at p≤0.001

B-Students' Perspectives

The following tables (11 and 12) show students' perspectives regarding the OSCE system. It was ranked as very satisfactory to satisfactory by more than two thirds of the students; the mean score of students' opinion was 43.22 ± SD=13.59. In relation to student's perspectives regarding OSCE preparation, table (12) reveals that preparation to OSCE was ranked as very satisfactory to satisfactory by more than one third of the students regarding availability of time table, and conducting training sessions. The same rank was given to obvious preparation to OSCE by approximately half of the student's. As regards OSCE's laboratories, more than half of the students indicated that they were suitable, lighted and ventilated, clean, calm, with availability of the needed equipments and simulators. Comparison of means indicated highly statistical significant difference between preparation to OSCE mean scores and those of OSCE laboratory (t = - 16.14, p ≤ 0.000).

Table (11): Frequency Distribution of Students' Perspectives Regarding the OSCE System (N=190).

4. Discussion:

The acquisition of clinical skills is paramount to the development of a safe and competent practitioner (Brookes, 2007). OSCE as a performance-based assessment is a well established student's assessment tool for many reasons: competency- based, valid, practical and wise effective mean of assessing clinical skills that are fundamental to the practice of nursing and other health care related professions (Ainier, 2003).

The aims of the present study were to: Build capacity of nursing faculties and staff members for using OSCE; establish simulated learning experiences (OSCE) in nursing practice; compare the feasibility, utility, and effectiveness of using simulated learning experiences (OSCE) versus traditional clinical assessment; examine faculty and students perspectives for OSCE; and evaluate the effectiveness of OSCE versus traditional clinical assessment.

A quasi-experimental research design was used to accomplish aims of this study, and a total sample of 257 students as well as 31 faculty staff members, from Cairo and Ain Shams universities were recruited for the study. The included faculty staff members represented different categories of the academic rank of them more than two thirds were instructors and assistant lecturers, and the other one third was lecturers and professors.

The faculty staff members' knowledge about evaluation was assessed and more than two thirds of them provided complete definition about evaluation and identified different methods of traditional evaluation. However they commented on the traditional clinical evaluation to have certain disadvantages such as being time and effort consuming, in addition to subjectivity, and shortage of resources in clinical practice setting. As regards staff members who attended the preparatory workshops their knowledge about OSCE was assessed using pre/ post test which indicated that the proportion of those who provided correct answers related to OSCE system increased significantly in the post test as compared to pretest. In addition, there was a significant improvement in the post test responses / answers regarding characteristics of OSCE. High significant statistical difference was found in post test mean scores as compared to pretest scores. Regarding sources of knowledge about OSCE, approximately one half of the staff members had knowledge about OSCE, three fourth of them obtained their knowledge from workshops. This could indicate that preparatory workshops had positive impact on the faculty staff members' knowledge.

The great majority of those who knew OSCE recommended that it should start with establishing OSCE laboratories with simulators at first, staff members training, in addition to setting objectives and competencies required for practical training. Moreover, faculty staff members indicated that OSCE should involve teaching certain topics in the OSCE training sessions such as how to

use OSCE effectively as a method of evaluation in different specialties.

As well, more than three fourth of the faculty staff members indicated that using OSCE has certain benefits such as saving time for performing another activity in the institution, preparing highly qualified and competent graduates, and improving students' performance. In addition, the OSCE system was ranked as very satisfactory to satisfactory by more than two thirds of the faculty staff members. However, using OSCE was described to have certain obstacles such as the need for continuous maintenance, its high costs, and shortage of staff members who can implement OSCE. These findings are in agreement with study done by Pharm and Sturpe, (2010), Turner and Dankoski, (2008) who revealed that a major obstacle in the wide implementation of OSCEs is their high cost. However, it can be set up with reasonable cost and limited resources even in smaller institutions

In relation to student's perspectives regarding OSCE preparation, it was ranked as very satisfactory to satisfactory by more than one third of the students regarding availability of time table, and conducting training sessions. The same rank was given to obvious preparation to OSCE by approximately half of the student's. Regarding OSCE's laboratories, more than half of the students indicated that they were suitable, lighted and ventilated, clean, calm, with availability of the needed equipments and simulators (Alinier, 2003).

Regarding students' perspectives toward preparation to OSCE, comparison of mean knowledge scores indicated high statistical significant difference between knowledge about preparation to OSCE mean scores and those about OSCE laboratory ($t = - 16.14$, $p \leq 0.000$) . As regards students' opinion about the OSCE system, it was ranked as very satisfactory to satisfactory by more than two thirds of the students. This feedback can suggest that OSCE is an objective tool for evaluating clinical skills. The objectivity of OSCE was highlighted in different literature such as those done by Ahuja, (2009) and AL-Omari & Shawagfa, 2010) and (Miller, 2009).

These findings are in agreement with a study conducted by El Nemer & Kandeel, (2009) who reported that most students viewed OSCE as a fair assessment tool which covered a broad area of knowledge, allowed them to compensate in some areas and minimized their chances of failing. In addition, as indicated by Pierre et al., (2004) reported favorable student's responses concerning transparency and fairness of the examination process, and the authenticity of the required tasks per station.

Moreover, as found by Pierre et al., 2004; Duffield & Spencer, (2002), most students viewed OSCE as a fair assessment tool which covered a broad area of knowledge, allowed them to compensate in some areas and minimized their chances of failing. The fairness of OSCE was also reported by other studies. As well, in a study conducted by Turner & Dankoski, (2008) to assess the validity, reliability and feasibility of OSCE team, the majority of students felt that they had been marked fairly. Most students provided positive feedback about the quality of OSCE performance in terms of the clarity of the instructions of the exam, the sequence of OSCE stations, the reflection of the tasks taught and the time at each station. These findings are consistent with Pierre et al. (2004) study results where most students viewed OSCE as comprehensive, covered a wide range of knowledge and clinical competencies and a useful practical experience. As well more than two thirds of students believed that the assessment was fair and they reported their need for more time to complete the stations. In another study done by Alinier (2003) nursing students perceived OSCE as a favorable experience that should be repeated regularly.

However, the current study findings are in agreement with a study done by Nemer, and Kandeel, (2009) where OSCE was perceived as a stressful experience and intimidating by a considerable percentage of students, particularly first year nursing students. This perception could be due to the fact that it was a new experience for nursing students which increased their anxiety. As well nursing students' stressful experience with OSCE was also reported in another studies done by Pierre et al., (2004), Byrne and Smyth (2008) who related students' stress and anxiety to the new experience with OSCE. On the same line Allen, Byrne and Smyth (2008) indicated that studies surveying student attitudes during the OSCE have documented that it can be a strong anxiety-producing experience, and that the level of anxiety changes little as student's progress through the examination. This can direct the attention toward the importance of preparing students to OSCE.

Regarding the effectiveness of OSCE, the current study pointed out that, the third year students obtained higher mean scores in OSCE pediatrics exams (22.03+SD=2.56) as compared to their mean scores of the traditional method of evaluation (24.68+ SD=2.96) with a highly statistically significant differences ($t= 2.015$, at $p\leq0.046$). However, the opposite picture was observed in the other two specialties (Medical-Surgical Nursing & Obstetrics) where the mean scores of the traditional method of evaluation were higher than those of OSCE. However, global comparison between the two groups

of OSCE versus traditional method of evaluation revealed higher mean OSCE scores with a high significant statistical difference between the two groups in first trial. These findings support the idea that OSCE is not designed to replace the traditional clinical practice assessment method, but rather it is to complement students' assessment in the clinical setting. Therefore, assessing nursing students' OSCE competency level is carried out in combination with traditional method of assessment usually done for students undergoing traditional learning mode.

As well, comparing mean scores of students who undergone OSCE in the second trial revealed high statistical significance difference between the two groups who undergone OSCE as compared to the group who undergone traditional method of evaluation. The same picture was noticed regarding the total mean scores of the groups who undergone OSCE as compared to the group who undergone traditional method of evaluation, indicating a high statistical significant difference in second trial ($t= 6.23$, at $p\leq 0.000$).

On the same line with findings of the current study, the evaluation of OSCE by nursing students highlighted some areas that need to be enhanced in future, such as the inadequate time of some of the stations, and the limited period of orientation about OSCE. The insufficient time at OSCE stations was one of students' complaints in some of the studies which investigated students' perspective of OSCE (Pharm & Sturpe, 2010).

This could be the rational of why several authors suggest that no health professional educational program should be assessed by the OSCE alone, or indeed any other single method. Rather, in the absence of a 'gold standard', successful outcome in assessments using a range of methods is repeatedly advocated as producing the most inclusive evidence of practitioner competence (Ahmad, Ahmad & Abu Bakar, 2009 and McKinley & Boulet, 2004).

5. Conclusion:

Based on the findings of the study it is concluded that:

- OSCE is a valid and reliable technique uniquely capable of assessing many fundamental clinical skills that are not being assessed in a rigorous way in most undergraduate and postgraduate programs.
- OSCE seems to offer particular strengths in terms of assessor objectivity and parity of the assessment process for all students, especially when compared with other assessment of practice processes. However, it is not without limitations, not only in terms of student stress and its considerable demands on the academic study, but also in terms of the considerable challenges of ensuring the validity and reliability of the process.
- OSCE examination offers an attractive option for assessment of practitioner competency.
- Each new OSCE should be a subject to rigorous scrutiny and piloting to ensure that the reliability and validity of that particular assessment is maximized.
- Findings of the current study highlight the need for student participation in the development of new assessment tools in nursing curricula.

Recommendations:

- Based on findings of the current study, it is recommended that OSCE must be used as an integral part of the clinical evaluation system / students' assessment at the under graduate and post graduate educational programs.
- OSCE should be used as a method of evaluating clinical practice in a combination with traditional method.
- It can be suggested that OSCE has the potential to make a very effective and meaningful contribution to 'fitness for practice' assessment.
- The level of competency in OSCE should be tested not only for nurses using the traditional methods of learning, but also for distance learning students.

Nursing implication:

OSCE as an effective and valid assessment method can be used to assess students' clinical competencies in different nursing specialties. As well, OSCE can be used in other international countries in the same situation as Egypt i.e has a large number of students and it is difficult to evaluate their skills.

ABSTRACT: Low cement refractory concrete samples were prepared by mixing cement (containing 50% alumina) in percentages ranging from 10 to 20% with aggregate and the necessary amount of water. Two types of refractory aggregate were used: Bauxite containing 81% alumina and grog containing 52% alumina. Four particle sizes of each aggregate were used each time. The cast samples were left in their moulds for 24 hours in a 100% relative humidity cabin. The de–molded specimens were left in open air until their moisture content reaches 3–6%, then put in a drying oven at (110 ± 5) ºC until reaching constant weight. They were then tested for phase constitution, water absorption, bulk density, apparent porosity and cold crushing strength (after 28 days curing). It was found that bauxite based samples gave better results than those prepared with grog. It was also found using statistical analysis that the percent cement used affects all properties much more than does the particle size of aggregate.

Key Words: Refractory concrete – Alumina – Grog – Sodium citrate

1. INTRODUCTION

An analysis of the composition, the structure, and the properties of the conventional refractory concretes shows that their refractory properties are governed by the filler contained in them. The binder component (bonding agent) of the concretes imparts the strength required during transportation and erection; this strength is attained after setting and drying. During subsequent heating up to the temperatures preceding sintering, irreversible destructive processes occur, as a rule, in the binder. In view of the fact that the binder (along with the finely milled additives) forms a continuous matrix phase in the structure of the concrete, the thermo–mechanical characteristics of the material are adversely affected. Therefore, in order to improve the existing refractory concretes and to create new concretes, it is necessary to decrease the content of the conventional binders (e.g., high–alumina cements) in them to the maximum possible extent or to produce them without introducing the conventional (common) binders [1, 2, 3, 4].

Thermally stable aggregates combined with a bonding agent are the principal ingredients of a monolithic refractory. These raw materials are available both naturally and artificially. Raw materials available in nature unavoidably vary slightly in their compositions. But it is important to take advantage of the characteristics of these natural minerals that cannot be developed artificially rather than to avoid their use due to variations of chemical composition.

Unlike natural raw materials, artificial raw materials allow adjustment of chemical composition as well as their mineral constituents, and it is possible to get a uniform quality.

One common type of aggregate is bauxite, a raw material for alumina containing about 60% alumina. When calcined, the alumina level is usually raised above 85%. Bauxite for refractories is calcined in a rotary kiln to make a stable product. Calcined bauxite contains corundum as its principal component, mullite and a small glassy phase.

On the other hand, grog is an artificial aggregate usually obtained from crushed defective refractory bricks. Its alumina content depends on that of the original bricks. It usually ranges from 40 to 80%.

Other types of aggregate include diaspore ($Al_2O_3 . H_2O$), corundum (Al_2O_3), magnesia (MgO), zirconia (ZrO_2), etc.

In the present paper are studied the physico–mechanical properties of refractory concrete samples prepared from bauxite and grog with varying amounts of cement and varying particle size of aggregate.

2. EXPERIMENTAL

2.1 Raw Materials:

The raw materials used are:

- Refractory cement containing 50% alumina was obtained from Lafarge Cement.
- Calcined bauxite was obtained from the Alexandria Company for Refractories with an alumina content exceeding 80%.
- Grog was obtained from previously fired defective bricks that were crushed, ground and screened.

2.2 Particle Size Distribution of Aggregate:

In order to determine the grain size distribution, the procedure described by ASTM D 422/2007[(5)] was used. The standard sieves method was applied using screen apertures ranging from 6.68 mm (3 mesh) to 74 μm (200 mesh).

2.3 X–Ray Fluorescence Analysis (XRF):

X–ray fluorescence spectrometry (XRF) is a method of elemental analysis that assesses the presence and concentration of various elements by measurement of secondary X–radiation from the sample that has been excited by an X–ray source. The analysis was run on a AXIOS, panalytical 2005, Wave length Dispersive (WD–XRF) Sequential Spectrometer available at the National Research Center in Cairo.

2.4 X–Ray Diffraction (XRD):

X–Ray diffraction analysis differs from XRF in that it identifies, usually in a qualitative way, the phases present in the analyzed material rather than the elements.

For X–Ray diffraction study of bauxite and grog analysis, the aliquots for bulk mineral analysis were finely ground (–200 mesh), mounted randomly on an aluminum holder, and analyzed by a BRUKUR D8 ADVANCE COMPUTERIZED X–Ray Diffractometer apparatus (available at the Center of Metallurgical Research and Development Institute, Cairo) with mono–chromatized Cu Kα radiation, operated at 40 kV and 40 mA.

2.5 Preparation of Specimens:

Forty pastes of different size formulations for both bauxite and grog at different percentages cement (20%, 17.5%, 15%, 12.5%, 10%) by weight were kneaded with an adequate amount of water, which was determined for each batch according to the standard "good ball in hand test [(6)]". The mixed batches were then cast into cubes of 50 mm side length using a vibrating table at a frequency of 50 Hz and 4 minutes. The cast samples were left in their moulds for 24 hours in a 100% relative humidity cabinet. The hydrated samples were then demolded. The specimens were left in an open air until their moisture content reaches 3–6%, then put in the drying oven at (110 ± 5) ºC until reached constant weight. They were then tested for water absorption, bulk density and apparent porosity and cold crushing strength.

2.6 Apparent Porosity, Water Absorption, and Bulk Density:

These properties are determined according to ASTM Standards C 20/2007 [(7)]. For each test, the average measurements for five specimens at least are calculated.

The five specimens for each test are weighed to get the dry weight (D) for each. The test specimens are then placed in water and boiled for 2 h in a boiler and kept entirely covered with water with no contact with the heated bottom of the container. They are cooled to room temperature while still completely covered with water. The weight (S) of each test specimen is determined after boiling and while suspended in water. The saturated weight (W) is also determined.

Apparent porosity is calculated from:

$$P,\% = \frac{W - D}{V} \times 100 \qquad (1)$$

Water absorption is calculated from:

$$A,\% = \frac{W - D}{D} \times 100 \qquad (2)$$

While bulk density is calculated as follow**:**

$$\rho_B = \frac{D}{V} \times 100 \qquad (3)$$

Where:
P = apparent porosity, (%);
W = weight of the specimen as saturated with water, (g);
D = dry weight, (g);
S = weight of the specimen as suspended in water, (g);
V = exterior volume = W –S, (cm^3);
A = water absorption, (%);
ρ_B = bulk density, (g/cm^3).

2.7 Cold Crushing Strength:

This was done to determine the compression stress to failure of samples consisting of three specimens cured for 28 days. It represents an

indication of its probable performance under load. Each specimen was placed between two plates of the compression strength tester. This was followed by the application of an axial uniform load. The load at which a crack appears on the sample was noted, and it is calculated according to BS EN Standards 993–5/2000 [8]:

$$C.C.S(\sigma_c) = \frac{W}{a} \qquad (4)$$

Where:

σ_c = cold crushing strength, (MPa);

W = total maximum load at 3% deformation or at visible failure, (N);

a = average of gross areas of the two faces, (mm^2).

3. RESULTS AND DISCUSSION

3.1 Particle Size Distribution of Grog and Bauxite:

Grog and Bauxite were screened to different size fractions onto a set of standard sieves ranging form 3 mesh (Opening = 6.680 mm) down to 200 mesh (opening = 0.074 mm). The mean particle size of a fraction passing through a certain sieve and retained over the next was taken as the arithmetic average of the two openings. This way, the following mean sizes were used: 4.699 mm, 2.794 mm, 1.651 mm, 1.168mm, 0.991mm, 0.295 mm, 0.175 mm, 0.147 mm, and 0.074 mm.

Figure (1) shows the cumulative screen analyses for grog and bauxite used in the present investigation.

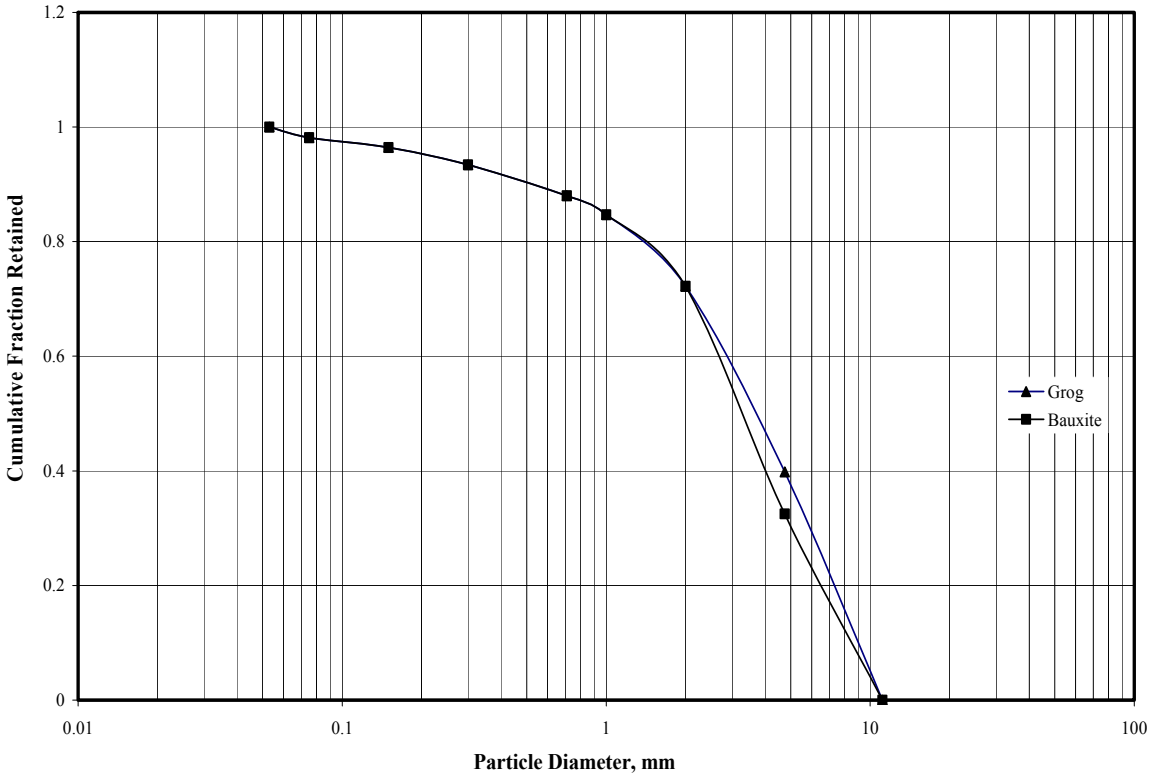

Fig. (1): Particle Size Distribution of Aggregates

3.2 Chemical Analysis of Raw Materials:

Table (1) shows the XRF results related to the chemical analysis of the refractory cement used, bauxite and grog.

Table (1): Chemical Analysis of Materials Used

Constituents (wt. %)	Cement	Bauxite Sample	Grog Sample
SiO_2	5.5	9.264	26.640
TiO_2	——	1.451	3.740

Cl	——	0.022	4.183
L.O.I	——	1.811	——
Total	**≈100**	**≈100**	**≈100**

3.3 XRD of Raw Materials:

The following figures (2 and 3) show the XRD pattern obtained on investigating bauxite and grog. As can be seen from the figures, calcined bauxite consists exclusively of corundum (Al_2O_3) and mullite ($3Al_2O_3.2SiO_2$). This is expected from the phase equilibrium diagram $Al_2O_3 - SiO_2$ for compositions containing > 80% alumina [9]. On the other hand, the XRD pattern shows besides the expected phases of mullite and quartz some non–equilibrium phases of corundum and cristobalite, are also present lines of halite present as impurity.

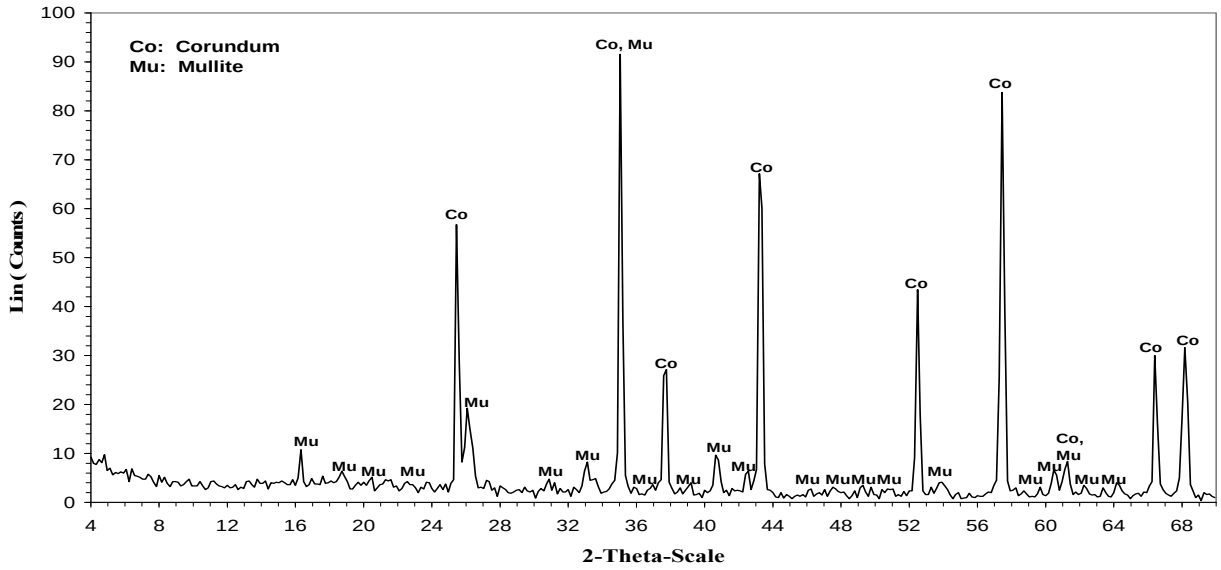

Fig. (2): XRD Pattern of Calcined Bauxite

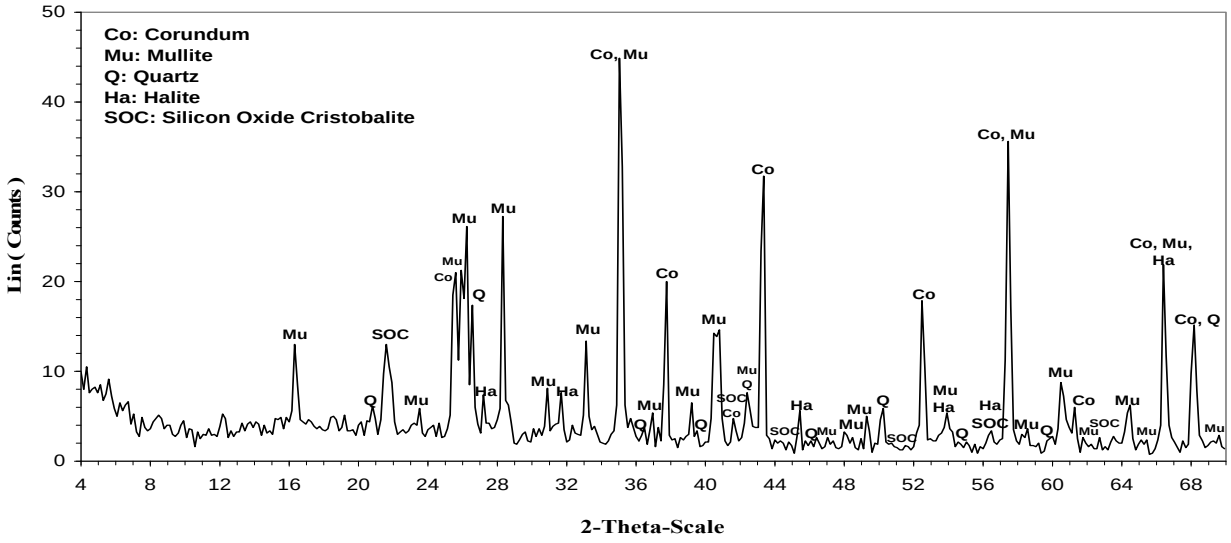

Fig. (3): XRD Pattern of Grog

3.4 Mean Particle Size of Aggregates:

In order to assess the effect of particle size of the aggregate used, bauxite and grog, on the workability, physical and mechanical properties of refractory concrete paste, four different particle size mixes were used. Each is a combination of three particle size ranges as is usually the case when wanting to maximize compactness. Table (2) shows the four mixes together with the average particle diameter of each as calculated using the method suggested by McCabe et al [(10)].

Table (2): Mean Particle Size of Aggregate Formulation Used

	% Weight			
	0–1 mm	**1–3 mm**	**3–5 mm**	**Mean Particle Size (mm)**
A	10	75	15	1.63
B	25	60	15	1.19
C	40	45	15	0.94
D	55	30	15	0.78

3.5 Effect of Mean Particle Size on Water Consumption:

During mixing, the addition ratio of water is directly affects the final product considerably [(2)]. When the amount of coarse particles in the particle size distributions used in this investigation increases, therefore the specific surface area of the particles decreases and less water is consumed because of this. The amount of consumed water as function of the mean particle size for both bauxite and grog are shown in figures (4 and 5).

It appears from these figures that the amount of water used increases with a decrease in particle size and with the amount of cement used. It is also seen that water consumption for samples containing grog is higher than for samples containing bauxite: these values range from 7.5 to 9.1% in case of bauxite based formulations against 9.5 to 10.9% in grog based formulations. This is presumably due to the presence of much more open pores in grog than in bauxite particles. To assess this point, the apparent porosity of samples of both types of particles was determined. It was found to be 6.7% for bauxite particles against 16.5% for grog particles.

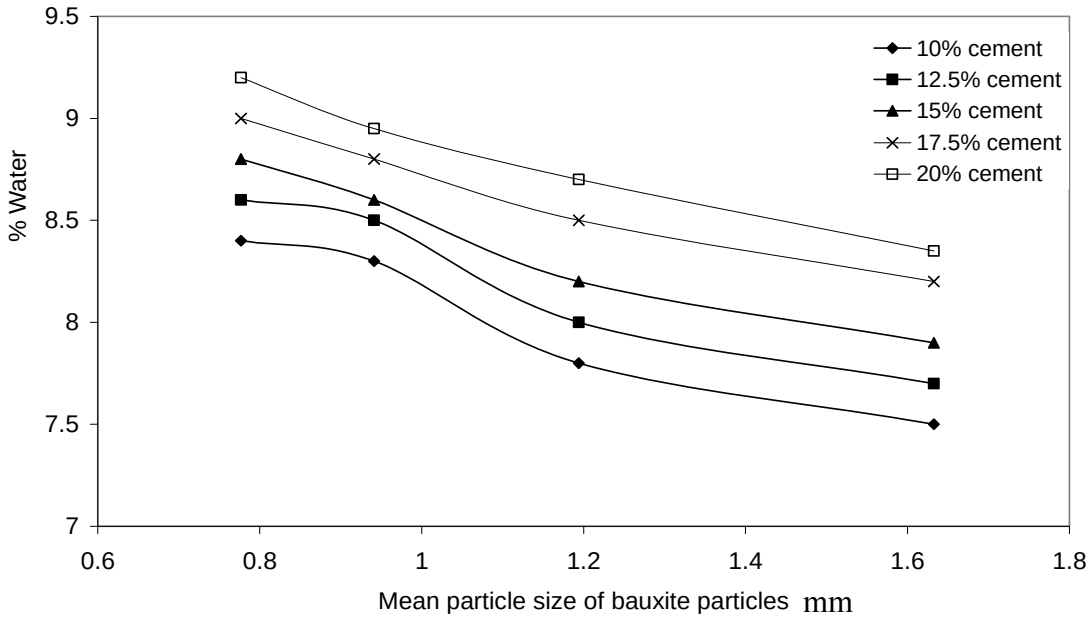

Fig. (4): Effect of Amount of Cement Used and Mean Particle Size of Aggregate on Water Consumption for Bauxite Based Mixes

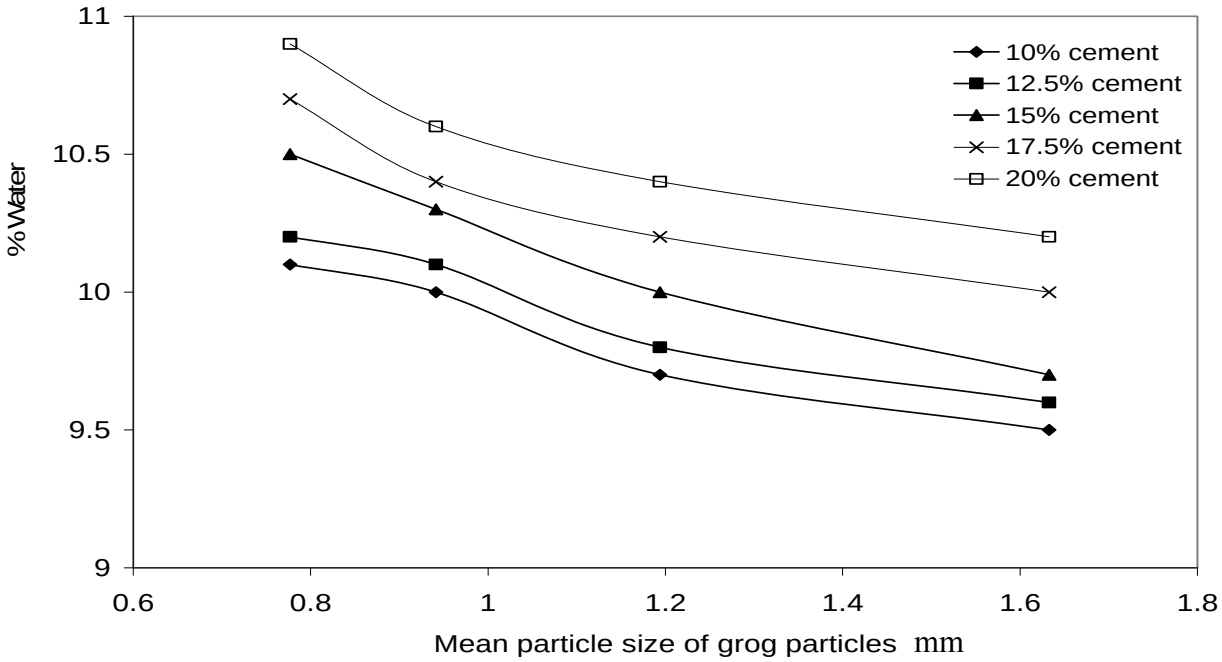

Fig. (5): Effect of Amount of Cement Used and Mean Particle Size of Aggregate on Water Consumption for Grog Based Mixes

Using the excel DATA ANALYSIS module it was possible to establish correlation tables in both cases that show the relative influence of percent cement and particle size on the percent water added. Such tables are shown below.

Table (3): Correlation Table for Water Added for Bauxite Based Mixes

	% Cement	Particle Size	% Water
% Cement	1		
Particle Size	0	1	
% Water	0.642372	− 0.7489	1

Table (4): Correlation Table for Water Added for Grog Based Mixes

	% Cement	Particle Size	% Water
% Cement	1		
Particle Size	0	1	
% Water	0.696767	− 0.68928	1

The previous tables point out to the following:

First, the relation between the percent water added and percent cement used is an increasing relation. On the other hand the negative sign associated with the effect of particle size means an inverse relation between the percent water added and particle size.

Second, it appears that in case of using bauxite the effect varying particle size on the percent water added is higher than that of varying the cement ratio. On the other hand, on using grog, the two variables have comparable effects.

3.6 Effect of Mean Particle Size on Water Absorption:

Figures (6 and 7) show the relations between the percent water absorption of cast cubes and the mean particle size of either bauxite or grog.

From these two figures, it can be seen that the percent water absorption appreciably decreases with an increase in cement content. However, as the cement content exceeds 15% its effect on water absorption diminishes. This is expected since higher cement content will have for effect to enhance the closure of available pores.

Of interest is the difference between the water absorption values observed in either case. It is clear from Fig. (6) that the values of water absorption in case of bauxite based formulations range from about 4.8% to 9.5% depending on the cement level and particle size. In case of using grog the range of water absorption is 5.3 – 10.5% showing that the use of grog has lead to higher water absorption presumably due to increased open porosity of samples.

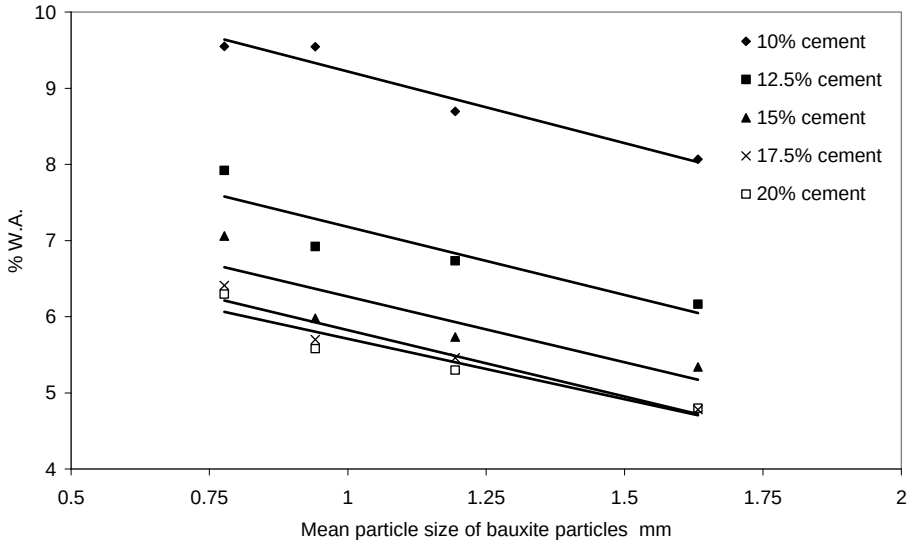

Fig. (6): Effect of Amount of Cement Used and Mean Particle Size of Aggregate on Percent Water Absorption for Bauxite Based Mixes

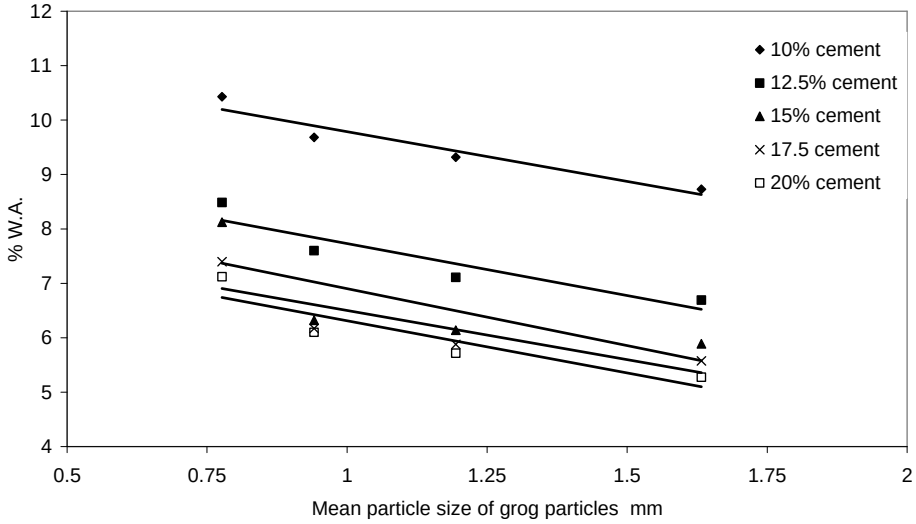

Fig. (7): Effect of Amount of Cement Used and Mean Particle Size of Aggregate on Percent Water Absorption for Grog Based Mixes

Also these figures show that the percent water absorption is only slightly affected by an increase in particle size. To assess this effect the excel DATA ANALYSIS module was used to establish correlation tables that show the relative influence of percent cement and particle size on the percent water absorption in both cases. Such tables are shown below.

Table (5): Correlation Table for Percent Water Absorption for Bauxite Based Mixes

	% Cement	Particle Size	% W.A.
% Cement	1		
Particle Size	0	1	
% W.A.	− 0.82455	− 0.39599	1

Table (6): Correlation Table for Percent Water Absorption for Grog Based Mixes

	% Cement	Particle Size	% W.A.
% Cement	1		
Particle Size	0	1	
% W.A.	− 0.79392	− 0.42302	1

These tables show that both variables affect negatively the percent water absorption where as the effect of the variation of percent cement is almost as twice as that of fineness.

3.7 Effect of mean particle Size on Apparent Porosity:

Fig. (8) and Fig. (9) show the relations between apparent porosity and the mean particle size for formulations containing bauxite and grog.

From these two figures, it can be seen that the apparent porosity decreases with an increase in cement content. This is expected since higher cement content will have for effect to enhance the closure of available pores. Also these figures show that the apparent porosity is negatively affected by an increase in particle size.

Using the excel DATA ANALYSIS module it was possible to establish correlation tables in both cases that show the relative influence of percent cement and particle size on the apparent porosity. Although such tables are not shown, their result indicates that is both variables affect negatively the apparent porosity where as the effect of the variation of percent cement on porosity is almost as twice as that of fineness.

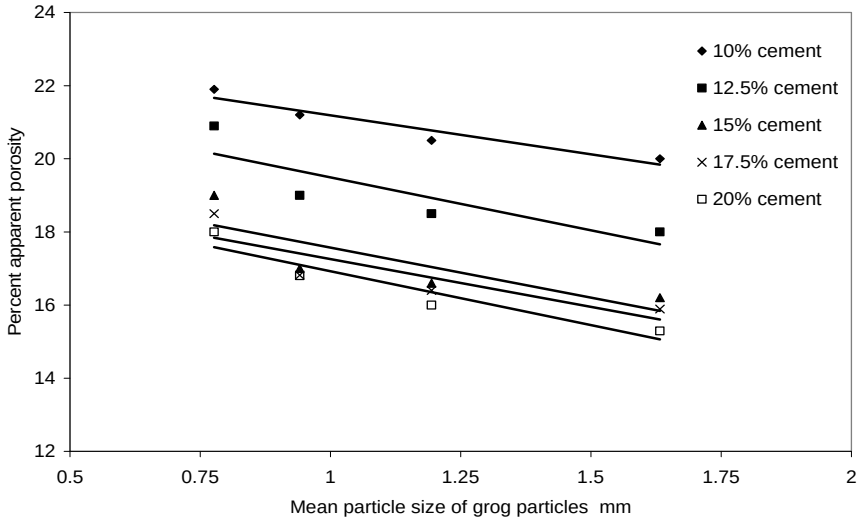

Fig. (8): Effect of Amount of Cement Used and Mean Particle Size of Aggregate on Percent Apparent Porosity for Bauxite Based Mixes

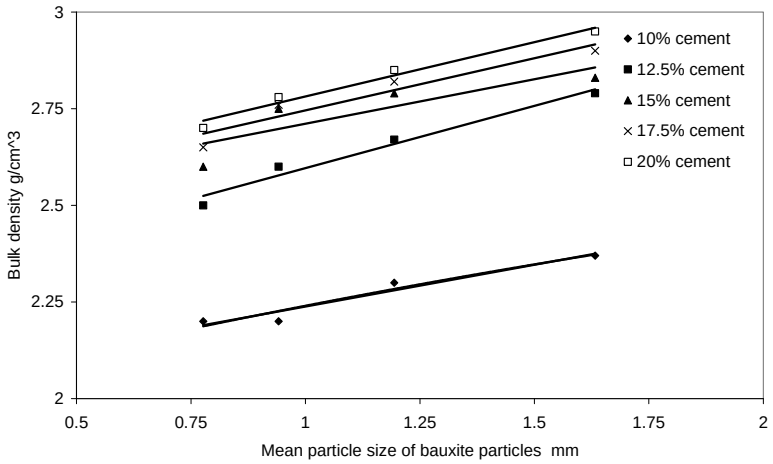

Fig. (9): Effect of Amount of Cement Used and Mean Particle Size of Aggregate on Percent Apparent Porosity for Grog Based Mixes

3.8 Effect of Particle Size Distribution on Bulk Density:

Fig. (10) and Fig. (11) show the relations between bulk density and the mean particle size for formulations containing bauxite and grog.

From these two figures, it can be seen that the bulk density increases with an increase in cement content. This is expected since higher cement content will have for effect to decrease porosity. Also these figures show that the bulk density slightly increases with an increase in particle size.

On the other hand, due to their lower porosity, the bulk density of samples containing bauxite is higher than that of samples containing grog, for the same particle size. For example, at mean particle size = 1.63 mm, the bulk density of samples containing bauxite ranged from 2.37 to 2.96 g/cm^3, depending on the amount of cement added while it ranged from 2.3 to 2.9 g/cm^3 for grog containing samples.

Also, due to the irregular shape of the grog particles with respect to bauxite, the packing efficiency of a body containing grog is less than that of bauxite. This assists the increased density in case of using bauxite.

Correlation tables were established to show the relative effect of variations in cement content and particle size on samples containing either bauxite or grog (Not shown). These tables show that that both cement content and higher particle size favor higher bulk density although the effect of cement variation on bulk density is more pronounced than that of particle size.

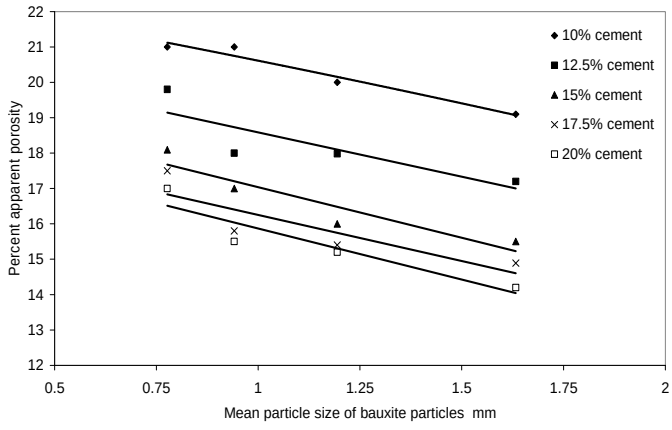

Fig. (10): Effect of Amount of Cement Used and Mean Particle Size of Aggregate on the Bulk Density of Bauxite Based Mixes

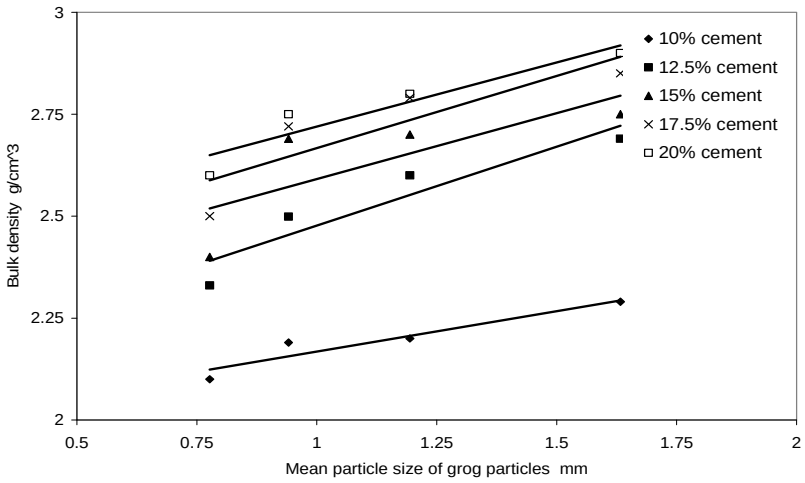

Fig. (11): Effect of Amount of Cement Used and Mean Particle Size of Aggregate on the Bulk Density of Grog Based Mixes

3.9 Effect of Particle Size Distribution on Cold Crushing Strength:

Figures (12 and 13) show the relations between cold crushing strength and the mean particle used for different cement contents (bauxite and grog). Three specimen samples were first prepared and air cured for 28 days before subjecting to the test.

From those figures, it could be seen that the compressive strength of specimens increases, as expected with an increase in cement content. The effect of mean particle size is however more complicated. All curves drawn seem to follow the same pattern: First, the cold crushing strength increases up to a mean particle size of about 0.95 mm then degreases with further increase in particle size. This mean particle size corresponds to formulation C in which the fine particles (D < 1 mm) constitute 40% of the mix where as the coarse portion represents the remaining 60% (Table 2). Such recipe approaches a state of minimum total porosity [11]. This had for effect to maximize the compactness of the mix leading to a maximum value in C.C.S.

Here also, the levels of crushing strength are higher in case of mixes containing bauxite than in those containing grog: In the former the C.C.S. ranges from 34 to 39 MPa, while ranging from 32 to 37 MPa in the latter case.

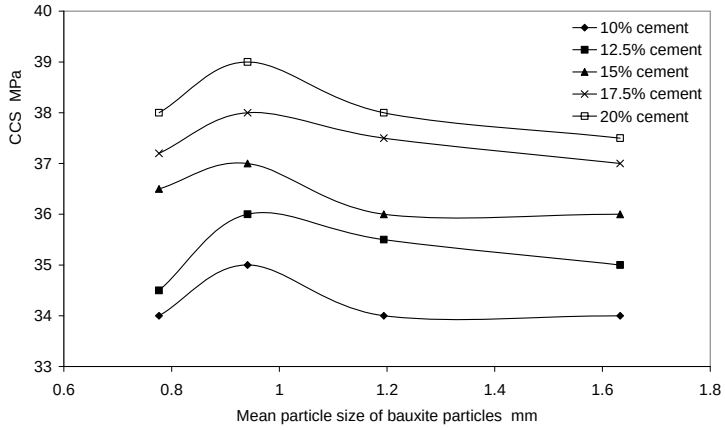

Fig. (12): Effect of Amount of Cement Used and Mean Particle Size of Aggregate on the Cold Crushing Strength of Bauxite Based Mixes

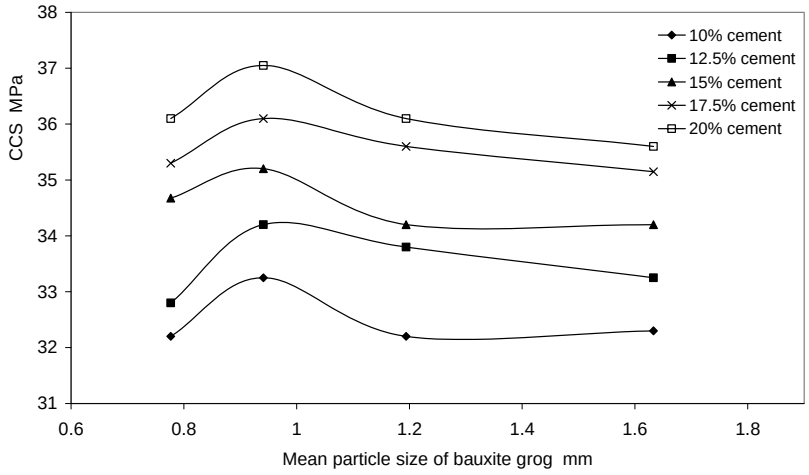

Fig. (13): Effect of Amount of Cement Used and Mean Particle Size of Aggregate on the Cold Crushing Strength of Grog Based Mixes

Tables (7) and (8) describe the relative effect of the variation in cement content and mean particle size on the variation in CCS for both types of samples. These tables show that in both cases, the variation of cement content plays a much higher role than that of particle size in assessing variations in CCS.

Table (7): Correlation Table for CCS for Bauxite Based Mixes

	% Cement	Particle Size	CCS
% Cement	1		
Particle Size	0	1	
CCS	0.945608	− 0.12905	1

Table (8): Correlation Table for CCS for Grog Based Mixes

	% Cement	Particle Size	CCS
% Cement	1		
Particle Size	0	1	
CCS	0.943331	− 0.12633	1

4. CONCLUSIONS

Samples of refractory concrete cubes were prepared using from 10 to 20% cement containing 50% alumina and two types of aggregate: calcined bauxite containing about 81% alumina and grog containing 52% alumina. These were graded to yield four portions of different mean particle size.

The following results could be deduced:

- Increasing the amount of cement added lead to higher water consumption, lower water absorption and porosity and higher bulk density.
- Using coarser aggregate resulted in a reduction in water used for mixing, lower water absorption and porosity and a higher bulk density.
- The effect of variation in cement content on the aforementioned properties is generally higher than that of variation of particle size.
- A higher cement content favored higher cold crushing strength but a maximum value was obtained at a mean aggregate particle size of about 0.95 mm

corresponding to a state of maximum compactness.

- Better results were generally obtained on using bauxite aggregate rather than grog presumably due to their lower intrinsic porosity.

Effect of Beta Radiation on Extraocular Muscles

Mohamed A. Marzouk ,MD*, Hossam E. Sayed*, Ayman A . Shoman , MD* , Hisham A .Hashim ,MD*.
* Ass. Professor – Research Institute of Ophthalmology – Giza – Egypt.

Abstract: Purpose: To evaluate the effect of different Beta radiation doses on frogs extraocular muscles. **Methods:** 50 frogs of species Rana Ridibunda were used in this study, they were divided into 5 groups, every group was treated with a different dose of radiation, and the first group was taken as control. **Results:** The estimation of soluble protein content in extraocular muscles of Beta radiated eyes showed a gradual decrease with the increase of dose. **Conclusion:** Significant changes in extraocular muscles were detected with the increase of Beta radiation dose.

Keywords: Effect; Beta Radiation; Extraocular; Muscle

Introduction:

Almost infinite variety of atomic, intra, and intermolecular changes will occur when living tissue is subjected to ionizing radiation. Some of these changes may be the goal of radiotherapy, while, of course, the others are considered to be harmful or even lethal changes [(1)].

Living tissue absorb the ionizing radiation through two mechanisms: ionization, and excitation depending on the energy of that radiation; if its energy is high enough, some molecules may be ionized causing direct damage to the other neighboring molecules, or even the far molecules through the formation of free radicals (indirect effect). If the energy of the radiation is not enough to ionize the molecules, it may cause its excitation to higher energy levels, therefore disturbing the normal balance of the organism [(2)].

Beta radiation is one of the most abundant radiation types being used in ophthalmology, it has a small penetrating power and that is to be highly considered while dealing with the eye which is one of the most radiosensitive organs of the body [(2)].

Beta radiation has been used for ocular radiotherapy since the forties of this century. Postoperative treatment of pterygium[(3)] ,and more recently primary pterygium with no prior surgical excision[(4)], may be the most pronounced application of Beta radiation in ophthalmic therapy, however, there are some other situations at which Beta rays are used successfully, like non malignant lesions of the eye lids, corneal scars, corneal vascularization, vernal conjunctivitis, superficial or deep keratitis[(5)], and in postoperative treatment of total and subtotal symblepharons[(6)] .It's also being applied in some centers now, with more advanced techniques, for the treatment of conjunctival squamous cell carcinoma , choroidal and ciliary body melanomas[(7)], also in controlling the elevated IOP by its effect on the ciliary body and wound healing alteration [(8)].

Many workers have early noticed complications due to Beta radiation such as telangiectasis of the conjunctiva, keratinization of the conjunctival epithelium that led to punctate keratitis resulted in severe lacrimation. Other late effects of beta radiation were also reported such as scleral thinning, scleral ulcers, atrophy of the sclera, superficial punctate keratitis, corneal vascularization, corneal scarring, perforation, iritis, iris atrophy, iridocyclytis, cataract, ptosis, glaucoma, and endophthalmitis[(5,9,10.11)].

These side effects became will known later and the strategies of Beta radiotherapists had to consider the dose-effect on such symptoms, so, many workers began to use smaller doses to overcome such complications, and also set dose-fraction systems to optimize therapy and minimize the side effects [(12)].

Such dose-fraction systems are being established and used in the Beta radiotherapy centers; and for the current study, the applied dose fractionation scheme for the experimental animals is that used for human application in the postoperative treatment of pterygium in the dept. of radiotherapy at the Research Inst. Of Ophthalmology, Cairo-Egypt. According to this scheme (which complies with the findings of Bahrassa et al, 1983; and El Dessoki, 1990), patients receive a total accumulated dose of 24 Gy (32 Gy in some cases) of beta radiation in three (four) divided sessions in a week[(3,13)] .

Materials And Methods:

Fifty frogs of species Rana Ridibunda, of average weight 74 gm., were used in the present study. Frogs were divided into 5 groups, each of which consist of 10 animals and labeled A, B, C, D,

and E. Group A was taken as the control (untreated) group. The other 4 groups were treated with different doses of radiation as follows: Group B received 8 Gy, group C received 16 Gy, group D received 24 Gy, and group E received 32 Gy.

The species Rana Ridibunda was chosen on the basis of its larger size and stronger musculature compared to the other available species. Eyes of the frog Rana Radibunda have close structure to human eyes and similar extraocular muscles[14].

The radiation source used in the study was a Strontium-90/Yttrium-90 source, which is contained in the eye applicator (SIA.20- Amersham, UK) found at the Research Institute of Ophthalmology, Giza, Egypt .

For all animals, the right eye was the treated eye. After irradiation, animals were left alive for up to 30 days from the last session.

For the extrusion of the extraocular muscles, the animal was slaughtered and the head was separated, the buccal cavity was opened and the lower jaw & tongue were removed and the upper membrane was peeled to uncover the eye globe and extraocular muscles. The extraocular muscles were excised from the globe and then weighted to determine the wet weight.

Due to the small size of the muscles from a single animal, a pooled sample of muscles from the individuals of each group was considered to increase the sample size. Enough impact sample of each group was preserved in formalin solution for the histological examination, and the rest of the pooled sample was then treated as described by Baldwin et al., (1955) [15].

We did use the following methods in detecting changes in extraocular Muscles:

1-Quantification of soluble protein content by Lowry method .

2-Determination of protein pattern by Gel Electrophoresis .

3-Spectrophotometric measurements.

4-Histopathological examination .

Results:

During the radiation process, the Beta applicator (type SIA 20- Amersham) was placed in contact with the cornea of the frog eye simulating the therapeutic technique used for human treatment.

This means that the cornea dose can be considered to be the same as the surface dose of the applicator[16]. Accordingly all Beta radiation doses mentioned in this study refer to the cornea dose, while that of the extraocular muscles is only 2-4% of the cornea dose which can be estimated from the dose curves of the strontium 90 Beta applicator, and this applies to all results[16].

Quantification of soluble protein content by Lowry method:

The soluble protein content of the treated extraocular muscles decreased gradually from 90% of the control and group B, (8Gy cornea dose) to 55% in group E, (32Gy cornea dose).

The decrease of soluble protein content of extraocular muscles as a result of Beta radiation indicates that some type of destructive action has occurred. Study of the protein content only is not enough to explain the possible changes. More explanations can be obtained if the different samples were subjected to electrophoresis. (Fig. 1 A).

Determination of muscle protein patterns by Gel Electrophoresis:

It can be shown from the separation pattern that the bands showed an apparent difference in the separation bands of Actin, Beta-actinin, and Tropomyosin of the last two treated groups (that received 24, and 32Gy Beta radiation corneal dose), the bands of Beta-actinin and Tropomyosin (bands 1 and 2) broadened and diffused together, while the other two bands of Actin and Myosin light chain (bands 3 and 4) became much more broadened which implies an alteration of the protein structure that may be due to the aggregation of some protein fragments in the samples. A structural deformation means malfunctioning of the affected muscle which needs further investigation in a future study. (Fig. 1 B).

Spectrophotometric measurements :

A general trend of higher absorbance values for the first two groups B&C (8 & 16 Gy corneal dose) compared to control, while the last two groups D&E (24 & 32 Gy corneal dose) which received higher radiation dosed showed lower absorbance values compared to control indicating some form of protein damage. (Fig. 1 C).

Histopathological examination:

-In group B (8 Gy):

The normal striation of muscles is unaffected, with some fatty infiltrations.

-In group C (16 Gy):

The presence of fatty infiltrations became more apparent, and the affinity to the haematotoxylin stain seems to be decreased.

-In group D (24 Gy):

The affinity to the haematotoxylin stain showed more decrease, and the muscle striation is disrupted compared to normal muscles and the myofibers showed some splitting.

-In group E (32 Gy):

The affinity to the haematotoxylin stain is much more decreased and the normal striation of myofibers is extensively disrupted. The myofibers showed more splitting and many myofibers showed the absence of nuclei (Fig. 2).

Discussion:

To our humbled knowledge this is the first study on the interaction of Beta radiation with the extraocular muscles.

Although the amount of Beta dose of the extraocular muscles of the frog was only 2-4% of the cornea dose, many changes could be found due to such doses.

The estimation of soluble protein content of extraocular muscles in Beta radiated eyes showed a gradual decrease with the increase of dose. This implies change in the nature of proteins of treated samples which increases with increase of applied dose.

Data from electrophoretic measurements also confirmed the same conclusion, where other molecular weights appeared in the separation pattern indicating the appearance of new protein fragments.

Spectrophotometric measurements focused on the effect of different Beta radiation doses on peptide bonds and nucleic acids which showed that there are different degrees of damage with different doses, which means that proteins were exposed to some type of damage which produced some new protein fragments which agrees with the previous conclusions.

The direct effect of Beta radiation can't be the only reason for such changes. The effect of Bremsstrahlung radiation can be considered to be an important factor in the appearance of many side effects of Beta radiation due to its higher penetration in tissue so that it can cause such distant changes.

Bremsstrahlung are X-rays that are emitted when high-speed charged particles suffer rapid acceleration. When a β particle passes close to a nucleus, the strong attractive Coulomb force causes the β particle to deviate sharply far from its original path. The change in direction is due to radial acceleration, and the β particle, in accordance with classical theory, loses energy by electromagnetic radiation at a rate proportional to the square of the acceleration. This means that the Bremsstrahlung photons have a continuous energy disruption that ranges downward from a theoretical maximum equal to the kinetic energy of the β particle. The likelihood of Bremsstrahlung production increases with the atomic number of the absorber [(17)].

Another factor to be considered, that is the free radicals which are formed in the aqueous medium within the tissue (which is abundant in the structure of the eye). Radiation-produced free radicals affect other molecules at a distance as they can transfer their "extra" electron to a nearby molecule, which in turn, may pass it on. The electron can be passed through a succession of molecules forming many free radicals. This chain reaction may occur in a large number of molecules and results in critical changes in organic molecules. Similarly, a free radical may "snatch" an electron from a neighbor, which then becomes a free radical. A chain of electron "snatchings" may ensue an organic molecule to be critically changed in the process. Therefore, the radiation damage that occurred in the β irradiated samples can be thought to be a result of the free-radical interactions [(17)].

Conclusion:

Therapeutic doses of Beta radiation on the eye can harmfully affect the structure and function of extraocular muscles despite its short penetrating range in tissues, and the risk to benefit ratio should be considered during its use.

We are in need for a future human studies on the extraocular muscles regarding it's balance and function after therapeutic Beta radiation.

*Department of Paediatrics, Faculty of Medicine, Cairo University
**Department of Childhealth
National Research Center

ABSTRACT: Chronic illness is clearly an important factor affecting psychosocial state of children and adolescents. This case-control study is an effort to clarify the effect of chronic asthmatic chest troubles, as chronic illnesses, on the cognition and psychological aspects of such chronically ill children. This study was executed in the Chest Clinic of the Abou El-Reesh Children's Hospital, Cairo University. The Study was carried out on 23 children suffering from chronic asthmatic chest troubles (13 boys and 10 girls) with an age range of 6-15 years (mean age ± SD = 9.6±2.67). Twenty three age and sex matched children not suffering from any disease and living under the same socioeconomic conditions were taken as controls. WISC-R and PSCL were used to assess the cognitive and psychosocial adjustment among children while the mid-year scores for Mathematics and Arabic language were used to evaluate the academic performance. Our results indicated that chronic asthmatic disease has a negative effect on cognitive abilities, psychosocial behavior and academic achievement of such children.

Keywords: Chronic; Asthmatic; Chest; Cognitive Functions; Psychosocial Behaviour

INTRODUCTION

Health, happiness, independence, and productivity are basic human desires. For children, this means achieving normal growth and development, acquiring a sense of accomplishment, developing an identity, and initiating independence. Although, over time, all children face the same developmental tasks, achieving these developmental milestones depends on many conditioning factors ***(*Charron-Prochownik, 2002*)***. One conditioning factor that greatly influences developmental outcomes and quality of life is chronic illness ***(*Jackson and Vessey, 2000*)***.

Chronic diseases affect an estimated 10-20% of all children during childhood and adolescence ***(*Geist et al, 2003*)***. Chronic chest troubles are the most common cause of chronic illness in children and can affect cognition, psychosocial behavior, and school performance of children. Children with chronic illness are at higher than average risk for behavioral disorders **(Tavormina et al, 1996).** The general consensus of the literature is that chronically ill children are at risk for psychological problems. In chronic childhood conditions, as a whole, the risk of psychopathology is about 2.5 times higher than in the general population **(Noeker et al, 2005)**. One epidemiological study showed that among 4-16 years old, those with chronic health problems were 2-4 times more likely to have a diagnosable behavioral disorder than their healthy peers. **(Goldberg et al, 1997)**

Psychosocial factors in chronic illness in the pediatric population may impede optimal outcome. Overt and covert adjustment problems and psychiatric illness may present as unexplained medical symptoms, non-compliance with medical treatment, school refusal and high-risk behaviors. These signs may alert the physician to the presence of underlying issues in the child and/or the family. Before referral to a mental health professional, the doctor should try to identify the presence of underlying issues, focus on family-centered care and schedule well visits to monitor compliance and other issues.

Early detection and treatment of psychosocial problems may lead to considerable health benefits. Psychosocial problems have a high prevalence rate and lead to high costs of disease. They also cause substantial restrictions in daily functioning in later life and are the major cause of long-term work disability in young adults **(Murthy et al, 2001)** Only a minority of children with psychological or psychosocial problems are under treatment **(Reijneveld et al, 2004).** If untreated, problems are likely to persist in later life and can lead to serious limitations in daily functioning **(Verhulst and vander Ende, 1996).** Research has shown that early detection and treatment improves these

children's prognosis substantially, but a complete analysis of its cost effectiveness has yet to be carried out (**Nelson, Westhues and MacLeod, 2003)**.

The aim of this study is to assess the cognitive functions, psychosocial behavior, and school achievement in asthmatic children and compare them with healthy children in the same age.

PATIENTS & METHODS

This case-control study had been carried out on 46 Egyptian children (23 patients and 23 controls). The two groups were examined for medical and psychological evaluation, to find whether ill children have psychological problems than healthy controls. Their age ranged from 6-15 years.

The study included 23 children previously diagnosed to have chronic asthmatic chest disease and randomly selected. They regularly attended the chest clinic at Abu El- Reesh Children's Hospital, Cairo University. Inclusion criteria included children previously diagnosed to have bronchial asthma, age range between 6-15 years and both sexes. Exclusion Criteria included children less than 6 years old and those more than 15 years old, neurological diseases e.g. cerebral, mentally retarded children and asthmatic chest diseases less than 6 months duration. A control group of 23 healthy children matched for age, sex, educational level and socio-economic state as the patients group. They were selected from the brothers and sisters of the patients group. The controls were free from any chronic illness especially chronic asthmatic chest diseases.

All studied cases were subjected to the following:

1) History taking: including: age, sex, onset of disease and its duration.

2) Clinical examination: full clinical examination was done including general examination and local chest examination in order to diagnose chronic chest disease and exclude any other diseases. Diagnosis of chronic chest disease was confirmed by reviewing the laboratory and radiological findings of the patients.

3) Assessment of anthropometric measures (weight and height).

4) Assessment of cognitive abilities: They were assessed by a battery of psychological tests that covered verbal and non-verbal intelligence, memory, learning, problem solving, and attention. The children were individually assessed. All psychological evaluations were administered in one session. The tests used were:

A-The Arabic Version of the Revised Wechsler Intelligence Scale for Children (WISC-R) (Wechsler, 1977, Kamel and Ismail, 1993). This is the most widely used test for intellectual assessment and covers an age range of 6-16years. The test is scored according to a manual from which verbal and performance score and intelligent quotient are obtained from.

B-The Auditory Vigilance test: It measures the attention ability of the child. It is a measure of the efficiency of identifying signal stimuli in the context from the non-signal ones. **(Pollite, 1984).**

C-The Figural Memory Test: This is a measure of the free recall of visual objects. **(Pollite, 1984).** The free recall score is the number of items recalled correctly. The classification score is obtained by counting the number of the shifts from one category to the other, which is made by the subject during his recall. This was considered as an indicator of how he can organize aspects in his memory.

5) Assessment of psychosocial behavior: Children's behavior was evaluated by a brief version of parent-completed Pediatric Symptom Checklist (PSC-17). Although certain responses may suggest a diagnosis, the PSC is a screening tool and not a diagnostic one. If positive, the clinician should pursue a brief interview, reviewing the child's major areas of functioning (school, family, activities, friends and mood). If this brief interview supports the PSC findings, the clinician then decides whether a follow-up appointment, further evaluation or referral is indicated **(Jellinek et al, 1995).**

6) Assessment of academic Achievement: Was assessed using the mid-year test scores of Arabic language and arithmetic subjects for each child. It is considered as a good indicator of academic and learning performance **(Silver, 1989).** Each group is classified according to the mid-year scores into good achiever (the mid-year score is $\geq$ 70%) and poor achiever (the mid-year score is < 70%).

Statistical Methods: Data were statistically described in terms of range, mean ± standard deviation (± SD), frequencies (number of cases) and percentages when appropriate. Comparison of quantitative variables between the study groups was done using Student *t* test for independent samples. For comparing categorical data, Chi square (χ^2) test was performed. Exact test was used instead when the expected frequency is less than 5. A probability value (*p* value) less than 0.05 was considered statistically significant. All statistical calculations were done using the computer programs Microsoft Excel 2003 (Microsoft Corporation, NY, USA) and SPSS (Statistical Package for the Social Science; SPSS Inc., Chicago, IL, USA) version 15 for Microsoft Windows.

RESULTS

The study was conducted on 23 patients and 23 age and sex matched controls (table 1, 2).

Table (1) Age of children in the study sample

	Asthmatics	Controls
Range	6-15 y	6-15y
Mean	9.6	10.5
±SD	2.67	2.75

P value > 0.05(non significant)

Table (2) Sex distribution of children.

		Asthmatic group	Control group
F	Count	10	10
	%	43.5%	43.5%
M	Count	13	13
	%	56.5%	56.5%

P value > 0.05 (non-significant)

Anthropometric measures between the two groups were highly significant as shown in table 3.

Table (3) Results of anthropometric measures in asthmatics and controls

	Asthmatics		Controls		P value
	Mean	±SD	Mean	±SD	
Weight	25.57	10.65	35.26	7.98	.008*
Height	125.32	13.38	135.44	9.03	.010*

*P value < 0.05 (significant)

Cognitive abilities:

A- Full Scale IQ: Table (4) shows analysis of the full scale IQ for the two groups. The mean full scale IQ for asthmatics was 73.61% compared to 93.54% for the control group. It shows significant diminution in asthmatics. (P value < 0.05)

Table (4) Full scale IQ and results of Figural Memory test

	Asthmatics		Controls		P value
	Mean	±SD	Mean	±SD	
Full scale IQ	73.61%	12.79	93.54%	12.72	.000*
Free recall	8.13	3.49	11.22	2.67	.001*
Classification	2.83	2.19	4.54	1.59	.034*

B-Figural Memory test:

- **Free recall:**

The mean free recall scores for asthmatics was 8.13±3.49, while the mean free recall scores for the controls was 11.22± 2.67 which is highly significant in asthmatics (P= .001) (Fig. 1).

- **Classification :**

The mean of classification scores for asthmatics was 3.83±2.19 while the mean of classification scores for controls was 4.54±1.59. It shows significant diminution in asthmatics (P value =.034) (Fig. 1).

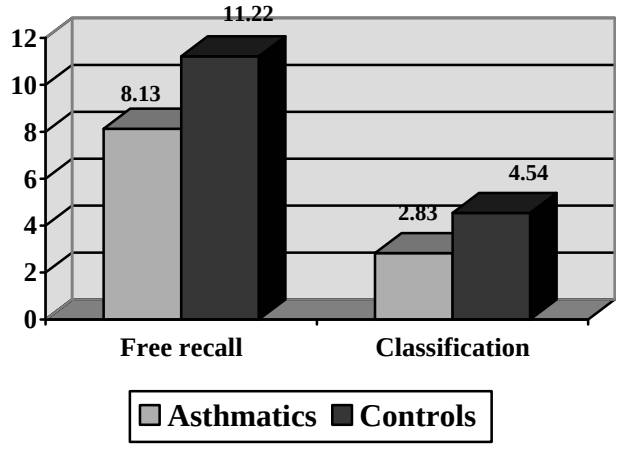

Figure (1) results of Figural Memory test in asthmatics and controls.

C-Auditory Vigilance test: Table (5) shows the results of auditory vigilance among study groups.

Table (5) Results of Auditory Vigilance test in asthmatics and controls.

		Asthmatics		Controls		P value
		Mean	±SD	Mean	±SD	
Test A	Right answers	9.83	2.25	14.00	1.28	.000*
	Wrong answers	3.17	2.25	1.02	1.27	.000*
Test B	Right answers	10.65	2.12	12.16	1.24	.001*
	Wrong answers	4.52	2.37	0.88	1.26	.000*

* P value < 0.05 (significant)

- **Test A**

The mean for right answers in asthmatics was 9.83±2.25 while the mean for right answers in controls was 14.00± 1.28 with highly significant diminution in asthmatics (P= .000) (Fig. 2). The mean for wrong answers in asthmatics was 3.17± 2.25 while the mean for wrong answers in controls was 1.02 ±.1.27 with highly significant diminution in asthmatics (P= .000) (Fig. 2).

- **Test B**

The mean for right answers in asthmatics was 10.65 ±2.12 while the mean for right answers in controls was 12.16 ±1.24 with highly significant diminution in asthmatics (P= .001) (Fig. 2). The mean for wrong answers in asthmatics was 4.52 ±2.37 while the mean for wrong answers in controls was 0.88 ±1.26 with highly significant diminution in asthmatics (P= .000) (Fig. 2).

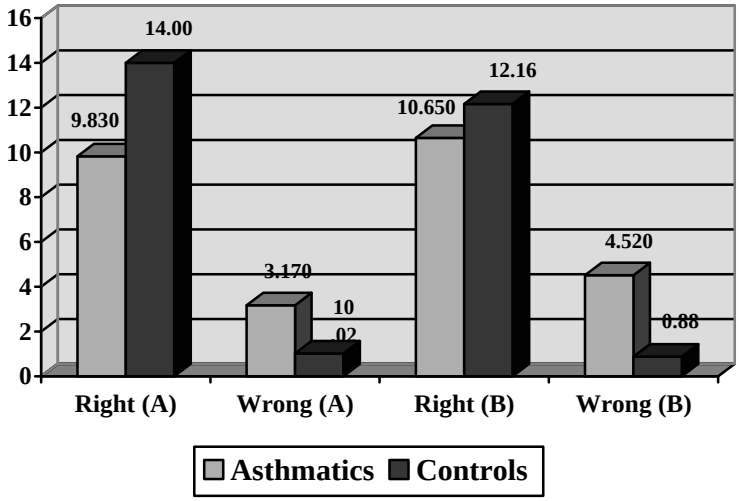

Figure (2) Results of Auditory Vigilance test in asthmatics and controls

iii.Psychosocial behavior for asthmatics and controls is shown in Table 6.
iv.

Table (6) Results of psychosocial behavior in asthmatics and controls

		Asthmatics		Controls		P value
		N	%	N	%	
Externalizing behavior	**Positive**	3	13%	0	0%	0.007*
	Negative	20	87.0%	50	100%	
Internalizing behavior	**Positive**	9	39.1%	3	6.0%	0.001*
	Negative	12	60.9%	47	94.0%	
Attention problems	**Positive**	3	13.0%	0	0%	.007*
	Negative	20	87.0%	50	100%	
Normal children		9	39.1%	47	94.0%	.000*

*P value < 0.05 (significant)

1- Externalizing abnormalities:

The behavioral questionnaire (PSCL) showed that: 3 asthmatics (13.0%) had externalizing behavior and no one had the same behavior in controls. 20 asthmatics (87.0 %) were normal compared to 50 controls (100%) with highly significant diminution in asthmatics (P= .007) (Fig. 3,4).

2- Internalizing disorders:

The internalizing behavior was found in 9 asthmatics (39.1%) as compared to 3 controls (6.0%). 12 asthmatics (60.9 %) had no internalizing behavior compared to 47 (94.0%) in controls with highly significant diminution in asthmatics (P=.001) (Fig. 3,4).

3-attention disorders:

As regard to the attention problems, there were 3 asthmatics (13.0%) compared to 0 controls (0%) had attention problems with highly significant diminution in asthmatics (P= .007) (Fig. 3,4).

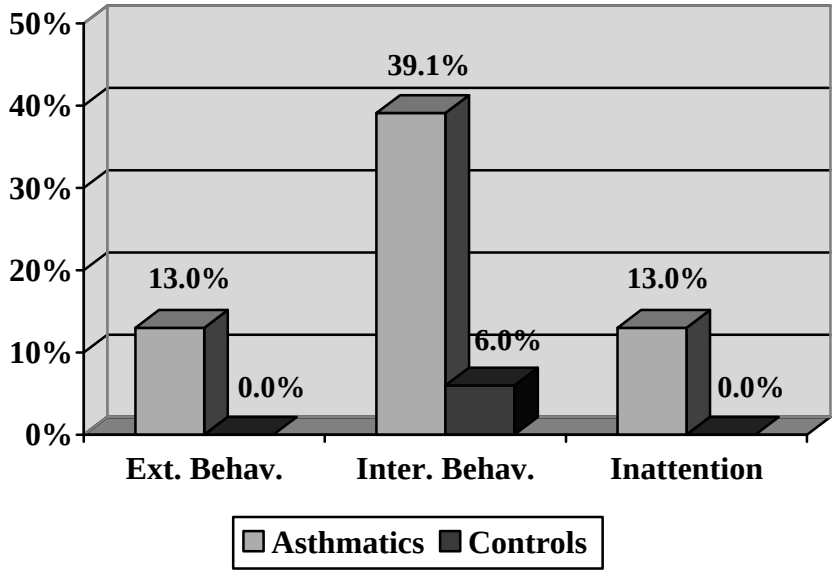

Figure (3) positive behavioral problems in asthmatics and controls.

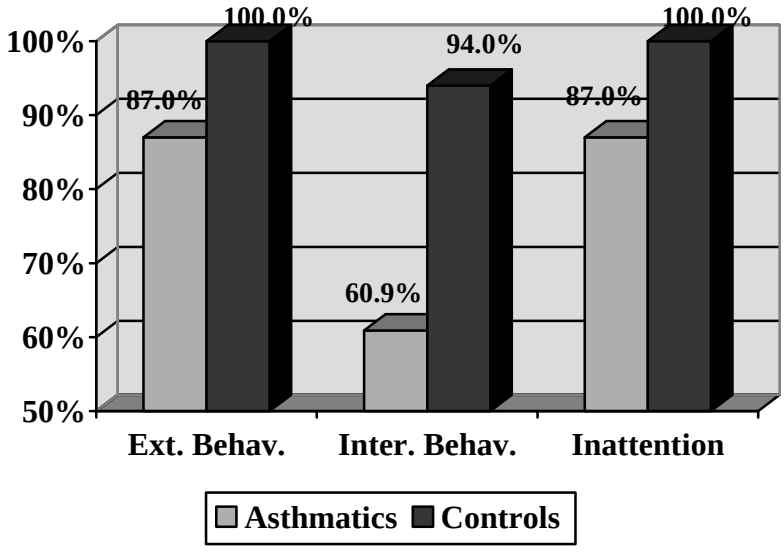

Figure (4) negative behavioral problems in asthmatics and controls.

v. **Academic Achievement:** Table (7) shows results of academic achievement among study groups.

Table (7) Results of academic achievement in asthmatics and controls

		Asthmatics		Controls		P value
		N	%	N	%	
Midyear Mathematics scores	**Good achiever**	13	56.5%	50	100%	.000*
	Poor achiever	10	43.5%	0	0%	.000*
Midyear Arabic scores	**Good achiever**	13	56.5%	50	100%	.000*
	Poor achiever	10	43.5%	0	0%	.000*

*P value < 0.05 (significant)

A- Midyear Mathematics scores:

10 (43.5 %) asthmatics compared to 0 (0%) controls were poor achievers with a highly statistically significant difference between the two groups (P= .000) (Fig. 5).

B- Midyear Arabic scores:

10 (43.5 %) asthmatics compared to 0 (0%) controls were poor achievers with highly statistically significant difference between the two groups (P= .000) (Fig. 5).

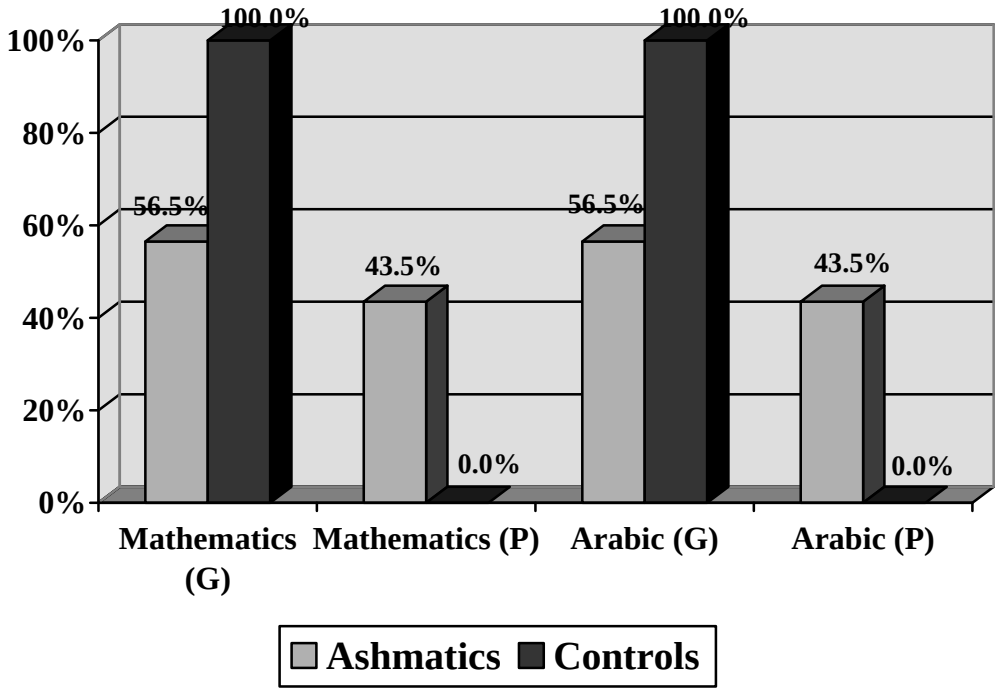

Figure (5) Results of academic achievement in asthmatics and controls.
G: good achievers P: poor achievers

iv. Nocturnal Enuresis (NE): Table 8 shows that nocturnal enuresis was found in 6 asthmatics (26.1%) compared to 0 (0%) controls with highly statistically significant difference between the two groups (P= .000).

Table (8) Results of nocturnal enuresis in asthmatics and controls

	Asthmatics		Controls	
	N	%	N	%
Positive cases	6	26.1%	0	0%
Negative cases	17	73.9%	50	100%

P= 0.000 (highly significant**)**

DISCUSSION

Epidemiologic studies indicate that up to half of pediatric visits reflect behavioral, psychosocial, and educational concerns **(Starfield et al, 1980).** Most of these problems are psychosocial problems that are not severe enough to be classified as psychiatric disorders but interfere with children's social and academic development **(Sharp et al., 1992).** Identification of parental concerns about children's behavior and evidence of problematic behavior are increasingly accepted as part of the basic responsibilities of primary care providers **(Perrin and Stancin, 2002).**

Children who have symptoms of illness for more than 3 months, or who require hospitalization or extensive home based services for more than one month in 12 months period are said to have chronic disease. **(El-Baz et al, 1995)** Contrary to El-Baz definition, **Leblan et al (2003)** suggested that the term chronic illness refers to illnesses that require at least 6 months of continuous medical care, permanent life style changes and continuous behavioral adaptation to the unpredictable course of the illness

The finding in the present study indicate that there are obvious differences between children with chronic asthmatic chest troubles and healthy children as regard to cognitive abilities, behavior and school performance. Nevertheless, pediatricians are not adequately trained and/or do not have the time to evaluate every child's psychosocial status **(Costello and Janiszewski, 1990, Jellinek et al, 1995).** One method of focusing on the limited time available to those children likely to have psychosocial problems is to use a screening procedure **(Jellinek, 1982).** As with any screening test, a psychosocial screening procedure must be economical, brief, and accurate, and easy to understand, administer and interpret **(Jellinek, 1995).**

In this study, PSCL was used as a screening test that provided a quick, valid, and reliable method for detection of psychosocial problems. It reflects parent's impressions of their child's psychosocial functioning with acceptable sensitivity and specificity (**Fielding, 1990).** Using PSCL for behavioral assessment showed that asthmatics had significantly more behavior problems across several domains compared with normal controls. **McQuaid et al. 2001**, found evidence of behavioral problems in both externalizing and internalizing domains (mainly anxiety and depression). Our findings agreed with other studies, which showed a relationship between asthma and internalizing behaviors generally **(Mrazek et al 1998).**

In a more recent review, the authors showed that in child/adolescent populations with asthma, up to one third met criteria for co-morbid anxiety disorders **(Katon et al., 2004)** particularly children with severe asthma **(Ortega et al, 2004**). Additionally, a link between higher levels of global internalizing symptoms and childhood asthma has been shown **(Gillaspy et al., 2002).** We found significant differences between asthmatics and controls as regard to attention problems. However, **Jonathan et al. (2006)** didn't find such affection.

Robert Finn (2003) studied the effect of asthma on sleep and attention of children by Questionnaires administered to the children's parents. The study revealed a significant difference between asthmatics and controls.

James et al (2007) showed that on top of physical symptoms like coughing, wheezing, and difficulty of breathing, children with asthma are also at increased risk of behavioral, emotional, and developmental problems. According to this study, parents of children with asthma were twice as likely to report that their child has severe problems with behavior, emotions, concentration, or getting along with others. The study also found that children with asthma are at increased risk for: attention deficit hyperactivity disorder (ADHD), depression behavioral and conduct problems and learning disabilities. ADHD was twice as common among children with asthma and three times more common among those with severe asthma. These results are consistent with our results in which we found significant diminution in asthmatics compared to controls as regard to psychosocial problems.

Asthma has medical, psychological and physical effects on school age children. The flare-up of asthma may lead to impaired daily function and absence from school. A study from California showed that on average, 7 children with active asthma missed 2.6% of school days per year. Sixty six percent of the studied cases mentioned that bronchial asthma affected their school attendance and they missed several school days. We have to consider this finding as a warning signal to give more attention to the role

of health education as an important preventive tool for many health problems, which in turn affect the school attendance and the scholastic achievement of the students.

Calam et al 2005 documented lower scores on a measure of attention and concentration for children with asthma which is consistent with our findings. Because behavioral problems are associated with poorer school adjustment and academic achievement, the identification and treatment of problems at this young age potentially could prevent subsequent disruptive behaviors and school difficulties (**Raver 2002**). Agreeing with our findings, a research suggested that children with asthma experience more internalizing and total behavior problems than healthy children **(Klinnert et al, 2000).**

Rosa Alati et al (2005) provided information on the association between both asthma prevalence and internalizing symptoms but didn't report any association between externalizing symptoms and prevalence of asthma. Their number of asthmatics was 5153 and they used different methods of assessment**.** We found a greater prevalence of internalizing behavior problems among children and adolescents who had asthma compared with non asthmatics. These results are consistent with the results of **Craske et al, 2001.** Consistent with the findings of **Linda et al(1989)**, in this study, academic performance and intelligence test scores indicated that, overall, the academic capabilities of children with asthma were less, compared with healthy children of the same socioeconomic status.

We noticed significant effect of bronchial asthma on cognitive and behavioral functioning of asthmatic children. These findings are consistent with **Naude and Pratorius (2003).** Children with asthma may be at risk for decreased school functioning due to acute exacerbations, increased absenteeism, iatrogenic effects of their asthma medication, and the stress associated with a chronic illness. Factors that may contribute to poor school performance among children with asthma include iatrogenic effects of oral steroids, poor medical management of the disease, and psychological problems **(Marianne et al, 1993).**

Bender and Bruce (1995) discussed the impact of asthma on children's school achievement. They found negative effect on the educational process, consistent with our results. They suggested that the cause may be due to medications that produce mild, temporary changes, affecting learning and classroom performance. For most asthmatic children, their illness does not result in permanent brain function changes that compromise their educational adaptation and performance. Increased school absence, stress of chronic illness, isolation from peers, diminished physical activities, reduced adult expectations and self esteem, and depression can compromise children's academic adaptation and progress. Co-occurrence of factors like severe illness, poverty, and family dysfunction may increase the risk for educational and psychosocial impairment. In our study, there is no opportunity to discuss the effects of such factors in the asthmatics.

Epidemiological studies showed that roughly one in ten children under the age of 15 suffers from a chronic disease. Other epidemiologic studies estimated that one third of children under 18 years of age are suffering from one or more chronic disorders or diseases**. (Costello et al 2006, Shah et al 2006 and Gallasi et al 2006)** In addition, there is an increased prevalence of learning and speech difficulties, sensory dysfunctions, mental handicaps and behavioral problems. **(Smith, 2003 and Williams et al, 2006)**. In our study chronic asthmatics and non asthmatic chest troubles (chronic diseases) were at increased risk of behavioral problems than healthy children.

CONCLUSION

1-Children with chronic asthmatic chest troubles represent a population at possible high risk for mental and psychosocial maladjustment.

2-Asthmatic children have more psychosocial problems than healthy children.

3-Asthmatic children have lower cognitive abilities and academic performance than healthy children.

4-Chronic asthmatic chest troubles have retarded weight and height compared to healthy children.

5-Medical school training needs to be more focused on the psychosocial issues and psychiatric disorders that affect adolescents with chronic illness rather than on the specific biological factor issues associated with the medical illness itself. Psychosocial issues and psychiatric disorders are clearly important factors affecting adolescents with chronic illness.

ABSTRACT: A field experiments were carried out during the two successive seasons of 2007/2008 and 2008/2009, in Qualubia Governorate, Egypt, to study the effect of different sources of potassium fertilizer (banana residue and potassium sulphate) on yield, and chemical composition of herbs and flowers of *Calendula Officinalis***.** It had been deduced that application of potassium fertilizer from different sources; potassium sulphate and banana residue were effective in increasing all tested growth yields compared with unfertilized treatment. Data also, showed that mixing potassium sulphate or/ and banana residue led to a marked increase in fresh and dry weight of herbs and flowers as compared with application of potassium sulphate or/ and banana residue solely in both seasons**.** Data also, showed that mixing potassium sulphate or/ and banana residue increased N and P and K content and uptake as compared with the control, potassium sulphate and banana residue alone.

[Yassen, A.A; Habib, A. M.; Sahar, M. Zaghloul, and Khaled, S.M. Effect of different sources of potassium fertilizers on growth yield, and chemical composition of *Calendula Officinalis*. Journal of American Science 2010;6(12):1044-1048]. (ISSN: 1545-1003). http://www.americanscience.org.

Key words: *Calendula Officinalis* - potassium fertilizer - banana residue - growth – yield - NPK.

INTRODUCTION

Calendula Officinalis (Pot Marigold) is a plant in the genus Calendula (marigolds), in the family Asteraceae. It is probably native to southern Europe through its long history of cultivation makes its precise origin unknown, and may be of garden origin. It is also widely naturalized further north in Europe (north to southern England) and elsewhere in warm temperate regions of the world.

Calendula Officinalis is used for the treatment of skin disorders and pain, and as a bactericide, antiseptic and anti-inflammatory Fuchs *et al.*, and (2005) Bolderston *et al.*, (2006). The petals and pollen contain triterpenoid esters (an anti-inflammatory) and the carotenoids flavoxanthin and auroxanthin (antioxidants, and the source of the yellow-orange coloration) Hamburger *et al.*, (2003) and Bashir *et al.*, (2006).

Potassium is a multifunctional versatile nutrient indispensable for plants. In plants, the function of K has several roles, such as enzyme activation, stimulation of assimilation and transport of assimilate anion / cation balance as well as water regulation through control of stomata Krauss and Jin Jiyun (2000) Zhou *et al.*, (2006) and TAN De-shui (2007). Dutta *et al.*, (2001) Balliu and Ibro, (2002) and Ali and Mowafy (2003) and Gent, (2004) and Liu, *et al.*, (2008) indicated that adding potassium fertilizer significantly increased number of branches and yield in crops.

Singh *et al.*, (2005 and 2007) and Munnu Singh and Ganesha Raoa (2009) found that application of N and K produced significant higher patchouli herbage and compared with controls. Similarly, N and K uptake were also higher compared with controls.

This field experiment was, therefore, conducted to investigate the influence of different sources of potassium fertilizer on yield and chemical composition of herbs and flowers of *Calendula Officinalis.*

MATERIALS AND METHODS

Two field experiments were carried out during two successive seasons of 2007/2008 and 2008/2009, in Qualubia Governorate, Egypt, to study the effect of potassium fertilizer on yield, and chemical composition of herbs and flowers of *Calendula Officinalis.*

Prior to any practices, a composite soil sample was taken from the soil surface (0-30 cm) of the experimental site, air dried, sieved by 2 mm sieve and analyzed (table 1). The physical and chemical

properties of soil were determined according to Chapman and Pratt (1961).

Table (1) some characteristics of the experimental site in two seasons

seasons	Physical properties				Chemical properties						
	Sand	Silt	Clay	Texture	pH	EC dSm^{-1}	$CaCO_3$ %	OM %	N	P	K
	%								(ppm)		
07/08	14.1	26.9	59.0	Clay	8.20	0.66	2.80	1.40	115	2.11	26.3
08/ 09	13.2	27.8	59.0	Clay	7.97	0.59	3.11	1.60	120	2.20	25.4

Potassium fertilizer at a rate of (50kg K/ fed) and two sources of potassium, one type of organic material (Banana residues) and the other inorganic potassium (potassium sulphate) were added. Application rate of organic matter used to depend on its content of potassium and the total required K (50 kg K/ fed), which added by organic material only and / or by complete the rest by K fertilizer as follows:

- Control (recommended doses)
- 50 kg K / fed (K_2SO_4)
- 10 kg K / fed (Banana residues) + 40 kg K / fed (K_2SO_4)
- 20 kg K / fed (Banana residues) + 30 kg K / fed (K_2SO_4)
- 30 kg K / fed (Banana residues) + 20 kg K / fed (K_2SO_4)
- 40 kg K / fed (Banana residues) + 10 kg K / fed (K_2SO_4)
- 50 kg K / fed (Banana residues)

From the above mentioned treatments that increasing K fertilizer associated with decreasing in the amount of organic material applications.

The seeds of *Calendula Officinalis* L. plants were kindly provided by the Department of Medicinal and Aromatic Plants, Ministry of Agriculture, Egypt.

Seeds were sown on October 1st during both seasons. The experimental design was complete randomized blocks with five replicates. The experimental area (plot) was $2m^2$ (2m x 1m) containing 4 rows; and the distance between the hills was 25cm and 50 cm apart. Thinning for one plant/hill was done 45days after sowing. The irrigation was carried out whenever plants needed.

All agricultural operations other than experimental treatments were done according to the recommendations of Ministry of Agriculture; Egypt Chemical analysis of used organic fertilizer (Banana residues) is presented in table, 2.

Table (2): Chemical analysis of Banana residues used in this study.

Contents	pH 1:20)	EC dSm^{-1} 1:20)	OM %	O.C %	N %	P %	K %
Banana residues	8.72	3.38	76.16	44.18	1.34	0.59	5.92

Plant samples and analysis

Fresh and dry weights (g/plant) of herbs and flowers of *Calendula Officinalis* which dried at 70 ^{O}C. were recorded. The following chemical analyses were determined: nitrogen, phosphorus, and potassium according to the methods described by Cottenie *et al.*, (1982). Collected data was subjected to statistical analysis of variance according to Snedecor and Cochran (1980). Physical and chemical properties of the soil were determined according to Chapman and Pratt (1961)

RESULTS AND DISCUSSION

Effect of potassium fertilizer on vegetative growth:

It is quite clear from the data presented in table (3) that application of potassium fertilizer from different sources; inorganic (potassium sulphate) and organic (banana residue), affected herbs and flowers of *Calendula Officinalis.* Fresh and dry weights were significantly increased in first and second seasons when compared with the control Singh, *et al.*, 2007 and Munnu Singh, and Ganesha Raoa, 2009) found that potassium application increased growth parameters (fresh and dry plant weight) as compared with control (no K fertilizer).

Results mentioned above indicate that superiority of fresh and dry weight of herbs and flowers under K application might be due to the role of K in the enhancement and development of plant tissues through the synthesis of simple sugars and starch and also, the translocation of carbohydrates and protein synthesis.

Comparing application of potassium fertilizer, as potassium sulphate and as compost (banana residue), data showed that mixing potassium sulphate or/ and banana residue led to marked increase in fresh and dry weight of herbs and flowers as compared with application of potassium sulphate or/ and banana residue solely in both seasons (El- Ghadban 1989), investigating *Mentha viridis*, showed that K and organic fertilizer were generally more effective in increasing fresh and dry weight of herb. The data of dry weight followed a nearly similar trend of fresh weight in herbs and flowers in both seasons.

The maximum recorded values were 14.9 and 13.2g / plant dry weight in flowers and 24.2 and 24.6g / plant in herbs in first and second seasons respectively. Similar trend noticed with fresh weight in herbs and flowers in both seasons.

From the data presented in table (3) clearly the high value of fresh and dry weight of herbs and flowers was obtained when K was added at a rate of 20kg K/ fed as potassium sulphate + 30kg K / fed as an organic source (banana compost) in both seasons.

Table (3) effect of potassium fertilizer on fresh and dry weight (g / plant) on herbs and flowers of *Calendula Officinalis.*(in both seasons)

Treatments		Flowers				Herbs

Org: banana residue Inorg : potassium sulphate

Chemical composition:

Data of nitrogen and phosphorus, content and uptake in the various sources of potassium fertilizers application treatments on herbs and flowers of *Calendula Officinalis* in the two successive seasons are presented in tables (4 and 5). Generally, the present results indicate that, nitrogen and phosphorus, content and uptake increased as compared with the control treatment. These results were on line with those reported by Liu *et al.,* (2008) and Munnu Singh and Ganesha Raoa (2009)

Data also, showed that application of potassium fertilizer in different sources inorganic (potassium sulphate) and organic material (banana residue) increased N and P content and uptake as compared with potassium sulphate and banana residue alone. The highest values of N and P were recorded at 30 kg K / fed as an organic source (banana residue) + 20kg K/ fed as potassium sulphate application (2.00 and 2.12% N) and(0.41 and 0.44% P) in flowers and (1.54and 1.58% N) and (0.28 and 0.26% P) in herbs in the two successive seasons, respectively.

Concerning the effect of potassium application on potassium content and uptake it is evident to data that the previous mineral in all plant organs, in the tow growing seasons, were increased by using potassium, especially by using the mixture potassium sulphate with banana residue. Similar conclusion was also reported by Singh *et al.,* 2005 and 2007.

Abstract: The packing of meat in retail markets plays important role in controlling of microbial load. Trails for extension of shelf-life of meat was studied during chilling. The comparative between the different types of packing as well as compared with fresh and chilled meat have low available data. Therefore, this study was carried out to assessment the effect of packing (Aerobically and anaerobically) on chilled meat as compared with fresh ones in retail market.

Keywords: packing; meat; retail market; microbial load

Introduction

The packing of meat in retail markets plays important role in controlling of microbial load. Trails for extension of shelf-life of meat was studied during chilling **(White et al, 1988; Nortje et al, 1990;Cliver and Riemann, 2002 and Ashton et al, 2006)** as well as the effect of packing in aerobic **(Byun et al, 2003)** and anaerobic **(Plaatjies et al, 2004)** was done for reduction the microbial load on retail meat.

The acceptable limits of microbial load in meat cuts was stated by **(ICMSF, 1986, Grau and vanderlinde, 1990 park et al, 1994 and E.O.S.Q.C, 2001-2004)** as well as the offensive odour and change in colour were appeared when the count reached 10^7CFU/g **(Jay, 1986; Shelef et al, 1997; Moje, 1999 and Byun et al, 2003).**

The comparative between the different types of packing as well as compared with fresh and chilled meat have low available data.

Therefore, this study was carried out to assessment the effect of packing (Aerobically and anaerobically) on chilled meat as compared with fresh ones in retail market.

Material & Methods

1- Experimental samples:

Seven kilograms of fresh beef were obtained from recent slaughtered animal after arrival of the meat to butcher's shop. The collected meat was taken from hindquarter after preparation (without visible fat). The collected meat was rapidly transferred as possible to laboratory in ice box with minimum delay.

2- Experimental design:

The techniques recommended by Gill et al. (2002) was applied as follows:

The collected meat was divided into two parts:

- The first part was sliced to samples; each weighed 100 g and 7 x7 x 0.5 cm in dimensions; then, kept at room temperature (about 25-30ºC) and daily examined (3 samples each time) till spoilage.
- The second part was divided into samples as previously mentioned, then kept into three groups at chilled temp (5ºC), the first group was preserved without packing (aerobic) and the secand group aerobically was packed in polyethylene bags and finally, third group, was anaerobically (vacuumed) packed. The samples were examined with 48 hours intervals (3 samples in each time).

3- Preparation of samples.

The techniques recommended by **AOAC (2000)** was applied as follows:

4- Techniques:

i) Aerobic plate count at 35ºC (mesophiles).

ii) Aerobic plate count at 25ºC (Psychrotrophs).

iii) Enumeration of coliforms (MPN).

iv) Isolation and identification of *E. coli*.

v) Isolation and Identification of Salmonellae.

vi) Determination of *Staphylococcus* count.

vii) Isolation and identification of *Staphylococcus aureus.*

viii) Isolation and identification *of Listeria monocytogenes*.

Experimental design (Gill et al., 2002):

DISCUSSION

- From the results achieved in Table (1) fig. (1), it was evident that the mean value of aerobic plate count of fresh meat at 1st day was $8 \times 10^5 \pm 5 \times 10^5$ organisms/g while it was reached to $9 \times 10^8 \pm 10^7$ organisms/g at 5th day. Aerobic plate count was significantly increased at ($p<0.05$) at the 5th day, constituting $9 \times 10^8 \pm 10^7$ organisms/g. Concerning psychrotropic count, it was $2 \times 10^4 \pm 2 \times 10^3$ organisms/g as well as it was reached to $9 \times 10^5 \pm 2 \times 10^5$ organisms/g at 5th day. There is a significant increase in psychrotrophic count at 5th day ($9 \times 10^5 \pm 2 \times 10^5$ organisms/g.).
- Most probable number of coliforms was $6.7 \times 10 \pm 1.7 \times 10$ organisms/g at the first day while it was reached to $10^3 \pm 4 \times 10^2$ organisms/g at the 5th day. It was significant at ($P < 0.05$) at 4th and 5th days, each constituting, $8 \times 10^2 \pm 2 \times 10$ and $10^3 \pm 4 \times 10^2$ organisms/g, respectively. Dealing with most probable number of fecal coliforms, it was $2.8 \times 10 + 0.7 \times 10$ organisms/g at 1st day while it was reached to $10^3 \pm 3 \times 10^2$ organisms/g at 5th day. A significant increase in fecal coliforms (MPN) at 5th day, constituting $10^3 \pm 3 \times 10^2$ organisms/g. *Staphylococcus aureus* count was $5 \times 10^2 \pm 2 \times 10^2$ organisms/g at 1st day while it was reached to $2 \times 10^4 \pm 4 \times 10^3$ organisms/g at 5th day. There are a significant differences between *Staphylococcus aureus* counts starting from 2nd day till the 5th day, each constituting $2 \times 10^3 \pm 6 \times 10^2$ and $2 \times 10^4 \pm 4 \times 10^3$ organisms/g, respectively.
- The total bacterial counts for microbial species is freshly cut meat surfaces are likely to vary. It may be attributed to these organisms are mainly derived from exterior and the gut of animal but also from knives, other utensils; butchery tables. Therefore, variations in counts often reflect the hygienic conditions under which that meat produce. This agrees with that reported by **Nottingham (1982).** Aerobic storage of meat allowed total aerobic counts to reach high levels. The growth of initial bacterial counts in fresh meat may enhanced by the time of storage due to highly enrichment of meat with nutrient elements required for multiplication of microorganisms. The shelf-life of the meat will depend upon the rate of spoilage. Spoilage microorganisms may represent only a very small part of the initial flora they will consistently become predominant in raw meat under storage conditions **(Forsythe and Hayes, 1998 & Skandmis and Nychas, 2002).** In this respect, **Ingram (1971)** stated that some 10^8 bacterial cells per gram may be necessary to induce measurable spoilage in food over a number of days of storage. On the other hand, **Gardner (1965)** stated that sliced meats hold at 15 or 10ºC develop off-odors after to five days storage and surface slime is evident at about seven days.
- The present data in table (2) fig.(2), it is revealed that the aerobic plate count of meat at 1st day was $6 \times 10^4 \pm 2 \times 104$ organism/g. Such count was gradually increased during storage at chilling (5ºC) to reach $4 \times 10^8 \pm 10^7$ organisms/g at 11th day. Psychrotrophic count of meat/gm at 1st day of chilled storage was $2 \times 10^2 \pm 5.7 \times 10$ as well as it was highly increased to reach $8 \times 106 + 106$ organisms/g after 11th day chilled storage. There is a significant differences at ($P<0.05$) in counts of each of aerobic plate and psychrotrophic at 11th day of storage. Most probable numbers of each of coliforms and fecal coliforms were $2.1 \times 10 \pm 0.7 \times 10$ and $0.4 \times 10 \pm 0.1 \times 10$ organisms/g, respectively at the 1st day. After 11th day of chilled storage, such counts were reached to $2 \times 10^2 \pm 10^2$ and $5.3 \times 10 \pm 2 \times 10$ organisms/g; respectively. No significant variations in both most probable numbers of each of coliforms and fecal coliforms during chilled storage at $P<0.05$.
- The Staphulococcus aureus count was $10^2 \pm 3 \times 10$ organisms/g at 1st day of chilled storage while it was reached to $3 \times 10^4 \pm 2 \times 10^4$ organisms/gm after 11th day storage. There is a significant differences between the Staphylococcus counts during chilled storage at $P< 0.05$.

The obtained results were in accordance with that achieved by **Ayres (1960) and Forsythe and Hayes (1998).**

- The general viable count should be less than 10^7 organisms/g in chilled meat **(ICMSF, 1986).**
- The bacterial growth is usually inhibited at chilling room temperature, the meat continues to lose water by evaporation, and the air, becoming humid, creates a condition which is suitable for the growth of mould. This held the view reported by **Gracey and Collins (1992)** and **(Patterson and Gibbs, 1978).**
- The gradual variations in microbial counts during chill storage may be attributed to the storage in chilled temperatures at 5ºC or below a definite lag phase is apparent. The length of this phase depends on storage temperature and extends for 24 hours at 5º C before the onset of the first signs of spoilage is extended and off-odor and slime production take 8 and 12 days, respectively, to develop at 5ºC and 16ºC. This substitutes the hypothesis mentioned by **Forsythe and Hayes (1998).**
- On contrary, **Gould (1995)** stated that, in chill-stored proteinaceous foods such as meat, this generally results in the inhibition of Gram-negative e.g. Enterobacteriaceae whilst the Gram-positive

bacteria become the dominant organisms. On the other hand, **Farber (1991)** stated that the oxygen stimulate the growth of aerobic bacteria and can inhibit the growth of strictly anaerobic bacteria, although there is a very wide variation in the bacterial counts according to sensitivity to oxygen.

- From table (3) fig. (2), it was achieved that the aerobic plate count of aerobically packed meat at 1st day was $5 \times 10^3 \pm 8 \times 10^2$ organisms/g. It was reached to $3 \times 10^6 \pm 10^6$ organisms/g at7th day. Finally, it became $8 \times 10^7 \pm 5 \times 10^6$ organisms/g at the end of the experiment (11th day). Dealing with psychrotrophic count in aerobic packed meat, it was $2 \times 10^2 \pm 8.8 \times 10$.organisms/g at first day of storage. At the end of the experiment, it was reached $4 \times 10^5 \pm 10^5$ organisms/g at 11th day. There are significant variations in either of aerobic plate count and psychrotrophic count at 11th day of storage of aerobically packed meat at $P< 0.05$.
- Most Probable number of coliforms and fecal coliforms of aerobically packed meat were $4 \times 10 \pm 10$ and $0.3 \times 10 \pm 0.1 \times 10$.organisms/g, respectively at the 1st day of storage as well as they were reached to $10^3 \pm 3 \times 10^2$ organisms/g at 11th day of storage. A significant variation was observed between the Most Probable number of both coliforms and fecal coliforms during storage at ($P <0.05$). Concerning *Staphylococcus aureus*, it was $10^2 \pm 8.8 \times 10$ organisms/g, it was gradually increased; reaching $8 \times 10^4 \pm 3 \times 10^2$ organisms /g at the end of the experiment (11th day). There is a significant differences in count stating from 9th and 11th day of storage at $P <0.05$.The growth of microorganisms on vacuum-packed fresh meats may be attributed to initial bacterial contamination. Subsequent growth is slow so that by the time the final total count of 10^7 per gram will reached. The gradual changes in the spoilage flora are observed. This held with that reported by **Egan and Roberts (1987).**
- Packing of meat may be an effective method for meat shelf-life extension. The bacterial counts including the spoilage-related microbial groups had changes depending on the packing condition. When the beef was packed in air, all microbial groups showed viable counts higher than those of the other packing conditions. This in-agreement with that reported by **Skandamis and Nychas (2005); Ercolini et al. (2006) and Koutsoumanis et al. (2006).** Microbial spoilage on aerobically packed meats can be detected as off odor when surface counts reach 10^7 organisms/gm **(Jay, 1986).**
- From the present data reported here in (table 4) and fig.(2), it is evident that the aerobic plate count and psychrotrophic count of anaerobically packed meat (vacuum packed) at 1st day of storage were $10^3 \pm 4 \times 10^2$ and $10^2 \pm 25 \times 10$ organisms/g, respectively. Such counts reach $7 \times 10^7 \pm 2 \times 10^7$ and $10^6 \pm 8 \times 10^5$ organisms/g after 11th day of storage. There is a significant variations between aerobic plate counts during storage period at $P<0.05$ while this variation was significantly only on 11th day storage in psychotropic count.
- Either of Most Probable number of coliforms and fecal coliforms of anaerobic packed meat at 1st day were $0.32 \times 10 \pm 0.2 \times 10$ and $0.3 \times 10 \pm 0.1 \times 10$ orgamisms/g, respectively while it reached to $4 \times 10 \pm 3 \times 10$ and $4 \times 10^2 \pm 3 \times 10^2$ organisms/g, respectively; at the end of the experiment (at 11th day). There is only significant variation in counts during storage at 11th day in both of coliforms and fecal coliforms at $P< 0.05$.
- Concerning Staphylococcus aureus, the count was $10^2 \pm 4 \times 10$ organisms/g as well as it was not change till the 5th day. It reached to $3 \times 10^4 \pm 2 \times 10^4$ organisms/g at 11th day of storage. A significant variations ($P <0.05$) was observed in the day and continued till the end of experiment (11th day).
- The change of spoilage-related microbial flora during storage of beef under different packing condition. The large variation of gas composition during packing due to microbiological growth, which, in the contrary, is inhibited by using anaerobic condition (under vacuum). This was confirmed by suggestion reported by **Kennedy et al. (2004).**
- Vacuum packages prevent the growth of high spoilage potential aerobic microorganisms. Reaching potential spoilage numbers under anaerobic storage conditions does not necessarily coincide with the onset of spoilage. On contrary, **Sadler and Swan (1997)** stated that the storage life was shorter in vacuum-packing because a small amount of oxygen can enter the pack, allowing more rapid bacterial growth, and because there is no inhibitory carbon dioxide atmosphere.
- Vacuum packing of fresh meats provides sufficient shelf-life of primal cuts for long-term storage and intercontinental transport. Vacuum package beef held in films with oxygen permeability had a storage life of 11 weeks at 0ºC. The extension of the shelf- life of vacuum packed meat as compared with aerobic packed may be attributed to change of microflora from aerobic to anaerobic organisms in the vacuum packaged meat. This substitutes the hypothesis reported by **Pierson et al. (1970); Seideman et al. (1976) & Lee and Yoon (2001).**
- On the present data, it could be concluded that, the anaerobically packing of retail meat in markets was the preferred method for extension of shelf

life of meat as compared with aerobic packing. The suggestive measures showed that the vacuum pack of fresh meat provides sufficient shelf life of cuts at 1-5ºC for long term storage then aerobic pack of chilled beef which prefer to butchers. Finally cold storage under different packing condition for freshness of meat would benefit both consumers and meat industry**.**

- Application of HACCP (Hazard Analysis Critical Control Points) system in retail meat production and industries.

SUMMARY

This experiment was carried to assessment the effect of packing (aerobically and anaerobically) on chilled meat as compared with fresh ones. Aerobic plate count was significantly increased at $p<0.05$ at the 5th day, constituting $9 \times 10^8 \pm 10^7$ organisms/g. There is a significant increase in psychrotrophic count at 5th day $9 \times 10^5 \pm 2 \times 10^5$ organisms/g. Most probable number of coliforms was significant at $P < 0.05$ at 4th and 5th days, each constituting $8 \times 10^2 \pm 2 \times 10$ and $10^3 \pm 4 \times 10^2$ organisms/g, respectively. A significant increase in fecal coliform (MPN) at 5th day, constituting $10^3 \pm 3 \times 10^2$ organisms/g. Staphylococcus aureus count starting from 2nd day till the 5th day, each constituting $2 \times 10^3 \pm 6 \times 10^2$ and $2 \times 10^4 \pm 4 \times 10^3$ organisms/g, respectively.There is a significant differences at $P<0.05$ in count of each of aerobic plate and psychrotrophic at 11th day of storage. No significant variation in both most probable numbers of coliforms and fecal coliform during chilled storage at $P<0.05$.There is a significant differences between the Staphylococcus counts during chilled storage at $P< 0.05$. There are significant variations in either of aerobic plate count and psychrotrophic count at 11th day of storage of aerobically packed meat at $P< 0.05$. A significant variation was observed between the Most Probable number of both colifrm and fecal coliforms during storage at $P <0.05$. There is a significant difference in Staphylococcus *aureus* count stating from 9th and 11th day of storage at $P <0.05$. Significant variations between aerobic plate counts during storage period at $P <0.05$ while this variation was significantly only on 11th day storage in psychotropic count. There is only significant variation in count during storage at 11th day in both of coliforms and fecal coliforms at $P< 0.05$. A significant variation ($P <0.05$) was observed in Staphylococcus *aureus* between the days and continued till the end of experiment (11th day). Suggestive for measure extension shelf-life time of marketed retail meat in butcher's shops was discussed.

الملخص العربي

أجريت هذه الدراسة لمعرفة مدى تأثير والتغليف (هوائى ولا هوائى) على المبردة مقارنة باللحوم الطازجة وذلك فى 4 تجارب:

1) **التجربة الأولى** : حفظ عينات اللحوم الطازجة فى درجة حرارة الحجرة 25–30 ^{5}م التى تمثل محل الجزارة حتى الفساد وكانت من يوم الذبح حتى اليوم الخامس والفحص الميكروبيولوجي لهذه العينات.
2) **التجربة الثانية** : حفظ عينات اللحوم الطازجة والغير معبأة فى درجة حرارة 1–5 ^{5}م حتى الفساد فيحدد الزمن والحالة الميكروبيولوجية لصلاحية اللحوم فى التبريد بدون تغليف حتى اليوم الحادي عشر.
3) **التجربة الثالثة** : حفظ عينات اللحوم المعبأة هوائياً فى درجة حرارة 1–5 ^{5}م حتى الفساد فى اليوم الحادي عشر.
4) **التجربة الرابعة** : حفظ عينات اللحوم المعبأة لاهوائياً فى درجة حرارة 1–5 ^{5}م حتى اليوم الحادي عشر الذى حدث به الفساد وتم الفحص الميكروبيولوجي ومنها ومنها الوصول إلى طريقة الحفظ الأمثل وتحديد درجة الحرارة المثالية لحفظ جودة اللحوم لأطول فترة ممكنة.

وأظهرت النتائج الآتية :

التجربة الأولى : متوسط العد الميكروبات الهوائية فى اليوم الأول كان العد 8×10 ^{5} ± 8× 10 ^{5} وزادت 3× 10 ^{7} ± 10 ^{7} ووصلت إلى الفساد فى اليوم الخامس وكانت 9×10 ^{8} ±10 ^{7} ميكروب/جرام ومتوسط الميكروبات المحبة للبرودة بدأت فى الزيادة من اليوم الثاني حتى اليوم الخامس ووصلت والميكروب القولوني زاد فى اليوم من اليوم الثاني إلى اليوم الخامس 10 ^{3} ± 3×10 ^{2} ميكروب/جرام.

والميكروب المكور الذهبي بدأت فى الزيادة من اليوم الثاني حتى الفساد فى اليوم الخامس من 5×10 ^{2}± 2×10 ^{2} و 2×10 ^{4} ± 4×10 ^{3} ميكروب/جرام.

وهذه الطريقة للحفظ غير مجدية حيث أنها تفسد اللحوم بسرعة ويرجع هذا إلى تلوث الأسطح الملامسة للحوم.

التجربة الثانية : متوسط العد الميكروبات الهوائية للحوم المبردة الغير مغلفة بدأت فى الزيادة والميل إلى الفساد من اليوم السابع وبلغت أقصاه فى اليوم الحادي عشر 4×10 ^{8} ± 10 ^{7}ميكروب/جرام. الميكروبات المحبة للبرودة بدأت فى الزيادة من اليوم التاسع حتى اليوم الحادي عشر 8×10 ^{6} ± 10 ^{6}. الميكروب القولوني يبدأ يتزايد من اليوم السابع حتى أقصاه فى اليوم الحادي عشر. الميكروب العنقود الذهبي بدأ فى الزيادة تدريجياً من اليوم الحادي عشر 4 × 10 ^{4} ± 2 × 10 ^{4}.

التجربة الثالثة : اللحوم المبردة المعبأة هوائياً قد يتضح أن متوسط العد الكلي للميكروبات الهوائية تبدأ فى التزايد التدريجي فى اليوم السابع حتى اليوم التاسع ويرتفع أقصاه فى اليوم الحادي عشر 5×10 ^{3} ± 8× 10 ^{2} ، 3×10 ^{6} ± 10 ^{6} ، 8× 10 ^{7} ± 5× 10 ^{6}ميكروب/جرام على التوالي.

والميكروبات المحبة للبرودة أيضا تبدأ الزيادة من اليوم السابع تدريجيا حتى اليوم التاسع يبلغ أقصاه عن النسبة المقررة فى المواصفات القياسية المصرية وكذلك الميكروب المكور العنقود الذهبي وجدت أنها تبدأ فى الزيادة من اليوم التاسع وتصل إلى الفساد فى اليوم الحادي عشر 8×10 ^{4} ± 3×10 ^{2} ميكروب/جرام. الميكروبات القولونية فقد وجدت أنها تبدأ من اليوم السابع فى الزيادة حتى اليوم التاسع ثم فى اليوم الحادي عشر.

التجربة الرابعة : اللحوم المبردة المعبأة لاهوائيا وجد أن المتوسط العد الكلي للميكروبات الهوائية والمحبة للبرودة تبدأ فى الزيادة تدريجياً حتى اليوم الحادي عشر 7×10 ^{7}± 2×10 ^{7} 10 ^{6} ± 8× 10 ^{5} ميكروب/جرام على التوالي. والميكروبات القولونية وجدت أنها تبدأ فى الزيادة فى اليوم التاسع إلى اليوم الحادي عشر حيث الفساد. وكان متوسط المكور العنقود الذهبي يبدأ فى الزيادة اليوم السابع ويصل إلى 4× 10 ^{4} اليوم الحادي عشر.

ومن هذه النتائج : اتضح ان حفظ اللحوم المبردة المعبأة لاهوائيا تحفظ اللحوم مدة 7–9أيام عند درجة حرارة 1–5م وتساعد على زيادة مدة الصلاحية لها. ثم يليها حفظ اللحوم المبردة المعبأة هوائياً فى زيادة مدة الصلاحية لحفظ اللحوم.

1. ناقشت الباحثة الأهمية الاقتصادية للميكروبات المعزولة وكذلك الأهمية الصحية لها والاقتراحات المناسبة اللازمة لحفظ اللحوم لأطول فترة ممكنة.

Abstract: Objectives: This study aimed to evaluate the diagnostic yield of estimation of serum cartilage oligomeric matrix protein (COMP) as a screening tool for osteoarthritis (OA) among patients with knee joint pain.
Patients & Methods: The study included 140 female patients with knee pain and 20 volunteers to donate blood as a control group for laboratory findings. All patients underwent full history taking, clinical examination for evaluation of pain severity using a visual analogue scale (VAS) and extent of patient mobility using mobility score (MS) and had knee anteroposterior radiographs that were scored using the Kellgren-Lawrence scoring (K-L score) system. Patients were classified according to K-L scores into: group A: pain plus no radiographic findings (K-L score=1), group B: pain plus doubtful or minimal radiographic findings (K-L score=1) and group C: pain plus radiographically determined OA (K-L score≥2). Venous blood samples were obtained from all patients and controls for erythrocyte sedimentation rate (ESR) determination and ELISA estimation of serum COMP and high-sensitivity C-reactive protein (hsCRP) levels. Results: Group C patients had significantly higher pain scores and lower MS compared to groups A and B. Mean patients' serum COMP levels was significantly higher compared to control levels and in group C compared both to controls and to groups B and A levels with significantly higher levels in group B compared to controls and group A. However, serum COMP levels were non-significantly higher levels in group A compared to control levels. There was a positive significant correlation between serum COMP levels and body mass index (BMI), pain VAS score and radiological grade and a negative significant correlation with MS. ROC curve analysis revealed that elevated serum COMP is a sensitive predictor and high BMI is a specific predictor for the presence of OA. Serum COMP at 1097.5 ng/ml was the best cutoff point with high sensitivity (87.7%), positive predictive value (PPV, 92.6%) and accuracy (84.3%) for differentiation between patient with and without OA radiological manifestations and serum COMP at 1290 ng/ml showed 100% specificity and PPV and accuracy rate of 65.7% for diagnosis of the presence of radiological findings of OA. Conclusion: Estimation of serum COMP level could be considered as screening modality for patients with knee pain and using cutoff point of 1097.5 ng/ml helps to define patients free of OA and cutoff of 1290 ng/ml could define patients with OA.

1. Introduction:

Arthritis is a chronic disease with a significant impact on the population. It damages the cartilage, synovium, and bone of the joints causing pain, impairment, and disability in patients. Current methods for diagnosis and monitoring the disease are only able to detect clinical manifestations of arthritis late in the process. However, with the recent onset of successful treatments for rheumatoid arthritis and osteoarthritis, it becomes important to identify prognostic factors that can predict the evolution of arthritis. This is especially critical in the early phases of disease so that these treatments can be started as soon as possible to slow down progression of the disease, [(1)].

A valuable approach to monitor arthritis would be by measuring biological markers of cartilage degradation and repair to reflect variations in joint remodeling. One such potential biological marker of arthritis is cartilage oligomeric matrix protein (COMP). In various studies, COMP has shown promise as a diagnostic and prognostic indicator and as a marker of the disease severity and the effect of treatment. This review highlights the progress in the utilization of COMP as a biomarker of arthritis, [(2)].

Articular cartilage is a multiphasic material with at least 2 major phases: a fluid phase composed of water and electrolytes, and a solid phase composed of chondrocytes located in lacunae together with matrix molecules that include collagen and

proteoglycans. The extracellular matrix of hyaline cartilage contains an elaborated collagen fibrillar network, which imparts its tensile strength and is essential for the mechanical stability and the proper function of the tissue, [3].

As articular cartilage degenerates in OA, so chondrocytes upregulate their biosynthetic activities, including type II collagen, as if to compensate for this damage. Only after secretion, as the molecules reach the extracellular space, the non-helical domains at the end; the procollagen type II amino-terminal propeptides and procollagen type II carboxy-terminal propeptides, are cleaved from the helical domain. The c-propeptide content and release from the cartilage is directly correlated with collagen synthesis, [4].

Cartilage oligomeric matrix protein is a member of the thrombospondin family of extracellular matrix proteins, [5]. COMP consists of five 87-kDa subunits held together by interchain disulfide bonds forming a 435-kDa pentameric protein. COMP is expressed in all types of cartilage, [6]. Immunohistological staining of articular cartilage has revealed a developmentally regulated localization of COMP to the chondrocyte territorial and interterritorial matrix, [7]. COMP binds in a zinc-dependent manner to collagen type I and type II and also to collagen type IX, [8]. COMP contains type 2 (epidermal growth factor-like) and type 3 (calmodulin-like) repeats in their central domains, [9]. It is becoming known that the mechanisms of cartilage matrix destruction such as roles of degradative enzymes and cytokines, so it is important to develop the reliable biomarkers to detect the early stage of cartilage destruction. The biomarker could be useful tool not only to understand the progression of joint destruction in osteoarthritis and rheumatoid arthritis but also to develop new treatment, [10]. Thus, the present study aimed to evaluate the diagnostic yield of estimation of serum COMP as a screening tool for OA among patients with knee joint pain.

2. Patients & Methods

The present study was based as screening study of patients attending the outpatient clinic of Rheumatology with knee joint pain. Only female patients were enrolled in the study to equalize the impact of gender on the serum level of COMP. Patients with history of knee trauma, rheumatoid arthritis, previous surgery at knee joint or previous treatment of osteoarthritis were excluded of the study. All patients underwent full history including duration of symptoms, mode of onset, precipitating and relieving factors and history of medical treatment. Patients' age, weight, height and body mass index (BMI) were determined.

Pain severity was assessed using a visual analogue scale (a 10 mm-scale, with "0" indicating no pain and "10" indicating worst pain ever), [11]. Local clinical examination was conducted for evaluation of the presence of swelling, stiffness, grinding or locking. The mobility score, which provides an estimate of the patient mobility ranging between being able to walk and undertake shopping unaided (score 9), through to being bedridden (score 0) was also estimated, [12].

Radiological examination to obtain anteroposterior radiographs of the knee in a weight-bearing extended position by using a standard radiographic technique and then radiographs were scored using the Kellgren-Lawrence scoring (K-L score) system, [13]: grade 0: normal knee, grade 1: doubtful and minimal OA of the knee, grade 2: mild OA of the knee, grade 3: moderate OA of the knee and grade 4: severe OA of the knee. The anteroposterior views characterize OA of the knee in the medial and lateral femorotibial compartments, with exclusion of the patellofemoral compartment. Patients were classified according to radiological findings into 3 supposed groups: group A: pain plus no radiographically determined OA (K-L score=0), group B: pain plus doubtful or minimal radiographically determined OA (K-L score=1) and group C: pain plus radiographically determined OA (K-L score≥2). Twenty healthy volunteers with no pain plus no radiographically determined OA of the knee and mobility score of 9 and accepted to give blood samples were included as control group for comparisons of laboratory findings.

Laboratory Investigation

All patients and controls gave fasting blood samples (1.6 ml blood for each 0.4 ml sodium citrate) for determination of ESR and another a 5-ml blood sample was collected in plain tube and allowed to clot and centrifuged at 3000 rpm for 10 minutes and serum was collected for ELISA estimation of:

1. Determination of serum hsCRP level using ELISA Kit (Phoenix Pharmaceuticals, Inc.). In the assay, 100 µl of each standard and samples were added into wells, covered and incubated for 2 hours at room temperature and then washed 4 times with wash solution. Then, 100 µl/well of anti-human CRP-HRP detection antibody were added, incubated for 2 hour at room temperature with gentle shaking and wash was repeated. TMB One-Step Substrate Reagent (100 µl/well) was added and wells are incubated for 25 minutes at room temperature. Reaction was terminated with 100 µl/well of stop solution and the degree of enzymatic turnover of the substrate is determined by dual wavelength absorbance

measurement at 450 nm immediately, [14].

2. Determination of serum COMP level using ELISA Kit (AnaMar Medical, Lund, Sweden). On the 1st day afternoon, serum sample was diluted 1/50 with dilution buffer and 75 µl of each standard and diluted samples were added into the pre-incubation plate (round bottom plate). Anti-COMP reagent (75 µl/well) was added, mixed on a shaker for 5 min and incubated overnight for about 15 hours at 4°C. On the 2nd day, 100 µl were transferred from the pre-incubation plate to the antigen coated plate and incubated at room temperature for 60 minutes. After wash for 3 times with wash solution, wells are emptied by trapping the strip on an absorbent tissue. Then, 100 µl/well of conjugate are added and wells are incubated for 60 minutes. After wash and drying, substrate reagent (100 µl/well) was added and wells are incubated for 50 minutes at room temperature. The degree of enzymatic turnover of the substrate is determined by dual wavelength absorbance measurement at 450 nm immediately, [15].

Statistical analysis

The obtained results were compared using Wilcoxon Rank test (Z-test) for unrelated data. The Receiver Operating Characteristic (ROC) curve was used to evaluate the predictability of serum COMP levels for the presence of OA and results were assured using the Regression multivariate analysis (Stepwise Method) to verify the diagnostic yield of combined measurements. The validity of multiple cutoff points to identify the valid cutoff points was assessed using the test validity characters including sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy for various cutoff points. Statistical analysis was conducted using SPSS statistical program, (Version 10, 2002). P value <0.05 was considered statistically significant.

3. Results

The study included 140 female patients fulfilled the inclusion criteria. Radiological findings identified 26 patients with K-L score=0 (Group A), 52 patients had K-L score of 1 (Group B), 32 patients had K-L score of 2, 18 patients had K-L score of 3 and 12 patients had K-L score of 4; thus, group C included 62 patients. Patients included in groups B and C were significantly obese with significantly higher body weight and BMI compared both to controls and to patients included in group A with non-significantly higher body weight and BMI in group A compared to controls and in group C compared to group B, (Table 1). Patients included in group C had significantly higher pain scores and significantly lower mobility scores compared to groups A and B, with non-significant difference in favor of group A, (Table 2, Fig. 1).

All patients showed significantly higher ESR levels and serum hsCRP compared to controls with significantly higher levels in group C compared to both group A and B and a significantly higher levels in group B compared to group A, (Table 3, Fig. 2).

Mean serum COMP levels estimated in patients (1331.6±264.2; range: 890-1940 ng/ml) was significantly higher compared to levels estimated in control group. Moreover, mean COMP serum levels estimated in patients of group C were significantly higher compared both to control group and to groups B and A levels. Furthermore, mean COMP serum levels estimated in patients of group B were significantly higher compared to control group and group A levels with non-significantly higher levels in group A compared to control group, (Table 4, Fig. 3).

There was a positive significant correlation between serum COMP levels and BMI, ($r=0.246$, $p=0.040$), pain VAS score, ($r=0.521$, $p<0.001$) and radiological grade, ($r=0.778$, $p<0.001$) and a negative significant correlation ($r=-0.397$, $p=0.001$) with mobility score, (Table 5).

Evaluating the diagnostic predictability of serum COMP for the presence of OA, as judged by radiological finding, in patients with knee joint pain using ROC curve analysis versus clinical data revealed that elevated serum COMP is a sensitive and high BMI as specific predictors for the presence of OA with AUC=0.065 and 0.856, respectively, both AUC are significant ($p<0.001$) versus the null hypothesis. Knee joint mobility score was found to be specific predictor but with AUC=0.272 which despite being significant ($p=0.011$) versus the null hypothesis was less significant compared to BMI, (Fig. 4).

Verification of the obtained results for a cutoff point of serum COMP for identification of patients with OA among those who had knee joint pain, irrespective of the clinical data, defined serum COMP at 1097.5 ng/ml as the best cutoff point with high sensitivity (87.7%), positive predictive value (92.6%) and accuracy (84.3%) for differentiation between patient with and without radiological manifestations of OA. On contrary, serum COMP at 1290 ng/ml showed 100% specificity and positive predictive value and accuracy rate of 65.7% for diagnosis of the presence of radiological findings of OA, (Table 6).

Table (1): Patients' demographic data

	Control	Patients

4. Discussion:

The detection of COMP in serum of studied population including patients and control indicated a fact that COMP, as a cartilage turnover marker is normally present in serum indicating continuous renewal of joint cartilage. This finding agreed with *Neidhart et al.,* [16] who found elevated serum COMP in seven of eight runners and during the run, the serum levels rose significantly, and gradually returned to baseline within 24 h. and attributed that elevated baseline levels of COMP might reflect increased joint matrix turnover due to prior extreme physical training, the reported significant increase during the run was possibly due to the severe physical strain on joint structures and concluded that serum COMP is a marker for distinct aspects of joint metabolism and/or damage in both disease and sport. Also, *Andersson et al.,* [17] reported that during normal daytime activities, serum COMP levels are constant and significantly decreased during the night indicating a rapid elimination of COMP once it has reached the circulation. Moreover, *Gordon et al.,* [18] tried to understand sources of variation in biomarkers for OA through evaluation of variation due to activity and food consumption and found all serum biomarkers increased after 1 h of non-exertional activity, but food consumption following activity was associated with a return of biomarker concentrations to baseline levels and demonstrated a positive association between the mean level of activity and serum COMP concentration.

Mean serum COMP levels estimated in patients was significantly ($P<0.05$) higher compared to levels estimated in control group and in patients with radiological evidence of OA compared both to control levels and to levels estimated in patients without radiological evidence of OA that were non-significantly higher compared to control levels. Moreover, there was a positive significant correlation between serum COMP levels and OA radiological severity and elevated serum COMP was found to be significant sensitive markers for differentiation between patients had or free of OA among patients had knee joint.

These results go in hand with the previously reported in literature concerning value of estimation of serum COMP in patients with OA; *Vilím et al.,* [19] found serum COMP positively correlated with knee joint space width both at baseline and after disease progression and knees that had progressed by two K-L grades were shown to have had significantly higher COMP levels at baseline and concluded that serum COMP has the potential to be a prognostic marker of disease progression. *Sharif et al.,* [20] found serum COMP concentration at baseline was significantly higher in the OA progressors compared with the non-progressors and the AUC was significantly higher in the progressors compared with the non-progressors and also that serum COMP concentrations were higher during periods of radiographic progression and identified periods of progression. *Fernandes et al.,* [21] reported that patients with symptomatic knee OA presented significantly higher serum COMP levels compared to healthy controls and to those with non-symptomatic narrowing of the articular space. Patients with clinical evidence of knee OA and without radiological abnormalities (K/L grade 0 or 1) had intermediate serum COMP levels, significantly higher than those observed in healthy controls.

Recently, *Kraus et al.,* [22] reported that serum COMP correlated negatively with total joint space narrowing burden. *Berry et al.,* [23] found COMP was significantly associated with a reduced rate of medial cartilage volume loss.

Regression analysis for estimated serum COMP levels versus clinical and demographic data for differentiation between cases with and without radiological findings defined estimation of serum COMP as significant predictor in two models and BMI in one model and test validity character determination for assigned cutoff points defined serum COMP at 1097.5 ng/ml as the best cutoff point with high sensitivity (87.7%), positive predictive value (92.6%) and accuracy (84.3%) for differentiation between patient with and without radiological manifestations of OA and serum COMP at 1290 ng/ml showed 100% specificity and positive predictive value and accuracy rate of 65.7% for diagnosis of the presence of radiological findings of OA. These finding go in hand with *Hunter et al.,* [24] who performed a logistic regression to examine the relation of levels of cartilage biomarker to the risk of cartilage loss in any knee and reported that with the exception of COMP, none of the other biomarkers was a statistically significant predictor of cartilage loss. *Kraus et al.,* [22] reported that biomarkers and demographics predicted 35-38% of variance in total burden of OA (total joint space narrowing or osteophyte).

The reported association between knee clinical and radiological features of OS, serum COMP and BMI spot line on a possible role for weight burden on the initiation and/or progression of OA and indicated the necessity for weight reduction as a prophylactic and/or therapeutic line for OA patients. Such assumption was supported by the findings of *Richette et al.,* [25] who investigated the effect of massive weight loss on knee pain and disability, low-grade inflammation and metabolic status and joint biomarkers in obese patients with knee OA and found massive weight loss improves pain and function and decreases low-grade

inflammation and concluded that change in levels of joint biomarkers with weight loss suggests a structural effect on cartilage.

In conclusion, estimation of serum COMP level could be considered as screening modality for patients with knee pain and using cutoff point of 1097.5 ng/ml helps to define patients free of OA and cutoff of 1290 ng/ml could define patients with OA. However, wider scale studies are recommended for establishment of cutoff points and defining the benefit of weight reduction as prophylactic and/or therapeutic modality.

Abstract: Pregnancy is the more prevalent stress in under feeding small ruminant with multiple bearing. Fifty Ossimi ewes of two years old and their body weight ranging between 35 and 50 kg were allotted into three groups; Group I: contains ten non pregnant non lactating ewes were used as control group. Group II: contains twenty single pregnant ewes* and Group III: contains twenty twin pregnant ewes used as experimental animals. Our study focused on the comparison between single and twin bearing ossimi ewes in the last four weeks of pregnancy and the day of parturition by measurement of reduced glutathione (GSH) level and the activities glutathione peroxidase (GSH-Px); glutathione reductase (GR-ase); glutathione-S-transferase (GST) and total superoxide dismutase (t-SOD) in erythrocytic haemolysate. In addition, glucose, non esterfied fatty acid (NEFA), Beta hydroxyl butyric acid (BHBA), cortisol, insulin and protein electrophoric patterns were measured in serum. Our results concluded that, In erythrocytic haemolysate the mean values of GSH-Px and GST in group II and III during the period of 2nd and last week before parturition and at the day of parturition were high significantly increased. While, GSH and t-SOD were high significantly decreased ($P<0.01$) and GR-ase activities were significantly decreased. While serum insulin level decreased while serum NEFA, BHBA and cortisol were increased in single and twin but in twin the values is more significant. The data showed that twin bearing ewes are more susceptible to pregnancy toxemia than single bearing that may be influence the productivity and performance of those animals.

1. Introduction:

Pregnancy, parturition, and lactation represent a physiological load to the female body. Where pregnancy toxemia (gestational ketosis) caused by negative energy balance in late gestation is commonly observed in ewes and does (Kulcsar et al, 2006), in beef cows (Rook, 2000), and also in monogastric species as rabbits, guinea pigs, dogs and in ferrets (Lewington, 2007). The background of the disease is the result of the fetal carbohydrate- or energy-demand exceeding maternal supply during the last trimester of pregnancy.

In ruminants, dietary carbohydrates provide well over one half of the energy needs for maintenance, growth and production. Glucose is a primary energy source for certain animal tissues and a precursor for lactose synthesis in the mammary gland. Consequently, understanding carbohydrate digestion and absorption, dietary glucose availability, and the involvement of gluconeogenesis in the regulation of glucose homeostasis is essential for the manipulation of the production and quality of agricultural foods (Rafael and Donald, 2007). Lipid digestion in ruminants is unique in that after ingestion feed lipids are placed into a hydrolytic and reductive environment. The result is that glycerol from triacylglycerols and phospholipids are fermented to VFA and those unsaturated fatty acids which are hydrogenated to mostly saturated fatty acids before absorption (Van Saun, 2000). In ewes, number of fetuses plays role in keeping the homeostasis. The last trimester of pregnancy is very demanding for that homeostasis, because fetuses gain over half of their weight in this period (Seidal et al., 2006). Pregnancy toxemia is a metabolic disease that commonly affects pregnant ewes with multiple fetuses and does during late gestation. It is characterized by hypoglycemia, increased concentrations of ketone bodies in the blood and elevated plasma concentrations of free fatty acids is the result of energy demand exceeding maternal supply during the last trimester of pregnancy (Kulcsar et al., 2006).

The endocrine system especially the pancreas probably is involved in the development of ruminant ketosis. Insulin inhibits ketogenesis when free fatty acids levels are high, as well as growth hormone secretions inhibited by cortisol and free fatty acids. Insulin also appears to be important in regulating the utilization of ketone bodies as the uptake of β-hydroxybutyrate and acetate (Abd-Elghany et al., 2010).

Cortisol is a regulator of glucose in ruminants, which acts to increase gluconeogenesis from amino acids. In starving ruminants the gluconeogenesis is maintained by elevated levels of glucocorticoids (Azab and Abdel-Maksoud, 1999). In lactating ruminants the rate of hepatic gluconeogenesis and the relative concentrations of glycogenic precursors regulate the level of milk production (Huntington, 1990).

Ketone bodies serve as an alternative fuel for many tissues, but they probably do not or only to a minor extent contribute to energy supply of the fetus (Battaglia and Meschia, 1988). Glucose remains most important metabolite for fetal and placental growth. The ability of the ewe to provide a sufficient amount of glucose to the fetus from dietary sources is limited because about 70 to 75% of the dietary carbohydrate is converted in rumen into nonglucogenic products. The remaining fraction of digestible carbohydrate provides 40 to 60% of the circulating glucose through propionate. During periods of a negative energy balance and increased demand for glucose, up to 23% of the glucose may be synthesized from liberated glycerol from the adipose tissue. Along with this glucogenic precursor, a larger amount of fatty acids is released into circulation that may give rise to an increased rate of ketone body formation (Schlumbohm and Harmeyer, 2004). Our study aimed to investigate carbohydrate and fat metabolic changes in single and twin bearing ossimi sheep.

2. Materials and methods

A. Experimental design

The present study was carried out in field farm of Veterinary medicine, Moshtohor, Banha University. Fifty apparently healthy, multiparous Ossimi sheep, of two years old and their body weight ranging between 35 and 50 kg. All animals were kept at the same environmental and nutritional conditions. All over the experimental period, the ewes were allotted into three groups as following:

Group I: included ten ewes (non pregnant non lactating) were used as control group.

Group II: included twenty single pregnant ewes used as experimental animals.

Group III: included twenty twin pregnant ewes used as experimental animals.

Animals were fed free in feedlot. Concentrate feed mixtures were adjusted to the changing of body weight every two weeks. Concentrate mixtures were given twice daily at 10 a.m. and 2 p.m. while wheat straw was offered (*ad lib*.).

B. Blood samples

The blood samples were collected from jugular vein of all animals in the examined groups in the early morning with one week interval during the last month of pregnancy and the day of parturition. Blood samples were divided into two portions; The first portion was collected in heparinized Tube contained 20 I.U. heparin for one mL blood for preparation of haemololysate by using digitonin and washing by physiological saline according to (Kornburg and Korecker 1955).

Table (1) Chemical and cell wall constituents of feed concentrate mixture and corn stalks (on DM basis)

Items	Feed concentrate mixture ϴ	Wheat straw
Chemical composition		
DM	91.51	93.48
OM	89.64	89.58
CP	14.34	3.26
CF	8.47	40.23
EE	2.24	1.32
NFE	64.59	44.77
ASH	10.36	10.42
Cell wall constituents		
NDF	34.62	78.24
ADF	16.24	54.13
Hemi cellulose	18.38	24.11
NFC*	38.44	6.76

*NFC: Non fibrous carbohydrates= 100 - % (CP+ NDF + EE + ASH) (Calsamiglia et al., 1995).

ϴ Feed concentrate mixture consists of 18% undecorticated cotton seed meal, 4% soybean meal, 36% yellow corn, 36% wheat bran, 3% Vinass, 1.5 % limestone, 1.4% sodium chloride and 0.1% common salts.

This was used for estimation of erythrocytic GSH (Sedlak and Lindsay, 1968); t-SOD (Misra and Fridovich, 1972); GSH-Px (EC: 1.11.1.9) (Chiu et al., 1976); GR-ase (EC: 1.6.4.2) (Bergmayer, 1983); GST (EC: 2.5.1.18) (Vessey and Boyer, 1984). The second one was collected without anticoagulant for obtaining a clear non-hemolyzed serum by centrifugation of the blood sample at 3000 r.p.m for 5 minutes. The clear sera were freshly used for determining of blood glucose (Trinder, 1969), non esterified fatty acid (NEFA) and Beta hydroxyl butyric acid (BHBA) (Duncombe, 1964), Commercial radioimmunoassay kits were used to measure concentration of cortisol and insulin (Tietz, 1968 and Wilson and Miles, (1977). C. Electrophoretic pattern of serum protein by SDS-PAGE which performed according to the method of (Laemmli, 1970). D-Statistical analysis was done by (SAS, 1996).

3. Results

The data presented in (Table 2) revealed a high significant increase (P<0.01) in the mean values of GSH-Px and GST in group II and III during the period of 2nd and last week before parturition and at the day of parturition. In contrast, GSH and t-SOD were high significantly decreased (P<0.01) and GR-ase activities were significantly decreased (P<0.05) at the same period of experiment.

Serum glucose level (Table 3) of single pregnant ewes showed significant (P<0.05) decrease than control during last 3 weeks of pregnancy. But of twin pregnant ewes was decreased significantly (P<0.05) during last 4 weeks of pregnancy.

Concentration of serum non esterified fatty acid (Table 3) of single pregnant ewe showed significant (P<0.05) increase than the control during the last 3 weeks of pregnancy as well as at the day of parturition. But of twin pregnant ewes showed significant (P<0.05) increase during the last 4 weeks of pregnancy. Serum BHBA level (Table 3) of single pregnant ewes showed significant (P<0.05) increase than the control during the last 3 weeks of pregnancy and the day of parturition. And twin pregnant ewes showed significant (P<0.05) decrease than the control during the last 4 weeks of pregnancy and the day of parturition. Serum insulin level (Table 3) of single and twin pregnant ewes showed significant (P<0.05) decrease than the control during the last 4 weeks of pregnancy and the day of parturition.

Serum cortisol level (Table 3) of single and twin pregnant ewes showed significant (P<0.05) increase than the control during the last 2 weeks of pregnancy as well as the day of parturition.

The electrophoretic pattern of serum protein revealed that albumin, alpha (α)-1-globulin, alpha (α)-2-globulin and gamma (γ) globulin of single pregnant ewes (Table, 4 and Figure, 1) were significantly decreased during the last week of pregnancy and the day of parturition. But, the concentration of serum beta (β) globulin showed significant (P<0.05) decrease during the last week of pregnancy as well as the day of parturition.

Figure (1): show the electrophoretic serum pattern of Control (A), the last week of pregnancy (B) and the day of parturition (C). In each picture, bands were arranged Albumin, Alpha (α)-1- globulin, Alpha (α)-2- globulin, Beta (β) globulin and Gamma (γ) globulin (From left to right).

4. Discussion

Our study revealed a high significant increase in the mean values of GSH-Px and GST in group II and III during the period of 2nd and last week before parturition and at the day of parturition. Also, showed high significantly decreased in GSH and t-SOD and a significant decrease in GR-ase. This result indicated that t-SOD activity decreased as it is a first line in antioxidant enzymes defense. In the second line, GSH-Px and GST were consuming GSH as a reductant cofactor. For that reason GSH-Px and GST activities were increased and GSH level was decreased. In addition, GR-ase activities were decreased because of GR-ase enzyme generates GSH (Mandour and Abou-El-Ela, 1999 and Abdel-Maksoud et al., 2000). As the glutathione assumes pivotal roles in bioreduction, protection against oxidative stress, detoxification of xenobiotics and endogenous toxic metabolites, transport, enzyme activity, and sulfur and nitrogen metabolism. Its biological significance comes from the free sulfhydryl moiety of the cysteine residue and nucleophilic properties. In cells, glutathione mainly exists in the reduced form (GSH), as the oxidized form (GSSG) (Taisuke et al., 2009). Erythrocytes are permanently in contact with potentially damaging levels of oxygen, but their metabolic activity is capable of reversing this injury under normal conditions. Erythrocytes are equipped by many defence systems representing their antioxidant capacity. This protective system includes superoxide dismutase (SOD), catalase (CAT), reduced glutathione, glutathione peroxidase (GPx), glutathione-S-transferase, and glutathione reductase (GR). However, the cellular antioxidant action is reinforced by the presence of dietary antioxidants (Nakbi et al., 2010).

The present study showed that a significant decrease in the mean values of glucose of single and twin that lower plasma glucose levels came in accordance with (Seidal et al., 2006 and Balikci et al., 2007). The observed decrease in serum glucose level may be due to the, negative energy balance increases lipid mobilization, which results in hepatic lipidosis with subsequent impairment of hepatocellular function, glucose deficiency with intermittent hypoglycemia and accumulation of ketone bodies. The hypothesis that cows suffering from stress and/or painful diseases have elevated blood glucose levels due to an increase in serum cortisol (Forslund et al., 2010).

NEFA and BHBA concentrations in single and twin pregnant ewes were significantly increased than control but in twin were more significantly increased; these results were proved by (Nazifi et al., 2002 and Moghaddam and Hassanpour, 2008).

Serum cholesterol level of single and win pregnant ewes showed significant increase than the control during the last 2 weeks of pregnancy as well as at the day of parturition. The high cortisol level inhibits the growth of the axial skeleton in the sheep fetus during the late pregnancy which enhances the parturition process (Fowden et al., 1996).

Serum insulin level of single and twin pregnant ewes showed significant decrease than the control during the last 4 weeks of pregnancy as well as at the day of parturition. The decrease of insulin level may be attributed to negative energy balance which leads to decrease in glucose level and increase the liploysis (Faulkner and Pollock, 1990). The shift of energy metabolism in a catabolic direction is characterized by a wide range of endocrine changes, such as insufficient pancreatic β-cell function with a coinciding increase in insulin resistance.

The data illustrated in table (3) showed significant increase in cortisol level than the control during the last 2 weeks of pregnancy as well as the day of parturition in Single and twin pregnant ewes. This observation may be due to a hypothesis that the known relation between stress and/or painful diseases in high yielding dairy cows and pregnant ewes may be mediated through a concurrent increased cortisol secretion leading to hyperglycaemia (Rohrbach et al., 1999). On the other hand, Forslund et al., (2010) reported significantly low levels of cortisol in Cows with ketonemia (BHBA > 1.5 mmol/l). The significant increase in cortisol and presence of significant negative correlation between plasma glucose concentration and cortisol level and the significant positive relationship with β-hydroxybutyrate may be due to increased adrenal output or to impaired ability of the fatty liver, which was a consistent finding in pregnancy toxemia, to mobilize and excrete the hormone (Ford et al., 1990 and Abd-Elghany et al., 2010).

The concentrations of serum albumin, alpha-1-globulin, alpha-2- globulin, beta globulin and gamma globulin of single pregnant ewes showed significant decrease than the control during the last week of pregnancy as well as the day of parturition. These results may attributed to consequence increase in the mother's basal metabolic rate, the maximal nutrient requirements of the placenta and the growing fetus, together with the transfer of serum albumin, immune globulins, and amino acids from the blood stream to the mammary gland for synthesis of colostrums (Batavani et al., 2006).

5. Conclusion

Late pregnancy in ewes is a very stressful period specially the late period in which in erythrocytic haemolysate the mean values of GSH-Px

and GST were high significantly increased; GSH and t-SOD were high significantly decreased (P<0.01) and GR-ase activities were significantly decreased. While, serum glucose, total protein, albumin, globulin and insulin were decreased while serum NEFA, BHBA and cortisol were increased in single and twin but in twin the values is more significant. Our research results recommended that twin bearing ewes need a special care during pregnancy and after parturition by supplementation of ewes by a demands of appositive energy balance.

Abstract: Background Ventilator-associated pneumonia (VAP) is the most common hospital acquired infection seen in ICU in patients on mechanical ventilation. A diversity of microbes can cause VAP, causative agent differ according to patient populations and types of ICUs. Atypical bacteria not cultured by routinely used methods , have been implicated as causes of VAP, still no sufficient studies to assess size of their role as causative agent in VAP. In this study we aim at estimation of the potential role of atypical bacteria as Mycoplasma pneumoniae, Chlamydia pneumoniae and Legionella pneumophila in ventilator-associated pneumonia in the intensive care units of Alexandria Main University Hospital. Materials and methods: 60 endotracheal aspirates were collected from VAP ICU patients. Samples were subjected to routine culture as well as PCR amplification using specific primers for detection of the following atypical bacteria : Mycoplasma pneumoniae, Chlamydia pneumoniae and Legionella pneumophila. Results: Out of the 60 endotracheal aspirate, routine culture revealed growth of: enterobacteriaecae in 14 (23.3%) aspirate, pseudomonas in 13(21.7%), candida in14(23.3%) , and MRSA in 10 (16.7%) . In 19 (31.7%) endotracheal aspirates, no growth was encountered on routine culture. PCR reaction was positive for Atypical bacteria in 9 (15%) out of 60 samples, five were positive for mycoplasma, three for Legionella, and only one was positive for Chlamydia. Atypical bacteria positive results were encountered in 4 (21%) out of 19 aspirates with no growth culture results. Conclusion: Our results point that atypical bacteria are not an uncommon cause for VAP. This finding has to be taken into consideration while tailoring the empiric antimicrobial coverage of patients diagnosed with VAP.

1. Introduction:

Ventilator-associated pneumonia (VAP) is considered as the most frequent ICU-acquired infection among patients receiving mechanical ventilation (MV). This kind of respiratory tract infection prolong the duration of Mechanical ventilation and delay the release from ICU. Most antibacterial chemotherapy prescribed in an ICU are administered for respiratory tract infections. (1)

VAP can be caused by a large variety of microorganisms . the causative agent may differ according to the population of patients in the ICU, the durations of hospitalization and stay in the ICU. "Atypical" pneumonia differ from typical one in not to be associated with shaking chills (2) and caused by atypical bacteria which cannot be grown by routinely used microbiologic culture media and techniques as *Mycoplasma pneumoniae, Chlamydia pneumoniae and Legionella pneumophila* (3-5).

Mycoplasma pneumoniae was first atypical pathogens to be identified as a cause of respiratory tract infection in 1944.(6,7) Characterized by absence of a rigid cell wall, poor staining by Gram method, and high nutritional requirements for its culture as it needs a high concentration (10-20%) of serum or supplements . This makes diagnosis of mycoplasma by conventional microbiologic examination difficult. (7) *Chlamydia pneumonia* laboratory diagnosis depended on non- specific and technically demanding techniques till 1990 but now it has been replaced by detection of chlamydial antigens or detection of DNA by PCR. (7) *Legionella pneumophila* are nutritionally fastidious, intracellular bacilli, gram negative organisms. (8) Infection with *legionella is* associated with exposure to artificial water systems ,condensers and respiratory therapy equipments .(9) Use of PCR as a rapid and specific diagnostic method for legionella infection overcame the long culture time needed for its growth (3-5 days) and the need of media supplemented with iron and cysteine as well as difficult colonial identification in mixed cultures. (7)

Accurate diagnosis of VAP remains a difficult target to achieve, that relies mainly on clinical, microbiological and radiological diagnosis.(10,11) Main clinical criteria for VAP

diagnosis have been reported to be new lung infiltrate on chest X-ray with fever , leukocytosis or leukopenia, and purulent secretions. [12-14] Inadequate antibiotic treatment have been always reported by researchers to be related to poor prognosis of VAP. [15,16] Microbiological culture and sensitivity results remains a gold standard for planning treatment for the VAP patient before empirical antibiotic administration [17] . This have been emphasized by the Guidelines from the Infectious Disease Society of America(IDSA).[18]

It is well established that Beta-lactams are not effective against such organisms because *Chlamydia pneumoniae* and Legionella species are intracellular organisms and *Mycoplasma pneumoniae* lacks a cell wall. In those cases Erythromycin and tetracycline can be useful . Other antibiotics effective against atypical bacteria, includes Macrolides, Doxycycline and Flouroquinolones.[6] Our study aims at assessment of the potential role of atypical bacteria as Mycoplasma pneumoniae, Chlamydiae pneumoniae and Legionella pneumophila in ventilator-associated pneumonia in the intensive care units of Alexandria Main University Hospital.

2. Materials and methods

Materials

The study was conducted on 60 patients on Mechanical ventilators for more than 48 hours and acquired VAP during their stay in the ICU of Critical Care Department in the Alexandria Main University Hospital in the period between April 2009 and April 2010.Cases included in this study have been informed and consented. Inclusion criteria were fever, leukocytosis, development of persistent radiographical pulmonary infiltrate during stay in the ICU and with no history of a previous pulmonary disease or pulmonary symptoms at the time of admission. Thirty ICU patients on ventilators for more than 48 hours without developing VAP, within the same period of time, were included as a control group.

Methods

Endotracheal aspirates as well as clinical data have been collected from patients and controls. Samples were subjected to routine culture as well as DNA extraction with subsequent PCR amplification for detection of specific DNA sequences of the following atypical Bacteria genus : Mycoplasma pneumoniae, Chlamydia pneumonae and Legionella pneumophila.

The endotracheal tube was previously inserted guided by a laryngoscope. A sterile suction catheter was introduced blindly into the endotracheal tube after disconnecting the ventilator. 2 ml of endottracheal aspirates were obtained by suction. The part of the catheters containing the aspirates were cut and placed in sterile test tubes and sent to the laboratory.

The endotracheal aspirates, within catheters in test tubes, were homogenized and liquefied by adding 2 ml sterile 1% N-acetyl L-cysteine (equal volume of the specimen). All tubes were centrifuged for 15 minutes at 4×10^3 rpm and then vortexed and left at room temperature for another 15 minutes.[19,20] Each homogenized specimen was then divided into 2 equal portions in 2 sterile Eppendorfs. The first part was used for conventional microbiological studies while the other was kept at -20^{o} C for PCR assay. Each aspirate was streaked on Blood agar, MacConkey's agar and Sabouraud's Dextrose agar plates. All plates were incubated aerobically at 37 ^{o}C for 24 hours. Any growth was identified according to the conventional bacteriological and mycological techniques.[19,20]

PCR assay:

Extraction of DNA was performed using QIAamp DNA blood mini kit (Qiagen). Separate PCR reactions were performed for amplification of each DNA sequence of each organism using Techne Progene thermal cycler. Reaction mixture consisted of 5µl DNA extract, 25 picomoles of each of the forward and reverse oligonucleotide primers specific for Mycoplasma pneumonia [21], Legionella pneumophila [21] and Chlamydia pneumonia ([22], 12.5 µl Taq PCR master mix (MBI Fermantas), and 4.5 µl nuclease free water. For detection of the amplified products: [21] 10 µl of the amplification products were electrophorised into 2% agarose in Tris-borate EDTA containing 0.5 µg/ml ethidium bromide at 80 volts for 45 minutes. Revealed DNA bands were visualized on an ultraviolet transilluminator.

3. Results

The mean age of the VAP study group was 43.1 ± 24.68 (18-85) year, while that of the control group was 49.7 ± 20.5 (12-70). There was no statistically significant difference between them as regards age and gender: male to female ratio was 33:27(55:45%) in patient group while in the control group, the male to female ratio was 19:11 (63:36.6%). As regards causes of hospital admission for the 60 VAP patients and the control group It has been found that cardiac problems were the most commonly encountered among both patients (38%) and controls (28%), rest of causes for admission included accidents, poisoning, Renal and hepatic problems. In the endotracheal aspirates obtained from

the 60 VAP patients included in this study, 41 specimens were positive by conventional microbiological cultures and 19 were culture negative. In the control group, 11were positive and 19 specimens were culture negative(See table 1).

The conventional microbiological culture revealed that among cultures of the patients group, *Candida* spp was the commonest organism isolated accounting for 23.3%. Only 16% were of significant count ($\geq 10^5$ CFU/ml). This was followed by *Pseudomonas aeruginosa* (21.6%) and 15% were of significant count, then the polymicrobial growth 20% and 16% with significant count, *Staphylococcus aureus* 16% and 10% with significant count, *Acinetobacter* spp 8.3% and 6.6% with significant count, *Proteus* spp 6.6% and 5% with significant count, *Klebsiella* spp 6.6% and 5% with significant count, *E-coli* 5% and 1.6% with significant count, *Coagulase-negative staphylococci* 1.6% which were of significant count and *Diphtheroids* 1.6% which were also of significant count. It is also to be noted that 31.6% of the total endotracheal aspirates of the 60 VAP cases were negative by conventional microbiological culture.

Table 1: The results of conventional microbiological culture of the endotracheal aspirates from the 60 VAP patients and the control group

	Conventional microbiologic Culture results*	
	Positive	**Negative**
Cases n=60	41 (68.3%)	19 (31.7%)
Controls n=30	11 (36.6%)	19 (63.3%)
Total n=90	52 (57.7%)	38 (42.2%)

*P value = 0.004

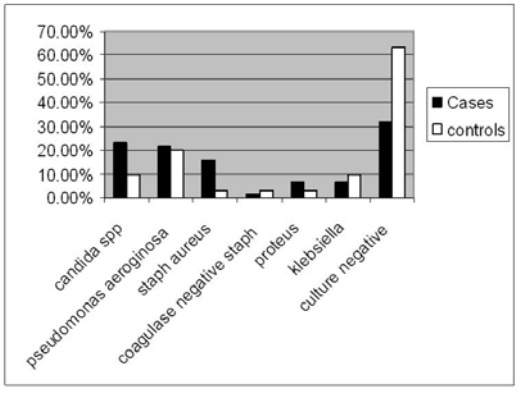

Figure 1: The conventional microbiological culture results for cases & controls group.

While in the control group, bacteria revealed from cultures were *Pseudomonas aeruginosa* accounted for 20%, *Klebsiella* spp 10%, *Candida spp* 10% also, then *Staphylococcus aureus* 3.3%, *Coagulase-negative staphylococci* 3.3% and *Proteus* spp 3.3%. In addition, 10% were culture negative and 13.3% were polymicrobial. The growth counts of the endotracheal aspirates of the control group were insignificant ($\leq 10^5$ CFU/ml). Atypical bacteria DNA detection by PCR was positive in 9 (15%) out of 60 samples, the majority of them (5) were mycoplasma, 3 were positive with Legionella, and only one sample was positive with Chlamydia. The Atypical bacteria positive results was encountered in 4 (21%) out of 19 aspirates with no growth culture results. See figure 1

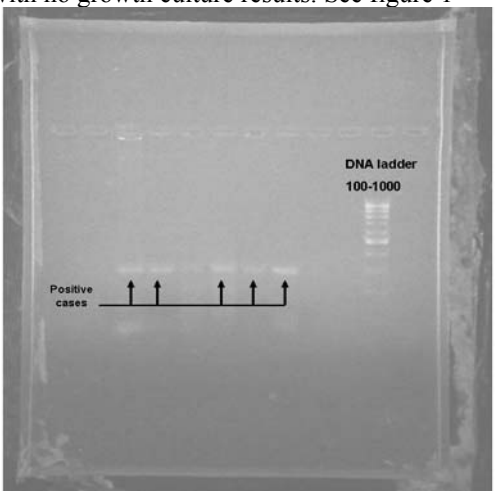

Figure 2: Gel electrophoresis showing 5 positive Mycoplasma pneumoniae cases by PCR.

Table 2: PCR and culture results of cases and control

	Culture**		PCR*	
	Culture positive	**Culture negative**	**PCR positive**	**PCR negative**
Cases	41 (68.3%)	19 (31.7%)	9 (15%)	51 (85%)
Controls	11 (36.6%)	19 (63.3%)	0 (0%)	30 (100%)

* PCR was done using primers for Mycoplasma pneumonia, Legionella pneumophila, Chlamydia pneumonia .

**All specimens were cultured on Blood agar, MacConkey's and SDA.

It was found that 5 specimens were positive for *Mycoplasma pneumoniae*, three were positive for *Legionella pneumophila* and only 1 was positive for

Chlamydia pneumoniae. Among the 5 positive specimens for *Mycoplasma pneumoniae*, 3 were positive by conventional microbiological cultures and grew other associating microorganisms, while 2 were culture negative. The 3 specimens that were positive for *Legionella pneumophila*, only 1 grew other microorganism by conventional cultures and the other 2 were culture negative. The only positive specimen for *Chlamydia pneumoniae* did not grow any microorganisms by conventional microbiological cultures. As for the control group included in this study, none of their DNA extracts were positive in the PCR assay for atypical bacteria.

Table 3: Results of PCR assay in relation to conventional microbiological culture resutls inVAP patients.

PCR assay	Conventional microbiological culture		Total
	Positive(n= 41)	Negative (n= 19)	
Mycoplasma pneumoniae	3(7%)	2 (10%)	5 (8.3%)
Legionella pneumophila	1 (2.4%)	2 (10%)	3 (5%)
Chlamydia pneumoniae	0	1 (5%)	1 (1.6%)
Total	4(9%)	5(26%)	9 (15%)

4. DISCUSSION

VAP complicates the course of 9 – 20% of mechanically ventilated patients and mortality varies greatly from 8 to 76%,. Once pneumonia is suspected, bacteriologic confirmation should be obtained and empiric therapy must be instituted as soon as possible, as a delay in therapy or inappropriate therapy greatly increases mortality.[23] Awareness of the potential microbial causes of VAP and confirmation of the specific cause in an individual patient are essential to guide optimal antibiotic therapy.[24]

Endotracheal aspirates, chosen in this study as the respiratory specimen, are used more frequently as a diagnostic method in intubated patients with suspicion of pulmonary infection, because of its simplicity and minimal training required, but the fact that the culture also contains other non-pathogenic organisms from the upper respiratory tract flora, results in a low positive predictive value of this test. However, this can be avoided by the use of the semiquantitative method of culture of the obtained specimen, with a designated threshold value above which diagnosis of VAP can be established.[25,26] Cultures revealed that *Candida* was the commonest organism isolated accounting for 23.3%, while 16% only were of significant count ($\geq 10^5$ CFU/ml). This was followed by *Pseudomonas aeruginosa* 21.6% and 15% were of significant count, then the polymicrobial growth 20% and 16% with significant count, *Staphylococcus aureus* 16% and 10% with significant count,

The results of our study agree with the results of several previous studies.[27 -31] where *Pseudomonas aeruginosa* was the predominant organism isolated by endotracheal aspiration and bronchoalveolar lavage, followed by *Staphylococcus aureas* and *Klebsiella pneumonia*.[32] The significantly high rate of Gram negative bacilli in our study and many other studies probably indicates the high incidence of prolonged hospital stay and the prolonged duration of mechanical ventilation that predisposes the patients to acquire infections from the multidrug-resistant pathogens . In contrast , Other authors reported other bacterial strains as *Acinetobacter baumanii and Streptococcus* .[33-34]

.

The results of PCR assay for atypical bacteria of the DNA extract of the endotracheal aspirates of the 60 VAP patients revealed a total of 9 positive cases (15%) for the tested microorganisms, 5 cases were positive for *Mycoplasma pneumonia* (8.3%), 3 cases were positive for *Legionella pneumophila* (5%) and only 1 case was positive for *Chlamydia pneumonia* (1.6%).

Many were studies conducted for detection of atypical bacteria by PCR. Hassan et al reported detection of legionella and Chlamydia pneumonia in VAP cases while no cases were positive for *Mycoplasma pneumonia*e.[28] Moreover, Bachinskaya et al reported that 9% of their patients were positive for *Mycoplasma pneumonia*e and 9% were also positive for *Chlamydia pneumoniae*.[35] In another study by Apfalter et al, where real time PCR was used as a fast diagnostic tool for non-conventionally cultured microorganisms, they reported that 3% of their cases were positive for *Mycoplasma pneumonia*e and 2% of cases were positive for *Chlamydia pneumoniae*. They concluded that *Mycoplasma pneumonia*e and *Chlamydia pneumoniae* should be considered as causative agents in critically ill patients who develop early-onset nosocomial ventilator-associated pneumonia. Thus, empirical antimicrobial regimens should cover *Chlamydia*, and *Mycoplasma*.[36] Furthermore, El-Ebiary et al also diagnosed six cases of *Legionella* pneumonia among patients with definite VAP. Using specific culture for *Legionella* and serology for *Legionella pneumophila, Mycoplasma pneumoniae Coxiella burnetti, and Chlamydia pneumoniae,* only

Legionella was diagnosed in 2 patients by serology and in 4 patients by culture.[37] Our results draw attention towards the possibility of these rarely diagnosed agents as being not infrequent causative agents for VAP. The prevalence of such atypical pathogens is to be taken into consideration while tailoring the empiric antimicrobial coverage of patients diagnosed with VAP.

Abstract: Twenty three new 2-cyanomethyl benzoxazole derivatives were synthesized by different methods. Their structures were elucidated by many ways as elemental analysis, spectroscopic analysis and chemical methods. The herbicidal activity of the newly synthesized compounds was evaluated against wheat as pattern for monocotyledonous plants, three plant parameters were studied, seed gerimination, root and shoot growth under laboratory conditions. Compounds that showed an observable inhibition on one or more of the growth parameters under study were considered as promising compounds and needs more studies from the toxicological, soil, environmental and formulation points of view to stand on the most potent derivative that can be formulated in a suitable formulation form to be used in the field of pest control. Compounds (**16a**),(**16b**),(**16f**),(**13b**),(**10a**),(**7a**) and (**3b**) inhibited all growth parameters under study by different degrees. While compounds (**13b**) and (**13a**) were more effective on root and gerimination respectively. Most synthesized compounds inhibited markedly shoot growth.

Introduction

Our present work is a continuation of our ongoing programme in utilizing readily obtainable materials in the synthesis of different biologically active heterocylces [1].2-cyanomethyl benzoxazole and its related compounds play an important role in pharmaceutical and agricultural fields due to their broad spectrum of biological activities. Such a ring system has been reported to be used as herbicides [2-14], bactericides [15], fungicides [16-25], antiviral [26-30] and antimicrobial agents [22]. Also , 2-cyanomethyl benzoxazole connected to pyridine carbonitriles have been found to be of great interest due to their broad spectrum of biological activities [31]. So that depending on the biological activities and due to the high chemical activity of 2-cyanomethyl benzoxazole ring system , it was found that synthesis and study of the herbicidal activity of some new 2-cyanomethyl benzoxazole derivatives is a subject of great interest hoping that these new compounds could be applied as a new herbicidal agents in the field of pest control.

Results and discussion

1-Chemistry part

The key starting material 2-cyanomethyle benzoxazole (**1**) is characterized by the presence of an active methylene as well as nitrile group which makes it chemically very active so it can be used as a precursor to synthesize many biologically and chemically active ring systems. Condensation of acetonitrile (**1**) with different heterocyclic or aromatic aldehydes in ethanol and triethylamine as an organic base under reflux afforded -2- arylidene benzoxazole-2- acetonitrile (**za-e**),[31](c.f.Schem1). both elemental and spectral data of the obtained compounds are consistent with the assigned structure (c.f.Experimental). benzoxazole (**1**) as a result of the presence of the active methylene, it was allowed to react with o-hydroxy napthaldhyde (**4**) in ethanol and ammonium acetate to give coumarine (**5**)[32,33], the structure that was supported by the disappearance of the characteristic absorption band of CN with the appearance of carbonyl group band in IR spectra as well as the appearance of the signal corresponding to the ethylenic proton of coumarine ring as singlet at

9.92 ppm in 1H-NMR spectrum of compound (**5**) due to oxidation of nitrile group followed by elimination of water and cyclization on coumarine ring .

Moreover , mass spectrum of compound (**5**) showed the expected molecular ion peak at m/z=313 with relative abundance of 27.7 corresponding to the correct molecular formula . in the same way ,2-cyanomethyle benzoxaole (**1**) on treatment with different ketones (**6**) in ethanol in the presence of piperidine as a basic catalyst under reflux afforded α-(benzoxazole -2-yl)-B- alkyl (aryl) crotonitrile (**7a-c**).

Structural elucidation of derivatives (**7a-c**) was carried out by different ways as elemental analyses as well as spectroscopic data, whereas, IR spectra of compound (**7a**) revealed the appearance of the characteristic absorption band for CH aliphatic at 2225 cm^{-1} region. Also, ^{1}H-NMR (DMSO-d6) of the same derivative showed two singlets at 2.40 and 2.55 ppm corresponding to two methyl groups of compound (**7a**)

Moreover , mass spectrum of this compound showed the expected molecular ion peak at m/z= 198 with relative abundance of 50.0 corresponding to the correct molecular formula.

On the other hand, compound (**1**) was reacted with α,B – unsaturated nitriles (**8a-c**) in ethanol in the presence of piperidine as a basic catalyst under reflux to afford the corresponding dicarbonitrile derivatives (**10a-d**). structural elucidation of derivatives (**10a-d**) was carried out by different ways as elemental analyses, spectroscopic data as well as chemical ways. Whereas, IR spectra of all obtained compounds revealed two absorption bands at 1940 and 2198 cm $^{-1}$ region due to the presence of two (CN) functional groups . Also, structure (**10**) was confirmed by the presence of the characteristic signal at 5.23 ppm in ^{1}H-NMR spectrum of compound (**10b**) due to the formation of NH_2 functional group. More over the mass spectrum of compound (**10b**) showed the expected molecular ion peak at m/z=346 with relative abundance of 2.6 corresponding to the correct molecular formula .

Refluxing arylidene (**3**) with malononitrile (**a**) in ethanol in the presence of sodium ethoxide gave dicarbonitrile (**10d**) which was confirmed by m.p,mixed m.p and IR spectrum that revealed the presence of two absorption bands at 1940, 2195 cm $^{-1}$ region corresponding to two (CN) functional groups and mass spectrum of the same derivative that displayed molecular ion peak at m/z =401 with relative abundance of 2.9corresponding to the molecular formula $C_{22}H_{18}N_4O_4$.

Benzoxoazole (**1**) on treatment with the arylidene ethyl α-cyanocinnamate (**11**) in ethanol in the presence of sodium ethoxide as a basic catalyst afforded pyridine carboxylic esters (**13a-d**).

Structures (**13a-d**) was confirmed by different ways as elemental analyses and spectroscopic analyses. whereas , IR spectra of all obtained compounds revealed new absorption bands at 3375, 3237 and 1662 cm $^{-1}$ region due to the presence of NH_2 and C=O group . Also, ^{1}H-NMR (DMSO-d6) of compound (**13b**) showed signals at 1.28-1.33 (t,3H,CH_3),4.26-4.36 (q,2H,CH_2), 7.34-7.39 (m,3H,thiophene – H) , 8.07-8.23(m-5H,Ar-H)and 8.62(s,2H,NH_2). Moreover ,treatment of arylidene (3)with ethyl cyano acetate (**12**) in ethanol and sodium ethoxide as a basic catalyst under reflux gave pyridine carboxy ester(**13 a**), which was considerd as chemical tool for structural elucidation of compounds (**13b-d**) . Structure of (**13 a**) was confirmed by compatible elemental analysis and spectral data (c.f. Experimental).

In addition, 2-cyanomethyl benzoxazole (**2**)was reacted with α,β-unsaturated nitriles(**14**) in ethanol and sodium ethoxide under reflux to afford 3-cyanopyridine -2(1H)-(thi)ones(**16a-f**) was carried out by different ways as elemental analysis, Spectroscopic data as well as chemical ways. Where as IR spectra of all obtained compounds revealed new observation band at 1244 and 1657 cm^{-1} region due to the presence of c=s and c=o functional groups in pyridine thions and pyridine ones respectively .Also, ^{1}H-NMR (DMSO-d6) of compound (**16e**) showed signals at 2.72 (a,3H,cH_3) 6.62-6.86 (br.s,2H,NH_2), 7.7.49-7.96 (m,8H,Ar-H) and 8.0 (s,1H,pyridine –NH). Moreover, mass spectrum of compound (**16e**) showed the expected molecular ion peak at m/z=371 with relative abundance of 8.9 corresponding to the correct molecular formula.

As another method to elucidate structure of compound (**16**), arylidene (**3**) was treated with cyano(thio)acetamidein ethanol in the presence of catalyst amount of sodium ethoxide to afford compounds (**16d,f**).both elemental and spectral data of compounds (**16d,f**) provided satisfying evidence for the proposed structures (c.f. Experimental).

EXPERMENTAL

All melting points are uncorrected and were determined on an electric melting point (Gallenkamp) 9200 A apparatus. IR spectra were recorded (KBr) on pye Unicam SP-1000 Spectrophotometer. 1H–NMR spectra were obtained from Varian Gemini 200 MHz spectrometer and chemical shifts are expressed in δ (ppm) using TMS as internal reference. Mass spectra were recorded on a GCMS–QP 1000 mass spectrometer opening at 70 eV. Microanalytical data were obtained from the microanalytical data center at Cairo University.

2-Arylidene benzoxazole–2–acetonitrile (3a–e).

Method A

Solution of (1,3–benzoxazole–2–yl) acetonitrile (1) (1.58g, 0.01 mole) in absolute ethanol (30 ml) was stirred with triethylamine or piperidine (seven drops) for 1h and the appropriate aldhyde (2) (0.01 mole) was added gradually to the reaction mixture and stirring was maintained for about 4 hrs. The formed crystalline precipitate was filtered off, washed with ethanol, dried and crystallized from the proper solvent to afford arylidenes (3a–e).

Method B

A mixture of (1,3–benzoxazole–2–yl) acetonitrile (1) (1.58g, 0.01 mole), aromatic or heterocyclic aldhyde (2) (0.01 mole) and piperidine (five drops) in ethanol (30 ml) was heated under reflux for 2 hrs. The reaction mixture was left aside at room temperature to cool, poured into an acidified crushed ice and filtered off. The obtained solid product was crystallized from suitable solvent to give arylidenes (3a–e).

(3a) yield (2.45g, 90%); (pet.ether); mp 163–65ºC. IR (cm1): 3083 (CH–arom), 2925 (CH–aliph.), 2221 (CN), 1606 (C=N), 1583 (C=C), 1030 (C-O-C); 1H–NMR (DMSO–d6): 7.33-7.48 (m, 3H, thiophene-H), 7.81-8.18 (m,4H, benzoxazole–H), 8.73 (s, 1H, =CH). MS m/z (%): 254 (M+ +2, 19.2), 253 (M+ +1, 13.1), 252 (M+ , not detected), 251 (M+ -1, 41.5), 196 (16.9), 179 (10.8), 158 (5.4), 63 (100). Ana. calcd. for C14H8N2OS (252.27) C66.65, H3.19, N11.10, S12.71. Found: C66.29, H3.09, N11.19, S12.85%.

(3b) yield (2.73g, 80%); (n–Hexane); mp 159-61ºC. IR (cm^{-1}): 3064 (CH–arom.), 2923 (CH-aliph.) 2227 (CN), 1601 (C=N), 1542 (C=C), 1031 (C-O-C); ^{1}H–NMR (DMSO–d6): 7.49–7.90 (m, 4H, benzoxazole–H), 8.14–8.18 (m, 4H, Ar–H), 8.57 (S, 1H, =CH). MS m/z (%): 328 (M^+ + 3, 0.1), 327 (M^+ + 2, 1.0), 326 (M^+ + 1, 4.2), 325 (M^+, 4.7), 324 (M^+ -1, 4.4), 245 (100), 123 (11.3), 63 (100). Ana. calcd. for $C_{16}H_9BrN_2O$ (325.16) C 59.10, H 2.79, Br 24.57, N 8.62. Found: C 59.07, H 2.70, Br 24.53, N 8.57%.

(3c) yield (2.53g, 85%); (pet. ether); mp 163–65ºC. IR (cm^{-1}): 3055 (CH–arom.), 2926 (CH–aliph), 2229 (CN), 1608 (C=N), 1583 (C=C), 1042 (C-O-C); MS m/z (%): 282 (M^+ + 2, 2.0), 281 (M^+ + 1, 3.7), 280 (M^+ , 8.1), 279 (M^+ -1, 7.3), 245 (66.1), 216 (12.16), 63 (100). Ana. Calcd for. $C_{16}H_9ClN_2O$ (280.71) C 68.46, H 3.23, Cl 12.63, N 9.98. Found: C 68.39, H 3.17, C l12.48, N 9.75%.

(3d) yield (2.60g, 85%); (EtOH); mp 160-62ºC. IR (cm^{-1}): 3067 (CH-arom.), 2919 (CH-aliph.), 2230 (CN), 1606 (C=N), 1549 (C=C), 1060 (C-O-C); MS m/z (%): 288 (M^+, not detected), 287 (M^+ -1, 60.0), 245 (80.0), 128 (66.7), 56 (100). (3e) yield (2.76g, 90%); (Toluene); mp 246–48ºC. IR (cm^1): 3022 (CH–arom.), 2915 (CH–aliph), 2211 (CN), 1603 (C=N), 1570 (C=C), 1063 (C–O–C); ^{1}H–NMR (DMSO–d6): 3.13(s, 6H, 2CH3), 6.88–8.08 (m, 8H, Ar-H), 8.28 (s, 1H,=CH). MS m/z (%): 290 (M^+ + 1, 13.9), 289 (M^+, 89.7), 288 (M^+ -1, 100), 144 (11.8), 127 (7.5), 63 (86.9). Ana. Calcd. for. $C_{18}H_{15}N_3O$ (289.33) C 74.42, H 5.23, N 14.52. Found: C 74.55, H 5.18, N 14.44%.

2-(-2`H-Chromn-2`-oxo-3`-yl-(5`,6`-e)-napthyl)benzoxazole (5).

To a solution of (1,3-benzoxazole-2-yl) acetonitrile **(1)** (1.58g, 0.01 mole), ammonium acetate (7.79, 0.01 mole) in ethanol (40 ml), 2-hydroxyl napthaldhyde **(4)** (1.72g, 0.01 mole) was added and the reaction mixture was heated under reflux for 4 hrs. The reaction mixture was left to cool at room temperature, poured into crushed ice, filtered off and the finally obtained solid product was crystallized from toluene to afford coumarine derivative **(5)**.

(5) yield (2.31g, 70%); (Toluene); mp 242-44ºC. IR (cm^1): 3055 (CH-arom.), 2922 (CH-**aliph**), 1746 (C=O), 1622 (C=N), 1563 (C=C), 1030 (C-O-C); ^{1}H–NMR (DMSO–d6): 7.52–7.90 (m, 6H, Ar-H), 8.10–8.73 (m, 4H, benzoxazole–H), 9.92 (s, 1H, =CH). MS m/z (%): 314 (M^+ + 1, 8.0), 313 (M^+ , 27.7), 312 (M^+ -1, 8.8), 285 (19), 228 (13.9), 164 (18.2), 138 (10.2), 63 (100). Ana. Calcd. for. $C_{20}H_{11}NO_3$ (313.31) C 76.67, H 3.54, N 4.47. Found: C 76.65, H 3.47, N 4.45%.

α-(Benzoxazole-2`-yl)-β-alkyl (aryl) crotonitrile (7).

(1,3-Benzoxazole-2-yl) acetonitrile (1.58g, 0.01 mole) was stirred in ethanol (40 ml) containing catalytic amount of piperidine (0.5 ml, 0.02 mole) for l h, ketone **(6)** (0.01 mole) was added. The reaction mixture was heated under reflux, left to cool at room temperature, poured into an acidified crushed ice, filtered off and the finally obtained solid product was crystallized from ethanol to give crotonitrile derivatives **(7a-c)**.

(7a) yield (1.94g, 90%); (EtOH); mp 128–30ºC. IR (cm^{-1}): 3060 (CH–arom.), 2922 (CH–aliph), 2225 (CN), 1603 (C=N), 1550 (C=C), 1038 (C–O–C); ^{1}H–NMR (DMSO–d6): 2.40 (S, 3H, CH_3) 2.55 (s, 3H, CH3), 7.40–7.48 (s, 2H, benzoxazole–H), 7.78–7.83 (s, 2H, benzoxazole–H). MS m/z (%): 199 (M^+ + 1, 16.7), 198 (M^+, 50.5), 159 (25.0), 158 (58.3), 63 (100). Ana. Calcd. for. $C_{12}H_{10}N_2O$ (198.22) C 72.71, H 5.08, N 14.13. Found: C 72.70, H 5.01, N 14.9%.

(7b) yield (1.619, 70%); (EtOH); mp 66–68ºC. IR (cm^{-1}): 3057 (CH–arom.), 2975 (CH-aliph), 2225 (CN), 1612 (C=N), 1552 (C=C), 1045 (C–O–C); MS m/z (%): 213 (M^+ + 1, 10.06), 212 (M^+ , 79.8), 211 (M^+ -1, 34.6) 198 (5.8), 158 (29.8), 133 (39.4), 93 (22.1), 63 (100). Ana. Calcd. for. $C_{13}H_{12}N_2O$ (212.25) C 73.56, H 5.70, N 13.20. Found: C 73.49, H 5.65, N 13.14%.

(7c) yield (2.519, 80%); (EtOH); mp 88–90ºC. IR (cm^{-1}): 3105 (CH-arom.), 2935 (CH-aliph), 2210 (CN), 1604 (C=N), 1523 (C=C), 1106 (C-O-C). Ana. Calcd. for. $C_{17}H_{11}N_3O_3$ (305.29) C 66.88, H 3.63, N 13.76. Found: C 66.64, H 6.53, N 13.72%.

1-Amino-3-aryl-3H-pyrido[2,1–b]benzoxazole-2,4-dicarbo–nitriles (10a-d).

Method A

A mixture of arylidene malonoitrile **(8a–c)** (0.01 mole), (1,3-benzoxazole-2-yl) acetonitrile **(1)** (1.58g, 0.01 mole) in ethanol (30 ml) containing catalytic amount of piperidine (0.5 ml, 0.02 mole) were heated under reflux for 5 hrs. The reaction mixture was left to cool at room temperature, poured into an acidified crushed ice, filtered off, left to dry and the obtained solid product was crystallized from a suitable solvent to afford the substituted amino pyridine dicarbonitrile derivatives **(10a–c)**.

Method B

2-arylidene benzoxazole–2–acetonitrile **(3)** (0.01 mole), sodium ethoxide [prepared from sodium metal (0.46 g, 0.02 mole) in ethanol (30 ml)] and malonoitrile **(9)** (0.66 g, 0.01 mole) was heated under reflux for 7 hrs. The reaction mixture was left aside at room temperature to cool, poured into an acidified crushed ice and the precipitated solid product was filtered off, dried and crystallized from ethanol to give dicarbonitrile derivative **(10d)**.

(10a) yield (2.54 g, 80%); (EtOH); mp 180–82ºC. IR (cm^{-1}): 3327, 3219 (NH_2), 3085 (CH–arom.), 2210, 2340 (CN), 1611 (C=C), 1033 (C–O–C); MS m/z (%): 319 (M^+ + 1, 20.7), 318 (M^+ , 31.0), 291 (34.5), 226 (17.2), 194 (20.71), 127 (17.2), 63 (100). Ana. Calcd. for. $C_{17}H_{10}N_4OS$ (318.35): C 64.14, H 3.17, N 17.60, S 10.07. Found: C 64.11, H 3.12, N 17.48, S 10.10%.

(10b) yield (2.78 g, 80%); (Acetonitrile); mp 245-47ºC. IR (cm^{-1}): 3460, 3437 (NH_2), 3061 (CH-arom.), 2198, 1940 (CN), 1642 (C=C), 1039 (C–O–C); ^{1}H-NMR (DMSO–d_6): 5.23 (s, 2H, NH_2), 6.69 (s, 1H, pyridine-H), 7.32–7.53 (m, 4H, Ar-H), 7.66–7.78 (m, 4H, benzoxazole-H). 1-Amino-3-aryl-3H-pyrido[2,1-b)benzoxazole-4-carbonitrile-2-ethyl carboxylate (13a-d).

Method A

To a solution of (1,3-benzoxazole-2-yl) acetonitrile **(1)** (1.58 g, 0.01 mole), sodium ethoxide [prepared from sodium metal (0.46 g, 0.02 mole) in absolute ethanol (40 ml)], arylidene ethyl α-cyanocinnamate **(11)** (0.01 mole) was added, and the reaction mixture was heated under reflux for 10 hrs. The reaction mixture was left to cool at room temperature, poured into an acidified crushed ice, filtered off, dried and crystallized from ethanol to afford pyridine ethyl carboxylate derivatives **(13b–d)**.

Method B

2-Arylidene benzoxazole-2-acetonitrile **(3)** (0.01 mole), catalytic amount of sodium ethoxide [prepared from sodium metal (0.46 g, 0.02 mole) in ethanol (40 ml)] and ethyl cyanoacetate **(12)** (1.13 g, 0.01 mole) was heated under reflux for 10 hrs. The reaction mixture was left to cool, then poured into ice cold water mixture and neutralized with dilute hydrochloric acid. The solid product which

precipitate was collected by filtration, washed with ethanol, dried and crystallized from ethanol to afford compound **(13a)**.

(13a) yield (2.72 g, 70%); (EtOH); mp 175–77ºC. IR (cm^{-1}): 3431, 3330 (NH_2), 3042 (CH-arom.), 2978 (CH-aliph), 2220 (CN), 1704 (C=O), 1600 (C=C) and 1023 (C–O–C); MS m/z (%): 389 (M^+ , not detected), 386 (M^+ -3, 0.17), 305 (36.38), 275 (100), 232 (15.72), 181 (13.54), 149 (13.64). Ana. Calcd. for. $C_{22}H_{19}N_3O_4$ (389.40): C 67.86, H 4.92, N 10.79. Found: C 67.84, H 4.74, N 10.65%.

(13b) yield (2.37 g, 65%); (EtOH); mp 200–02ºC. IR (cm^{-1}): 3375, 3237 (NH2), 3103 (CH–arom.), 2923 (CH–aliph), 2221 (CN), 1662 (C=O), 1584 (C=C), 1034 (C–O–C); ^{1}H–NMR (DMSO–d_6): 1.28–135 (t, 3H, CH_3), 4.26–4.36 (q, 2H. 6–Amino-5-(benzoxazole-2-yl)-4-aryl-3-cyanopyridine-2 (1H)-thio) nes) (16a-f).

Method A

A mixture of α,β-unsaturated nitrile **(14)** (0.01 mole), (1,3-benzoxazole-2-yl) acetonitrile **(1)** (1.58 g, 0.01 mole), sodium ethoxide [prepared from sodium metal (0.46 g, 0.02 mole) in ethanol (40 ml)] was heated under reflux for 12 hrs. The reaction mixture was left to cool at room temperature, poured into an acidified crushed ice, filtered off and the finally obtained solid product was crystallized from a suitable solvent to afford the substituted 3-cyano-pyridine-2(1H)-(thi) ones **(16a-c,e)**.

Method B

Equimolar amount of 2-arylidene benzoxazole-2-acetonitrile (**3**), cyano (thio) a cetamide (**15**) in ethanol (40 ml) containing sodium metal (0.46 g, 0.02 mole) was heated under reflux for 12 hrs. The reaction mixture was treated as before to produce the corresponding 3-cyanopyridine-2(1H)-(thi)one derivatives (**16d,f**).

(16a) yield (3.16 g, 90%); (ACOH); 219–20ºC. IR (cm-1): 3329, 3206 (NH2, NH), 2216 (CN), 1614 (C=N), 1555 (C=C), 1244 (C=S), 1048 (C–O–C); 1H–NMR (DMSO–d6): 6.86–7.20 (br.s, 2H, NH2), 7.5 (s, 3H, thiophene-H), 7.73 (s, 4H, benzoxazole–H), 8.98 (s, 1H, pyridine–NH). 2- Biological study

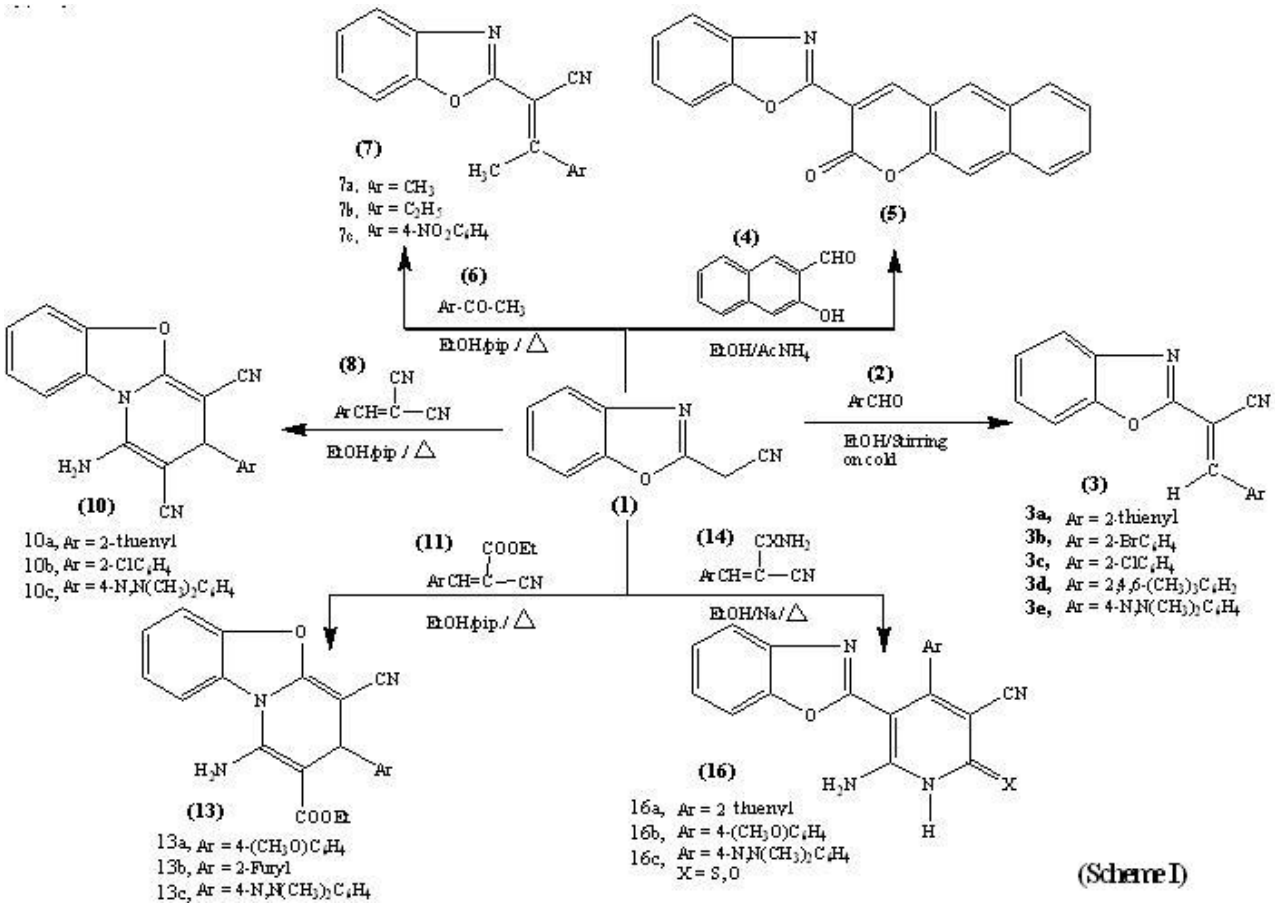
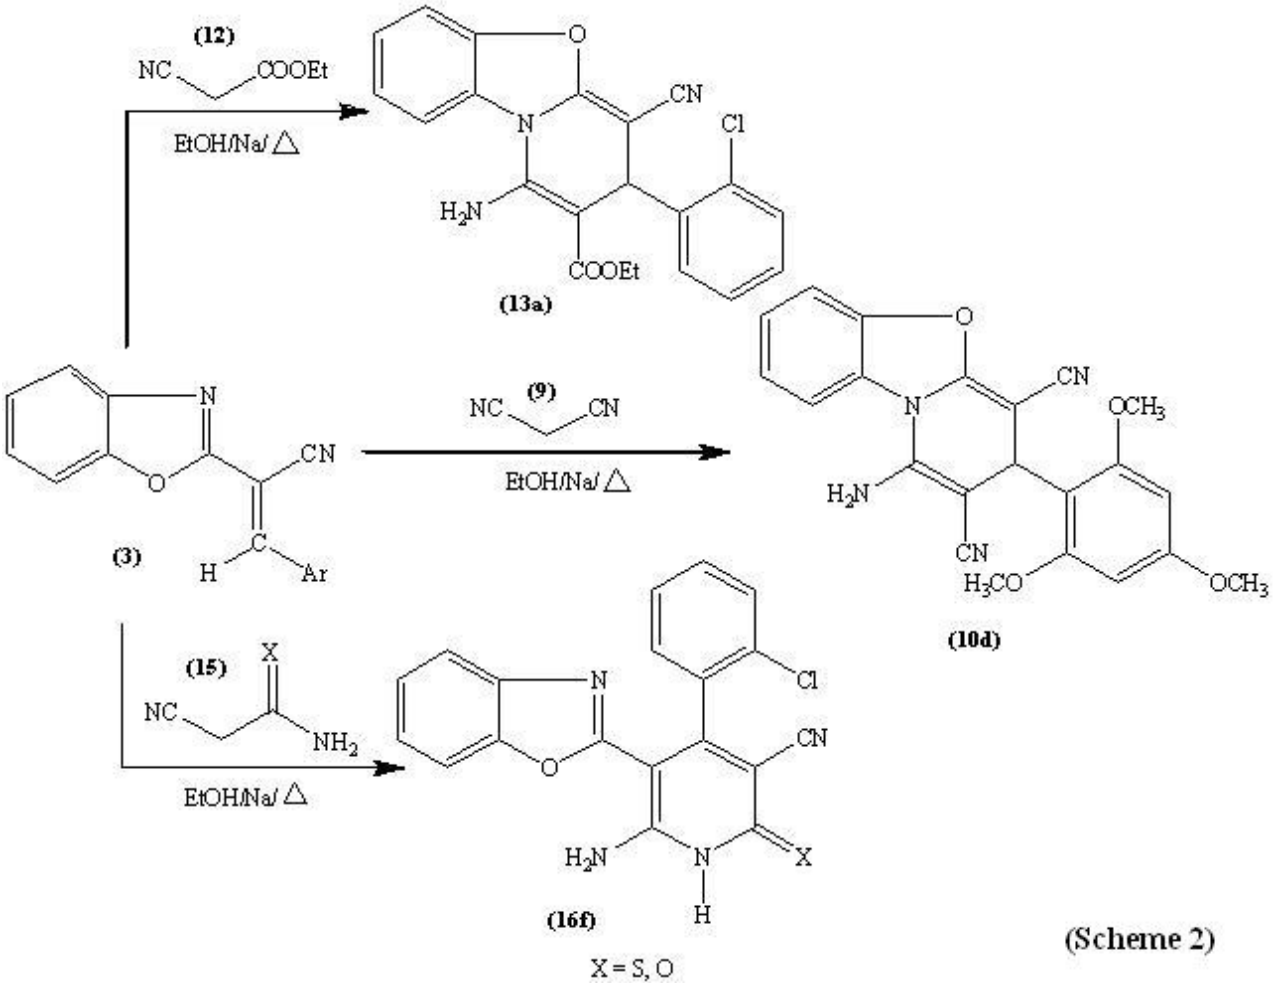
The herbicidal evaluation of the newly synthesized compounds on wheat as pattern for monocotyledonous plants.

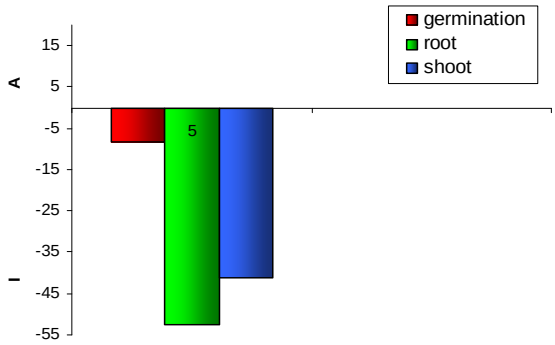
The herbicidal efficiency of the newly synthesized compounds and their derivatives was evaluated laboratory conditions against wheat as pattern for monocotyledonous plants with concentration of 2000 ppm. the percentages of inhibition of wheat growth parameters such as gerimination, root and shoot growth were taken as indicators to determine the herbicidal effect of these compounds .



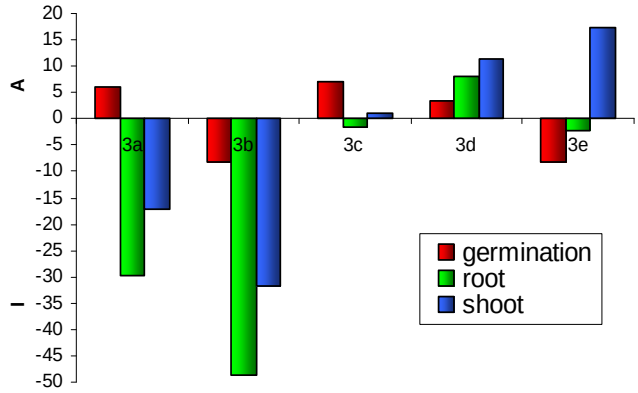
(Scheme I)



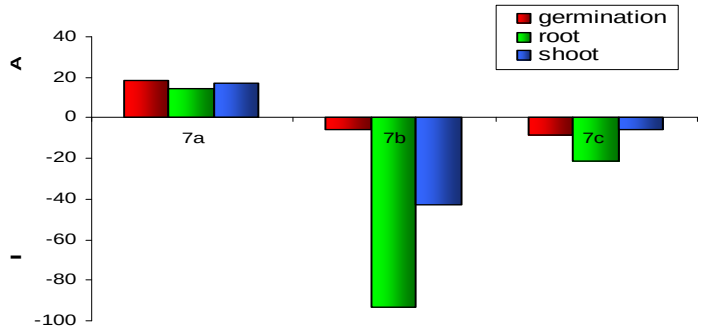
(Scheme 2)



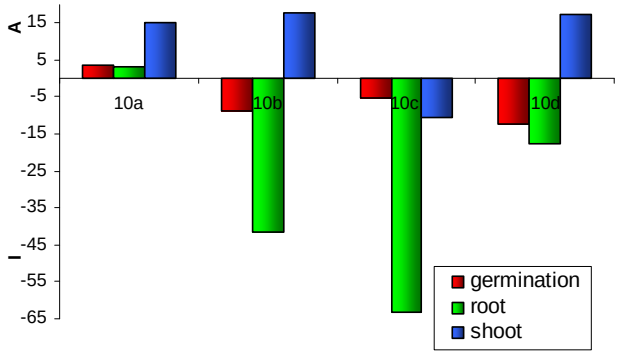
The effect of arylidenes (3a-e) on germination, root and shoot growth of wheat.



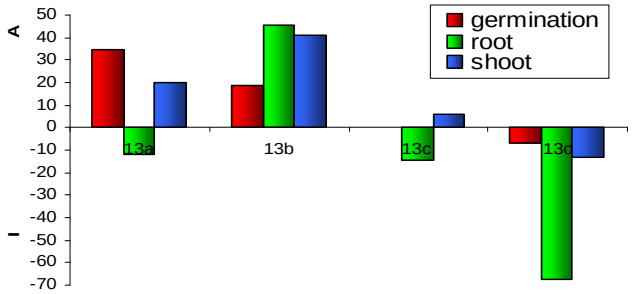
The effect of Coumarine (5) on germination, root and shoot growth of wheat.



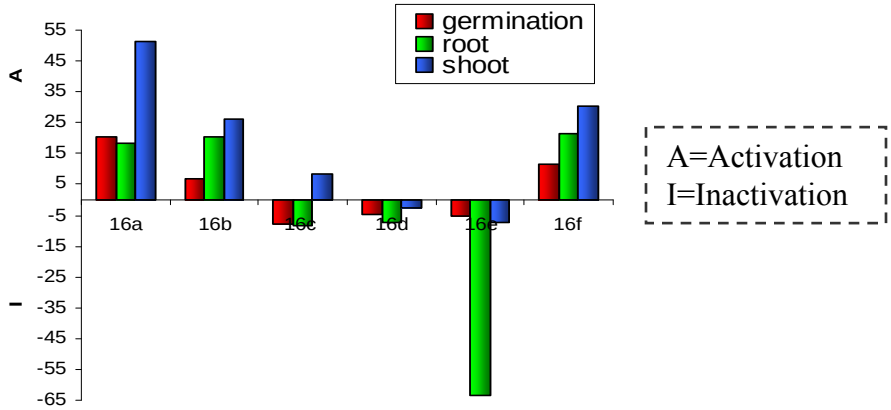
The effect of benzoxazoles (7a-c) on germination, root and shoot growth of wheat.



The effect of pyridobenzoxazoles (10a-d) on germination, root and shoot growth of wheat.



The effect of benzoxazoles (13a-d) on germination, root and shoot growth of wheat.



The effect of pyridine(thi)ones (16a-f) on germination, root and shoot growth of wheat.

According to figures (1-6) all compounds showed biological changes in growth parameters of wheat these changes were between activation to inhibition. Depending on the biological activity against growth parameters of wheat, the tested compounds could be classified as follow:

a) Compounds activated all growth parameters.
Compounds (**3b**),(**5**),(7b),(**7c**),(**10c**),(**13d**) and (**16e**) activated all growth parameters under study.

b) Compounds activated one or more of the growth parameters and inhibited the other parameter.
Compounds (**3e**),(**10d**) and(**16e**) activated gerimination and root growth, while compounds (**3c**),(1**3a**) and (**13c**) activated root growth and compound (**3a**) that activated both root and shoot growth.

c) Compounds inhibited all growth parameters.
Compounds (**16a**),(**16**b), (**16f**), (**13b**),(**10a**),(**7a**) and (**3b**) inhibited all growth parameters under study. Generally compounds that showed high inhibition percentage against all growth parameters were considered as promising compounds followed by that showed high inhibition effect against two growth parameters. So that, compounds (**16a**) ,(**16b**) ,(**16f**), (**13b**) and (**13a**) were considered as promising herbicide active ingredients . on the other hand all promising compounds except (**13b**) and (**13a**) were more effective against shoot growth than the other

growth parameters, whereas compounds (**13b**) and (**13a**) were more effective against root and gerimination respectively than the other growth parameters.

According to the obtained data , differences were found in activity between derivatives of the same compound. This differences may be explained on the basis of substitution, for example the presence of thienyl group, 2-chlorophenyl and methoxy phenyl substituents in (**16a**),(**16b**),(**16f**) respectively inhibited all growth parameters , while the presence of dimethyl amino phenyl in derivatives (**16a**) and (**16e**) resulted in an activation of all growth parameters.

From another point of view there is a relationship between some substituents and the herbicidal activity of the synthesized compounds as in case of compounds (**10a**),(**13b**) and (**16f**) due to the presence of thienyl group and as in compounds (**10a**) and (**10f**) due to the presence of 2-chorophenyl.

Conclusion

1. All synthesized compounds showed biological activity against growth parameters of wheat, the effect that was between activation to inhibition.
2. Compounds (**16a**),(**16b**),(**16f**) and (**13b**) were considered as promising herbicide active ingredients. These compounds caused high inhibition effect on all or on two from the growth parameters under study
3. Substituents play an important role in effectiveness of different derivatives of the same compound
4. There is a relationship between some Substituents and the herbicidal efficiency of the synthesized compounds including them such as thienyl and 2-chorophenyl groups .

Eperimental

Evaluation of Herbicidal Efficiency of the Newly synthesized compounds. Bioassay. Under laboratory conditions.

- Seed germination, root and shoot growth inhibition were carried out according to the procedure described by Powel and Spencer [34], some modifications were made for this work as described below.
- Serial concentrations from each compound was prepared by dissolving it in dimethyl sulfoxide and dilution with water. The calculated amount from each concentration was pipetted on thirty seeds of wheat as a test plant and agitated to coat the seed surface. Each ten seeds were transferred to petridish (90 mm diameter), lined with a dry filter paper and left at 25°C without led to grant solvent evaporation. After that, 6 ml distilled water was pipetted on the filter paper, Petridish was sealed with (PVC) electrical insulting tape. After complete germination of control (Petridishes containing untreated seeds), the number of germinated and non germinated seeds and radical length were recorded. Three replicates were done for each treatment.

Designing a Reliable Supply Chain Network Model under Disruption Risks

Nader Azad, Hamid Davoudpour

Department of Industrial Engineering, Amirkabir University of Technology, P.O. Box 15875-4413, Tehran, Iran
n.azad@aut.ac.ir

Abstract: In this paper, we consider random disruption risks in designing a reliable distribution network model. We consider the disputations in the location and the capacity of the distribution centers. In our model, the probability of disruption in distribution centers is dependent to the amount of investment for opening and operating them.
We show that this problem can be formulated as a non-linear integer programming model, and then for obtaining optimal solution, we linearize the mentioned model. In the following to solve the model in large-sized instances, a tabu search algorithm is developed. The results indicate that the tabu search method is efficient for a wide variety of problem sizes.

Keywords: Supply chain network, Distribution network, Facility location, Random disruption risks, Tabu search.

1. Introduction

Supply chain disruptions have gained considerable attention, especially in the last ten years. Although supply chain disruptions occur with very low probability, the consequences are typically catastrophic. In the literature, disruption risks are divided in two sections: random disruption risks and premeditated disruption risks. Random disruption risks may occur at any point in the supply chain networks, for example natural hazards (earthquake…) may strike at any point in the supply chain network. Premeditated disruption risks are more likely to target a supply chain to cause the maximum disruption. Terrorists and labor union are the examples of the premeditated disruption risks.

In this study, we focus on issues related to facility random disruption risks. For a thorough review of facility location problem and supply chain network design, see Hamacher and Drezner (2002), Barmel and Simchi-Levi (2000), Daskin (1995, 2003), Qin and tang (2010) and Klibi et al. (2010).

There are some papers in the literature for designing reliable network systems. Daskin (1983), ReVelle and Hogan (1989) and Batta et al. (1989) studied on the reliable network systems that their objective function was the maximizing the expected demand coverage while Hogan and ReVelle (1986) and Batta and Mannur (1990) focused on individual demand coverage with some degree of redundancy. Ostfeld and Shamir (1993) described the reliability methods for designing water distribution networks. Drezner (1987) proposed a reliable p-median problem and used a heuristic method for solving it. Recently, Tang et al. (2008) presented a facility location model based on reliability. They considered the level of customer service in their model. Gade and Pohl (2009) developed a capacitated facility location model with unreliable facilities. They used sample average approximation algorithm to solve their model. Wagner and Neshat (2009) developed an approach based on graph theory to quantify and mitigate supply chain disruption risks. Tancel and Alpan (2010) used a timed Petri nets framework for designing supply chain networks under risk.

The papers in the literature, consider the disruptions in the location of distribution centers. They assumed that when a disruption occurs at a distribution center, it fails. In this paper, we consider the disputations in the location and the capacity of the distribution centers. In this paper is assumed that when a disruption occurs at a distribution center, it dose not fail and the distribution center misses some of the capacity to service in disruption situation. The probability of disruption in distribution centers is dependent to the amount of investment for opening and operating them, i.e., we can reduce the probability of disruption in distribution centers with additional investments. In our model, distribution centers can ship goods together under disruption situation.

The remainder of this paper is organized as follows: In Section 2, mathematical formulation of the problem is presented. Section 3 discusses the solution approach for solving the problem. Our computational results are in Section 4. Conclusions are given in Section 5.

2. Problem description

Here, we present the reliable distribution network design model considering random disruption risk. We assume that there are two types of distribution centers in the model: reliable distribution centers and unreliable distribution centers. Disruptions occur in the unreliable distribution

centers. Reliable distribution centers are safe against disruptions and also when a disruption occurs in an unreliable distribution center, it does not fail. In this case, the unreliable distribution center misses some of the capacity to service in disruption situation. In our model, the probability of disruption in unreliable distribution centers and the amount of the capacity which the unreliable distribution center misses in the disruption situation are dependent to the amount of investment for opening and operating unreliable distribution center, and finally, the reliable distribution centers can ship goods to the unreliable distribution centers in disruption situation.

Before presenting the model, let us introduce the notations that will be used throughout the paper:

Index sets

K : Set of customers.

JT : Set of potential distribution centers. $(JT = JU \bigcup JR)$

JU : Set of potential unreliable distribution centers.

JR : Set of potential reliable distribution centers.

N : Set of available investment levels for opening and operating unreliable distribution centers.

Parameters and notations

D_k : Demand of customer k , ($\forall k \in K$).

fU_{jn} : Fixed cost for opening and operating unreliable distribution center j with investment level n , $(\forall j \in JU, \forall n \in N)$.

fR_m : Fixed cost for opening and operating reliable distribution center m , $(\forall m \in JR)$.

d_{jk} : Transportation cost from unreliable distribution center j to customer k , $(\forall j \in JU, \forall k \in K)$.

l_{mk} : Transportation cost from reliable distribution center m to customer k , $(\forall m \in JR, \forall k \in K)$.

C_{mj} : Transportation cost from reliable distribution center m to unreliable distribution center j , $(\forall m \in JR, \forall j \in JU)$.

Cap_j : Capacity of unreliable distribution center j , $(\forall j \in JU)$.

a_{jn} : The percentage of total capacity of unreliable distribution center j that is affected by disruption when it is opened with investment level n , $(\forall j \in JU, \forall n \in N)$.

q_{jn} : Disruption probability in unreliable distribution center j when it is opened with investment level n , $(\forall j \in JU, \forall n \in N)$.

Decision variables

$$XU_{jn} = \begin{cases} 1 & \text{if unreliable distribution center } j \text{ is opened with investment level } n. \\ 0 & \text{otherwise} \end{cases}$$

$$XR_m = \begin{cases} 1 & \text{if reliable distribution center } m \text{ is opened.} \\ 0 & \text{otherwise} \end{cases}$$

$$YU_{jk} = \begin{cases} 1 & \text{if customer } k \text{ is assigned to unreliable distribution center } j. \\ 0 & \text{otherwise} \end{cases}$$

$$YR_{mk} = \begin{cases} 1 & \text{if customer } k \text{ is assigned to reliable distribution center } m. \\ 0 & \text{otherwise} \end{cases}$$

T_{mj} : Amount of goods that is shipped from reliable distribution center m to unreliable distribution center j , $(\forall m \in JR, \forall j \in JU)$.

In terms of the above notations, the problem formulating is as follows:

$$Min: \sum_{j\in JU}\sum_{n\in N} fU_{jn}\, XU_{jn} + \sum_{m\in JR} fR_m\, XR_m + \sum_{j\in JU}\sum_{k\in K} d_{jk}\, D_k\, YU_{jk} + \sum_{m\in JR}\sum_{k\in K} l_{mk}\, D_k\, YR_{mk} + \sum_{j\in JU}\sum_{n\in N} q_{jn}\, XU_{jn}\left(\sum_{m\in JR} T_{mj}\, C_{mj}\right) \quad (1)$$

Subject to:

$$\sum_{j\in JU} YU_{jk} + \sum_{m\in JR} YR_{mk} = 1 \quad \forall k \in K \quad (2)$$

$$\sum_{m\in JR} XR_m \geq 1 \quad (3)$$

$$XR_h + \sum_{n\in N} XU_{hn} \leq 1 \quad \forall h \in JT \quad (4)$$

$$YR_{mk} \leq XR_m \quad \forall m \in JR, k \in K \quad (5)$$

$$\sum_{k\in K} D_k\, YU_{jk} \leq \sum_{n\in N} Cap_j\, XU_{jn} \quad \forall j \in JU \quad (6)$$

$$\sum_{m\in JR} T_{mj} + \left(1 - \sum_{n\in N} a_{jn}\, XU_{jn}\right) Cap_j \geq \sum_{k\in K} D_k\, YU_{jk} \quad \forall j \in JU \tag{7}$$

$$XR_m \in \{0,1\} \quad \forall m \in JR \tag{8}$$

$$XU_{jn} \in \{0,1\} \quad \forall j \in JU, \forall n \in N \tag{9}$$

$$YR_{mk} \in \{0,1\} \quad \forall m \in JR, \forall k \in K \tag{10}$$

$$YU_{jk} \in \{0,1\} \quad \forall j \in JU, \forall k \in K \tag{11}$$

$$T_{mj} \geq 0 \quad \forall m \in JR, \forall j \in JU \tag{12}$$

The model minimizes the total expected costs of the fixed cost for opening distribution centers, the transportation cost from distribution centers to the customers, and the expected cost of disruption situation. Constraints (2) make sure that each customer is assigned exactly one distribution center. Constraints (3) ensure that we locate at least one reliable distribution center. Constraints (4) state that we can not locate both reliable and unreliable distribution center at any potential node h. Constraints (5) link the location and allocation variables. Constraints (6) are the capacity constraints associated with the unreliable distribution centers. Constraints (7) state that for each unreliable distribution center j, the sum of the goods which is shipped from reliable distribution centers and the total capacity which is not affected by disruption, must be greater than the total demands of the customers that is assigned to it. Constraints (8)-(11) enforce the integrality restrictions on the binary variables and finally constraints (12) enforce the non-negativity restrictions on the corresponding decision variables.

2.1. Linearization of the model

Formulation (1)-(12) is nonlinear. However, the only nonlinear terms are $T_{mj} \times XU_{jn}$, each being a product of a continuous variable and a binary variable. We define a new variable as follows:

$$W_{mjn} = T_{mj} \times XU_{jn} \tag{13}$$

The formulation (1)-(12) can be written as follows:

$$Min: \sum_{j\in JU}\sum_{n\in N} fU_{jn}\, XU_{jn} + \sum_{m\in JR} fR_m\, XR_m + \sum_{j\in JU}\sum_{k\in K} d_{jk}\, D_k\, YU_{jk} + \sum_{m\in JR}\sum_{k\in K} l_{mk}\, D_k\, YR_{mk} + \sum_{j\in JU}\sum_{n\in N}\sum_{m\in JR} q_{jn}\, W_{mjn}\, C_{mj} \tag{14}$$

Subject to:

(2)-(12)

$$W_{mjn} \leq T_{mj} \quad \forall m \in JR, j \in JU, n \in N \tag{15}$$

$$W_{mjn} \leq M \times XU_{jn} \quad \forall m \in JR, j \in JU, n \in N, \quad M \text{ is a large number} \tag{16}$$

$$W_{mjn} \geq T_{mj} + M\left(XU_{jn} - 1\right) \quad \forall m \in JR, j \in JU, n \in N, \quad M \text{ is a large number} \tag{17}$$

$$W_{mjn} \geq 0 \quad \forall m \in JR, j \in JU, n \in N \tag{18}$$

3. Tabu search algorithm for solving the problem

In this section, for solving the large-sized instances, a tabu search algorithm is developed. Tabu search is a well known global search heuristic method to solve the combinatorial problems such as the proposed problem. The most important feature of tabu search algorithm is to avoid search cycling by systematically preventing moves taking the solution, in the next iteration, to points in the solution space previously visited. In the next sections, we describe the tabu search algorithm which we use for solving the problem.

3.1. Initial solution construction

For obtaining the initial solution, first we assign customers to the distribution centers, randomly. The procedure for obtaining the initial solution is as follows:

Step1: Put customers into a set K'.

Step2: 1- Select a customer from K' randomly. 2- Delete the customer from K'.

Step3: Select a distribution center randomly.

Step4: If the selected distribution center is reliable then assign the customer to the reliable distribution center and go to Step 7 otherwise (the selected distribution center is unreliable) go to Step 5.

Step5: If we select this unreliable distribution center for the first time then select an investment level for this distribution center randomly.

Step6: If remaining capacity of the unreliable distribution center is greater than the demand of the customer then assign the customer to the distribution center and go to Step 7 otherwise go to Step 3 for selecting another distribution center.

Step7: Is K' empty? If yes, go to Step 8, otherwise go to Step 2.

Step8: By using the heuristic algorithm (H1), determine amount of goods must be shipped form the

reliable distribution centers to the unreliable distribution centers in disruption situation.

Before presenting the improvement phase, let us describe the heuristic algorithm (H1). The steps of (H1) are as follows:

For each of the opened distribution center (a'_j), let L'_j be the sum of the demands of the customers that are assigned to a'_j.

Step1: 1-Put all of the unreliable opened distribution centers into a set K''.

2- Put all of the reliable opened distribution centers into a set E'.

Step2: Select an opened unreliable distribution center (a'_j) from K'', randomly.

Step3: For each reliable opened distribution center m in the set E', calculate $H'_{mj} = (L'_j - (1 - a_{jn})Cap_j)C_{mj}$.

Step4: Select the supplier from E' that has the minimum value H'_{mj} (Supplier m), then $T_{mj} = H'_{mj}$.

Step5: Delete the unreliable distribution center (a'_j) from K''.

Step6: Is K'' empty? If yes stop, otherwise go to Step 2.

3.2. Improving the initial solution

In this phase, the main objective is to improve the initial solution. We apply five different types of move for generating a candidate move: mov1, mov2, mov3, mov4, mov5. We generate a candidate move (from X_0 to the candidate solution X_n) using one of the five moves randomly.

Mov1: Randomly, one of the opened distribution centers (a'_j) is closed and all of the customers are reallocated among the remaining opened distribution centers. Finally, we apply heuristic algorithm (H1) to determine amount of good that must be shipped from the reliable distribution centers to the unreliable distribution centers in disruption situation. In this move, we must check that at least one reliable distribution center is located.

Mov2: In this move we select two opened distribution centers randomly, (a'_i, a'_j), and exchange a'_i and a'_j. Finally, we use the heuristic algorithm (H1) to determine amount of good that must be shipped form the reliable distribution centers to the unreliable distribution centers in disruption situation. In this move capacities of a'_i and a'_j are checked for serving the customers. Also, we must check that at least on reliable distribution center is located.

Mov3: One of the opened distribution centers (a'_i) is closed randomly, and a closed distribution center (a'_j) is opened randomly. If the opened distribution center is unreliable, we select an investment level for this distribution center randomly. Then we assign all of the customers corresponding to the eliminated distribution center (a'_i) to the new opened distribution center (a'_j). Finally, we use the heuristic algorithm (H1) to determine amount of good that must be shipped form the reliable distribution centers to the unreliable distribution centers in disruption situation. In this move the capacity of a'_j is checked for serving the customers.

Mov4: Select two opened distribution centers, randomly, (a'_i, a'_j). Then randomly select a customer (c'_i) in a'_i and a customer (c'_j) in a'_j and exchange c'_i and c'_j. Finally, we use the heuristic algorithm (H1). In this move we must check the capacities of distribution centers.

Mov5: Select one opened unreliable distribution center, randomly. Then randomly change the investment level for this distribution center.

4. Computational results

To evaluate the performance of our overall solution procedure, extensive computational experiments are designed with respect to series of test problems. The program is coded in Visual Basic 6.

4.1. Comparison of tabu search solution with optimal solution

For evaluating the tabu search method, nineteen instances are solved by LINGO.8 software (Table 1). For each instance, the tuning of the parameters is done by carrying out random experiments. For each instance, we run the tabu search method 20 times, and the average objective value is reported in Tables 1 to 2. Also, in Tables 1, 2 the coefficient of variation for each instance is reported (Coefficient of variation for the random variable X is defined as: Standard Deviation (X)/Average (X)). In the following tables DC and CV are the abbreviations of Distribution Center and Coefficient of variation, respectively.

It can be seen that the proposed tabu search solution are optimal (or near optimal) in different problem instances (Table 1). For instances 1 to 19, the average CPU time are less than or equal to 268 seconds for the proposed tabu search method; however, the maximal average CPU time for obtaining the optimal solutions is equal to 6783 seconds, and for problem instances 15 to 19 by a reasonable amount of time limit, LINGO cannot find the optimal solution, and the tabu search solutions in these problem instances are better than the best solutions that are obtained by LINGO software.

4.2. Comparison of tabu search solution with simulated annealing (SA) solution

For evaluating the proposed tabu search algorithm, we compare the proposed tabu search with the case that we use the simulated annealing (SA) algorithm instead of tabu search algorithm. The procedure of obtaining candidate moves used in the SA algorithm is the same as that in the tabu search algorithm.

From Table 2, it can be seen that the Average costs and CV values obtained by the tabu search algorithm are better than those obtained by the SA algorithm. This shows that selection of tabu search method is a good strategy in our solution method.

5. Conclusions

In this paper, we have considered random disruption risks in designing reliable distribution network model. We considered the disputations in the location and the capacity of the distribution centers. In our model, we assumed that the distribution centers can ship goods together under disruption situation.

We showed that our model can be formulated as a linear model. Also, we presented an effective tabu search algorithm to solve the large-sized instances. We comprised the tabu search algorithm with optimal solution and simulated annealing algorithm. The computational results indicated that the tabu search method is effective for solving the problem. For future works, it is interesting to consider disruptions in the transportation costs.

nadhussein@hotmail.com

Abstract: Background/Aim: Fetuin-A is a circulating calcium-regulatory glycoprotein that inhibits vascular calcification. In the present study, serum fetuin-A was studied as a novel risk factor for the development of endothelial dysfunction (ED) and hemostatic alteration in patients with chronic renal disease (CRD). **Patients and Methods:** 15 CRD patients on conservative treatment, 15 end stage renal disease (ESRD) patients on regular hemodialysis (HD) treatment and 15 healthy volunteers were enrolled in the study. Fetuin-A, thrombomodulin (TM), von Willebrand factor (vWF), tissue plasminogen activator (t-PA), plasminogen activator inhibitor (PAI-1), D-dimer, high sensitivity CRP (hs CRP) and IL-6 were measured by ELISA. **Results:** There was a significant reduction in Fetuin-A levels in CRD and HD patients compared to controls. A significant decrease was also detected in HD group when compared to CRD group. The inflammatory markers, hs CRP and IL-6, were significantly increased in CRD and HD patients in comparison to controls. The increase was also significant on comparing HD group to CRD group. A strong inverse correlation was found between serum fetuin-A and each of hs CRP and IL-6. In addition, regression analysis revealed that hs CRP is an independent determinant of serum fetuin-A level. The traditional markers of ED, TM and vWF, were significantly increased in CRD and HD patients compared to controls. The increase was also significant when HD patients were compared to CRD patients. The significant inverse correlation between fetuin-A and each of TM and vWF supports the hypothesis that low serum fetuin-A with subsequent vascular calcification could be one of the contributing factors for the development of ED in CKD and HD patients. The fibrinolytic parameters tPA, PAI-1 and D-dimer levels were significantly higher in CRD and HD compared to controls. HD patients had significantly higher values of the previously mentioned parameters in comparison to CRD patients. t-PA, PAI-1 and D-dimer were significantly correlated to fetuin-A in CRD and HD patients. **Conclusion:** The results of this study demonstrate that in CKD and HD patients inflammatory processes are increased and linked to low fetuin-A and vascular calcification which represents a novel risk factor for the development of ED. The interplay of these phenomena could be responsible for the development and progression of accelerated thrombogenesis that is peculiar to renal patients.

Introduction:

Hemostasis is a process of blood clot formation at site of vessel injury. When a blood vessel wall breaks, the hemostatic response must be quick, localized and carefully regulated. Bleeding or thrombosis may occur due to missing or dysfunctional moieties of the coagulation or fibrinolytic factors [1]. Disturbances in hemostasis are common complications of chronic renal disease (CRD). Their occurrence and severity correlate quite well with the progressive loss of renal function to end stage renal disease (ESRD) [2]. The association of CRD with thrombotic events is somewhat puzzling because renal disease is typically associated with increased bleeding tendency due to platelet dysfunction and disturbed plasma coagulation [3]. However, recent studies have indicated that CRD is associated with an impaired function of the vascular endothelium [4]. Profound endothelial dysfunction is a prominent pathologic feature of uraemia [5,6]. Endothelial cell injury is the probable cause due to uremic toxins retention, dyslipidemia, hypertension and secondary hyperparathyroidism as well as increased levels of interleukin-1 (IL-1) and tumor necrosis factor-α (TNF-α) [1]. If such a defect also involves the endothelial fibrinolytic system, it may provide a potential mechanism of reduced thromboresistance. It is probable that disturbances in fibrinolytic activity and endothelial dysfunction may play a role in vascular complications such as stroke or ischemic heart disease [7] which represent the

leading causes of morbidity and mortality in CRD [8].

Fetuin-A, a circulating calcium-regulatory glycoprotein that inhibits vascular calcification, is predominantly synthesized in liver. It is secreted into the blood stream and deposited as a noncollagenous protein in mineralized bones and teeth. During fetal life, there is high serum concentration of fetuin-A. Its level declines following infection, acute or chronic inflammatory states and malignancy [9,10]. Low serum fetuin-A levels have been reported in CRD and dialysis patients and is associated with inflammation and outcome [11,12]. Recent data have shown a relationship between vascular calcification and endothelial dysfunction (ED) in vascular disease [13]. Therefore, low serum fetuin-A level could be one of the contributing factors for the development of ED in CRD patients.

This study was designed to unveil the possible role of fetuin-A in the development of ED and hemostatic alteration in CRD patients.

Subject and Methods

Study population

The study was conducted on 30 patients admitted to Nephrology Department and Dialysis unit (Theodor Bilharz Research Institute). The patients were divided into two groups:

Group A: This included 15 CRD patients on conservative treatment (8 males and 7 females, ages ranging between 19-70 years with a mean of 44±14.9).

Group B: This included 15 ESRD patients (9 males and 6 females with ages ranging between 33-65 years with a mean of 52±9.9) on regular hemodialysis (HD) treatment (3 sessions weekly, 4 hours each for a period of more than 3 months) using Fresenius 4008 B machine, Hemophane filters with 1.4 surface area and sodium acetate solution as a dialyzate.

The etiology of CRD was variable between the 2 studied patient groups (hypertension, diabetes mellitus, urologic and unknown causes). None of the patients received blood or blood components transfusion therapy in the past 21 days and none of them was receiving erythropoietin therapy. This study was approved by the ethical committee of Theodor Bilharz Research Institute. Informed consents were obtained from all patients in accordance with the Declaration of Helsinki.

Fifteen age and sex matched healthy subjects selected from medical and paramedical staffs were included in the study to serve as a control group.

Sampling

A sample of 6 ml blood was collected from each subject into sterile endotoxin- free vacuum blood collection tubes, of which 2 ml were collected on potassium EDTA for hemogram by automated hematology analyzer ACT Differential (Beckman Coulter, France), 2 ml on trisodium citrate to measure thrombomodulin (TM), von Willebrand factor (vWF), tissue plasminogen activator (t-PA), plasminogen activator inhibitor (PAI-1) and D-dimer levels. In addition, 2 ml were withdrawn into a plain tube and left to clot. Sera obtained were collected for kidney function tests using standard methods. The rest of the sera were aliquoted, stored and kept frozen at -70° to measure the serum levels of fetuin-A, high sensetivity CRP (hs CRP) and IL-6.

Assay methods

Quantitative analysis of fetuin-A:

Serum fetuin-A level was measured by ELISA technique using human fetuin-A kit (BioVendor, France).

Quantitative analysis of inflammatory markers:

- High sensitivity CRP (hs CRP) was assayed by ELISA technique using hs CRP kit (BioVendor, France).
- Interleukin 6 (IL-6) was measured by ELISA technique using human IL-6 kit (BioSource, USA)

Quantitative analysis of endothelial and fibrinolytic markers:

- Plasma thrombomodulin (TM) level was assayed by ELISA technique using Asserachrom TM kit (Diagnostica Stago, France).
- Plasma von Willebrand factor (vWF) antigen level was assayed by ELISA technique using an Asserachrom vWF kit (Diagnostica Stago, France).
- Plasma level of tissue plasminogen activator (t-PA) antigen was assayed by ELISA technique using ZYMUTEST t-PA antigen kit (Hyphen BioMed, France).
- Plasma level of plasminogen activator inhibitor (PAI-1) antigen was assayed by

ELISA technique using ZYMUTEST PAI-1 antigen kit (Hyphen BioMed, France).

- Plasma D-dimer level was assayed by ELISA technique using ZYMUTEST D-dimer kit (Hyphen BioMed, France).

Statistical analysis

Statistical analysis was done by a statistical software package (SPSS 16.0 for Microsoft windows, SPSS Inc.). The levels of studied parameters were analyzed by Mann-Whitney test. Data were expressed as arithmetic mean ± standard deviation. Pearson correlation coefficient 'r' was used to measure the relationship between two variables. Stepwise multiple regression analysis was employed to evaluate any association between the serum level of fetuin-A and markers of endothelial dysfunction , inflammation and fibrinolysis markers tested. P values <0.05 were considered statistically significant.

Results

The results of all parameters studied in different groups are shown in table (1). The significant correlations detected in CRF and HD groups between the studied parameters are illustrated in table (2). Stepwise multiple regression analysis revealed that hs CRP is a significant independent determinant of serum fetuin A (B= -27.946, p=0.000) table (3) and that hs CRP as a marker of inflamation together with t-PA as a marker for fibrinolysis , are significant independent determinant of serum fetuin A {(B= -31.702, p=0.000) , (B= 1366.314, p=0.000) respectively} table (4).

Discussion and Conclusion

ED is common in patients with CRD and in patients on renal replacement therapy such as HD [14]. Progression of CRD is associated with both decreased endothelial function and increased prevalence of atherosclerosis, and vascular media calcification. All of which have been associated with mortality. ED precedes clinically detectable vascular disease [15-17]. It has been recognized for over 150 years that abnormalities in blood flow, vessel wall and blood components may contribute towards thrombosis (Virchow's triad) [18]. This simplified view is now modified by the recognition that the process of thrombus formation (thrombogenesis) requires complex interactions involving injury to the vascular endothelium, platelet adherence, aggregation and release, and clotting factor activation; this process eventually leads to thrombin generation and fibrin formation [19].Under physiological conditions, the vascular endothelium produces many substances which are closely associated with hemostasis, fibrinolysis, synthesis of growth factors, and the regulation of vessel tone and permeability. The etiology of ED is complex and involves dysregulation of multiple pathways [20].

In the present study, serum fetuin-A was measured in CRD and HD patients in a trial to clarify its potential contribution to ED and haemostatic alteration frequently encountered in these patients. The results obtained revealed significant reduction in Fetuin-A levels in CRD and HD patients compared to controls. These findings are in accordance with previous studies [21-24]. On the other hand, Ix et al,. [25] reported that serum fetuin-A concentration was not reduced in 970 patients with mild CRD. Caglar et al., [13] found that serum fetuin-A concentrations were decreased in all stages of CRD except stage 1. On the basis of these observations, it could be suggested that serum fetuin-A levels decline during the course of progression of CRD. This suggestion could be supported by the highly significant inverse correlation detected between serum fetuin-A and creatinine in CRD and HD patients included in the present work. The results also revealed significant decrease in serum fetuin-A levels in HD group in comparison to CRD group. Similar finding was reported by Ketteler et al [21] and Balon et al., [26]. A significant decrease of fetuin-A levels after a single HD session was also detected by Ciaccio et al., [27] and Errakonda et al., [28]. The results of the present study are in accordance with previous studies (Weinhol et al., [29] and Chang et al., [30], showing that CRD and HD patients had higher levels of inflammatory markers, as evidenced by the significant increase in hs CRP and IL-6 levels, in comparison to controls. Additionally, HD patients had significantly higher CRP levels compared to CRD patients. Chronic low-grade inflammation is a common feature of CKD. The causes of the highly prevalent state of inflammation in CKD are multiple and include factors such as volume overload, co-morbidity, intercurrent clinical events, the dialysis procedure *per se* as well as genetic factors [31, 26]. Chronic inflammation in CKD patients may contribute to down regulation of fetuin-A serum levels [32, 33, 24]. Our results revealed a strong inverse correlation between serum fetuin-A and each of hs CRP and IL-6. In addition, regression analysis revealed that hs CRP is an independent determinant of serum fetuin-A level. These findings support the hypothesis of inflammation-dependent down-regulation of fetuin-A expression and highlight the close relationship between inflammation and vascular calcification in CRD.

To evaluate the potential role of fetuin-A in endothelial cell activation and damage which could induce thrombosis, several measures of endothelial function and fibrinolytic parameters were assessed in

the current study. The traditional biomarkers of ED namely, TM and vWF were evaluated. They were significantly increased in CRD and HD patients compared to controls. The increase was also significant when HD patients were compared to CRD patients. This increase reflects the endothelial cell injury and denotes the presence of ED in CRD patients which was more pronounced in HD patients. Although ED in CRD and HD patients has been reported by many authors [7, 34, 35, 36], the precise mechanism that induces it is not clear. There are many postulations among which the accumulation of certain uremic factors [37], systemic inflammation which is closely associated with augmented oxidative stress [38], decreased oxygen supply to endothelial cells as a result of anemia [39], hypertension and shear stress [40], and the massive release of cytokines during dialysis [38]. Recent studies have demonstrated a possible role of fetuin-A in the pathogenesis of ED in CRD [41-43]. The present study demonstrated that the circulating biomarkers of ED (TM and vWF) showed a progressive and significant increase, in relation to the decrease of fetuin-A in CRD and HD patients. These findings are in accordance with those reported by previous studies [13,43] and support the hypothesized that low serum fetuin-A with subsequent vascular calcification could be one of the contributing factors for the development of ED in CKD and HD patients.

vWF is synthesized by, and stored in, endothelial cells. When released, it appears to mediate platelet adhesion and aggregation. The close association between vWF and the processes of thrombogenesis suggests that high vWF levels may be a useful indirect indicator of thrombosis [44] and also suggests that high vWF levels could contribute to thrombotic episodes in CRD and HD patients. The significant inverse correlation between fetuin-A and vWF clarifies the possible role played by fetuin-A in inducing thrombosis in CRD and HD patients.

The results of this study revealed that CRD and HD patients had significantly increased fibrinolytic parameters, t-PA, PAI-1 and D-dimer, compared to controls. HD patients had significantly higher values of the previously mentioned parameters in comparison to CRD patients. Gray et al., [45] and Bono,[46] stated that in patients with ischemic heart disease and diabetes respectively there is an approximately linear relation between t-PA and PAI-1 plasma concentrations; the equilibrium of the reaction is such that high t-PA and higher PAI-1 antigen concentrations are associated with low t-PA activity. The significantly increased t-PA, PAI-1 and D-dimer levels in our study population are consistent with a procoagulant state usually associated with the underlying ureamia, ED and proinflammatory changes. This finding was clarified by the significant inverse correlation between fetuin-A and each of t-PA, PAI-1 and D-dimer, in addition to the significant direct correlation between each of t-PA and PAI-1, and the inflammatory markers (hs CRP and IL-6) in CKD and HD patients studied. Similar findings have been reported by previous authors and they indicated that the increase in t-PA and PAI-1 reflected a mediated or facilitated endothelial cell injury as supported by certain clinical and experimental data [43, 47, 48]. An alternative explanation was that PAI-1 is an acute-phase protein that can rise in response to several stimuli, including cytokines such as IL-6. It has been speculated that the development of atherothrombotic events in CRD patients is due, at least in part, to an impaired fibrinolysis [49]. Regression analysis data revealed that hs CRP, as a marker of inflammation, together with t-PA, as a marker for fibrinolysis, are significant independent determinant of serum fetuin A which prove the impact of inflammation and fibrinolysis on serum fetuin A in patients with CRD.

In conclusion, the results of the present study seem to indicate that in CKD and HD patients inflammatory processes are increased and linked to low fetuin-A and vascular calcification which represents a novel risk factor for the development of ED. The interplay of these phenomena could be responsible for the development and progression of accelerated thrombogenesis that is peculiar to renal patients. Therefore, the use of therapeutic agents, such as sevelamer, which decrease inflammation and increase levels of the fetuin-A could be tried in CRD and HD patients to improve the endothelial function and minimize the thrombotic complications.

Abstract: Objectives: This work was designed to detect any changes in the gastric electrical activity and gastrin levels in infants with cerebral palsy (CP) and correlate them to the clinical findings.
Patients and methods: The study was conducted on 30 CP patients in comparison to 12 age and sex matched clinically healthy infants. All enrolled infants and children were initially subjected to complete history taking with special emphasis on gastrointestinal symptoms, clinical examination and routine laboratory procedures as well as total serum gastrin hormone by ELISA. Electrogastrographic (EEG) recording for gastric electrical activity was performed for all subjects upon enrollment.
Results: The initial power ratio was non-significantly higher in CP patients compared to the controls while the dominant frequency (DF) was non-significantly lower. Regarding the initial visual analysis of the EGG, ١٣ patients (٤٣.٣%) were normogastric compared to bradygastria in 16 (٥٣.٣%) of them. Initial serum gastrin was higher in CP patients compared to the controls. The regression analysis revealed that gastrin was the most determinant factor for dominant frequency values followed by the power ratio in the CP patients.
Conclusion: In conclusion, CP patients have disturbed gastric motility which explains the different proximal gastrointestinal clinical manifestations experienced by our patients and this should be considered during their nutritional rehabilitation programs.

[Nassar M.F. Aly R.H., Mahmoud N.H., El-Batrawy, S.R.and Abdel-Kereem N. **Electrogastrographic findings in cerebral palsy patients.** Journal of American Science, 2010; 6(12): 1106-1113]. (ISSN: 1545-1003). http://www.americanscience.org.

Key words: electrogastrography; gastrin; cerebral palsy.

1. Introduction:

Cerebral palsy (CP) refers to a group of childhood neurologic syndromes (pyramidal and extrapyramidal subtypes) resulting from a wide variety of genetic and acquired insults to the developing brain, with abnormalities in tone, posture, and movement on clinical examination [1, 2].

The survival of children with severe central nervous system damage has created a major challenge for medical care [1, 3]. Numerous clinical reports, in small series of patients, have indicated that brain damage may result in gastrointestinal (GI) dysfunction [4, 5].

A number of investigators have reported that neurologically handicapped children have abnormalities of lower esophageal function [6] and delayed gastric emptying is common in such patients [7]. Additionally, foregut dysmotility was previously reported in children with cerebral palsy [5, 7].

Gastrointestinal motility is defined as the action enabling the passage of food and waste products through the four main regions of the digestive system: esophagus, stomach, small intestine, and large intestine or colon. Gastric motility is regulated by a variety of mechanisms to insure that it occurs at a rate optimal for the digestion and absorption of nutrients and neutralization of gastric contents as neural and hormonal mechanisms [8]. Gastric motility can be evaluated by many methods as gastric emptying time, Electrogastrography, antroduodenal manometry, barostat studies and other newer methods for evaluation.

Gastrin is a gut hormone produced by cells called G cells in the lateral walls of the glands in the antral portion of the gastric mucosa. In addition, it is also found in the anterior and intermediate lobes of the pituitary gland, in the hypothalamus and medulla oblongata, and in the vagus and sciatic nerves. Stimulation of gastric motility is probably a physiologic action. Gastrin causes contraction of the musculature that closes the gastro esophageal junction [9]. It may have a physiological role in regulating proximal gastric mechanics by inducing gastric fundal relaxation and increasing gastric wall compliance. The effect of gastrin is dependent on acid secretion [10].

Hence, the aim of this study was to detect any changes in gastric electrical activity and serum gastrin hormone levels in CP patients and correlate them to the clinical findings.

2. Patients and methods:

This study was a cross- sectional, case-control study conducted on 30 children with CP following up in the Out-patient Pediatric Neurology Clinic, Ain-Shams University, in the period from March 2007 to September 2007.

The CP patients were 17 males and 13 females, with mean age of 6.38±3.77 years. They were compared to 12 clinically healthy children serving as a control group who were 6 males and 6 females with mean age of 7.50±2.24 years. The study was conducted after obtaining an approval from the Pediatric board at the children`s Hospital, Ain Shams University and taking an informed consent from the subjects' parents or caregivers.

Enrolled patients were free of any infection, with no history of epilepsy, or any other chronic disease or drug that might affect gastric motility and secretion.

All patients and controls were subjected to detailed history taking including perinatal, developmental and dietetic history as well as symptoms of GIT disturbance and feeding problems. Thorough clinical examination was done laying stress on anthropometric measurements and full neurological examination with special emphasis on the motor system.

Weight was measured using regularly calibrated scale with minimal clothing. Height was measured using a special board calibrated in centimeters and millimeters. Weight and height, were plotted against the percentiles to obtain the percent from the median for age. Body mass index (BMI): [Wt (kg)/ Ht2 (m)] was calculated from the previous weight and height measurements.

Routine laboratory procedures were performed including complete blood count, total protein and serum albumin as well as total serum gastrin hormone by ELISA using the Kit supplied by BIOHIT plc. (Biohitplc. Laippatie 1 Fin-0088 Helsinki, Finland). Normal fasting gastrin levels in our studied age group was considered as follows; 3-4 hours: 0.96-80.8 pmol/L, 5-6 hours: 1.44-56.3 pmol/ L, >8 hours: 0.48-60pmol/L [11].

Venous blood samples were collected under complete aseptic conditions from all enrolled subjects while fasting. The samples were divided into two halves the first was taken on EDTA for the complete blood count and the remaining part was kept in a dry sterile tube from which serum was separated by centrifugation. Samples for gastrin hormone were stored at -70^{o} C freezers till the time of test procedures.

Electrogastrographic recording for gastric electrical activity was done for all subjects upon enrollment. Recording was done from five disposable pre gelled silver/silver chloride surface electrodes placed on the upper abdomen after the skin had been carefully abraded to decrease resistance to obtain a good signal to noise ratio [12]. Infants and children under examination were kept in a reclining position to minimize motion artifact. Four electrogastrography (EGG) signals were recorded bipolarly from these five electrodes as the potential differences between each of the four electrodes. A reference electrode was placed at the left clavicle. The electrical signal was recorded with appropriate amplification and filtering. Filtering is needed to exclude cardiac and small intestinal electrical activity artifacts as well as respiratory and movement artifacts [13].

One hour recording was done while the patients were fasting then they were given a standardized test meal. The test meal was a semisolid one (milk, rice and high protein additive) which was adjusted to provide a volume of 20 cm^3/kg/feed and a caloric value of one eighth of the daily needs that are approximately 100 kcal/kg/day then post prandial recording was done for one hour [14].

EGG recordings were analyzed by computer using the Fast Fourier Transform (FFT) to detect the dominant frequencies in fasting and post prandial time periods. The FFT transforms the signal from the time domain to the frequency domain. An extension of the FFT technique is the so called Running Spectrum Analysis (RSA). In this technique power spectra of short over lapping stretches of EGG signals are computed and displayed as a function of time [15].

The following parameters were evaluated for each patient:

1. Mean dominant frequency (DF): The frequency of gastric peak was determined by the absolute peak value, and the mean frequency was computed by averaging the individual spectra.
2. Power ratio (PR): The ratio of power of the mean spectrum of post prandial state to the power of the mean spectrum of the fasting state. It is indicative of the post prandial increase in gastric motor activity and was calculated for the total post prandial period [16].

Higher harmonics were identified in the spectrum using the criteria that occur at frequencies that are exact multiples of the fundamental frequency and their power should be at least 5% of the power of the fundamental component. The early post prandial frequency dip of the normal 3 cycles per minute (cpm) gastric component was identified. A rhythmic electrical activity ranging from 2.5-3.75 cpm was defined as normal gastric electrical activity. Tachygastria was considered to be present when the power spectrum contained a sharp peak component with a frequency more than 3.75 cpm and less than

10.8 cpm. For a definite diagnosis of tachygastria it was required that at the same time the normal gastric signal was absent in all four EGG signals and that the abnormal rhythm was present for at least 2 min. When a tachygastric frequency was found in the presence of a normal gastric signal the diagnosis of tachygastria was considered probable but not definite.

Bradygastria was considered to be present when the dominant peak was less than 2.5 cpm. A dysrhythmic episode had to be present at least for 2 minutes with the absence of normal gastric signal [17].

The standard computer program SPSS for Windows, release 10.0 (SPSS Inc, USA) was used for data entry and analysis. All numeric variables were expressed as mean ± standard deviation (SD) as well as median [interquartile range (IQR)]. Kalmogrov Smirnov test was used to differentiate parametric from non parametric data. Comparison of different variables in various groups was done using student t test and Mann Whitney test for normal and nonparametric variables respectively. Chi-square (χ^2) test was used to compare frequency of qualitative variables among the different groups. Spearman's correlation test was used for correlating non-parametric variables. For all tests a probability (p) less than 0.05 was considered significant. Graphic presentation of the results was also done [18].

3. Results:

The results of the current study revealed that CP patients and the controls had matching age and sex. Repeated vomiting was present in 46.7% of our CP patients, 50% had chronic constipation and 36.7% suffered from gaseous distension. The CP patients were all non ambulatory and had significantly lower weight %, BMI as well as weight for age z scores compared to the controls (table 1). Additionally, although CP patients had lower hemoglobin levels and higher white cell counts, these comparisons were of no statistical significance.

As regard the EGG study, table (2) shows that CP patients had non-significantly higher PR and non-significantly lower DF compared to the controls. Additionally, table (3) demonstrated that by visual analysis more CP patients had bradygastria compared to the controls yet this result didn't reach statistical significance.

There was a highly significant lower DF in patients who complained of vomiting compared to those who didn't [mean values are 1.35±0.78 and 2.83±0.68 respectively and z (p) is 3.40 (<0.001)], while their mean PR was higher yet the latter comparison didn't reach statistical significance [mean values are 2.60±1.80 and 1.82±0.95 respectively and z (p) is 0.42 (>0.05)]. Additionally, 14 of the 15 children who suffered from vomiting had dysrhythmia.

Similarly, there was a highly significant lower DF in patients who complained of constipation compared to those who didn't [mean values are 1.33±0.63 and 2.95±0.66 respectively and z (p) is 4.16 (<0.001)], while their mean PR was higher yet the latter comparison didn't reach statistical significance [mean values are 2.57±1.85 and 1.84±0.97 respectively and z (p) is 0.33 (>0.05)].

Regarding serum gastrin, Fig (1) shows that the CP patients had significantly higher levels compared to the controls yet both patients and controls had their gastrin values within normal levels for age and sex.

Significant negative correlation was detected between serum gastrin levels and weight percentage for age (r = -0.495 and p<0.05) (Fig 2). Meanwhile there were no statistically significant correlations between DF and PR and weight percentage for age. There were no statistically significant correlations between serum gastrin, dominant frequency or power ratio and BMI.

Studying the effect of various studied parameters on dominant frequency of EEG in patients using multiple regression test revealed a significant effect (f = 2.50, p=0.06). Further analysis revealed that the factors causing this significance are serum gastrin (beta coefficient = -0.42 and p=0.03) and power ratio (beta coefficient = -0.42 and p=0.03) in the presence of the other studied factors.

Table (1): Comparison between the anthropometric measurements of the patients and controls.

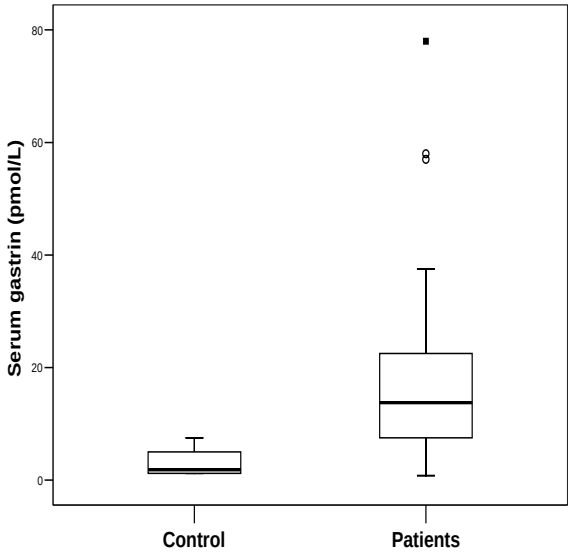
Variable	Patients		Controls		t/z*	p
	Mean±SD	Median(IQR)	Mean±SD	Median(IQR)		
Weight percentage from median for age	69.58±16.53	71.50 (22.00)	92.67±6.87	90.00 (9.00)	6.39	<0.001
Body mass index	15.13±3.82	14.05 (3.83)	20.27±5.58	18.45 (7.00)	-3.45*	<0.05
Height percentage from median for age	85.93±7.74	87.00 (12.00)	90.33±3.55	90.50 (7.00)	-1.87*	>0.05
Weight for age Z score	-2.58±1.37	-2.50 (2.10)	-0.53±0.55	-0.64 (0.81)	4.99	<0.001

Table (2): Comparison between patients and controls regarding power ratio and dominant frequency of the EGG study.

variable	Patients		Controls		z	p
	Mean±SD	Median(IQR)	Mean±SD	Median(IQR)		
Power ratio	2.21±1.50	1.49 (2.50)	1.53±0.60	1.60 (1.10)	-1.00	>0.05
Dominant frequency (cpm)	2.14±1.04	2.32 (2.20)	2.41±1.18	3.09 (2.40)	-0.84	>0.05

Table (3): Comparison between patients and controls regarding visual analysis of the EGG study

Variable		Patients number (%)	Controls number (%)	χ^2	p
Visual analysis	Normogastric	13.00 (43.30%)	8.00 (66.70)	2.05	>0.05
	Bradygastric	16.00 (53.30%)	4.00 (33.30)		
	Tachygastic	1.00 (3.30%)	0.00 (0.00)		



P=0.01

Figure (1): Serum Gastrin of patients and control groups.

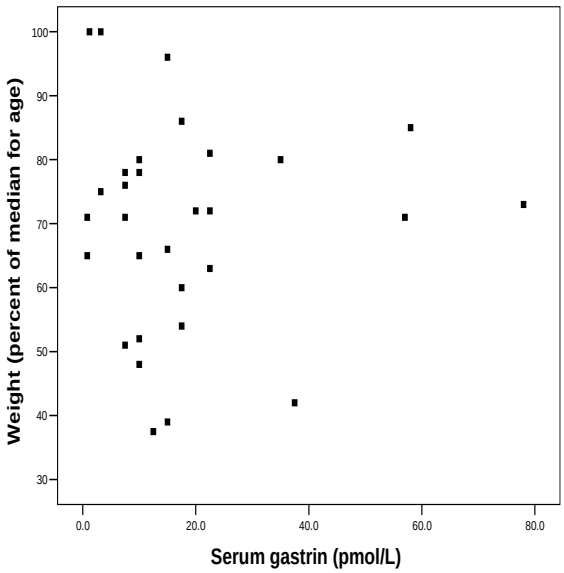


Figure (2): Serum gastrin levels with weight percentage for age of patients.

4. Discussion:

The current study revealed that the weight %, the body mass index and the weight for age Z score were statistically lower in CP patients when compared to those of the controls. Additionally, 76% of our series of CP patients had failure to thrive (mean BMI <19 [19] and Z score ≤-2 [20]).

In agreement with our results, Hurvitz et al., [21] who investigated the prevalence of overweight in a clinic-based population of children with CP and its association with gross motor function status reported that analysis of BMI in their study suggested that ambulatory children with CP had a high rate of overweight and are at risk of overweight than normal controls. On the other hand, they found that underweight is more prevelant in non ambulatory children, which is the case in our series of patients. Additionally, Feeley et al., [22] concluded that in an ambulatory CP population, patients with lower functional status or quadriplegia had significantly lower body mass index, suggesting that even highly functioning ambulatory CP patients are at risk for malnutrition.

Moreover, both Del Giudice et al., [5] who studied gastrointestinal manifestations in children with CP and Reyes et al., [23] who studied gastro esophageal reflux in children with CP, found that 52% of patients suffered from failure to thrive. Moreover, Ravelli and Milla [7] who studied vomiting and gastroesophageal motor activity in children with disorders of the central nervous system (CNS) reported that 62% of patients showed failure to thrive.

In an attempt to find the causes behind this problem, Vik et al., [24] suggested that this may in part be due to the cerebral injury and central dysfunction, in addition to the insufficient nutrition and lack of ability to self-feed.

As regards chronic GIT problems, 46.7% of our patients suffered from chronic vomiting, 50% had chronic constipation and 36.7% suffered from gaseous distension. In agreement with these findings, Ravelli and Milla, [7] found that all patients in their study suffered from vomiting and 46% of patients suffered from constipation. They concluded that in patients with CNS disorders, at least, the extrinsic innervation is abnormal, with gastric antral dysrhythmia resulting from abnormal activation of the efferent limb of the emetic reflex or from lack of inhibition of excitatory fibers as a consequence of either disturbed input to the hindbrain from higher centers or anatomic and functional disturbances of the vomiting centre and the area postrema. They demonstrated that most children who have brain damage have gastrointestinal impairments and that vomiting is a severe manifestation with significant morbidity which may persist even after surgery.

Similarly, Werlin [25] studied antroduodenal motility in neurologicaly handicapped children with feeding intolerance and found that 50% of patients suffer from vomiting. The author concluded that symptoms present in these patients might be due to an underlying forgut motor disorder.

Moreover, Del Giudice et al., [5] found that 91% of patients affected by CP had gastrointestinal symptoms. They also demonstrated that gastrointestinal motor dysfunctions are known to occur frequently in children with different degrees of brain damage and in neurologically impaired children and that the degree of GI dismotility seems to correlate with the degree of CNS damage. They confirmed that in this subset of children, chronic constipation is mainly due to prolonged transit at level of the more proximal segments of the colon. The authors further added that no child with CP presented with chronic constipation associated with soiling in contrast with neurologically normal children in whom constipation is characterized by fecal soiling.

In the current study, we found that, there was no statistical significant difference in gastric motility, as denoted by the power ratio and the dominant frequency of the EGG study, between patients and controls. However, the median values of the power ratio and the dominant frequency of the patients were lower than those of the control group. Additionally, there were no statistical significant differences between patients and controls as regard the qualitative visual analysis of the EGG study, yet the percentage of individuals with gastric motility dysfunction was more in patients (53.3% bradygastric, 3.3% tachygastric) than controls (33.3% bradygastric, 0% tachygastric).

Similarly, Ravelli and Milla [7] found that 62% (31/50) of patients with CNS disorders had antral dysrhythmia. Four had bradyarrhythmia, 12 had tachyarrhythmia, 12 had unstable electrical activity and 3 had mixed dysrhythmia in which no dominant frequency could be detected. They concluded that antral dysrhythmias could be caused by disordered intrinsic nerves of the enteric nervous system. Since their patients had various types of gastric antral dysrhythmias characterized by slower, faster, or disorganized electrical activity, they explained that this variability may be the consequence of the variable etiology, pathology, severity and site of neural lesions at the level of the CNS or the enteric nervous system.

Additionally, Werlin [25] studied antroduodenal motility in neurologically handicapped children with feeding intolerance and found that all

studied children had abnormal antroduodenal motility. The author concluded that in neurologicaly handicapped children, foregut dysmotility may be more common than is generally recognized and can explain many of the upper gastrointestinal symptoms in neurologically handicapped children.

In the current study, we found that there was a highly significant lower dominant frequency in patients who complained of vomiting compared to those who didn't; while their mean of power ratio was higher yet the latter comparison didn't reach statistical significance. Additionally, 14 of the 15 children who suffered from vomiting had dysrhythmia.

In agreement with our results, Ravelli and Milla, [7] found that 62% of children with disorders of the CNS and vomiting had antral dysrhythmia while patients without vomiting had similar dominant frequency as that of controls. They concluded that vomiting is related to gastric dysrhythmias and delayed gastric emptying possibly due to activation of the emetic reflex at least as often as gastroesophageal reflux.

Similarly, Miki et al., [26] in a study about antroduodenal motor function and gastro-oesophageal reflux in neurologically impaired children, reported that fasting antroduodenal motility was abnormal in 11 neurologically impaired children with vomiting. In 1998, Levanon and Chen [27] reported that impaired myoelectrical activity observed in the EGG is associated with disturbed motility and upper gastrointestinal symptoms (nausea, vomiting, abdominal pain) and suggested that EGG could be a useful tool in the primary evaluation of symptoms suggestive of gastroparesis.

In the current study, we found that there was highly significant lower DF in patients who had constipation compared to patients with no constipation. In agreement with our results, Ravelli and Milla [7] found that 60% of patients with disorders of the CNS and gastric dysrhythmia suffered from constipation. They concluded that chronic constipation might affect the motor activity of the stomach and the proximal small bowel.

In the current study both the patients and the control groups showed within normal fasting gastrin levels for age. Nevertheless, statistically significant higher fasting gastrin levels were found in CP patients. Meanwhile, no statistical significant difference was detected between hypertonic and hypotonic CP patients as well as those with GIT complaints versus those without.

Although many studies reported the gastrin increases gastric motility [28], yet relatively higher gastrin levels were associated with the predominance of bradygastria in our series of patients. We hypothesize that these results could be attributed to the fore-mentioned malnourished state of our CP patients which could have consequently lead to gastric mucosal atrophy [29] and/or gastric acid hyposecretion that in turn increases gastrin as a feedback mechanism [30–32]. In support of this point is the statistically significant negative correlation between serum gastrin levels and the weight percent detected in our series of patients.

Additionally, it was reported that gastrin strengthens the antral contractions against the pylorus, and constricts the pyloric sphincter, which has the effect of slowing the rate of gastric emptying [33]. Meanwhile other authors had concluded that injection of gastrin delays gastric emptying either directly [34-36] or through gastric acid action [10, 37]. The high gastrin found could thus be considered among the causes of the detected gastric motility disturbances in our series of patients. The previous point is further reinforced by the regression analysis of data which revealed that gastrin was the most determinant factor for dominant frequency values followed by the power ratio in our series of CP patients.

In conclusion, CP patients have disturbed gastric motility which explains the different proximal gastrointestinal clinical manifestations experienced by our patients and the disturbed gastrin levels could be considered among the causes. We thus recommend further larger scale studies to study the other hormonal and non hormonal factors affecting motility in CP patients; meanwhile, their feeding protocols should include small frequent meals in a semisolid rather than solid nature to overcome the gastric dysrrhythmias and delayed gastric emptying that they could subsequently suffer from.

Abstract: Background and study aims: Hepatocellular carcinoma (HCC) is one of the most common malignancies worldwide and one of the major causes of death. The aim of this study was to investigate the potential role of Angiopoietin-2 as a non-invasive marker for HCC. Patients and Methods: This study was conducted on 30 patients with documented HCC and 30 cirrhotic patients with no evidence of HCC; as well as 30 healthy subjects who served as control group. The levels of alfa fetoprotein (AFP) and angiopoietin-2 (Ang-2) were measured for all cases together with full clinical assessment, liver biochemical profile, viral markers, ultrasound, abdominal triphasic computerized tomography (CT) scan and guided liver biopsy for HCC cases with atypical triphasic CT pattern. Results: There was a statistically highly significant elevation ($p< 0.001$) in the mean serum AFP in HCC group (155.5 ± 271.5 ng/ml) when compared with the control group (6.3 ± 2.4 ng/ml) and also a highly significant elevation ($p<0.01$) when compared to the cirrhosis group (29.3 ± 31.2 ng/ml). There was a statistically highly significant elevation ($p< 0.001$) in the mean serum Ang-2 in HCC group (10855 ± 5321.92 pg/ml) when compared with both the control (480.67 ± 202.3 pg/ml) and cirrhosis (5578.33 ± 2928.21 pg/ml) groups. The diagnostic sensitivity of AFP at a cutoff of 200 ng/ml was 24% and the specificity was 100%. The cutoff level of Ang-2 for diagnosis of HCC in this study was 8100 pg/ml, with a sensitivity and specificity of 70% and 80% respectively. Serum Ang-2 was significantly elevated in HCC patients with portal vein thrombosis than those without. There was a significant positive correlation between the number of hepatic focal lesions and the serum level of Ang-2. The combined use of the two markers (AFP and Ang-2) led to an increase in the sensitivity of AFP from 53.3% to 83.3%. Conclusion: Serum Ang-2 is elevated in patients with cirrhosis and further elevated in patients with HCC, so its use as an independent tumor marker in the diagnosis of HCC is to be considered. Simultaneous measurement of serum AFP and Ang-2 may enhance the sensitivity of HCC detection.

Journal of American Science 2010;6(12):1114-1123]. (ISSN: 1545-1003). http://www.americanscience.org.

Keywords: Hepatocellular carcinoma (HCC)**,** Alpha-fetoprotein (AFP)**,** Angiopoietin-2 (Ang-2)

1. Introduction:

Hepatocellular carcinoma (HCC) is the most common primary malignant tumor of the liver *(El Serag & Rudolph, 2007).* Over a decade (1993-2002), there was nearly a twofold increase of the proportion of HCC among chronic liver disease (CLD) patients in Egypt with a significant decline of hepatitis B virus (HBV) and slight increase of hepatitis C virus (HCV) as risk factors *(El-Zayadi et al., 2005)*. Alfa-feto protein (AFP) is an inadequate screening test for HCC *(Sherman, 2001; Bruix & Sherman, 2005),* but still has a role in the diagnosis, since in cirrhotic patients with a mass in the liver an AFP greater than 200ng/mL has a very high positive predictive value for HCC *(Trevisani et al., 2001).* Angiopoeitin (Ang)-2 is a 66 kDa protein consisting of 496 amino acid residues which was detected by homology screening as a naturally occurring antagonist for both Ang-1 and the Tie-2 receptor. In adult mice and humans, they found that Ang-2 is expressed only at the sites of vascular remodeling (*Maisonpierre et al., 1997).* As HCCs are hypervascularized tumors the generation of new arterial vessels is a prerequisite for their survival. The induction of neoangiogenesis is mainly driven by hypoxia, leading to activation of several angiogenic pathways, including the angiopoietin/Tie-2 pathway. In this context, Ang-2 [in presence of vascular endothelial growth factor (VEGF)] allows remodeling of arterial vessels not stabilized by the effects of Ang-1 *(Holash et al., 1999).* Ang-2 is overexpressed in HCC-as measured by immunohistochemistry-especially of the highly vascular type *(Sugimachi et al., 2003).* Its expression is associated with portal infiltration, microvessel density, recurrence of HCC and decreased survival *(Wada et al., 2006).*

Recent studies reported high serum Ang-2 values in patients with HCC suggesting that it might represent a useful marker for HCC and a complementary diagnostic tool *(Scholz et al., 2007).*

The aim of this work was to investigate the potential role of Ang-2 as a diagnostic serum marker for HCC in patients with liver cirrhosis and to assess its sensitivity and specificity as compared to AFP and to assess whether the combined use of both markers can improve the diagnostic power of HCC.

2. Materials and methods

Study groups:

This study was conducted on 60 patients admitted to the Hepatology and Gastroenterology Department, Theodor Bilharz Research Institute (TBRI) in the period between November 2008 and June 2009. In addition, 30 apparently healthy individuals served as a control group.

They were divided into three main groups:

Group I (HCC group):

Included 30 cirrhotic patients with HCC, 19 of them were males (63.3%) and 11 females (36.7%). Five patients with focal hepatic lesions did not show the typical HCC pattern on triphasic CT scan: these lesions were biopsied guided by ultrasound for histopathological assessment and proved to be HCC.

Group II (liver cirrhosis group):

Included 30 patients with post hepatitic liver cirrhosis; 17 of them were males (56.7%) and 13 females (43.3%).

Group III (control group):

Included 30 apparently healthy individuals, 9 of them were males (30%) and 21 females (70%). They were completely free clinically, with normal laboratory findings, negative viral hepatitis markers and normal abdominal ultrasonographic findings.

Exclusion criteria:

Inflammatory or septic conditions as spontaneous bacterial peritonitis
(SBP).

Focal hepatic lesions other than HCC (cholangiocarcinoma, hemangioma, hepatoblastoma, metastatic focal lesions…etc).

Carcinoma elsewhere.

Methodology:

Full history taking and clinical examination were done to all patients and the following routine laboratory investigations:

- Complete blood picture and erythrocyte sedimentation rate (ESR).
- Liver function tests: alanine transaminase (ALT), aspartate transaminase (AST), alkaline phosphatase (ALP), gamma glutamyl transpeptidase (GGT), serum bilirubin (direct and indirect), serum proteins and serum albumin, prothromhin time and concentration (PT and PC) and international normalized ratio (INR).
- Renal function tests: serum urea and creatinine.
- Hepatitis markers: hepatitis B surface antigen (HBsAg), antibody to hepatitis B core antigen (HBcAb) total, antibody to hepatitis B surface antigen (HBsAb) and anti-HCV antibody.
- Fasting and 2 hours post-prandial blood sugar.

Evaluation of the severity of liver cirrhosis was assessed in each cirrhotic patient with the Modified Child score (Pugh et al., 1973).

Imaging studies:

Abdominal ultrasonography:

Abdominal ultrasonography was performed for all groups. Patients were examined using a real time machine (Hitachi, EUB-515A).

Liver was assessed for size, smoothness of the surface, texture, portal vein diameter, and thickening of portal tracts as an indicator for schistosomal hepatic fibrosis (Abdel-Wahab et al., 1992). The presence of focal lesions and their detailed description as regards number, size, site, echogenicity was reported. Doppler ultrasound was used to assess the patency of the portal vein so as to detect the presence of malignant thrombi and assess their extension. It was also used to detect any Doppler signals inside and around the lesions as the presence of intra-lesional arterial signals is highly suggestive of malignancy (Maruyama et al., 2008). A complete abdominal scanning was done to detect any other abnormality including the presence of ascites, lymph nodes or abdominal masses.

Triphasic abdominal CT scanning:

Spiral triphasic CT abdomen was done to all patients in HCC group for the diagnosis of hepatic focal lesions with specific features of HCC as previously described (Van Leeuwen et al., 1996) (Paley and Ros, 1998) (Hoon Ji et al., 2001).

Ultrasonographic-guided liver biopsy:

Biopsy was done to 5 patients with focal lesions using Trucut needles under ultrasound guidance after careful explanation of the procedure to the patient, with informed written consent to the procedure and after fulfillment of the following criteria:

1. Acceptable prothrombin time (<17 sec) and concentration (>60%), INR <2 and platelet count > 75.000/cc.
2. No ascites at the time of biopsy.
3. No other obstacles to liver biopsy (e.g. inaccessible lesion or lesion adjacent to vital structures like blood vessels).

All biopsies were histopathologically graded by Steiner-Edmondson grading system (Edmondson and Steiner, 1954).

Tumor markers:

A 15 ml blood sample was drawn from each subject immediately after diagnosis. Blood samples were centrifuged and serum aliquoted and stored at –70°C until tested for AFP and Ang-2.

1-Measurement of serum AFP (ng/dl)

AFP assay:

Serum AFP was measured by enzyme-linked immunosorbent assay (ELISA) technique using commercially available immunometric assays utilizing enhanced chemiluminescence (EQUIPAR Diagnostics, France) with cutoff 20 ng/dl as a maximum level of normal.

2- Measurement of serum Ang-2

Ang-2 assay characteristics:

Sensitivity:

The minimum detectable dose of the human Ang-2 is <6 pg/ml. This was determined by adding two standard deviations to the mean O.D. obtained when the zero standard was assayed 30 times, and calculating the corresponding concentrations.

Specificity:

Buffered solutions of a panel of substances ranging in concentrations from 10.000 to 50.000 pg/mL were assayed with the Human Ang-2 kit and found to have no cross-reactivity: Human Ang-1, Ang-4, granulocyte monocyte colony stimulating factor (GM-CSF), interferon (IFN)γ, interleukin (IL)-1β, IL-2, IL-4, IL-5, IL-6, IL-8, IL-10 and tumor necrosis factor (TNF)-α. Random normal serum samples from various species were also evaluated with the Human Ang-2 kit. No crossreactivity was observed with the goat, hamster, mouse and rat serum samples. There was moderate cross-reactivity with rabbit and swine, and significant cross-reactivity with fetal bovine, calf, horse and monkey serum samples.

Principle of the test:

The Human Ang-2 kit (Biosource International, USA) is a solid phase sandwich ELISA. A monoclonal antibody specific to human Ang-2 has been coated onto the wells of the microtiter strips provided. During the first incubation, standards of known human Ang-2 content, controls, and unknown samples are pipetted into the coated wells, followed by the addition of biotinylated second anti-Ang-2 antibody. After washing, streptavidin-peroxidase (enzyme) is added. This binds to the biotinylated antibody to complete the four-member sandwich. After a second incubation and washing to remove all the unbound enzyme, a substrate solution is added, which is acted upon by the bound enzyme to produce color. The intensity of this colored product is directly proportional to the concentration of human Ang-2 present in the original specimen.

Statistical Analysis

Results were expressed as mean ± standard deviation (SD). Differences between groups were analyzed either by using the Chi square test or student's t test and non-parametric (Mann Whitney test) for comparison between two groups or ANOVA test for multiple group comparison. Spearman rank correlation coefficient was used to determine significant correlations among different parameters. The analysis was performed using Statistical Analysis System, version 6.03, on an IBM at personal computer.

3. Results

The mean age ± SD within the HCC group was (50.6 ± 6.7) compared to the cirrhosis group (50.7± 6.0) and the control group (32.2± 7.2). The number of males within HCC, cirrhosis and control groups were 19/30 (63%), 17/30 (57%) and 9/30 (30%) respectively. There was no statistically significant difference in age and sex between the three studied groups. Table (1) showed the results of the laboratory liver profile of the studied groups.

Table (1): Liver profile of the studied groups

Parameters	HCC (n= 30)	Cirrhosis (n= 30)	Control (n= 30)	p value
Total bilirubin (up to 1mg/dl)	2.54 ± 2.06 a	2.67 ± 2.35 a	0.88 ± 0.22	a p< 0.01 vs. control HS
Direct bilirubin (up to 0.25mg/dl)	1.42 ± 1.45 a	1.56 ± 1.67 a	0.25 ± 0.05	a p< 0.01 vs. control HS
ALT (30-65 U/l)	56.5 ± 34.2 a	44.03 ± 27.58 a	19.37 ± 8.5	a p< 0.01 vs. control HS
AST (15-37 U/l)	60.57± 36.62 a	49.87 ± 31.04 a	24.77 ± 10.89	a p< 0.01 vs. control HS

S= significant P< 0.05 HS= highly significant P< 0.01

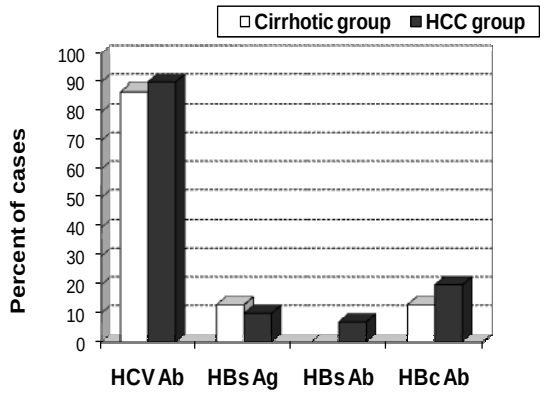

Figure (1): Viral markers of the studied groups

Among the cirrhosis group, 26 patients (86.7%) were positive for HCV antibody, while 4 patients (13.3%) had positive HBsAg and HBcAb and no patient was positive for HBsAb. Among the HCC group, 27 patients (90%) were positive for HCV antibody, 2 of those patients with HCV had previous exposure to HBV and were immune (HBsAb and HBcAb positive) and 3 patients (10%) were positive to HBsAg and HBcAb showing no statistically significant difference between both groups (Figure 1).

Five patients (17%) in the cirrhosis group were Child class A compared to 9 patients (30%) in the HCC group. Nine patients (30%) in the cirrhosis group and 10 patients (33%) of the HCC group were Child class B, while 16 patients (53%) in the cirrhosis group were Child class C as compared to 11 patients (37%) in the HCC group with no statistically significant difference between both groups.

The ultrasonographic features of the focal hepatic lesions in HCC patients showed that 19 patients (63%) had single focal lesion, 6 patients (20%) had 2 focal lesions, and 5 patients (17%) had multiple focal lesions. Four patients (13%) had focal lesions ≤ 2cms in diameter while 26 patients (87%) had focal lesions > 2cms in diameter. The focal lesions were located in the right hepatic lobe in 19 patients (63%), in the left hepatic lobe in 7 patients (23%), while 4 patients (13%) had focal lesions detected in both lobes. Twenty one lesions (70%) were hypo-echoic, 1 lesion (3.3%) was hyper-echoic and 8 lesions (26.7%) were iso-echoic. There were 5 cases (17%) of portal vein thrombosis in HCC group and none in liver cirrhosis group (0%).

As regards CT pattern of HCCs in triphasic CT scan: 25 lesions (83%) showed typical enhancement features of HCC (typical specific pattern of arterial uptake followed by venous washout in the delayed portal/venous phase), while 5 lesions (17%) showed atypical enhancement pattern on different CT scan phases and were biopsied under ultrasound guidance and examined histopathologically: 2 lesions (40%) were grade I, while the other 3 lesions were grade II (60%).

There was a statistically highly significant elevation ($p< 0.001$) in the mean serum AFP in HCC group (155.5 ± 271.5 ng/ml) when compared with the control group (6.3 ± 2.4 ng/ml) and also a highly significant elevation ($p<0.01$) when compared to the cirrhosis group (29.3 ± 31.2 ng/ml) (Table 2).

There was a statistically highly significant elevation ($p< 0.001$) in the mean serum Ang-2 in HCC group (10855 ± 5321.92 pg/ml) when compared with both the control (480.67 ± 202.3 pg/ml) and cirrhosis (5578.33 ± 2928.21 pg/ml) groups (Table 2)

Table (2): Mean levels of AFP and Ang-2 in studied groups

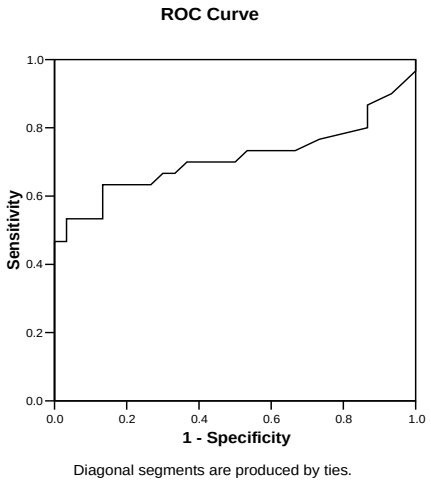
	HCC (n= 30)	Cirrhosis (n= 30)	Control (n= 30)	P value
AFP	*155.5±271.5* [a, b]	*29.3 ± 31.2*	*6.3± 2.4*	[a] *p< 0.001 vs. control* HS [b] *p< 0.01 vs. cirrhosis* HS
Ang-2	*10855.0 ± 5321.92* [ab]	*5578.33 ± 2928.21* [a]	*480.67 ± 202.30*	[a] *p< 0.001 vs. control* HS [b] *p< 0.001 vs. cirrhosis* HS

HS= highly significant P< 0.01

Specificity and sensitivity of AFP:

When using the receiver operator characterizing (ROC) curve, to improve the specificity and sensitivity of AFP in the differentiation between HCC and cirrhosis, the cutoff value of 75.5 ng/ml yielded a sensitivity and specificity of 53.3% and 86.7%, respectively (best cutoff). When the cutoff of AFP was increased to 200 ng/m1 the sensitivity dropped to 24% and specificity was 100% (Figure 2).

Figure (2): ROC curve for AFP



Specificity and sensitivity of Ang-2

1) Cirrhosis group *versus* control:

When using the ROC curve, to improve the specificity and sensitivity of Ang-2, the cutoff value of 1700 pg/ml yielded a sensitivity and specificity of 90% and 97%, respectively (best cutoff).

2) HCC group *versus* control:

When using the ROC curve, to improve the specificity and sensitivity of Ang-2, the cutoff value of 3900 pg/ml yielded a sensitivity and specificity of 93% and 100%, respectively (best cutoff).

3) HCC group *versus* cirrhosis:

When using the ROC curve, to improve the specificity and sensitivity of Ang-2, the cutoff value of 8100 pg/ml yielded a sensitivity and specificity of 70% and 80%, respectively (best cutoff) (Figure 3).

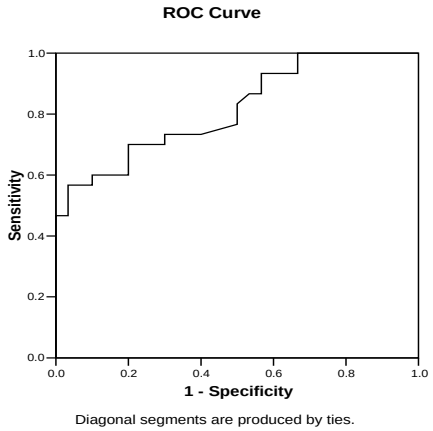


Figure (3): ROC curve for Ang-2 (cirrhosis versus HCC)

Table (3) showed the correlation between the level of Ang-2 and other parameters in the studied groups.

Figure (4) showed the inverse correlation between serum Ang-2 and serum albumin in patients with cirrhosis.

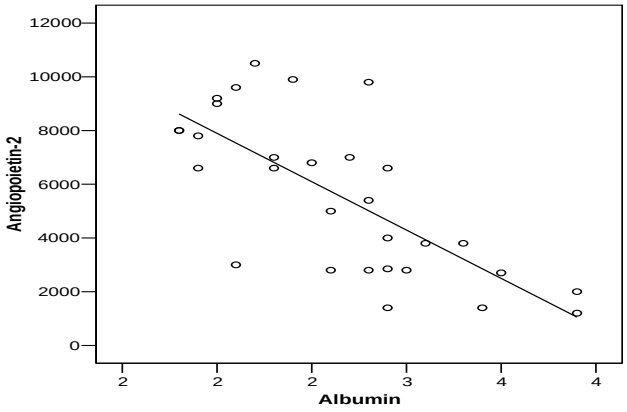

Figure (4): *Correlation between Ang-2 and albumin in cirrhosis patients.*

There was no significant correlation between serum level of AFP and the size or number of hepatic focal lesions.

There was a significant difference ($p < 0.05$) between the mean value of Ang-2 in HCC patients with portal vein thrombosis (5 patients) (19500.00 ± 4320.88) and those without (25 patients) (*9092.5 ± 3726)*.

4. Discussion:

At present, AFP is the most commonly used tumor marker in early HCC screening in populations at high risk, however serum AFP is associated with two main problems; first, the transient high rise in the serum level of AFP during exacerbation of hepatitis on top of CLD (serum level >100 ng/ml) and slight rise in the serum AFP in chronic hepatitis and cirrhosis (serum level >20 ng/dl) causing diagnostic difficulties (low specificity) (Kuntz & Kuntz, 2006). The second is that among all patients diagnosed with HCC, AFP levels may be normal in up to 40% of patients, particularly during the early stages (low sensitivity) (Sherman., 2001).

Serum angiopoietin-2 levels were elevated in patients with cirrhosis, implicating a possible role of the angiopoietin-Tie-2 system for neoangiogenesis in cirrhosis, and were further elevated in patients with HCC, suggesting the potential use of angiopoietin-2 as a marker for the detection of cirrhosis and HCC (Scholz et al., 2007).

This study was thus done to further investigate the potential role of Ang-2 as a diagnostic serum marker for HCC in patients with liver cirrhosis and to assess its sensitivity and specificity compared to AFP and whether -in association with AFP- Ang-2 improves the diagnostic power of HCC.

Chronic HCV infection, as a cause of cirrhosis, accounted for 90% of our HCC patients reflecting the close relationship between HCV and HCC. Our results are in agreement with El-Zayadi et al. (2005) who reported that HCV accounted for 86.9% of HCC cases during a single center study for HCC in Egypt over a decade. Darwish et al. (1997) reported also that viral hepatitis is strongly associated with the development of HCC in Egyptian patients and HCV seems to play a predominant role compared with HBV.

In our study HBV carriers were 10% in HCC group which was in agreement with El-Zayadi et al. (2005) who noticed a significant decline of HBV infection in HCC patients from 38.6% to 20.5% and attributed that partially to successful control measures of blood transfusion introduced in the mid-seventies and partially to the presence of undiagnosed cases of mutant or occult HBV infection, which requires costly assays for diagnosis. Yates et al. (1999) concluded that infection with HCV and HCV-HBV double infection, but not HBV alone, is strongly correlated with HCC in Egypt.

On using the ROC curve to reach the value of the best sensitivity and specificity of AFP; it has been shown that the sensitivity and specificity of AFP varied with the different cutoff values used. At a value of 75.5 ng/ml (the best cutoff), the sensitivity was 53% and the specificity was 87%. Bruix and Sherman (2005) reported the diagnostic cutoff of HCC at 200 ng/ml. In our study, when using this cutoff, the sensitivity declined to 24% while the specificity was 100%. This finding was comparable to that of Oka et al. (1994), who reported low sensitivity (13%) and a specificity of 97% at AFP values over 200 ng/ml. When we further increased the cutoff of serum AFP> 400 ng/ml, the specificity increased and the sensitivity decreased to 10% which was close to the results obtained by Rapaccini et al. (2004), who reported a sensitivity of 7.2% at a cutoff > 400 ng/ml.

In this study, AFP was elevated (>200 ng/ml) in only 23.3% of HCC patients and this was in agreement with Huo et al. (2004), who concluded that serum AFP level was a weak diagnostic predictor in HCC patients.

In this study, no significant correlation was found between AFP levels and the number and size of focal hepatic lesions. This is in accordance with Sato et al. (1994), who concluded that the rise in the serum AFP level did not usually correlate with the tumor size. This could be explained by the fact that tumor differentiation and its ability to secrete AFP are more important than the tumor size in determining the level of AFP produced by HCC (Okaet al., 1994).

In the current study, there was a significant correlation between AFP and the Child classification in the HCC group and this may be attributed to the presence of underlying CLD with subsequent cirrhosis and the progressive deterioration of the liver condition.

Our results revealed that there was a statistically highly significant elevation ($p< 0.001$) in the mean serum Ang-2 in cirrhosis group (5578.33 ± 2928.21 pg/ml) when compared to control group (480.67 ± 202.3 pg/ml).

These results are consistent with Scholz et al. (2007) who reported a statistically highly significant elevation of Ang-2 serum levels in cirrhosis patients when compared to control subjects. Although there are few data available regarding the expression of angiopoietins in cirrhosis in humans, many theories could be speculated in explanation:

Ang-2 is released in inflammatory conditions such as chronic HCV infection (Scholz et al., 2007). Salcedo

et al. (2005) reported that chronic HCV patients showed elevated serum baseline VEGF and Ang-2 levels. After treatment by interferon alpha 2b plus ribavirin, both factors were decreased, whereas antiangiogenic sTie-2 was increased, indicating a shift toward an "anti-angiogenic" profile of serum markers in chronic HCV patients.

In situ hybridization data had shown that Ang-2 mRNA expression was absent from hepatocytes of cirrhotic livers. Apart from endothelial cells of blood vessels, Ang-2 positive cells were found also within the connective tissue strands spanning between the portal tracts. Ang-2 expressing cells may include endothelial cells as suggested by their typical cellular morphology, as well as inflammatory and mesenchymal cells (Scholz et al., 2007). These data may argue against inflammation as the sole reason for elevated Ang-2 levels in serum of cirrhotic patients and emerge the fibrosis process as an extra explanation (Scholz et al., 2007).

Angiopoietins are overexpressed in the rat liver after partial hepatectomy but their role is less fully understood (Sato et al., 2001).

Other similar findings include generation of neovessels in livers of primary biliary cirrhosis patients accompanied by the increased expression of VEGF, Ang-2, and Tie-2 (Medina et al., 2005). Taken together, these published data suggest a causative role of angiogenic factors such as Ang-2 in the remodeling of the cirrhotic liver.

Furthermore, our results revealed that there was a statistically highly significant elevation ($p< 0.001$) in the mean serum Ang-2 in HCC group (10855.0 ± 5321.92 pg/ml) when compared to cirrhosis group (5578.33 ± 2928.21 pg/ml). These results are consistent with Scholz et al. (2007) who reported a statistically highly significant elevation of Ang-2 serum levels in HCC patients when compared to cirrhotic patients and also reported that Ang-2 mRNA was expressed in most of HCC cryopreserved biopsies (using in situ hybridization) in addition to positive staining of the intratumoral vessels.

In our study, when using ROC curve to improve the specificity and sensitivity of Ang-2, the cutoff value of 8100 pg/ml yielded a sensitivity and specificity of 70% and 80%, respectively (best cutoff). These results are consistent with Scholz et al. (2007) who reported a sensitivity of 70.56% and specificity of 73.28% when the high cutoff value of Ang-2 was used (12350 pg/ml), the sensitivity and specificity were 40% and 100% respectively. These results demonstrate that the high cutoff value of serum Ang-2 may show better results of specificity than the best cutoff value of (8100 pg/ml) at the expense of much decrease of sensitivity value.

Concerning the demographic features, hematological tests, ESR and liver function tests, our study revealed that there was no significant correlation between all of the previous parameters and serum Ang-2 levels, among both cirrhosis and HCC groups, with the exception of a significant positive correlation between direct bilirubin and serum Ang-2 level in cirrhosis group, and a significant inverse correlation between serum albumin, PC and serum Ang-2 in the cirrhosis group; consequently, there was a significant positive correlation between serum Ang-2 levels and Child classification in the cirrhosis group. Although Scholz et al. (2007) had reported no significant correlation between serum Ang-2 levels and Child classification, they found that discrimination between cirrhotic and control individuals by Ang-2 serum levels improved somewhat with the progression of cirrhosis. These interesting data are in need to be further studied to assess the significance of Ang-2 as a serum marker in liver cirrhosis and illustrate its role in liver remodeling process.

On the other hand, there was no significant positive correlation between serum Ang-2 levels and Child classification in the HCC group in our study, as was the case in Scholz et al. (2007). This may be explained by the fact that Ang-2 levels increase or decrease according to degree of differentiation of HCC, tumor density and portal vein invasion and not according to the degree of deterioration in liver functions.

In addition, serum Ang-2 did not exhibit a significant correlation with the tumor pathology or the size of focal hepatic lesions which was also in agreement with Scholz et al. (2007). However, there was a significant correlation between the number of hepatic focal lesions and serum Ang-2 level, but this may be attributed to the small number of patients having more than 2 hepatic focal lesions (16.6%) as compared to those with 1 or 2 lesions (83.3%), so, further studies are needed using larger number of patients with groups of comparable sizes to verify such correlation.

In our results, there was a significant difference ($p < 0.05$) between the mean value of Ang-2 in HCC patients with portal vein thrombosis (19500.00 ± 4320.88) and those without (9092.5 ± 3726). Li et al. (2006) reported a high expression of Ang-2 mRNA (using immunohistochemistry) in HCC cases with portal vein tumor thrombosis in comparison with those without; concluding that Ang-2 can promote tumor thrombus formation by modulating angiogenesis. Also, Kuboki et al. (2008) reported a significant relationship between high Ang-2 levels in hepatic vein and portal vein invasion. However, further studies are needed to verify such

correlation using larger number of patients and imaging modalities that can differentiate between malignant and non-malignant portal vein thrombosis.
There was no correlation between serum Ang-2 and serum AFP in patients of both the cirrhosis and HCC groups in our study. This was in agreement with Scholz et al. (2007) who reported no correlation between both markers in patients with HCC and in patients with cirrhosis.

In our results, the combined use of the two markers (AFP and Ang-2) led to an increase in the sensitivity of AFP from 53.3% to 83.3%. These results were in agreement with Scholz et al. (2007) who concluded that detection rates could increase from 71.0% when using AFP alone to 89.2% when using both markers.

5. Conclusion:

• Serum Ang-2 levels are elevated in patients with liver cirrhosis secondary to HCV infection, implicating a possible role of the Ang-2 in chronic HCV infection and remodeling in cirrhotic patients.
• The use of Ang-2 as an independent tumor marker in the diagnosis of HCC is to be considered as serum Ang-2 levels were more elevated in HCC patients when compared to cirrhotic patients.
• Ang-2 may be a helpful tool in the diagnosis of vascular invasion in patients with HCC, as it was significantly elevated in HCC patients with portal vein thrombosis when compared to those without.
• AFP was found to be a weak diagnostic predictor with low sensitivity. Decreasing the cutoff value was associated with improvement of sensitivity at the expense of specificity.
• Ang-2 could be combined with AFP to increase its sensitivity in HCC detection, as combined use of both markers gave the highest index of detection of HCC.

Double -Control, Randomized Study of Antibiotic Prophylaxis during Standard Dose Chemotherapy in Cancer Patients

Fatma Zakaria[*1] and Mohamad Zakaria[2]
Departments of Clinical Oncology[1] and Microbiology[2], Faculty of Medicine, Tanta University, Tanta, Egypt

Abstract: Background: Dilemma of antibacterial prophylaxis after chemotherapy still opened. Patients and methods:Double, control trial in patients who were receiving cyclic chemotherapy for solid tumors or lymphoma and who were at risk of temporary, sever neutropenia (fewer than 500 neutrophils/ml). Patients were randomly divided into two group, the first groups assigned to receive oral 500 mg of quinolone once daily for seven days during the expected neutropenic period, while the second group received no prophlaxis (control group). The primary end point was the incidence of clinically documented febrile episodes (FE) (temperature of more than 38^{o}C) due to infection. Assessment of the risk of FE in controll group on first versus non first cycles with or without first cycle FE in the light of different pretreatment factors. Secondary end point included the incidence of all infections, severe infections, hospitalization and cost. Results: A total of 403 patients randomly divided into 201 patients received antibacterial prophylaxis quinolone (levofloxacin®) and 202 patients as control group. The tumors included breast cancer 238 (59.1 percent), lung cancer 82 (20.3%), testicular cancer 34 (8.4%) and lymphoma 49 (12.2%). During the first cycle of chemotherapy, 3.5% of patients in the quinolone group had at least one febrile episode, as compared with 8.4% in the control group (P=0.009).The per- cycle FE rate for the first cycle was 8.4% compared with 4.4% in non first cycles in control group. During the entire chemotherapy course, 9.5% of patients in the quinolone prophylactic group had at least one febrile episode; as compared with 16.3% in the control group (P ≤0.005).There was significant reduction in the rate of G3&G4 neutropenia in quinolone group (52%). The respective rates of infections were 33.8% and 42.1% (p=0.098) for quinolone versus control group. Hospitalization was required for treatment of infection in 3% of patients in the quinolone group and 7% of patients in the control group (P≤0.05). Respective rates of reduction of cost and length of stay (LOS) were 51.8% and 51.6% for infections in quinolone prophylactic group. Respective rates of sever infections were 1.0% and 2.0% (p≤0.06), for quinolone and control group, with one infection related death in each group. An organism was isolated in 194/250 cycles (77.6% of infections). Conclusions: Quinolone prophylaxis (levofloxacin is preferred) should be offered to those receiving standard dose chemotherapy for solid tumors and lymphomas to reduce incidence of fever, infection, hospitalization and cost with rational selection of patients for antibacterial prophylaxis with first cycle chemotherapy.

Keywords: Antibiotic Prophylaxis; standard Dose; Chemotherapy; Cancer; Patient

1. Introduction:

Chemotherapy induced neutropenia (table 1) is not only a major risk factor for infection related morbidity and mortality, but also a significant dose - limiting toxicity in cancer treatment. Patients developing sever (grade 3/4) febrile neutropenia (FN) during chemotherapy frequently underwent dose reduction and/or delay to their chemotherapy. This may impact on the success of treatment, particularly when treatment intent is either curative or to prolong survival[(1)].

Meta-analysis of nine trials (731 patients) comparing fluoroquinolone prophylaxis with no prophylaxis demonstrated significant reductions in a number of outcomes of infections[(2-3-4)].

Quinolone (Levofloxacin ®) is an agent with an acceptable side-effect profile that is administered orally once daily, thus optimizing compliance, a major issue in prophylaxis[(5)].

It is active against a wide range of gram negative pathogens, as well as some gram-positive bacteria and organisms causing atypical pneumonias[(5)].

We conducted randomized trial designed to determine the efficacy of quinolone prophylaxis offering seven days prophylaxis during the period of anticipated neutropenia in patients with solid tumors or lymphomas.

2. Patients and Methods:

Four hundred and three adult patients with solid tumors and lymphomas treated inclusively during the period from January 2006 to December 2008, at Clinical Oncology Department, Tanta University. All patients at risk of bacterial infection were randomly divided into two groups the first one 201patients assigned to receive qinolone for seven days to cover the period of anticipated neutropenia

and another control group 202 patients. Patients remained enrolled in the trial for up to six cycles of chemotherapy. A cycle of chemotherapy was defined as the standard, minimal duration of a particular regimen between the start of one treatment and the next that was sufficient to allow recovery from acute adverse effects, including myelosuppression. Exclusion criteria at the time of randomization were active infection, current antibacterial therapy, planned use of G-CSF, a history of adverse reactions to fluoroquinolones, epilepsy, a creatinine clearance below 40 ml per minute, pregnancy, and breast-feeding. All patients gave written informed consent.

End points measures:

The primary end point was the incidence of clinically documented febrile episodes (FE), (defined by a temperature exceeding 38^{o}C due to infection) with or without neutropenia with assessment of grading for neutropenia, and assessment of febrile episodes in control group on first versus non first cycles with or without first cycle febrile episode. Infections incidence were the secondary outcome measure, infections were defined by at least one of the following: a clinically documented febrile episode, other signs attributed to a systemic response to infection, such as hypothermia (temperature below 35.6^{o}C), low grade fever (temperature, 37.5 to 37.9^{o}C), tachycardia (more than 90 beats per minute),or tachypnea (more than 20 breaths per minute), signs of a focus of infection, or the use of antibacterial therapy, we were reported episodes that occurred during each chemotherapy cycle or within four weeks after the final cycle. The incidence of hospitalization for infection and the frequency of severe infection were further secondary outcome measures. Severe infections were defined by the presence of infection-related sepsis syndrome (i.e. infection causing hypotension with or without evidence of impaired organ perfusion), death from infection or both.

Microbiologic outcomes included causative organisms isolated during infection, the clinical significance of isolates was assessed by a microbiologist. For episodes of infection, study medication was withdrawn for that cycle alone, but patients could remain in the trial for subsequent cycles.

Trial medication:

Trial medication consisted of 500 mg tablets of quinolone (as prophylaxis) once daily for seven consecutive days, treatment began on day 8 for 14 day and 21-day cycles, and on the day 15 for 28-day cycles.

Cost:

Costs were derived from charges reported on patients' tickets. Total costs per patient were computed by summing individual cost, where all patients were treated at our inpatient unit.

Statistical Analysis:

Statistical presentation and analysis of the present study was conducted, using mean, median, analysis of variance [ANOVA] test and the relative differences between the treatments groups were expressed as relative risks with 95 percent confidence intervals. Data on secondary outcomes relating only to cycles with infection are presented descriptively to identify patients at greater risk of infection during chemotherapy without antibacterial prophylaxis. The analysis assesses the association of baseline patients' characteristics with FE incidence using all the patients randomly assigned to the control arm and a multivariable analysis that includes all variables in the model is also used by SPSS v.12. P-value is considered significant, if ≤ 0.05, determined by chi-square test.

Table (1):Common chemotherapy regimens associated with intermediate or high risk of febrile neutropenia[1,2,3,4,5,6,7,8,9,10]

3. Results

From January 2006 to December 2008, 403 patients from Tanta University Hospital, Clinical Oncology Department, underwent randomization 202 as control group and 201 to quinolone prophlaxis. A total of 94.3 percent of patients had a WHO performance status of 0 or l, and more than half were treat in the adjuvant context. More than half of the patients had breast cancer, but substantial numbers were treated for lung and testicular cancer. The treatment groups were well balanced with respect to all baseline characteristics and risk factors (table 3). A total of 2278 cycles were analyzed and the number of cycles was studied.

Infection:

Of the 403 patients, 52 patients (13.0%) had at least one febrile episode, and there were 90 cycles with febrile episodes in total 2278 cycles (4.0% of cycles). At least one infection occurred in 153 patients (38.0%), and there were total of 250 cycles with infections in total of 2278 cycles (11.0% of cycles) (table 4). A clinically documented febrile episode occurred during the first chemotherapy cycle in 7 of 201 patients in the quinolone group (3.5 %), as compared with 17 of 202 patients in the control group (8.4 %) (Table 5). The relative risk of a clinically documented febrile episode was (relative risk 1.6, 95%CI (0.40-0.71), p≤0.009), indicating a (59%) reduction in the risk of fever during the first cycle with the use of quinolone therapy, as compared with control group. There was also a significant reduction in the incidence of the more inclusive category of infections with quinolone prophylaxis, as compared with control group, resulting in 39% reduction in the risk during the first cycle of chemotherapy (relative risk 2.33,95%CI (0.79-1.22), P≤0.001).

Data obtained during the entire chemotherapy were analyzed per patient rather than per cycle, and quinolone antibacterial prophylaxis was found to confer a protective benefit similar to that identified in the analysis of the first cycle (Table 5). During the entire course of chemotherapy, 19 out of 201 patients in quinolone group had a clinically documented febrile episode (9.5 %), as compared with 33 of 202 patients in the control group (16.3%). Prophylactic quinolone with thus associated with a 42.0% relative reduction in the risk of a febrile episode (relative risk 1.31, 95%CI (0.99-1.18), p=0.051) and a 20% relative reduction in the risk of infections (relative risk 0.98, 95%CI (0.76-0.91), P=0.098). Only 14 patients (7.0%) from the quionolone had more than one febrile episode. As regared neutropenia, from G1 to G4 was present 13 cycles in quinolon group in comparison to 38 cycles in control group with reduction rate 65.8% in febrile episodes with neutropenia. Thirty four cycles with neutropenia (G1 to G4) in comparison to 73 cycles in quinolone versus control group respectively with 53.4% reduction rate of infections with neutropenia.

Hospitalization for infection:

The reduction in the incidence of febrile episodes and infection associated with quinolone prophylaxis was reflected in a significant reduction in the percentage of patients hospitalized for infection (Table 5). There was 71.6 percent reduction in the risk of hospitalization during cycle 1 with quinolone therapy, as compared with control group (relative risk 0.70, 95%CI (1.15-1.96), P=0.011) and a 45.4 percent reduction across all cycles (relative risk 0.32, 95%CI (0.13-0.82), P value= 0.04).

Severe infections:

Severe infection characterized by infection related sepsis manifestations, death, or both occurred in two patients in quinolone group as compared with four patient in the control one (relative risk 0.11,95%CI (0.24-1.12), P=0.06), one patient died in each group. Two severe infections in the quinolone group occurred outside the period in which the white cell count was expected to be lowest, in comparison to four patient severe infections in control group, causing death in one patient, which occurred during the expected nadir period (Table 5).

Microbiologic outcomes:

The organism that was the probable cause of the febrile episode or episode of infection was isolated less frequently among patients in the quinolone group than among patients in the control group (46.9% vs 75.9% and 45.5% vs 60.9% respectively) (Table 6).

Adverse events:

Adverse events were reported in 38 cycles of 2278 cycles of chemotherapy (1.7 percent) there was a slight excess of adverse events in the quinolone group, owing to a higher rate of minor gastrointestinal symptoms and rash (Table 6).

Cost and length of stay (LOS):

Median duration of LOS were 6.5 days Vs 5 days for FE in quinolone group and control group per hospitalization respectively, with total length of stay 28 days in quinolone group Vs 73 days in, control group. Hospitalization for infections showed total LOS was 105 days for quinolone group in comparison to 217 days for control group with reduction of cost (51.8%) for hospitalization of infection in quinolone group (table 6).

Identifying risk factors for Infection and Hospitalization without antibacterial prophylaxis:

Tumor type: The different types carried different risks for FE across all cycles of chemotherapy and in cycle one (Table 7). Multivariable analysis identified lung and testicular cancers as the tumor types at significantly greatest risk for FE in all cycles and in cycle one (p=0.007&0.003).

Other pretreatment factors:

Poor performance status, advanced age 65 years or older and male sex have been linked to a higher risk of FE. The FE frequency was lower in patients undergoing adjuvant chemotherapy compared with those being treated for advanced disease, but this did not reach statistical significance (Table7).

First cycle versus later cycles:

Two hundred and two patients were randomly assigned to the control arm and received 1144 cycles of chemotherapy (mean, 5. 7 cycles per patient). Seventeen of them experienced a FE during the first cycle,(51.5%) (17|33).Thirty three controls, had at least one FE during the entire course of chemotherapy program,giving a per- patient FE rate of (16.3%) 33|202 .The FE rate for the first cycle was (8.4%) (17|202 cycles) compared with (4.4%)(41|942 cycles) in non first cycles.Approximately > 50% of episodes occurred in cycle one.

4. Discussion:

We studied the efficacy of antibacterial prophylaxis in patients treated for solid tumors and lymphomas with chemotherapy regimens associated with short periods of neutropenia and thus an increased risk of infection.

A simple, clinically relevant objective observation (fever, as defined by a temperature of more than 38^{o}C) attributed to infection as the primary outcome in our study,12.9 percent receiving conventional chemotherapy for solid tumors and lymphomas had at least one febrile episode with an over all incidence of 4.0% per cycle.

During the entire course of chemotherapy approximately 33.3% reduction in febrile episodes for patients in the quinolone group versus those in the control group (9.9% Vs 16.3%) and 58.9% reduction in febril episodes during the first cycle of chemotherapy for quinolone group compared tothe control group (3.5% Vs 8.4%) respectively in. There was significant reduction in grade 3&4 febril neutropenia in quinolone group (52%).

More than 50% of febrile episodes occurred in first cycle in the control group (table 5), with FE and hospitalization rates were twice more frequent in first cycle than subsequent cycle which is in agreement with other several trials[12,13,14,15,16,17] ,which recorded several explanations for this first-cycle effect, neutropenia, The explanation of this phenomena may be dose reduction of chemotherapy in subsequent cycles. The cytoreductive effects of the first chemotherapy cycle may enable resolution of a cancer related focus of infection (e.g. beyond an obstructed air way in lung cancer patients) or improvement in performance status. The first cycle of chemotherapy is noteworthy not only because of the high frequency of FE compared with later cycles, but also because FE in cycle one appears to separate patients into low and high-risk groups for subsequent episodes .[18,19]

Under pressure to limit antibacterial use, these exploratory data support offering prophylactic quinolone on cycle 1 only for myelosuppressive cancer chemotherapy and on subsequent cycles after a cycle-1 fever[19].

Pre-treatment factors and FE in first & non first cycles in control group, lung and testicular cancers in the control group were the tumor types with higher risksfor FE in first and non first cycles (p=0.007&0.003), the possible explanations for this effect may be due to, the majority of patients received etoposide which cause severe and unpredictable neutropenia[20], mucositis is also a frequent

consequence of etoposide exposure that predisposes to infection in control group. Poor PS has been linked to a higher risk of FE[21]. Age 65 years or older has been shown to confer a higher risk of FE[22], with male sex predominance for FE in first and non- first cycles without statistical significant difference (p=0.074). The reduction in the incidence of hospitalization for the treatment of infection was significant (45.9 percent), (p=0.04) for quinolone group for the entire course of chemotherapy. Seventy five percent of fever occurred outside the expected period of neutropenia (i.e. the period of prophylaxis), table (6). The two cases of sever infections and death from infection in the quinolone group occurred outside the expected period of neutropenia (i.e the period of prophylaxis), our results are supported by other studies that received prophylaxis with marked reduction in infection related outcomes, including death particularly in a cohort receiving intensified chemotherapy with G.CSF [23,24,25,26, 27].

Table (3): Patients characteristics:

Characteristics	Quinolone prophylaxis (n=201)	Control (n=202)
Sex- no%

Abbreviations: FE febrile episode, NHL Non- Hodgkin's lymphoma ,PS performance status, CT chemotherapy, RT radiotherapy.

Microbiologic confirmation was reported in our study where organisms were isolated in 65.6% of febrile episodes and (54%) of infections, also, organisms were isolated more frequently from cultures in the control group than in the quinolone group table (6), in agreement with where was reported in Michael et al. (2005) study [12]. The lower frequency of isolation of aganiones in cases of infection may be explained by fungal or viral causes. The effect on the development of resistance with the repeated use of short periods of fluoroquinolone prophylaxis on an out patient basis on patients receiving cytotoxic chemotherapy is unknown.

In our study, there is a significant reduction of cost of hospitalization with patients in quinolone group versus the control group (45.4 percent), for infection as reported in other studies [28, 29]. Cost associated with hospitalization for FN closely correlated with length of stay in hospitalization. Despite improved medical management, Febrile neutropenia continues to be associated with substantial morbidity, mortality, and cost not only placing a significant burden on the individual patient but on the health care system as a whole as reported in Caggiano et al study[29].

In conclusion, the administration of quinolone for seven days to cover the expected period of neutropenia after cyclic, standard dose, myelosuppressive chemotherapy in patients with solid cancer or lymphoma significantly reduced incidence of febrile episodes especially with the first cycle chemotherapy, clinically documented infection, hospitalization for the treatment of neutropenic infection and cost (where use of prophylaxis antibiotic limit the share of growth factors), with minimal adverse effects.Cycle 1 infection appear to identify patients at high risk of later FE who paradoxically, may benefit from prophylactic quinolone on later cycles, but further work is required to confirm these observations.

Abstract: The hepatoprotective effect of broccoli and red cabbage extracts against hepatocellur carcinoma induced by N- Nitrosodiethyamine (NDEA) in male rats were studied. Four groups of rats were used; group (1) was used as a negative control (normal), while rats of the other groups were given NDEA as a single interperoitenial dose with subcutaneous injection of carbon tetrachloride (CCl4) once weekly for six weeks to induce hepatocellular carcinoma. Group (2) was left as a positive control, while groups (3) and (4) were pretreated with broccoli and red cabbage 10%extract, for 12 weeks, respectively. At the end of the experiment, blood samples were taken for biochemical analysis and liver tissues were histopathologically examined. The obtained results revealed that rats with hepatocellur carcinoma (HCC) had significant increase in serum levels of AST, ALT, ALP, total protein, albumin, total and direct bilirubin and malondialdehyide (MDA), as well as significant decrease in reduced glutathione (GSH), glutathione peroxidase (GPX), superoxide dismutase (SOD) and catalase (CAT) enzymes, compared to the normal control group. Liver sections of rats with HCC showed fatty infiltration of hepatocytes, cytomegaly with karyomegaly as well as vesicular active nuclei and presence of more than one nucleolus in some hepatocytes. Oral administration of broccoli and red cabbage extracts caused significant reduction in serum levels of AST, ALT, ALP, total protein, albumin, total and direct bilirubin as well as MDA and produced significant increase in GSH, GPX, SOD and CAT, compared to the positive group. Liver of these rats revealed only slight hydropic degeneration of hepatocytes, while other sections showed apparent normal hepatocytes. This study concluded that broccoli and red cabbage have a protective effect against hepatocellular carcinoma in rats, therefore this study recommends increased dietary intake of broccoli and red cabbage may be beneficial for patients with liver cancer as a preventative measures.

Keywords: Broccoli; Red cabbage; Liver cancer; Biochemistry; Histopathology; Rat.

1. Introduction:

Hepatocellular carcinoma (HCC) is the most common form of liver cancer in adults, which accounts for about 75% of primary liver cancers. It is the 5th most common cancer in worldwide and represents 83% of all cases (Ferlay et al., 2001). In Egypt, HCC is frequent accounting for 13% of all cancer types (Inas, 2005). Liver cancers have different growth patterns; the first type begins as a single tumor that grows larger in hepatic tissue. The second type is spread through the liver almost from the beginning and is not confined to a single tumor. This is seen most often in people with liver cirrhosis. In the third type, the cancer develops as nodules in several parts of the liver (Strauss, 1995).

Risk factors for HCC include hepatitis B virus (HBV), hepatitis C virus (HCV) and aflatoxins are assumed to play an important role in the high incidence of HCC in Egypt. HBV vaccination of children and high-risk population must be the priority in reducing the incidence of HCC. Measures to reduce food spoilage by fungi and the associated dietary exposure to aflatoxins are a desirable public health goal (Wild and Hall, 2000).

Numerous compounds in the human diet have chemoprotective properties against chemical carcinogens (Wattenberg, 1990). Intake of a diet rich in fruits and vegetables is associated with a lowering risk of certain types of cancer (Steinmetz and Potter, 1991). Green leafy vegetables of all varieties and cruciferous plants such as cabbage, Brussels sprouts, cauliflower and broccoli are rich in anti-carcinogens (Block et al., 1992; Wargovich, 1999). Cruciferous vegetables contain a number of bioactive components such as folate, vitamin C, tocopherols, carotenoids, flavonoids and polyphenols (Price et al., 1998; Kurilich et al., 1999).

Broccoli is a plant of family *Brassicaceae* (formerly *Cruciferae)* which has large green flower heads (Murray and Lara, 2005). Recently, Elizabeth and Marcela, (2009) suggested that broccoli can decrease the risk for incidence of cancer. It contains many bioactive, including vitamins C and E, quercetin and kaempferol glycosides.

Red Cabbage *(Brassica oleracea* var. *capitata* f. *rubra)* is a type of cabbage, also known as Red Kraut or Blue Kraut after preparation (Michaelis et al.,

2008). The breakdown products of glucosinolates, which present in it such as isothiocyanates are considered responsible for the chemopreventive properties of red cabbage (Lynn et al., 2006).

The aim of the present study was to investigate the hepatoprotective effect of broccoli and red cabbage extracts against hepatocellur carcinoma induced by N - Nitrosodiethylamine in male rats.

2. Materials and methods:

2.1 Material:

2.1.1 Rats and Diet:

Male albino rats of Sprague Dawley strain weighing 175±5g were used. Their age between 14-16 weeks old and were purchased from the Laboratory Animal Colony, Ministry of Health and Population, Helwan, Egypt. Basal diet constituents were obtained from El-Gomhorya Company, Cairo, Egypt.

2.1. 2 Chemicals:

N-Nitrosodiethyamine (NDEA) was purchased from Sigma Chemical Company, USA. Carbon tetrachloride (CCl_4) was obtained from El-Gomhorya Company, Cairo, Egypt. Biochemical kits for serum analysis were purchased from the Gamma Trade Company for Pharmaceutical and Chemicals, Dokki, Egypt.

2. 1.3 Plants:

Broccoli and red cabbage were purchased from the local market, Cairo, Egypt. The plants were authenticated in the Botany Department, Faculty of Agriculture, Cairo University.

2. 2 Methods:

2.2.1 Preparation of plant extracts:-

Broccoli and red cabbage vegetables were cleaned, air dried and grinded into a fine powder. The powdered plants were extracted with 90% ethyl alcohol using Soxhlet apparatus and concentrated at low temperature(50Ċ) using a Rotary evaporator apparatus (manufactured in Basil, Switzerland) according to the method described by Mohamed, (2002). Each dried ethanol extract was dissolved separately in a mixture of carboxy methylcellulose and few drops of Tween 80 as a suspending agent to obtain 10% concentration liquid extract.

2. 2.2 Preparation of basal diet:

The basal diet (AIN-93M) was prepared according to Reeves et al., (1993). Diet was formulated to meet the recommended nutrients levels for rats.

2. 2.3 Experimental Design:

Forty male albino rats were fed on the basal diet and water was provided *ad libitum*. Animals were maintained under standard conditions of humidity (50-60%), temperature (20-25ºC) and light (12-h light: 12-h dark cycle) for one week before starting the experimental for acclimatization. Rats were divided into four groups of ten animals each as follows:

Group (1): Served as a control negative (normal rats) and fed on basal diet for 12 weeks.

Group (2): Kept as a control positive (with HCC) and fed on basal diet for 12 weeks.

Group (3): Fed on the basal diet and given orally 10% broccoli extract using stomach tube for 12 weeks.

Group (4): Fed on the basal diet and given red cabbage 10% extract orally by stomach tube for 12 weeks.

In first six weeks of experimental period, animals of groups (2), (3) and (4) were given a single intraperitoneal dose of NDEA (200 mg/kg b.wt.) followed by carbon tetrachloride (CCl4) tetrachloride (CCl4) given subcutaneously once weekly in a dose of 200 mg/kg b.wt. during the other 6 weeks for induction of HCC as described by Sundaresan and Subramanian (2003). At the end of the experimental period, blood samples were collected from the portal vein into dry clean centrifuge tubes for serum separation. Serum samples were frozen at -10°C until chemical analysis. Liver of sacrificed rats were kept in 10% formalin solution till processed for histopathological examination.

2.2.4 Biochemical analysis:

2. 2.4.1 Determination of liver functions:

Serum asprtate aminotransferase (AST) and alanine aminotransferase (ALT) activities were determined according to the method described by Kaplan, (1984). Serum alkaline phosphatase (ALP) was calorimetrically determined according to the method described by Roy (1970). Serum total protein concentration was calorimetrically determined according to the method described by Koller, (1984). Serum concentrations of albumin, total and direct bilirubin were determined as described by Kaplan, (1984).

2.2.4.2 Determination of malondialdehyde and reduced glutathione:

Serum malondialdehyde (MDA) was determined by the method of Draper and Hadly, (1990). Reduced glutathione concentration (GSH) in was measured by the method described by Beutler and Kelly, (1963).

2.2.4.3Determination of antioxidant enzymes:

The serum levels of glutathione peroxidase (GPX), superoxide dismutase (SOD) and catalase (CAT) were determined by autoanalyzer (Roche-Hitachi, Japan) according to the methods described by Hissin and Hilf, (1976); Kakkar et al., (1984); Sinha, (1972), respectively.

2. 2.5 Histopathological examination:

Liver of the scarified rats were taken and immersed in 10% formalin solution. The fixed specimens were then trimmed, washed and dehydrated in ascending grades of alcohol. Specimens were then cleared in xylol, embedded in paraffin, sectioned at 4-6 microns thickness, and stained with Heamtoxylin and Eosin stain for examination of the liver as described by Carleton, (1979).

2.2.6 Statistical analysis

The obtained results were expressed as Mean ± SE. Data were evaluated statistically with computerized SPSS package program (SPSS 9.00 software for Windows) using one-way analysis of variance (ANOVA). Significant differences among means were estimated at $p<0.05$ according to Snedecor and Cochran, (1986).

3. Results:

Data in Table (1) show that rats with HCC (positive control group) had significant ($p<0.05$) increase in serum level of AST (195.00±9.72 U/L), compared to normal rats (104.00±5.91 U/L). Oral administration of broccoli and red cabbage extract caused significant reduction ($p<0.05$) in serum level of AST (143.00±6.55 and 137.00±5.64 U/L, respectively) as compared to the positive control group (195.00±9.72 U/L). There were no significant changes in AST serum level between rats given broccoli or red cabbage extracts.

Table (1): Effect of oral administration of broccoli and red cabbage extracts on serum concentrations of AST, ALT and ALP of hepatocellular carcinoma rats.

(n=10 rats)

Groups	Liver enzymes (Mean ±SE)		
	AST (U/L)	ALT (U/L)	ALP (U/L)
Negative control	**e** 104.00±5.91	**d** 74.70±1.37	**d** 188.97±1.48
Positive control (HCC)	**a** 195.00±9.72	**a** 150.00±3.33	**a** 286.09±4.80
Broccoli extract (10%)	**cd** 143.00±6. 55	**cd** 84.40±3.35	**d** 193.34±2.62
Red cabbage extract (10%)	**d** 137.00±5.64	**bc** 95.00±3.87	**c** 211.79±1.31

Means with different superscripts letters are significant at $p<0.05$.

Results of hepatocellular carcinoma rats revealed that rats with HCC (positive group) had significant increase ($p<0.05$) in serum level of ALT (150.00± 3.33 U/L), compared to the negative control group (74.70±1.37 U/L). Oral administration of broccoli and red cabbage extracts to rats inflicted with HCC induced significant ($p<0.05$) reduction of levels in serum ALT (84.40±3.35 and 95.00±3.87, respectively) as compared to the control positive group. There were non-significant changes in serum levels of ALT between rats given orally either broccoli or red cabbage extract.

Tabulated results showed that serum level of ALP significantly ($p<0.05$) increased in positive control rats (286.04± 4.80 U/L) as compared to the negative control rats (188.97±1.48 U/L) as expected. Rats given orally broccoli and red cabbage extracts showed significant reduction ($p<0.05$) in serum level of ALP (193.34±2.62 and 211.79±1.31U/L, respectively), compared to the positive control group.

Results in Table (2) showed that rats with HCC had significant ($p<0.05$) increase in serum level of total protein and albumin (8.04±0.26 and 7.88±0.43 g/dL, respectively), compared to the normal rats (6.80 ± 0.26 and 4.88±0.10 g/dL, respectively). Oral administration of broccoli and red cabbage extracts caused significant ($p<0.05$) decrease in serum level of total protein and albumin as compared to the positive control group.

Table (2): Effect of oral administration of broccoli and red cabbage extracts on serum concentrations of total protein and albumin of hepatocellular carcinoma rats.

(n=1 0 rats)

Groups	Parameter (Mean ±SE)	
	Total protein (g/dL)	Total albumin (g/dL)
Negative control	**b** 6.80±0.26	**d** 4.88±0.10
Positive control (HCC)	**a** 8.04±0.26	**a** 7.88±0.43
Broccoli extract (10%)	**b** 6.49±0.33	**cd** 5.25±0.11
Red cabbage extract (10%)	**b** 6.63±0.11	**bc** 5.64±0.19

Means with different superscripts letters are significant at $p<0.05$.

Rats with HCC showed significant ($p<0.05$) increases in serum levels of total and direct bilirubin (0.71±0.01 and 0.94±0.02 mg/dL, respectively) as compared to negative control group (0.45±0.0 1 and 0.59±0.01mg/dL, respectively). Broccoli and red cabbage extracts significantly ($p<0.05$) decreased the serum levels of total and direct bilirubin, compared to the positive control group as shown in Table (3).

Results in Table (4) showed that rats with HCC had significant ($p<0.05$) increase in MDA (2.81±0.02 µmol/dL), however, GSH levels was decrease (25.42±0.25 µmol/dL), compared to the normal rats. Oral administration of broccoli and red cabbage extracts produced a significant ($p<0.05$) reductions in MDA (1.65±0.01 and 1.81±0.02 µmol/dL, respectively) and an increase in GSH levels (36.80±0.21 and 34.60±0.15 µmol/dL, respectively), compared to the positive control group.

Table (3): Effect of oral administration of broccoli and red cabbage extracts on serum concentrations of total and direct bilirubin of hepatocellular carcinoma rats.

(n=1 0 rats)

Groups	Parameter (Mean ±SE)	
	Total bilirubin (mg/dL)	Direct bilirubin (mg/dL)
Negative control	**d** 0.45±0.01	**c** 0.59±0.01
Positive control (HCC)	**a** 0.71±0.01	**a** 0.94±0.02

Means with different superscripts letters are significant at p<0.05.

Table (4): Effect of oral administration of broccoli and red cabbage extracts on serum concentrations of malondialdehyide and reduced glutathione of hepatocellular carcinoma rats.

(n=10 rats)

Groups	Parameter (Mean ±SE)	
	MDA (µmol/dL)	GSH (µmol/dL)
Negative control	f 1.23±0.03	a 40.21±0.12
Positive control (HCC)	a 2.81±0.02	e 25.42±0.25
Broccoli extract (10%)	d 1.65±0.01	c 36.80±0.21
Red cabbage extract (10%)	c 1.81±0.02	d 34.60±0.15

Means with different superscripts letters are significant at p<0.05

Antioxidant enzymes levels in serum of rats was significantly reduced in HCC rats compared to negative untreated group as shown in Table (5). Rats given orally broccoli and red cabbage extract showed significant (p<0.05) increases in serum levels of antioxidant enzymes as compared to the positive control group.

Histopathological examination of the liver of normal rats revealed normal histological structure of hepatic lobule as shown in Figure (1). Livers of rats with HCC showed fatty infiltration of hepatocytes, cytomegaly with karyomegaly as well as vesicular active nuclei and presence of more than one nucleolus as shown in Figure (2). Oral administration of broccoli extract at 10% to HCC rats revealed only slight hydropic degeneration of hepatocytes as shown in Figure (3). Other liver sections of the same group showed apparent normal heptocytes. Liver sections of rats with HCC given orally red cabbage extract at 10% revealed slight hydropic degeneration of some hepatocytes as shown in Figure (6), while other liver sections from the same group showed apparent normal heptocytes.

Table (5): Effect of oral administration of broccoli and red cabbage extracts on serum concentrations of antioxidant enzymes of hepatocellular carcinoma rats.

Figure (4): liver of rats with HCC rats treated with red cabbage extract showing slight hydropic degeneration of heptocytes. (H and E x 200).

4. Discussion:

The present study aimed to investigate the hepatoprotective effect of broccoli and red cabbage extracts at 10% against hepatocellular carcinoma induced by NDEA in rats. The biomarkers used in this study provide the measures

of carcinogen exposure in rats as an area of high risk for development of hepatocellular carcinoma. Results of this study showed that rats with HCC had significant increase in serum levels of AST, ALT, ALP, total protein, total and direct bilirubin as well as MDA. However, there were significant reductions in GSH, GPX, SOD and CAT, compared to the normal rats. The increase in these parameters in rats with HCC might be attributed to the injured structural integrity of the liver as they are released into the circulation after cellular damage induced by CCl4 and NDEA. These results agreed with those obtained by Pevicharova et al., (1997) who found that activities of AST, ALT and ALP were increased significantly following N-nitroso compounds treatment in rats. Moreover, Vozarova et al., (2002) mentioned that the elevated activities of AST, ALT and ALP enzymes were signs of impaired liver function in response to NDEA administration. Bansal et al., (2005) attributed the elevation of liver enzymes to their release from the cytoplasm into the blood circulation after rupture of the plasma membrane and cellular damage. Mittal et al., (2006) reported that NDEA administration caused a substantial liver damage as evidenced by the increases in the activities of AST and ALT enzymes in the treated rats.

Data in this study showed an increased in serum MDA concentration which may be related to the increased in free radicals. This finding was consistent with the observation that the free radicals reduced the activity of the endogenous antioxidant enzyme SOD (Conner and Grisham, 1996). It is known that free radical scavenging enzyme such as SOD protects the biological systems from oxidative stress. The current study showed a significant decrease in the activity of SOD in groups of rats administrated with NDEA (positive control). This reduction could be attributed to an enhanced production of free radicals during NDEA metabolism. Zwart et al., (1999) reported that lipid peroxidation produced several toxic byproducts such as MDA which can attack cellular targets including DNA, inducing mutagenecity and carcinogenicity. Administration of NDEA depleted the level of glutathione (GSH) in this study. Such depletion agreed with that reported by Kweon et al., (2003); Bansal et al., (2005); Sivaramakrishnan et al., (2007) and Pradeep et al., (2007) in their study. Since glutathione is required to maintain the normal reduced state of cells and to counteract all the deleterious effects of oxidative stress. Thus GSH is involved in many cellular processes including the detoxification of endogenous and exogenous compounds. NDEA is electrophilic carcinogens that interact with the large nucleophilic pool of GSH thereby reducing the macromolecule and carcinogen interaction (Ketterer and Meyer, 1989). The depletion of liver GSH in NDEA-treated rats may be responsible for the increased in lipid peroxidation. A significant decrease in the activities of GSH dependent enzymes, GPX and CAT in NDEA-treated rats may be due to decreased expression of these antioxidants during hepatocellular damage. Furthermore, the decreased levels of cellular GSH caused a reduction in their activities as GSH is a vital co-factor for these enzymes. The obtained results were in accordance with that reports by Kweon et al., (2003) who demonstrated that NDEA induced hepatocellular injury by a substantial fall in hepatic GSH, GPX and CAT activity, which then improved by administration of antioxidants. Boitier et al., (1995) reported that in hepatocellular carcinoma there is a disturbance between oxidant and antioxidant balance, which is tilted towards oxidant side.

Previous researches indicated that NEDA induced hepatocarcinogenesis in Wistar rats. It significantly elevated thiobarbituric acid reactive substances in the circulation of rats. Carcinoma indicated the higher levels of lipid peroxidation, which was accompanied by significantly decreased levels of antioxidants (reduced glutathione, glutathione peroxidase, superoxide dismutase and catalase) enzymes, as compared to the controls. Lipid peroxidation has been implicated as a major cause in cancer development (Sundaresan and Subramanian, 2003). A study by Dakshayani et al., (2005) demonstrated that the oxidative stress may be the reason for the elevated lipid peroxidation level in the liver of NDEA treated animals. These results were confirmed by Bansal et al., (2005) who reported that liver is the main site of NDEA metabolism, the production of ROS in liver may be responsible for its carcinogenic effects. In addition, Mittal et al., (2006) concluded that nitrosamines caused the generation of reactive ROS resulting in oxidative stress which alter the antioxidant defense system in the tissues.

With regard to the effect of NDEA on liver structure in rats, our results were agreed with Lijinsky, (1992) who showed that NDEA caused a wide range of tumors in all animal species and induce cancer in a variety of rodent organs, especially the liver. Devi et al., (2000) revealed that disarrangement of normal hepatic cells with centrilobular necrosis vacuolization of cytoplasm and fatty degeneration were observed in carbon tetrachloride intoxicated mice. This suggested that prolonged cell damage by chronic inflammation is critical in cancer development. Over production of nitric oxide has been implicated in the tissue damage caused by inflammation, contributing the tumor promotion (Nishikawa et al., 1998). Moreover, Singh et al., (2004) reported that oxidative stress caused by reactive oxygen species generated after administration

of NDEA has been reported in membrane lipid peroxidation, and has been associated with various stages of tumor formation process.

This study revealed oral administration of broccoli and red cabbage extracts caused significant decrease in serum levels of AST, ALT, ALP, total protein, total albumin, total and direct bilirubin and MDA. However, there were significant increases in the levels of GPX, SOD and CAT as well as improved liver structure, compared to the positive group. Consequently, administration of broccoli or red cabbage extracts could prevent or decreased the incidences of hepatocarcinogenesis in rats induced by NDEA. These results agreed with Wargovich, (1999) who reported that cruciferous vegetables namely cabbage, Brussels sprouts, cauliflower and broccoli are rich in anti-carcinogens. A possible mechanism of reduced activities of the tested enzymes and hepatoprotective effect of broccoli and red cabbage extract may be related to their antioxidant effect of the phenolic and flavonoids compounds. Previous study reported that polyphenols can inhibit nitrosation and flavonoides have hepatoprotective activities (Orhan et al., 2007). Since flavonoids are a group of potentially chemoprotective compounds and have similar structures that consist of 2 phenolic benzene rings linked to a heterocyclic pyre or pyrone (Aherne and O'Brien, 2002). It has many biological effects that play a role in cancer prevention, including free radical scavenging, antimutagenic and antiproliferative properties, regulation of cell signaling and cell cycle, and inhibition of angiogenesis (Moon et al., 2006). In vitro and vivo experimental studies suggested that flavonoids influence signal transduction pathways (Frigo et al., 2002), and inhibit proliferation in human cancer cell lines (Manthey and Guthrie, 2002).

Cruciferous vegetables contain several chemical compounds that may modulate the carcinogenic process. These compounds act as antioxidants or as inhibitors and/or inducers of phase I and phase II enzymes (Fong et al., 1990; Bradlow et al., 1991). Phytonutrients in Crucifers vegetables work at a much deeper level and actually signal genes to increase production of enzymes involved in the detoxification. Lampe and Peterson, (2002) revealed that anti-carcinogenic actions of cruciferous vegetables are attributed to their content of glucosinolates (GLS). Fowke et al., (2003) reported that cruciferous vegetables contain sulforophane, which has anticancer properties. The anticancer effects of cruciferous vegetables may attribute to organic sulfur compounds (diallyl disulfide) and isothiocyanates, which had the ability to modulate expression/activity of antioxidative and phase 2 drug-metabolizing enzymes and scavenging free radicals (Antosiewicz et al., 2008).

The cancer-preventive effect of broccoli may be due to its content of sulforaphane (Zhang et al., 1992). The chemoprotective effect of sulforaphane may to be due its ability to behave as an inducer of phase II detoxification enzymes (Prestera and Talalay, 1995). Sulforaphane was also shown to inhibit the CYP2EI isoenzyme of the cytochrome P450, thus emerging as an inhibitor of phase I enzymes (Barcelo et al., 1996). Nishikawa et al., (2009) also concluded that isothiocyanates sulforaphane presented in broccoli has inhibitory effects on tumor cell growth in vitro and in vivo. In addition to broccoli was reported to provide moderate antioxidant capacity, likely attributed to tocopherols and flavonoids (Plumb et al., 1997). However, Cindy and John, (2003) revealed that selenium-enriched broccoli activates certain pro-apoptotic genes linked to p53, NFκB and stress signal pathways in response to “danger signals” such as tumorigenesis.

The protective effect of red cabbage against HCC that reported in this study agreed with the finding of Fekadu et al., (2003) who mentioned that that the chemoprotective properties of red cabbage involve inhibition of the formation as well as development of preneoplastic lesions in liver. One of the most important mechanisms of chemoprotection is induction of phase II enzymes, which detoxify DNA-reactive metabolites and thereby inhibit the formation of initiated cells (De Flora and Ramel, 1990). Another possible mechanism of protection is the inhibition of enzymes which are involved in the activation of heterocyclic aromatic amines (Rauscher et al., 1998). The effect of red cabbage may be attributed to the prevalence of anthocyanins in its extract. In addition, Wu and Prior, (2005) reported that several highly conjugated anthocyanins were identified in red cabbage with potential antioxidant activities. However, Hagiwara et al., (2002) indicated that color extracted from red cabbage shown to inhibit adenoma and carcinoma formation in rats initiated with and subsequently fed a diet containing the heterocyclic amine. Kassie et al., (2003) also reported that administration of red cabbage extract to rats resulted in chemoprevention of liver and colon cancers induced by heterocyclic amine. On the other hand, Lynn et al., (2006) showed that breakdown products of glucosinolates such as isothiocyanates in red cabbage are responsible for the chemopreventive properties of cruciferous vegetables.

5. Conclusion:

This study concluded that broccoli and red cabbage have a protective effect against hepatocellular carcinoma in rats, therefore this study recommends increased dietary intake of broccoli and red cabbage may be beneficial for patients with liver cancer as a

preventative measures.

Child Health Department, National Research Centre, Dokki, Giza, Egypt
*zeinab_monir@yahoo.com

Abstract: Objective of this study is to examine the presence of disordered eating (ED) behavior among Egyptian adolescent boys and girls and detect the influence of obesity, body image, depression, somatic symptoms, binging and weight teasing by peers and family members as well as assessing dietary intake of macronutrients and micronutrients and its correlation to obesity and eating disorder. *Subjects and Methods*: The sample consisted of 1124 adolescents (642 girls & 482 boys) aged from 14-17 years, divided according to their BMI into four groups. The questionnaires used were EAT, ACDI, body image, and teasing, 24hr- dietary recall. and sociodemographic data were collected. *Results*: we found that 25.5% & 38.6% of boys and girls reported ED that was significantly correlated to body image, bad eating habits, depression and somatic symptoms. ED is more prevalent among overweight-obese adolescents of high social class. Adolescents have deficient intake of vitamin A, calcium, thiamine and niacin; girls are more deficient in iron and boys are deficient in vitamin C. On assessing weight teasing by peers and family member by weight status and ED after adjustment for socioeconomic standard; there was statistically significant association with obesity in girls & boys. *Conclusion*: Social back ground, obesity, negative body image , depression and teasing are the main risk factors for developing ED. Early detection and intervention for ED by biological and psychological approaches, treatment of overweight and obesity using family based treatment; early detection of depression and encouraging sports practice are recommended.

Keywords: eating disorder (ED), obesity, depressions, body image, teasing.

1. Introduction:

As the world has become a global village due to advances in communications, dietary habits have changed especially among adolescents through introduction of all types of fast food with its heavy fat content that goes hand in hand with changes in life style & physical activity. These factors lead to eating disorders, one of the most important risk factors for obesity, hypertension and cardiovascular diseases in adult life. Non Communicable Diseases (NCD) is emerging as a major health problem in Egypt, where 41 percent of all deaths are caused by chronic diseases. It is expected that NCD burden will rise to 60% by the 2020. The increasing NCD burden places a huge demand on health services in Egypt (WHO, 2005). Therefore action to reduce these major NCD should focus on preventing and controlling the risk factors in an integrated manner (WHO, 2003).

Aim of the Study:

Assessment of eating disorders among Egyptian adolescent girls and boys in relation to weight status, dietary intake, teasing, and psychosocial risk factors.

2. Methods

Study population:

The study population included 1124 adolescents (482 boys & 642 girls) attending four high schools in Giza; two public schools one for boys (264) and one for girls (458) and another two mixed private schools (218 boys & 184 girls) with age range from 14-17 years old.

Study design:

Data for the present study were drawn from project eating attitude among adolescents attending four high schools, after the approval of the scientific ethical committee at the National Research Centre and agreement of the ministry of education province office. A signed consent from parents was obtained. Survey and anthropometric data were collected from students within their classrooms under the direction of the research staff & a teacher. Height and weight were assessed by the research staff within the classrooms.

Survey development:

We preferred to use an Arabic scale for surveying eating disorders, binging and bad eating habits using Shoukeir assessment scales (Shoukeir 2002& Shoukeir 2000), derived from Marshall (1998). For Assessment of depression we used the Arabic Children's Depression Inventory (ACDI)

derived from Kovacs (1992) and Kazdin (1986) and constructed for Egyptian children by Abdel Khalek (1993). The questionnaires on body image were adopted from the original questionnaires by Moore (1998). Questionnaires for assessing teasing were quoted from Neumark (Neumark el al., 2002), that was based on the survey items developed by Thompson et al., (1995).

Measures:

Weight status was based on height and weight measurements taken by research trained staff in the classroom. Standardized equipments and procedures were employed. Body mass index (BMI) values were calculated according to WHO published standards

BMI = weight (kg)/ Height (meter)^2

Using gender, age specific cut-off points respondents were classified as underweight (BMI< 15th percentile); average weight (BMI 15th- < 85 th percentile), overweight (BMI >85 th. <95 th percentile) and obese (BMI > 95 th percentile).

We assess the frequency of teasing, source of teasing (peers or family members), and the effect of teasing, (i.e. how much it bothers those teased). The degree to which they were bothered by weight-teasing by peers and family members making them east more or less was then assessed; response categories were (1) never; (2) sometimes; (3) often.

School level and birth date were taken from the school files. Socio demographic data were based on self report. The prime determinant of socioeconomic status (SES) was parental educational level defined by 4 categories. (1) Illiterate; (2) primary-preparatory; (3) high school or similar; (4) university education; and parental occupation level defined by (1) not working; (2) workers; (3) employee; (4) professional. Family number and birth order of the participant were recorded.

Every student filled a 24hr dietary recall sheet; that was analyzed by a nutritionist to calculate the intake of macronutrients and micronutrients.

Data analysis:

Unadjusted association between eating disorder and psychosomatic variables as well as micronutrients and macronutrients intake as well other risk factors that include parental education and occupation, family number and birth order was studied. We studied also association between weight statuses, eating disorder and teasing using $\chi 2$ TEST and associations adjusted for SES and school level were conducted using logistic regression. Among the students who reported being teased by peers or family members, percentage of girls and boys bothered by teasing were examined across weight status using $\chi 2$.

Eating disorder and its association to weight teasing and weight status were examined using $\chi 2$ tests and associations adjusted for BMI, SES were examined using logistic regression. To conduct all analyses, SAS release 6.12 was used.

3. Results

Fig.1 shows that nearly 5% of boys and 3% of girls have lean body mass index (BMI) whereas, 58% of boys and 55% of girls have normal BMI; while the percentage of overweight of boys and girls were 17% & 27% and the obesity of boys and girls were 20% & 14.5 respectively, added to this obesity increases in girls with age and decreases in boys with age.

Fig.2 shows that 78% boys, 80% girls take $\geq$ 80% of RDA of their proteins; 94% boys and 93% girls receive $\geq$ 80% of RDA of their carbohydrates & 66% boys & 74% girls receive calories $\geq$ 80% RDA.

Fig.3 shows the micronutrients intake according to RDA whereas we found that the most prevalent deficient intake was in vitamin A intake and to less extent in both thiamine and niacin in boys, whereas in girls we found that the most deficient intake was in vitamin A, iron, thiamine and niacin & lesser percentage were deficient in calcium and vitamin C.

Table1 shows that BMI is significantly correlated to animal protein, animal fat in boys and girls (P = 0.00 & 0.01; P = 0.00 & 0.00 respectively). No statistically significant difference in caloric intake between normal weight and overweight-obese adolescent.

Table 2 shows that iron is negatively correlated with BMI in girls and boys (P = 0.01); vitamin A is positively correlated to BMI, and vitamin C is negatively correlated to obesity and overweight. Comparing dietary intake in girls to BMI, it was found that plant protein and vitamin C are positively correlated to obesity and overweight (P = 03.01 & 0.04 respectively); while in boys vitamin C intake only shows a significant difference between normal weight and obese (P = 0.04).

Table 3 shows psychosomatic symptoms in correlation to sex difference, it shows that: a. boys have more concern about overeating than girls (P = 0.05) and girls are concerned more about their bulimic behavior (P = 0.01). b. as regard body image there is statistically significant difference between girls and boys as girls are more concerned about their shape, size and fear of gaining weight as well, concerned for losing weight (P = 0.001). c. Somatic symptoms in boys was more significant as regard swelling of foot & hand (P = 0.000) while girls have more stomach aches (P= 0.001). d. girls show more

statistically significant difference in binging than boys (P = 0.001).

Table 4 assesses psychosomatic symptoms according to weight status in girls and boys; in girls, body image (P = 0.000), bad eating habits (P = 0.00), depression (P = 0.01) and eating disorder are positively correlated to overweight and obesity; while in boys, depression (P = 0.00), somatic symptoms (p = 0.03) and eating disorder (P = 0.01) are the factors that were correlated to overweight and obesity.

Table 5 assesses psychosomatic symptoms in relation to eating disorder in girls and boys. Body image, bad eating habits, depression and somatic symptoms have statistically significant values (P = 0.00) in both boys and girls.

Table 6 shows that girls with eating disorder shows statistical negative correlation with calcium intake (P = 0.04).

Table 7 shows that boys with eating disorder show statistical significant positive relation to animal fat (P = 0.04); calcium (P = 0.001); vitamin A (P = 0.01) and vitamin C (P = 0.01).

Table 8 shows significant statistical correlation of social status and weight status to eating disorder in boys and girls (RR = 3.48, 95%, CI = 2.37- 5.1; RR= 3.44, 95% CI= 2.6-4.55, RR= 7.83, 95% CI= 5.76 – 10.64 & RR = 2.04, 95% CI= 1.7-2.45 respectively). Eating disorder increases with highest parental education & occupation and obesity.

Association between weight status and weight teasing wer found to be statistically significant among girls and boys; high percentage of obese girls (74.3%) reported being teased sometimes (P < 0.001); 22.97% of girls reported being teased by peers (P < 0.000); and (28.88%) of girls reported being teased by family member (P < 0.000). A significant percentage of obese boys (49.0%) reported being teased sometimes (P < 0.001); 56.0% of boys reported being teased by peer (P < 0.001) and 33% of boys reported being teased by family member. There was also, a statistically significant association between underweight and weight teasing (51.9%) & (37%) of girls and boys respectively, reported being teased ; 21% & 41% of girls and boys reported frequent teasing by peers and (27% and 14%) of girls and boys reported being teased by family member. Normal weight and lean boys are more likely to be teased about their weight by peers but not by family members (table, 9).

In analysis adjusted for socio demographic characteristics overweight and obese girls but not underweight girls were at greater risk for being teased for their weight, some observation was found in boys. In analysis adjusted for sociodemographic characteristics overweight and obese girls but not under weight girls were at risk for being teased for their weight (P = 0.05 & 0.00); also over weight and obese boys were at risk for being teased for their weight (P = 0.05 & 0.00) (table, 10).

Table 11 shows number and percentage of overweight girls and boys reporting eating disorder behavior. High percentage of over weight and obese girls and boys who were teased about their weight engaged in bad eating habits and binging behavior, as compared to overweight boys & girls who were not teased about their weight. Overweight youth who experienced weight teasing were at significantly greater risk for engaging in bad eating habits and binging; all associations were statistically significant except for the association between weight teasing by family members and binging among boys, this association was of marginal statistical significance.

a. number reporting bad eating habits. b. number reporting binge eating.

4. Discussion:

Based an BMI cut-off points 17% & 27% of boys and girls were overweight and (20% & 14.5%) of boys and girls were obese: comparison of cross sectional data from United States and 13 European countries has shown that the prevalence of overweight varied between 5.2% - 28.9% for boys and 8.1% - 31.0% for girls; the prevalence of obesity varied between 1.9% - 13.9% for boys and 1.1-15.1% for girls among adolescents (Lissau, et al., 2004). The prevalence of overweight and obesity for Iranian has been found to be 12.1% and 7.8%

(Mohamed et al., 2004), and among adolescent Mexican 12.1% & 6.2%. In other Egyptian data the prevalence was 15.9% and 18.4%; lower than our results (Martinez et al., 2006).

Prevalence of over weight and obesity was found to be higher in boys than girls in Swedish adolescents (Berg et al., 2001) unlike our results and other Egyptian results (Martinez et al., 2006) the prevalence of over weight among girls was found to be higher than boys, in the same time the prevalence of obesity in our cases was found to be higher in boys (20%) than girls 14.5%. We found that percentage of obesity in girls increases with age while it decreases in boys with age. On the contrary Klein et al., (2008), reported that adolescents who perceived themselves to be overweight at baseline were 2-3 times more likely to be overweight at follow up compared to those with a normal weight. Boys were more likely (3 times) to transition to obesity at follow up compared with girls.

In our study according to weight status there was significantly statistical correlation of BMI status in girls to body image, bad eating habits , depression and eating disorder , whereas in boys weight status was significantly correlated to depression , somatic symptoms and eating disorder . French et al. (1995) found and inverse relationship between BMI and both self esteem and body image, also found that the most common consequences of obesity in children is poor psychological & social functioning, impaired academic success and reduced fitness & heath.

It was found that adolescents from more advantaged family backgrounds are more likely to be overweight with higher percentage of eating disorder (RR = 3.48, 95% Cl= 2.37-5.1 for boys and RR = 3.44, 95% Cl = 2.6 – 4.55 in girls & RR = 7.83, as Cl = 5.76 – 10.64 for boys & RR = 2.04, 95% Cl = 1.7 – 45 for girls) respectively; same results were found in Mexican adolescent (Martinez et al., 2006) whereas in USA adolescents from high socioeconomic level are less likely to be over weight (Needlham & Crosnoe, 2005) . Added to this, Ozmen, (2007) concluded that being male and being of higher socio economic level were predicators of obesity overweight based on BMI.

In this study, we used 24-hr dietary recall method as screening tool to throw the light on dietary pattern of Egyptian adolescents. Epidemiological studies on dietary pattern of Egyptian adolescents are scarce (Hassanyn, 2000).

Dietary assessment showed that energy consumption was inadequate among 40% of adolescent, close to 13% had low protein intake & 23% had low intake of carbohydrates. Data derived from several national surveys conducted by national nutrition institute in Egypt revealed, that Egyptian adolescents do not fulfill the recommendations of WHO for healthy diet, as only, 38% obtain their full requirement of energy (100 – 120% RDA) (Hassanyn, 2000) in our study 30% of boys & 28% of girls obtain their full requirements of energy. In our study animal protein ratio to plant protein was found to be (1.06 – 1 & 1 – 1.24 in boys & girls respectively) while in Hassanyn's study they found the total ratio to be 1-2. this reflects a problem of concern related to the low biological value of consumed protein on one hand and the low bioavailability of micronutrients mainly mineral, aggravated by the low daily intake of these mineral particularly iron & zinc.

Although it is often assumed that overweight children eat more than non-overweight children do, no data have been published to support this belief. In our study we found no significant difference in caloric intake between normal and overweight obese boys and girls. Rocandio et al., (2001) found that the percentage of energy intake was significantly lower in the overweight group compared to the non overweight children (8948 as 9590 K/day; $P < 0.01$) and carbohydrate intake was significantly greater in the non-overweight school children (250.9 + 58.8 us 221.1 + 77.4 g/day; $P < 0.01$) similar results were obtained by Bandini et al., (1999).

These findings suggested that the positive energy balance causing overweight and obesity is rather due to low energy out put due to lack of physical activity and the sedentary life adolescents are obliged to practice especially those running for high school certificate; where mostly parents stop all activities other than learning.

There was a significant difference in animal protein in boys and girls in both normal and overweight obese, where boys eat more animal protein than girls ($P < 0.001$), the same results were noticed in animal fat intake, this can be explained by the still existing cultural preference of males over females. Some studies found no differences in dietary protein and fat intakes between over weight and obese and normal weight (Ricardio et al., 2001) other studies noted that the proportion of fat in the diet was greater in obese children (Gazzaniga, and Bruns, 1993).

As regard micronutrients intake, girls have deficiency in vitamin A, iron, calcium, riboflavin, thiamine, niacin and vitamin C ; while boys have deficiency in vitamin A, thiamine, riboflavin, niacin and vitamin C .There were statistically significant difference in Iron, vitamin A & niacin intake between boys & girls normal or overweight-obese; also there was a significant difference in riboflavin intake in normal weight boys & girls, as girls have higher intake of vitamin C than overweight-obese boys.

Rocandio et al., (2001), found that vitamin A & vitamin D intakes were lower than recommended but in the contrary he found no significant difference between overweight and non-overweight. Ferandez et al.,(1996) and Failde et al.,(1997), found similar results. Szabo et al (2007), found that the average energy intake was appropriate, protein and fat intake was some what higher than the RDA; the intake of Ca and vitamin D was inadequate, Iron in girls was insufficient. In this study, 25.5% of adolescent boys have been found to have eating disorder (> 20) & 38.6% of girls were found to have scores > 20 as well, that was positively correlated to social status as it was significantly higher among high social standards as well as among those with higher BMI. Austin et al., (2008) in his study for screening eating disorder at high school's in USA observed less percentages than our results whereas 25% of girls & 11% of boys reported disordered eating (> 20); Sepulveda et al., (2008) in his study of eating disorder among Spanish university students reported the prevalence rate of students at high risk for eating disorder to be 14.9% (11.6 – 18) for males and 20.8% (181.7 – 22.8) for females (ED > 20) with statistically significant differences by gender.

Among adolescent girls, depressive symptoms for their bulimic behavior were significantly higher than boys, while boys were more concerned than girls about their overeating and binging most of the time, girls were more concerned about body image than boys; whereas boys have more physical complains than girls ; girls practice binging more than boys.

Field et al. (2008) found that among children (9-15 years old) girls show higher percentage of binging than boys (4.3% and 2.3%) as well as purging (5.3% & 0.8% respectively). On the contrary Sepulveda et al., (2008) found that males (11.6%) practice binging more than females who practice unhealthy weight control behaviors more than males (dieting, laxatives or self induced vomiting). Crosby et al., (2009) reported that depression is intimately tied to bulimic behavior and may in fact precipitate such behavior and that treatment of depressive symptoms can produce longitudinal decrease in bulimic symptoms.

According to BMI we found a significant statistical correlation of weight status in girls to body image, bad eating habits, depression, eating disorder ; whereas weight status in boys was significantly correlated to depression , somatic symptoms and eating disorder . Also, we found in our study that eating disorder (> 20) in girls was highly correlated to negative body image, bad eating habits, depression and somatic symptoms. In boys it was highly correlated to body image, bad eating habits, binging, depression and somatic symptoms. Some results were found by Costa et al., (2009) where he found that BMI and depressive symptoms for both sexes were positively associated with eating disorder symptoms. On opposition to our results; as we found that eating disorder in both sexes is higher in adolescents from higher socioeconomic level; Cost et al., (2009) found a sex effect on the association between socioeconomic status and eating disorder as girls with higher socioeconomic status and boys with lower socioeconomic status presented more eating disorder symptomatology. Suris et al., (2008) found that health risk behaviors in adolescents with chronic diseases are more than normal adolescents. Mahraj et al., (2009) stated that overweight and obesity are among the risk factors of eating disorder (11 & 7% respectively) and that many of the risk behaviors in adolescents were shown to be related to the adolescents family origin, home environment and parent child relationship as well the protective effect of the family and school connectedness and increased religiosity. Moreover Sampei et al., (2009) found that among premenarch group there is increase eating score (EAT-26) above 20 with a high correlation to body image that means that the concerns about body image develop at an earlier age.

Other studies (Mirza et al., 2005), Labera et al., (2009) and Calderon et al., (2009) stated that body weight status especially severe obesity is correlated to more concern about body image, in the same time adolescents with normal weight showed specific factor for developing eating disorders in the future (Calderon, et al., 2009). It has been suggested that body image may predict depression (Stice et al., 2000) and eating disordered symptoms that may lead to an increased prevalence of adverse psychological and health concern (Mirza, 2005).

As regard weight teasing, our results clearly showed that perceived weight teasing by both peers and family members is common among adolescents' girls who were teased more than boys; that may be due to extra sensitivity of girls towards their weight; this is evident in non-overweight girls who reported being teased for their weight more than boys. In analysis adjusted for sciodemographic characteristics, overweight and obese but not under weight girls were at greater risk for being teased for their weight by their family member, similar associations were found among boys, as they were mostly likely to be teased by family members and peers; in comparison normal weight boys and lean were more likely to be teased about their weight by peers but not by family member. Our results agree with Neumark et al., (2002) results who assessed the prevalence of weight teasing among adolescents as well, Sobal et al., (1995) who found that overweight students,

especially girls, were stigmatized regarding dating activities, added to these Jackson et al., (2000) found that obese women reported more weight and size teasing than non obese women.

We found strong associations between weight teasing and disordered eating behaviors, boys and girls who were bothered by being teased were significantly more likely to engage in these behaviors, our findings regarding association between weight teasing and unhealthy weight control/ binge eating behavior are consistent with findings from previous studies (Neumark et al., 2002, and Brown et al., 1989).

In this study, The nature of the study population (population based sample), allowed for more generalization than that of the clinical samples, added to this, collection of the anthropometric measurements was done more accurate than other studies that depend on collecting the self-reported measures. Also, its inclusion of a big number of boys and girls, and the trial to assess all the risk factors of eating disorders as well their dietary intake and the inclusion of teasing to body weight as another risk factor that may aggravate eating disorder, encourages us to assess bulimia and anorexia on those with high eating disorders scores ,that will be published later.

Early identification and treatment of disordered eating by weight control behaviors may prevent progression and reduce the risk of chronic health consequences, physician should have a high index of suspicion for eating disorders in adolescents by using the DSM-PC (Diagnostic and statistical manual for primary care); paying attention to risk factors (Musie, et al., 2003). Programs aimed at prevention and reduction of overweight and use of family-based treatment may result in a decrease in body dissatisfaction and increase in self-esteem, in turn, improving body image and self esteem may help with efforts to decrease obesity among high-risk youth population. Furthermore, school based educational interventions to learn the students about the balanced healthy food and the etiology of obesity as well as, the potential harmful effects of weight teasing and to improve the general attitude towards different body sizes and shapes. Added to this it is important for the community to change the criteria of evaluating a person only for his achievement disregarding the value of shape and size.

Acknowledgment:

I would like to thank Mrs. Wafeya Abdel Rahman for dietary intake collection and analysis.

Abstract: Objectives: To assess and raise the awareness of deaf students and their school care-givers about first aid intervention in medical emergencies. Participants: All deaf students in both the preparatory and secondary levels of education in a school for the deaf, who were under 18 years old (n = 44), in addition to school dormitories care-givers (n = 2) were participated in this study. Research Hypothesis: An implementation of first aid intervention program would have a positive outcome on raising awareness of deaf students and their school care-givers in medical emergencies. Methods: Participants' knowledge and skills were assessed using pre and post test questionnaire sheet contained thirty seven quiz multiple choices statement questions in Arabic language. Moreover, post-test intervention didactic and practical learning sessions consisted of six video films on DVD-ROM are presented to the participants accompanied by sign language translation in order to achieve the research objectives. Results: An intervention program showed a clear positive outcome on raising awareness of deaf students and their school care-givers about first aid intervention in medical emergencies. The highest percentage of deaf students (61.4%) obtained the lowest sum score lies between zero to less than 25% in the pre-intervention phase, while about half of them (45.5%) obtained sum score lies between 50 to less than 75%, and more than tenth (11.3%) obtained the highest sum score that lies between 75 to 100% in the post-intervention phase, which revealed statistical significant differences in the participants' knowledge of skills at p=0.001 and 0.000. Similarly, pre knowledge sum scores of the two school care-givers about first aid skills rose from 43.2% and 63.2% respectively reached to the mastery level of 100% in response to the study intervention programmed. Conclusion: Although not enough for all items to be statistically significant, first aid intervention program raised the awareness of deaf students and their school care-givers.

Keywords: Deaf children; First aid; school-age; Care-givers.

1. Introduction:

Hearing disability has gained great interest in the last decades. This growing interest stemmed from its devastating effects on communication, person's life and the economics of countries (1). International statistics for children with hearing impairment are reported to be 2-6 per 1000 live birth (2). Hearing loss represents a significant public health problem especially when compared to other commonly known childhood diseases. In Egypt, profound hearing loss is shown to be 6-7 per 1000 child (3).

Emergency situations are challenging for everyone (4). When someone becomes ill or injured there is usually a short period of time before get a professional medical assistance. That length of time is most critical to the victim. What someone do, or don't do during that period of time can make the difference between life and death. By having some first aid training and knowing cardiopulmonary resuscitation (CPR) the trained person can have a major impact to the successful outcome of a medical emergency (5).

First aid is the initial assistance or care of a suddenly sick or injured person. It is the vital initial care we all feel an impulse to give as soon as possible after an accident or illness. So, first aid is an important part of everyday life, both at home, work or at play. Everyone should learn first aid and be willing to administer basic care until emergency assistance arrives. Not every incident requiring first aid is a life-and-death situation. First aid knowledge is commonly used to manage minor injuries at home or work (10).

Children on the whole are more capable of learning first aid and applying that knowledge sensibly. Children usually do struggle to save others lives, but at least if they know the technique they can do something better. Inspite of there are special children out there for whom the knowledge may be inappropriate, but it is a minority (6). Inclusive first aid programme helps people with disabilities play a full role in learning life-saving skills. It is a unique programme designed to work with groups or individuals who may require a more flexible approach to learning first aid skills (7). In deaf

children, a communication barrier can derail interactions between emergency responders and members of the deaf and hard of hearing community, making an already difficult situation unmanageable (4).

Personal safety skills for deaf children is a group work programme on DVD-ROM designed to help give deaf children and their caregivers the knowledge, awareness and skills they need to stay safe and make better informed life choices. Learning and practicing first aid saving skills isn't just about making someone a potential life-saver; it helps increase confidence, social skills, independence and the ability to react to a crisis (8). It also helps to strengthen the self-confidence and self-esteem of deaf children, enabling them to seek help and advice when they need it (7).

Inclusive first aid tips in the school place offers deaf students and their caregivers a chance which includes, but is not limited to, the assessment and interpretation of emergency situations and safe responses to those situations. Those students can learn the proper methods for the control of bleeding and shock, maintenance of airway, breathing and circulation, the care of burns, poisonings and other first aid techniques (8).

The loss of children's lives that results from injuries combined suggests a staggering numbers of productive lives lost to society (11). Therefore, first aid is immediate help provided to a sick or injured person and sometimes consists of procedures and techniques requiring minimal or no equipment. "Basic practical life skills will not only benefit the students but also the community at large, when such important life skills can go a long way in saving lives when needed (9).

Aims of the Study

The aims of this study were:

1-To assess deaf students and their school care-givers' awareness about providing first aid intervention in medical emergency situation.

2- To raise the awareness of deaf students and their school care-givers about providing first aid intervention in medical emergency situation.

Research Hypothesis:

It was hypothesized that:

An implementation of first aid intervention program would have a positive effect on raising awareness of deaf students and their school care-givers in medical emergencies.

Operational Definition

A care-giver is a mentally stable adult, typically over 18 years, who provides care for another(s). Child care-giver is a person who are responsible for providing direct care, protection and supervision of children in a child-care center, school for children with special needs or at home. This person is generally assigned to provide assistance to a child who is no longer able to perform the routine care or critical tasks necessary for every day survival.

2. Materials and methods

Methods

This study used a quasi experimental design.

Setting

The study was carried out at a school for the deaf students, at El-Mansoura City, in the period of the second semester of the study year 2009-2010, started from March 2nd to June 2nd, 2010.

Participants

All students inside the previously mentioned school for deaf children belonged to the preparatory phase (n=30) and those in the secondary phase (n=14) who were under 18 years old, in addition to the assigned care-givers (n=2) who stayed with at school dormitories deaf students after the end of school day in order to provide the required care and help for those children with special needs were included in the study sample.

Tools

Two tools were used to conduct the current study:

1. First Tool:

This tool was divided into 2 parts:

A) Part I:

Socio-demographic characteristics of deaf students and their families, including; age, gender, level of education, family resident, degree of deafness, place of accommodation, students' fathers and mothers educational levels, their occupation, and family history concerning the presence of deaf spouses. This part also includes the socio-demographic characteristics of the students' supervisors, such as, age, level of education, years of experience, marital status, and residency.

B) Part II:

Pre and post test questionnaire sheet in the form of 37 quiz multiple choices statement questions in Arabic language, constructed for both deaf students and their school care-givers in order to assess their awareness about providing first aid intervention in emergency situations. First aid statement questions were focused on two domains, one of them was concerned with the participants' knowledge; including emergency contact

information, basic information about first aid, vital organs information, diagnosis of hyperglycemia, intervene with poisoning, chocking, the presence of eye foreign body, epileptic fit, and an asthmatic child. The other domain was concerned with the participants' skills including; priorities of action when intervening with a casualty, and how to intervene as a first aider in different emergency situations such as; shock, burn, bleeding from cutting wound or in case of nosebleed, and musculoskeletal emergency.

2. Tool of intervention:

Post-test video films on DVD-ROM by the British Red Cross accompanied by sign language translation were used. They are specifically geared to helping the deaf and hearing impaired to learn how to follow the initial steps when intervening with a casualty**,** and the simple procedure of caring for casualties in different emergency situations, including: the steps of cardio-pulmonary resuscitation (CPR) for children, recovery position, and intervening with cutting wound, bleeding nose, burns and scalds, choking and twisting and fracture.

Intervention

1. Preparation phase

I- Administrative process

An official request to conduct the study was directed from Faculty of Nursing El-Mansoura University to the manager of Directorate of Education, Dakahlia Governorate. The approval is sent very soon to the headmaster of the school for deaf students, and the start permission is obtained.

II- Development of the study instrument

a. The quiz multiple choices questionnaire sheet was used as a pre and post test to assess both the students and their school care-givers' awareness about first aid.

Content Validity and reliability

Because there is no validation for any Arabic tool in Egypt, two bilingual lecturers belonged to the critical and pediatric nursing departments, faculty of nursing El-Mansoura University translated the tool's questions from English to Arabic language, and then this tool is back translated by another two lectures from the same departments. On conflict, the four juries met together to solve the arisen language incompatibility until the translated Arabic tool returned to its original English one. The recommended modifications that ensured tool clarity were done.

Feasibility study (pilot study) is conducted on five students chosen randomly, as student number Five from the classroom list, and those students are excluded from a full-scale study. The pilot study aimed to testing adequacy of research instruments; refine quiz multiple choices statement questions, assessing whether the research protocol is realistic and workable, and identifying logistical problems which might occur. The necessary modifications were done accordingly.

b. Training material in the form of sign language video films on DVD-ROM, laptop, data show apparatus and screen for presentation, and supplies and manikin for demonstration were prepared.

2. Implementation phase

a. The headmaster of the school for deaf students nominated an experienced teacher in sign language from the study setting itself. She accompanied the researchers as a translator throughout the study phases to facilitate and ensure complete and accurate transmission of any message to the participants. The researchers spent the first day with the translator to clarify the aim of the study, all the study phases, and to explain the content of the awareness sessions; until she understood and became well prepared for active participation in the study.
b. Ethical consideration: The two researchers introduced themselves through the translator to the participants (deaf students and their school care-givers). A simple explanation about the aims of the study was illustrated to them. A written consent notifying deaf student's agreement to share in this study signed by his/her direct care-givers is obtained. The researchers emphasized in the consent that the participation is voluntary, any participant can withdraw at any time without any need to justify his/her decision, any raised question will be answered, and the collected data will be treated confidentially and will be used only in the current study.
c. For the purpose of data collection, the researchers attended the school day and met the participants three days per week on Tuesday, Wednesday and Thursday.
d. Students of the preparatory school level are divided into six groups each group included five participants, while those of the secondary level are divided into two groups each one composed of seven participants, in addition to the two school care-givers.
e. Pre-test data collection period is started in March 3 and completed in March 17, 2010. Through this period, a group of 5-7 participants were assessed using questionnaire sheet.
f. Post-test intervention methods in the form of two presentation sessions (didactic and practical) for

each group are started from March 23 to April 15, 2010. In the first didactic session, the researchers with the translator presented some knowledge about the meaning and aim(s) of first aid, ambulance phone number, ambulance call cost, organ of breathing and that pumping blood, sites of pulse counting, the normal pulse rate among school age children, defining hypothermia, occurrence of brain damage due to asphyxia, how to diagnose hyperglycemia, and the required steps to provide first aid assistance in case of poisoning, foreign body aspiration, presence of foreign body in the eye and nose, epileptic fits and asthma. The researchers used blackboard to write the content of the session as well as a translation to sings language to ensure complete and accurate explanation. In the second practical session, each group watched six video films presented on DVD-ROM, that explained how to follow the initial steps when intervene with a casualty, and the simple procedure of caring for casualties in different emergency situations, including: the steps of cardio-pulmonary resuscitation (CPR) for children, recovery position, and intervening with cutting wounds, bleeding nose, burns and scalds, choking and twisting and fracture. After that, the participants are randomly selected to demonstrate on a manikin three procedures that were listed by order exactly as the scenarios presented in the films.

3. Evaluation phase

The post-test conducted after the completion of the presentation sessions from April 20th to June 2nd, 2010. Through this period, the participants were assessed using questionnaire sheet.

Statistical analyses

Data were analyzed using SPSS software version 14.0, and proper statistical tests were used accordingly. The obtained pre-test scores were compared to those of the post-test in order to detect the level of significance.

3. Results

Table (1) shows the total of 44 deaf students that constituted the study sample; 38.6% of them were males and (61.4%) were females. 68.2% of the sample were in the preparatory school level and (31.8%) were in the secondary level. 61.4% of students resident at urban areas, the degree of deafness among more than half (54.5%) was hard of hearing, and the majority (81.8%) were accommodate with their families.

Table (2) shows that less than half (47.7%) of deaf students' fathers and mothers were illiterate, only (11.3%) of the fathers and none of the mothers had bachelor degree. The occupation of more than half of student's fathers and mothers (59%) were as workers. Only (15.9%) of students had deaf relative(s), with (71.4%) of them had some form of hearing difficultly.

Table (3) shows that the highest percentage of deaf students (61.4%) obtained the lowest sum score that is lying between Zero to less than 25% in the pretest aimed to assess their knowledge of skills about first aid intervention in emergency situation. While, about half of the deaf students (45.5%) obtained sum score lies between 50% to less than 75% in the post-test, more than tenth of them obtained the highest sum score that lies between 75% to 100%.

Figure (1) shows that although the pre knowledge sum scores of the two school care-givers about first aid skills in emergency situations were (43.2%) and (63.2%) respectively, their post knowledge sum score were improved in to reach the mastery level of 100%.

Table (4) shows percentage distribution of deaf students' correct knowledge about first aid intervention in different emergency situations. The awareness of students' participants showed an improvement among all items of first aid, except for the average pulse of an adolescent in response to the study intervention program. Furthermore, statistically significant differences were detected in deaf students' awareness with ambulance call coast ($p=0.005$), and intervening with a poisoned casualty by drug misuse ($p=0.000$).

Table (5) shows percentage distribution of deaf students' correct practice related to providing first aid intervention in different emergency situations. Participants' skills showed an improvement among all items of first aids, with highly statistically significant differences detected among determining first aid priorities for a casualty in medical emergencies ($p=0.000$), intervening with cutting wounds ($p=0.005$), twisting and fractures ($p=0.000$), and a shocked casualty ($p=0.000$).

Table (1) Socio-Demographic Characteristics of Deaf Students (N =44)

Item	Number *(n)*	Percentage *(%)*
Gender		
Male	17	38.6

4. Discussion

Hearing loss among school-going children has been widely reported as a significant health problem in the developing world, including Egypt (Quality Inn & Suites Conference Center, 2009). The results of an earlier study revealed that the prevalence of hearing loss in school-age children was almost 10% (Riad, 1975). Moreover, an Egyptian survey has pointed to hereditary and otitis media with effusion as the commonest causes of hearing loss among preschool children (Abdel-Hamid et al. 2007). Unlike to this study and similar to the most recent ones, the findings of the current study declared that the vast majority of parents of deaf children are not deaf (ITV Signed Stories, 2008 & The National Deaf Children's Society, 2010).

A national household survey conducted to present the prevalence and patterns of hearing impairment in Egypt found that, both male and female gender are equally presented with no significant sex differences (Nationally KECO & NISO Training Current Member, 2009). The current study found that females are more enrolled than male students among the study participants. This may be interpreted in the context of school dropout due to poverty that enforces parents to introduce their deaf children to work in technical workshops to provide financial support to their families and at the same time to relieve the educational financial burden. Klare (2004), supporting this notion noted that students with disabilities who left school did so by dropping out, and concluded that students with disabilities drop out of school at twice the rate of general students. As regarding the residence of deaf students, the study findings showed rural-urban inequities, that could be interpreted in relation to parents' fears from children's disability that keep those from rural areas more prone to the risk of exposure to road accidents because of the long distance between home-place and school-place that is located at an urban city.

The findings of this study does agree with an observation in the developing world that,

childhood hearing impairment is commonest in illiterate parents and those with low socio-economic classes, because of the impact of poor hygienic conditions, inadequate medical follow-up, low immunization rate and misuse of ototoxic medications (Olusanya, Okolo & Adeosun 2004). In contrast, some other studies reported a higher prevalence of otitis media in the higher socio-economic classes, while others found no association between otitis media and socio-economic status (Quality Inn & Suites Conference Center, 2009). Given this variability, parental literacy by itself is unlikely to be a universal predictor of hearing loss in school-aged children.

Inspite of drawing attention towards children with hearing disability that has taken place during the past few years; researchers have shown that deaf children feel more neglected and less accepted by other children, so that they behave more aggressively. They also added that not only do deaf children show more anger than hearing children; most deaf children also use aggression amongst themselves. So, they are more vulnerable to school accidents that may require first aid assistance (Rieffe, & Meerum Terwogt, 2006).

The gap is still very wide between the needs of deaf children and available services due to a lot of obstacles. The more striking are those posed in communicating with children who have some sort of hearing impairment to raise their awareness about a new issue that they did not hear about it before, such as an inclusive first aid programme (AWR 186 POI).

Emergencies can occur suddenly and without any advance warning. For all individuals who have physical, sensory or cognitive disabilities, medical emergencies present a real challenge. In order to protect them, this requires planning ahead, and adequate preparedness to be self reliant during an emergency. U.S. Department of Homeland Security, (2004) and Queen's Printer for Ontario, (2007), emphasizing that disabled individuals are in the best position to know their functional abilities, and possible needs during and after exposure to an emergency situation.

The study results found deficiencies among deaf children's recall scores. This notion is supported by Liben, (2004) who suggests that deaf children's inadequate recall probably reflect insufficient knowledge of category membership. However, an educational programme to help people prepare for medical emergencies would enable vulnerable people and their caregivers to feel more in control and less anxious. An educational campaign can be conducted for deaf students and their school care-givers about emergency situations and how to help themselves (O'Brien, 2003).

First aid is the provision of initial care for an illness or injury. It is usually performed by a lay person to a sick or injured casualty until definitive medical treatment can be accessed. Certain self-limiting illnesses or minor injuries may not require further medical care past the first aid intervention. It generally consists of a series of simple and in some cases, potentially life-saving techniques that an individual can be trained to perform with minimal equipment (First Aid Medical Information, 2010).

Much of first aid is common sense. Basic principles, such as knowing to use an adhesive bandage or applying direct pressure on a bleed, are often acquired passively through life experiences. However, to provide effective, life-saving first aid interventions requires instruction and practical training (First Aid Medical Information, 2010).

Taking an immediate action is the essential principle in first aid. Often bystanders are worried about "doing the wrong thing", so don't attempt any first aid at all. If a person is sick or injured, then they need help, and they need it immediately. A casualty who is not breathing effectively, or is bleeding heavily, requires immediate aid. Prompt effective first aid gives the casualty a much better chance of a good recovery. Careful and deliberate action undertaken without too much delay is most beneficial to the casualty (Principles of First Aid - PARASOL EMT Pty Limited).

There is an increasing recognition of the need to respond to and met the health needs of vulnerable groups within society. There is a range of who may, for a variety of reasons, be vulnerable and this includes people with hearing disabilities. Those people are an integral part of society and need to be recognized and valued as equal citizens (Dolan & Holt, 2008).

5. Conclusion:

Although not enough for all items to be statistically significant, first aid intervention program raised the awareness of deaf students and their school care-givers about first aid intervention in medical emergencies.

6. Recommendations:

Future programs should focus on one section, such as emergency procedures, and emphasize the importance of it.

The educational curriculum of deaf students should include basic information about health, emphasizing on the importance of how to satisfy the

physical as well as the psychological needs of the casualty in case of exposure to medical emergencies.

Sudeck's Atrophy, Hyperhydrosis and other Hypersympathetic Syndromes, what is the Recent Proper Surgical Management?

Abulazaym A.A.[1*] and Horria H.[2]

[1]Neurosurgery Department, Faculty of medicine, Cairo University, Cairo, Egypt.
[2]General surgery Department, Faculty of medicine, Mansoura University, Mansoura, Egypt.
abaaaza51@yahoo.com*

Abstract: Twenty eight patients with upper limb Sudeck's atrophy (minor causalgia), hyperhydrosis (palmar and axillary) and causalgia were submitted to endoscopic transthoracic sympathectomy as a definitive treatment. There were 9 patients with Sudeck's atrophy, 16 patients with upper limb hyperhydrosis and 3 patients with major causalgia. The procedure was successful in curing 26 patients (92.86%) and gave mild improvement in two patients (7.14%) whom belonged to the Sudeck's atrophy (minor causalgic) group because of the advanced dystrophic changes in their limbs. The commonest side effects were compensatory sweating. The procedure is effective, very simple, and required only two nights stay, and is recommended as a method of choice for the surgical treatment of hypersympathetic syndromes of the upper limbs as Sudeck's atrophy, hyperhydrosis and major causalgia.

Keywords: Sudeck's Atrophy, Hyperhydrosis and other Hypersympathetic Syndromes, what is the Recent Proper Surgical Management

1. Introduction:

Our modern civilization is plagued with chronic sympathetic hyperactivity secondary to chronic tension. Painful conditions such as myocardial ischemia (which is also prevailing), soft tissue trauma, bone and joints trauma or even trivial painful conditions frequently induce in those predisposed patients what is classically known as Sudeck's atrophy. Sudeck in a comprehensive series of papers beginning in 1900 described in detail the characteristics of this ambiguous chronic painful condition characterized by the predominance of muscular, bone and joint manifestations including osteoporosis. The difficult issue in this syndrome is that the chronic embarrassing pain and the gradual dystrophic changes are resistant to usual measures and medicines and thus these patients constitute a protracted problematic group. Many descriptive terms as hand-shoulder syndrome, post traumatic painful osteoporosis, acute bone atrophy, pseudo-rheumatism..etc are within a list of 26 German, 20 English and 6 French terms under which these disorders are termed; denoting their ambiguity and prevalence especially in communities of chronic tensions and frustrations as in the west communities. However, either minor causalgia or reflex sympathetic dystrophy is the term that is recently slowly dominating. These latter recent names are referring to the common denominator in the clinical picture, as also in the classic causalgia, which is the relief of the chronic heavily agonizing pain and other manifestations by effective sympathetic block. Hyperhydrosis is a more common interrelated syndrome that reflects hypersymathetic activity and affects mostly a younger age group and also responds to sympathetic block. We present in this paper our experience in a minimally invasive operation, the endoscopic trans-thoracic sympathectomy that we found effective, easy and short timed. We also stress that the endoscope is a valuable surgical indispensable armament that is very beneficial and minimally invasive and every surgeon can easily and should master it. A barrier of fear may hinder the trans-thoracic approach in surgeons and neurosurgeons, however as happened to us after few operations we found in our selves the courage and the feel at home feeling. It goes without saying that as in the second step of any operative intervention, we must (after the proper anatomical opening) do exploration and safeguard the relevant vascular, nervous and organ structures.

2. Patients and Methods

28 patients (11 men and 17 women) underwent endoscopic transthoracic sympathectomy for upper limb causalgia or hyperhidrosis. As hyperhidrosis is more common, 16 patients (12 women and 4 men) underwent 30 endoscopic transthorathic sympathectomies for upper limb and axillary hyperhidrosis. The mean age was 24.2 years (range 17-32 years). The chief complaint in all patients was excessive sweating. In 3 patients (18.75%) it was confined to the hands; in 2 patients (12.5%) it was confined to the axillae, and in 8

patients (50%) it was affecting both areas. There were 2 patients with recurrent palmar and one axillary hyperhidrosis.

The chief complaint of the major causalgic group (3 patients; all men) was the classic severe agonizing burning pain in the palm; while the chief complaint of the minor causalgic [sympathetic dystrophy] group (9 patients; 5 males and 4 females) was predominantly milder dull burning pain in the palms and distal forearms that was worse on motion and emotional excitement and associated with gradual atonic muscle atrophy and dystrophic skin changes as a series of events following the precipitating factor (myocardial infarction, angina pectoris, joints and bones trauma, soft tissue trauma, phlebitis with phlebothrombosis).

Routine laboratory and radiological screening tests were carried out preoperatively. Under general anaesthesia a 0.5 cm incision was made in the anterior axillary line over the third rib space. The Verres needle was inserted. The lung was slowly deflated by instilling one liter of CO2 into the intraplural space. The upper sympathetic chain was easily visualized lying over the necks of the ribs from the second to the six ganglia. The diathermy probe was inserted through a similar incision in the fourth space. The sympathetic chain overlying the lower part of the first, second and third ribs was treated with diathermy down to the periostium. The intercostal space left untouched. The nerve of Kuntz (a branch parallel and lateral to the main trunk) was coagulated if present. The fourth thorathic segment was coagulated in patients with axillary hyperhidrosis. In one patient with failure of a previous open surgery and recrrence of hyperhidrosis there were some pleural adhesions which were treated by the electrocautery probe. Before closure of the wound, the lung was expanded by positive endexpiratory pressure combined with suction through a small tube. A post operative chest X- ray was performed in the recovery room. The procedure took about 15-20 minutes. Patients

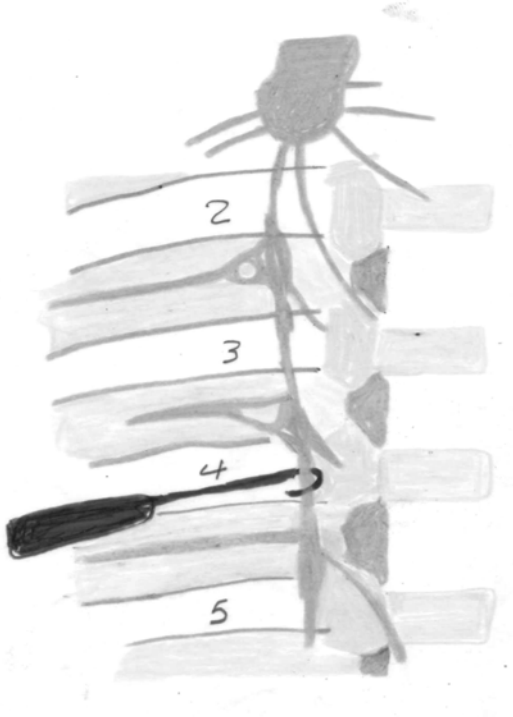

Fig. 1 The schematic drawing showing T_4 sympathectomy was performed by simple diathermic severance of the sympathetic trunk were discharged after two days (range 1-5 days) after surgery. In cases of hyperhldrosis, the contralateral sympathectomy was undertaken 6 weeks later. Patients were followed up for an average of four months (range 2-11 months) to assess the operative results and the occurrence of any complication.

3. Results:

Sixteen patients underwent endoscopic transthoracic electrocautery for hyperhidrosis of the upper limb, 14 patients underwent bilateral and 2 patients underwent unilateral surgery. There were 12 females and 4 males of mean age 24.2 years (range 17-32 years). The hands alone were affected in 3 patients (18.75%), the axillae alone in 2 patients (12.5%), and both areas in 8 patients (50%) (Table 1). There were 2 patients with recurrent palmar hyperhidrosis after the cervical approach, one with bilateral and one with unilateral recurrence. There

was another patient with recurrent unilateral axillary hyperhidrosis after open surgery. All the patients were completely relieved of sweating of the hands and axillae on returning from the operating theatre. As regard the causalgic (sympathalgic) group, the total number were 12 patients; 3 with major causalgia (all males) and 9 with minor causalgia (5 males and 4 females); all with failure of conservative treatment (including repeated sympathetic blocks done in different pain centers) to provide adequate sustained relief. The major causalgic subgroup patients presented with persistence of the typical major causalgic pain. The diagnosis could often be made from across the room based on the appearance of extreme distress shown by a patient cradling the affected limb without touching it to protect it from being touched or even to avoid a breeze inciting a paroxism of pain. The median nerve alone or with other nerves of the upper limb was involved in 2 cases and the brachial plexus in another case. The mean age was 26.7 (range 19-42). In the minor causalgic dystrophic subgroup; the extremely varied clinical presentation, often associated with features not typical of sympathetic hyperactivity with the predominence of muscular and joint symptoms as well as the usual presence of psychogenic features have led to protracted futile therapy in most patients. This eventuated in advanced dystrophic changes that were built up slowly and gradually. The mean age was 39 years (range 21-66 years).

There was no mortality and no serious morbidity. Horner's syndrome occurred in one patient with unilateral recurrent palmar hyperhidrosis, and was resolved in 6 weeks. Pneumothorax requiring a chest drain occurred in two patients. Some transient signs of pleural irritation (3 patients) and intercostal neuralgia (4 patients) were reported. The mean duration of hospital stay was two days (range 1-5 days). In the follow up period of three months, (range 3-12 months), compensatory sweating occured in 14 patients (50%) and gustatory sweating in 10 patients (35.7 1%). This compensatory and gustatory sweating were considered much less embarrassing than the original complaint. Despite the above mentioned side effects, 15 of 16 patients (93.75%) with hyperhidrosis, all patients with major causalgia and 5 patients with minor causalgia (5.55%) were very much improved in the follow up period and considered the result of endoscopic surgery highly satisfactory (Table 2). The remaining patient with hyperhidrosis (6.25%) and two patients with minor causalgia (2.22%) were moderately improved and were only satisfied. Two patients with minor causalgia (22.2%) had other residual symptoms associated with limitation of movement, stiffness of joints and other trophic changes. These were usually related to the delay between the onset and the diagnosis, which averaged 7 months. However both patients experienced gradual and moderate improvement. In a total number of 28 patients with hyperhidrosis or causalgia of the upper limb, transthoracic endoscopic sympathectomy gave excellent results in 89.28% of cases (25 cases) and mild to moderate improvement in 10.72% (3 cases).

Table (1): area affected by hyperhydrosis in 28 patients.

area	No. of patients	percent
Hands only	3	18.75
Axilla only	2	12.5
Both areas	8	50
Recurrent hands	2	12.5
Recurrent axilla	1	6.25

Table (2): subjective assessment of the results of endoscopic surgery by 28 patients.

	Improvement	Immediate postoperative	At follow up
Hyperhidrosis	Very much improved Moderately improved	15 (93.75%) 1(6.25)	15(93.75%) 1(6.25%)
Major causalgia	Very much improved Moderately improved	3(100%)	3(100%)
Minor causalgia	Very much improved Moderately improved Slightly improved	5(55.55%) 2(22.2%)	5(55.55%) 2(22.2%)

4. Discussion:

Twenty eight patients with upper limb hyperhidrosis (palmar and axillary) or causalgia (major and minor) were submitted to endoscopic transthoracic sympathectomy as a definitive treatment. There were 16 patients with upper limb hyperhidrosis (including three patients with recurrence after open surgery), and 12 patients with upper limb causalgia (3 with major causalgia and 9 with minor causalgia). The procedure was successful

in curing 25 patients (89.28%) and gave moderate improvement in 3 patients (10.72%); two of them belonged to the minor causalgic group because of the advanced dystrophic changes in their limbs. The commonest side effects were compensatory sweating. There was a high level of patient satisfaction. Horner's syndrome occurred in one patient. The procedure is effective, simple, and required only two nights stay, and is recommended as a method of choice for the surgical treatment of upper limb hyperhidrosis or causalgia.

HYPERHIDROSIS is defined as sweating above and beyond the physiological needs. It can be very distressing and the source of intense embarrassment (Symptoms usually appear at puberty with an incidence of 0.6-1.0%). Hyperhidrosis is usually localised to the palm, axillae and feet, but the face, back, groin and legs may also be affected [1]. Sympathectomy remains the cornerstone of surgical management.

Cases of causalgia of the upper limb are extremely embarrassing and renders the patient almost completely useless and miserable. Major causalgia is a clinical syndrome associated with a lesion of a peripheral nerve that contains sensory fibers and is characterized by burning pain in the affected extremity, usually in the hand or foot. It occurs as a complication in about 3% of major nerve injuries. It is most often associated with incomplete lesions of the median nerve in the upper limb and the sciatic nerve (the tibial part) in the lower limb. These two nerves account for about 60% of the cases; the rest of the cases involved primarily the nerves of the upper extemity [7]. Despite the recognition that the sympathetic nervous system is involved, the specific pathophysiology is unknown. Various theories as to the cause of causalgia have been proposed, including short - circuiting effects at the area of the injury, permitting irritation of sensory afferent fibers by the efferent sympathetic impulses, periarteritis in volving the vessels about the injured neural segments, and abnormal feedback into the internuncial centers of the spinal cord. The syndrome is one of excruciating burning pain often described as having a superimposed throbbing, aching, bursting pressure, knife like stabbing, twisting, or crushing component. In many instances (about one third); pain begins immediately after injury; it usually begins sometime during the first week. The pain is usually located in an area corresponding to the cutaneous distribution of the nerve but is not necessarily limited to this area. Another characteristic of the pain, one usually necessary for a positive diagnosis, is accentuation by stimuli to such emotions as surprise and anger and by other disturbances in the patient's environment. To touch, feel, or even hear the name of a slick object such as a paper or a sheet will cause severe increase in pain in some patients. In many instances light touch, heat, or minor movements of the trunk and extremity will increase existing pain. Some patients insist the pain seems less severe on cool, damp days or at night. After having seen a patient with severe causalgia one is not likely to forget the picture of a pain- racked patient guarding the affected extremity with extreme care. The skin of the affected part may show evidence of vasodilatation early after injury, and this may or may not be replaced later by vasoconstriction. Thus the skin of the affected part may be dark red, dry glossy, and atrophied or cold, mottled, and moist. The skin may be devoid of hair or, on the contrary, may have an abnormal growth of hair, hyperhidrosis is common. Accurate evaluation of the completeness of the nerve lesion is commonly impossible because of the extreme pain caused by handling the affected limb. When causalgia is severe, the diagnosis is usually clear and is easily confirmed by procaine block of the second and third sympathetic ganglia. Rarely will other neurologic conditions be confused with true causalgia [7].

Both major and minor causalgia seem to constitute a closely related conditions; Horowitz [17] had already concluded that (the post traumatic pain syndromes seem to be identical in type with minor causalgia), Bonica [7] has taken the logical view that effective treatment by sympathetic denervation justifies classifying the entire group under one rubric. Omar et al., [21] & Buker et al. [8] have reported successful treatment of early minor causalgic states (reflex sympathetic dystrophy) by a long series of sympathetic ganglion blocks with local anesthetics (occasionally and especially in the early stages of the disease, a series of several sympathetic blocks with procain will relieve the pain or make it tolerable); failure of this conservative measures is the indication of surgery.

Sympathectomy remains the cornerstone of surgical management to hyperhidrosis and causalgias (major and minor), various operative approaches have been described, each with its advocates; the cervical or supraclavicular approach (Tel- ford, 1935)[6], the posterior approach [2], the transaxillary approach [4], and the transthoracic endoscopic sympathectomy[3]. This study was an experience in endoscopic transthoracic electrocautery of the sympathetic chain for the treatment of upper limb hyperhidrosis or causalgia.

Endoscpic transthoracic sympathectomy is a minimally invasive procedure with several advantages over the open surgery. It provides excellent visualization of the sympathetic chain. The simplified technique described in this series of 28 patients was successful in treating around 90%

(89.28%) of the patients with upper limb hyperhidrosis or causalgia; the rest of the patients obtained moderate to mild improvement. It was not followed by any major complication, there was no wound infection and the two scars of 0.5 cm. length are almost invisible. The operative time varies, but the average for the unilateral procedure was 20 minutes. Gothberg et a! [16] reported a 25 minutes for a bilateral procedure; while Edmondson et al. who reported an average time of 45 minutes for bilateral procedure. The hospital stay average 2 days in this study which compares good with that reported by other workers.

Postoperative Homer's syndrome is largely a complication of the open approaches, but the danger of creating a Homer's syndrome (6.25%) and of pneumothorax (12.5%) was less than that reported by Edmondson et al. They reported percentages of 14% and 16% for these two complications respectively. Compansatory sweating represents a thermoregulatory response and is usually over the trunk and upper thighs in 13 patients (46.42%) in our sires, which is near the incidence reported by Adar [1]. Gustatory sweating occurred in 9 patients (32.14%) which was nearly similar to that reported by Edmondson et al. [13]. In general compensatory and gustatoy sweating were not very embarrassing to the patients.

In summary,

Endoscopic transthoracic electrocautery of the sympathetic chain for the treatment of upper limb causalgias and hyperhidrosiss is a safe, simple, fast and cosmetically acceptable procedure. It is considered the treatment of choice for these conditions.

Abstract: Study design: A prospective study to evaluate the outcome of a novel operation for cervical myelopathy secondary to cervical canal stenosis; the Reconstructive Cervical Laminoplasty with the preserved fixed spinous processes row as an intervening bone graft. **Objective:** To explore a more effective, less invasive and more physiological operative technique for cervical myelopathy of cervical spinal canal stenosis. **Background:** The popular two cervical laminoplasties for the nowadays becoming common in elderly people cervical myelopathy of cervical spinal canal stenosis, i.e. open door laminoplasty and double doors laminoplasty are plagued with many drawbacks such as around 50% diminution in the range of cervical movements, 25% occurrence of kyphotic deformity, laminar fusions, from 10% to 50% chronic axial neck pain and nuchal musculature atrophy. A more physiological modification of this very beneficial operation is badly needed. We presented our novel reconstructive cervical laminoplasty with the preserved fixed spinous processes row as an intervening bone graft to avoid such drawbacks. **Methods:** This prospective preliminary study included 14 patients who underwent the novel reconstructive cervical laminoplasty with the preserved fixed spinous processes row as an intervening bone graft operation for their cervical myelopathy. **Results:** The novel operation is proved to be easier, more physiological and succeeded to avoid to a great extent the aforementioned drawbacks of the two popular cervical laminoplasties; only about 30% diminution of cervical movements occurred, no kyphotic deformities, post-operative axial neck pain was moderate and occurred in only 21% of the patients and the post operative nuchal musculature atrophy was avoided. **Conclusion:** Cervical myelopathy secondary to cervical spinal canal stenosis can be managed adequately with our novel cervical reconstructive myelopathy with the preserved fixed spinous processes row as an intervening bone graft. This technique obtained satisfactory outcomes and avoided the drawbacks of the popular laminoplasty operations. It can be a standard procedure for the surgical treatment of this nowadays becoming common disease.

Keywords: Reconstructive Cervical Laminoplasty; Spinous; Processes Row; Intervening Bone Graft; Novel Surgical Approach

1. Introduction

Cervical laminoplasty is a posterior spinal operation where the position of the laminae is altered to augment the cervical spinal canal width and volume without intersegmental fusion. Laminoplasty is primarily used to treat cervical myelopathy caused by cervical spinal stenosis. Spinal multisegmental stenosis of the cervical vertebrae is common in old age secondary to moderate to severe cervical spondylosis with osteophytic bars. Laminoplasty was first described in 1968, and much of the literature regarding it comes from Asia, where cervical myelopathy from ossification of the posterior longitudinal ligament is common. In our area as well as universally, many surgeons choose and prefer laminoplasty over anterior fusion techniques when more than two levels require decompression. Laminoplasty can be used in other situations where the volume of the cervical spinal canal needs augmentation, but fusion is not desired.

2. Methodology:

Study design: A prospective (longitudinal) preliminary study on the novel cervical laminoplasty with preservation of the fixed posterior longitudinal band operation.

Inclusion criteria: Presence of cervical myelopathy with cervical spinal canal stenosis, documented tight cervical spinal canal and cervical spinal cord compression with absence of the subarchnoid space in the MRI, Pavlov ratio (canal depth / vertebral depth)= < 0.82 in the lateral view plain X ray.

Exclusion criteria: Cervical Kyposis.

Anterior osteophytic bars thickness > 7mm

Advanced myelopathy with marked spastic paraplegia or scissoring of the lower limbs and marked atrophy and weakness and of the upper limbs (grades 0, I).

Elderly debilitated patients.

Initial evaluation: 14 patients were included in this preliminary study they were submitted to complete neurological history taking and thorough examination.
Radiological assessment: cervical MRI and plain cervical antero-posterior lateral and dynamic views were done to all the patients.
Physiological studies: Electromyogram EMG of the upper limbs is done to all patients.

Operative maneuver:

Patient positioning: A general endotrachial anesthesia is used and the patient is given a preoperative dose of antibiotics and steroids. Positioning is accomplished by placing a pin-type head rest, and turning the patient prone. Chest rolls elevate the thoracic cage and decompress the abdomen, thereby lowering the venous pressure and diminishing the operative blood loss. The head and neck are positioned in a neutral position, and the head rest mechanism is locked. The shoulders are taped down to the table with 4 inch adhesive tape. We prefer and found beneficial to elevate the head by tilting the surgical table 35 degree. A standard midline approach is utilized, dissecting down to the fascia then via the cutting diathermy in the ligamentum nukae. The secret of success in this step and the following one is to keep the diathermy cutting strictly midline and restricted to the thick fibrous tissue of the ligamentum nukae to minimize blood loss and to approach the spinous processes row atraumatically and easily. A standard bilateral subperiosteal dissection is carried out including the levels immediately superior and inferior to the pathologic levels, with preservation of the midline posterior tension band consisted from the spinous processes row and the intervening interspinous ligaments via restricting the diathermy cutting dissection only bilateral to the spinous processes, i.e. neither cutting in the upper nor the lower borders of the spinous processes. Using a small drill or a thread wire saw we cut at the bases of the spinous processes leaving 6-mm projections from the laminae; the scissors are used alternatingly to cut at the bases of the interspinous ligaments. The separated spinous processes, with their ligamentous attachments, are retracted to one side. The spinous processes are making the bony components of the preserved midline posterior tension band that is left as a whole fixed upwards and downwards to the spinous processes immediately superior and inferior to the pathologic levels. The laminae (devoid from the spinous processes) are thereafter cut in the midline with the same instrument. Two bony hinges are constructed bilaterally at the junction of the laminae to the facet complexes using a high-speed drill down to thinning partially and suitably the inner cortex, taking strict care not to injure the facets. Care must be taken so that the lamina is not thinned to the point that it fractures, or that it offers no spring like resistance to deformation. The proper resistance is checked and made so that with gentle finger pressure the laminoplasty segment is opened. A gentle capacious and sufficient release and separation of the dura surrounded by its thin vascular film from the undersurface of each lamina is done, with gradual and gentle rotation of the lamina to open the segment. Then the ligamentum flavum in the mid line is opened and excised for about half a centimeter, with utmost care to avoid laceration of the epidural thin vascular film or the epidural venous plexus. Sufficient time is awaited for the dura to re-expand and regain its healthy pulsations. Now after securing hemostasis, the (to the side) retracted tension band is regained to the mid line and the spinous processes portions are used as an intervening bone grafts via drilling 1-mm holes in the medial edges of the hemilaminae and the sides of the corresponding properly opposed spinous process at each level. The spinous processes are sutured carefully into place using nonabsorbable sutures. These sutured spinous processes portions are actually the left portions after they had been cut leaving 6 mm of their bases projecting from the laminae. This induces about 4-5 mm enlargement along the anterior posterior line of the canal which was found ideal. A proper closure of the hemilaminae segments with the intervening spinous processes' portions included within the posterior tension band after expanding the spinal canal should be secured. If radiculopathy is found on the preoperative electromyogram (EMG), we always perform selective foraminotomy for the affected roots. We also always intentionally perform reconstruction of the semispinalis cervicis and re-suture it back to the C2 spinous process in both sides to strengthen the posterior tension band as well as to cover and secure water-tightness of the spinous processes-to-the medial hemilaminal edges sutures. After proper hemostasis of the back muscles, we close in layers. A rigid cervical collar is used for three weeks.

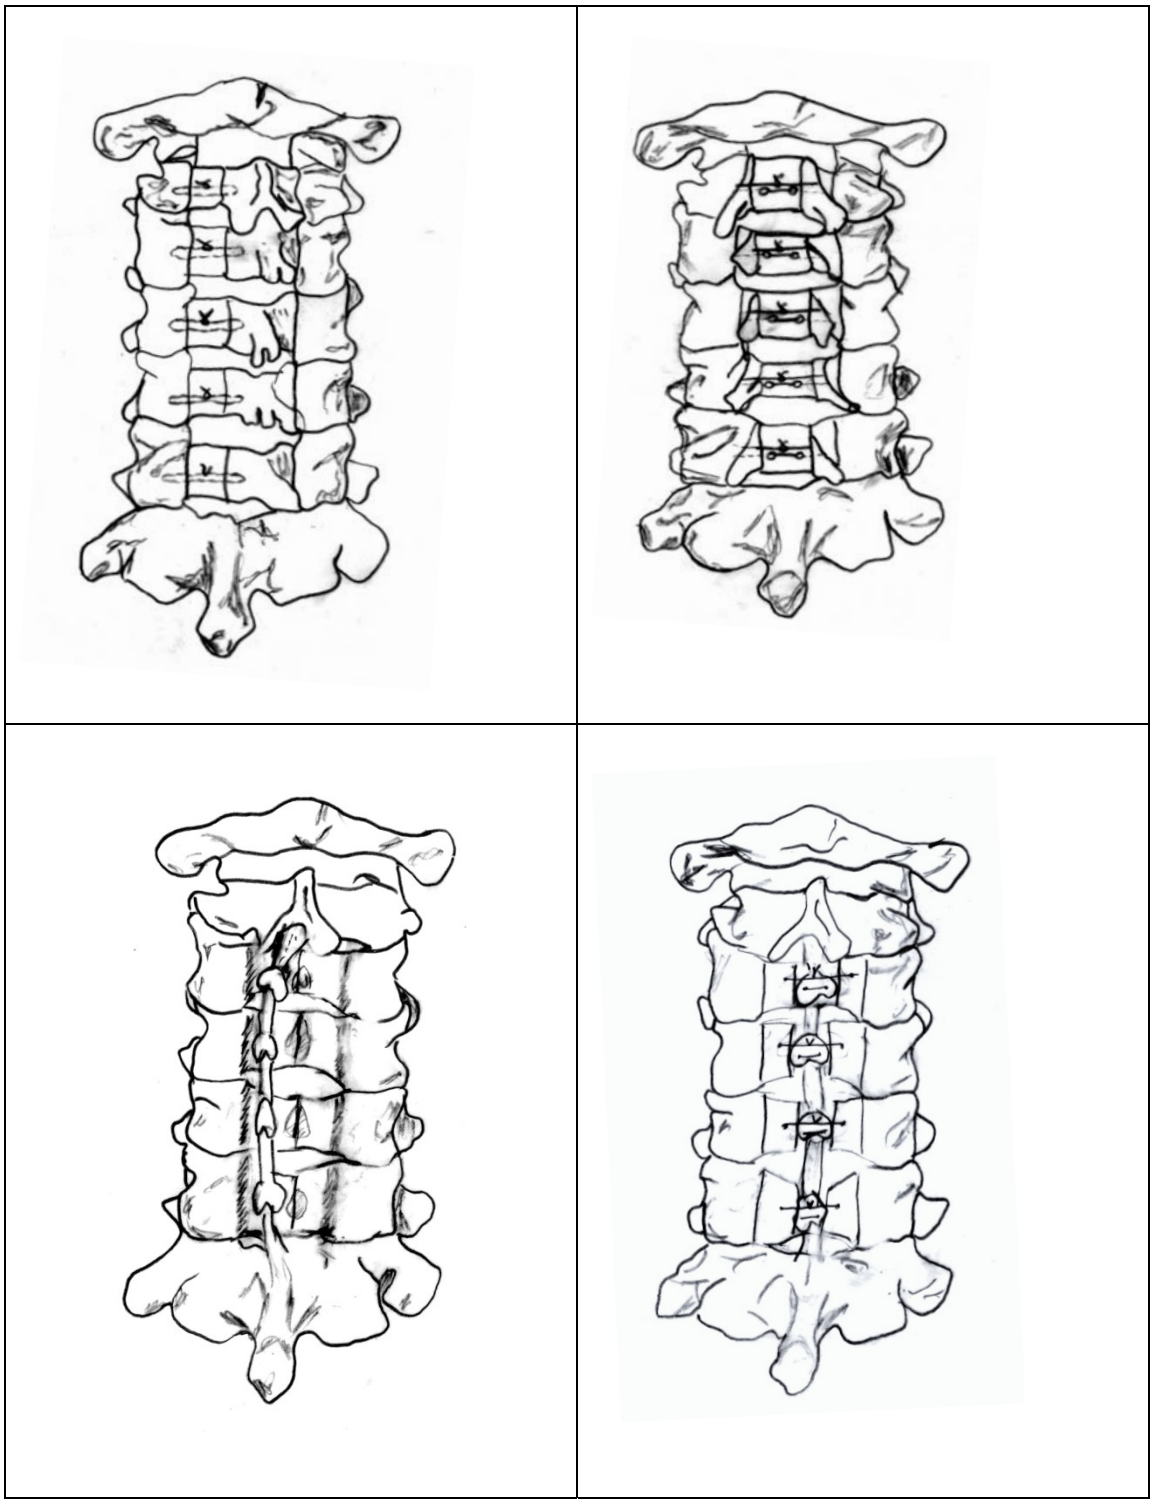

Fig. 1 Upper left: open-door laminoplasty. **Upper right:** double-door laminoplasty. **Lower left:** reconstructive laminoplasty with preservation of the fixed (to the superior and inferior spinous processes) midline longitudinal band; that is retracted to the side to permit the midline cuts in the laminae. **Lower right:** reconstructive laminoplasty with preservation of the posterior longitudinal band, after suturing of the spinous processes row in place.

3. Results:

Because most of the cervical laminoplasty operations are performed to treat myelopathy, the preoperative and post operative conditions are usually scored using the Japanese Orthopedic Association (JOA) scoring system for cervical myelopathy that gained universal acknowledgement and approval as much of the literature regarding laminoplasty comes from Asia where OPLL is prevailing. However some items in that score is strange to other communities (handling chopsticks), thus we used the same score with minimal modification that will not make any difference to suit our community. In this score:

The recovery rate percentage =100 (post operative score minus preoperative score/ 17 minus preoperative score).

Excellent recovery rate :>75%, Good:50-75%, Fair:25-50% and Poor recovery:<25%.

Ages of the patients ranged from 38 years up to 71 years. Average age was 49 years. 71% were males, the rest were females 39%.

Duration of the disease averaged 8 years (from 3 to 14 years).

To assess the success of our novel operation of laminoplasty we assessed the 14 patients as a group. Collectively, we found that there is a 72% recovery rate in JOA scoring system in our 14 patients as the following table 1.

Table 1: The collective recovery rate of our 14 patients.

	Pre-operative	**Post-operative**	**Recovery rate**
Motor dysfunction of the upper extremity 0=unable to feed oneself, 1=able to eat with spoon, 2= able to the full use of the teeth sticks with slight difficulty, 3=none	21	26	
Motor dysfunction of the lower extremity 0=unable to walk, 1=walking on flat floor with walking aid, 2= up stairs with hand rail, 3=None	24.5	29	
Sensory deficit of the upper extremity 0=severe sensory loss or pain, 1=mild sensory loss,2=none	12	16	
Sensory deficit of the lower extremity 0=severe sensory loss or pain, 1=mild sensory loss,2=none	11	16	
Trunk 0=severe sensory loss or pain, 1=mild sensory loss,2=none	10.5	17	
Sphinchteric dysfunction 0=unable to void, 1=marked difficulty in micturition, 2=difficulty in micturition, 3=none			
	28	31	
Total	**107**	**125**	**72%**

However, four factors were found related to the outcome in an ascending relevance: older age, lower JOA scores, lower Pavlov ratio (width of the canal divided by the width of the vertebral C6 body in the lateral plain X ray), and the presence of an abnormal spinal canal signal in the preoperative MRI. They were found significantly related to poorer outcome. In this preliminary study we correlated the three patients mostly affected with the previous 4 factors in relation to the rest of the patients. We found that respectively each of them correlated to 16%, 20%, 26%, and 33% diminution in the overall good result.

4. Discussion:

Two types of laminoplasty gained popularity; the open door and the double door laminoplasty. All literature on laminoplasty is class 3 data, therefore, at present; laminoplasty is listed as a treatment option for cervical spondylotic myelopathy as well as ossified posterior longitudinal ligament (OPLL) in Japan and East Asia. It is heavily documented in the literature that laminoplasty is effective in treating cervical myelopathy caused by stenosis. Theoretically, laminoplasty benefits compared to anterior fusion include preservation of cervical motion and prevention of the adjacent motion segments degeneration. Its benefits compared to the decompression laminectomy include prevention of post laminectomy kyphosis, avoiding the development

of post laminectomy membrane formation and the recurrence of stenosis as well as avoidance of the development of retrolisthesis and instability. However, unfortunately, these benefits are not always realized as there are three drawbacks that plagued this beneficial maneuver in its popular two types. It was shown by previous researchers that the range of movement diminishes approximately 50% after laminoplasty, kyphotic deformity occurs in around 25% of the patients, and intralaminar membrane formation as well as laminar fusions has been recorded frequently. Additionally there is from 10% to 60% incidence of chronic axial neck pain compared to 19% after anterior fusion.

We present our easy and straightforward novel surgical maneuver that neither necessitates any extra manipulations for bringing bone grafts from elsewhere nor is technically demanding; in addition to its benefits in avoiding to a great extent the aforementioned complications. We found that preservation of the posterior tension band that is left fixed to the spinous processes immediately superior and inferior to the pathologic motion segments prevents the tendency to kyphous deformity. This band is strengthened via the resuture of the semispinalis cervicis back to the C2 spinous process. It should be mentioned that reconstruction of this muscle alone as was done before by some researchers without the preservation of the midline structures that constitute the posterior tension band will never suffice to prevent the kyphotic tendency as the muscle tissue is a stretchable tissue.

This preservation of the normal lordotic curve was found also very beneficial to prevent the chronic axial neck pain that was repeatedly recorded by many researchers to occur in up to 60% of post-laminoplasty patients. We think that this pain arises to a great extent from the posterior uncovertebral joints either because of their injury during surgery or due to post operative abnormal stretching of their capsules secondary to the post operative kyphotic tendency. We succeeded to prevent both factors, thus the post laminoplasty axial pain was reduced to minimum as only 21% of the patients complained of it.

We also succeeded to avoid the interrelated triad of post-operative diminution of the range of movement only about 30% in our maneuver compared to 50% in the two popular manuevers, laminar fusions and perilaminar membrane formation via minimizing the surgical tissue injury and strict hemostasis. From the start we keep strictly our sharp mid line cutting within the fibrous tissues of the ligamentum nukae, we preserve the midline structures that are crucial in the biodynamichs of the cervical vertebrae as it prevents the occurrence of postoperative kyphosis which continuosly stretches and stimulates the laminar periosteum to form new bone, also we keep the posterior joints untouched.

The latter three factors are also fundamental in preventing the post laminoplasty nuchal nusculature atrophy and size reduction that was repeatedly recorded. The nuchal muscles may lose up to 25% of their preoperative size in some patients of the classical two types of laminoplasty. Avoiding this complication in our novel operation is largely due to the preservation of the midline tension band that prevents kyphosis which stretches the nuchal muscles and invite shearing tissue injury in them also may provide nutrient vasculature to the muscles in the post-operative period as well as keeping the posterior joints untouched preserve the nutrient vasculature and nerves of these muscles.

Strict hemostasis, post operative drain for 36 hours and post operative alpha chemotrypsin one amp/12 hours were also done and found very beneficial.

Limitations:

Our preliminary results are very encouraging. The novel operative maneuver is logic and straightforward. It is considered a conservative modification of the already popular and the established successful two types of cervical laminoplasty. In addition to preserving the proved very crucial posterior longitudinal tension band that is kept fixed superiorly and inferiorly; an employment of its bony element that is also kept fixed in it i.e. the spinous processes row as an intervening bone graft is easy and novel. Thus the time of the operation is greatly shortened, which is considered a welcomed element in this elderly age group. However, the limited number of our patients is considered a limitation that necessitates further studies on a greater scale.

5. Conclusion:

We presented our novel operation of reconstructive cervical laminoplasty that exploited the preserved fixed spinous processes row as an intervening bone graft. To our knowledge it is a pioneering and also a logic operation that conserves the crucially relevant posterior midline tension band fixed superiorly and inferiorly. We managed to avoid much of the drawbacks and complications of the popular two types of cervical laminoplasty, and thus our easy operative maneuver proved to be very beneficial.

Abstract: The purpose of this study is to investigate the effect of the Barton Intervention Program on the attitude and self-concept of dyslexic students. The Dyslexia Screening Instrument (DSI), and Reading Text were employed in order to identify the dyslexic students in schools in Ilam, Iran. The population of the study included 138 dyslexic students studying in elementary schools in Ilam, Iran and from this population, 64 students were selected randomly and assigned equally to an experimental group and a control group (32 students in each group). The experimental group was taught for 36 sessions using the Barton method, in two levels, and ten lessons were provided to improve their reading skills. Reading attitude and self-concept to read instruments were employed to measure their attitude and self-concept, before and after the intervention program. The reliability of the reading attitude and self-concept were confirmed. The content validity of the scales was investigated using the judgment of 10 psychology experts. The analysis of the finding through independent t-test showed a significant difference between the control group and the experimental group after the intervention, at $\rho<0.000$.

Keywords: Intervention program; attitude; self-concept; dyslexia

1. Introduction

Most students with learning disability have problems in one or several basic skills. Dyslexia is one of the learning disability affecting these students in their basic skills (1), where dyslexia students were found to hold more negative self-concept (2), feel more helpless (3) and have negative attitudes about school learning (4). Attitude toward reading has been defined by Smith (5) "as a state of mind, accompanied by feelings and emotions, that make reading more or less probable" (p.125). A student's attitude toward reading is an essential factor affecting reading performance. Positive attitudes can compensate for relatively weak skills, while negative attitudes can prevent a student from applying existing knowledge (6). Reading attitude fulfills a pivotal role in the development and use of lifelong reading skills. Richeck, List and Lerner (7) declared that "the final success of education is strongly affected by the reader's attitude". Lipson and Wixson (8) concluded that "the student's attitude toward reading is an essential factor affecting reading performance". A number of researchers have postulated that attitudes affect one's motivation and consequently reading achievement by increasing or decreasing the amount of time that learners spend engaged in reading (9).

The result of studies by Polychroni, Koukoura and Anagnostou, (10), as well as Lazarus and Callahen (11) showed that students diagnosed with learning disability in reading have negative attitudes toward reading. Attitudes can also consist of one's affinity for a particular activity. The importance of the affective characteristics of learning- disabled students has long been noted, and these students are often attributed with negative affective

characteristics. Despite this somewhat general acceptance in the field (12), it has not been definitively ascertained whether the negative affective variables cause the learning disability, are a consequence of it, are related in origin to the actual disability, or are simply behaviors which happen to occur concurrently with the difficulty in learning. There seems to be a general agreement nevertheless, that the prolonged failure experiences of learning disabled children have a profound and lasting effect (13). Students' attitudes toward reading are positively linked to reading improvement. When students are interested in what is being taught and have access to materials that interest them, then learning, and attitudes improve (14). Reading attitude is typically viewed as a multidimensional concept related to the functions of reading. A number of attitudes to reading models of have been proposed (15-16). Across all models, the decision to read is viewed as largely determined by attitudes toward reading. Mathewson (16) supported that attitudes function as a causal agent upon the reading process. The factors that may influence children's positive attitudes toward reading are what the child believes about others' expectations; and what the child believes about his or her reading outcome and the type of prior reading experience. Thus, children's prior beliefs and cognitive-affective knowledge may affect their reading comprehension (17).

Comparisons with low-skilled, without disability students suggest that students with learning disability have negative attitudes toward reading, and some studies exist to support these inferences (10, 18). Nevertheless, there are studies which have documented that students with dyslexia who received reading instruction in special education and resource rooms expressed attitudes to academic and recreational reading that equaled or exceeded those expressed by low and average without disability students, implying that perceptions of ability are important (11). Moreover, when individuals with dyslexia get involved in voluntary reading in areas of personal interest, they improve their reading ability (19).

Many studies have examined differences between students with and without learning disability across multiple domains of functioning and these studies have revealed that their academic failure may affect their self-concept, and adjustment (20-22). Results of these studies have shown that, when compared to peers without learning disability, students with learning disability have lower level of social-emotional difficulties.

Research has been fairly consistent in demonstrating that students with learning disability have a lower self-concept than other categories of students (Bryan, Burstein, & Ergul, 2004). However, studies regarding lower self-concept among students with learning disability are somewhat equivocal (23). There is general consensus that students with learning disabilities show lower self-concept, in particular on school-specific tasks associated with their disability, such as reading (24). Research among students with learning disability particularly has shown that these students tend to attain lower school specific self-concept scores. Bender and Wall (25) suggested that there may be a developmental trend in which students with learning disability demonstrate a lower self-concept, and these students, as they grow up, may learn to think more highly of themselves in general but are predisposed toward maintaining a lower self-concept relative to academic tasks (Bender, 2008).

Several researches have shown that students with learning disability display poorer self-concepts and poorer perceived academic skills than those without disability (Bender & Wall, 1994; Elbaum & Vaughn, 2003a). Furthermore, research suggests that poorer self-concept affects social and academic achievement. Since students with learning disability experience repeated academic failure, disappointments, and frustrations, it is not surprising that many of them have low feelings of self-worth. Some students may even refuse to try a task due to fear of failure. Bryan and Pearl (13) found that the self-concepts of students with learning disability with regard to their academic performance are more negative than those without disability, while their general feelings of self-worth are equivalent to those without disability. Montgomery (26) and Kloomok, and Cosden (27) in their research found that the students with learning disability exhibited self-concepts similar to those students without disability in nonacademic areas, but displayed significantly more negative self-concepts in the areas of academics and skills. A current comprehensive meta-analytic review by Zeleke (28) showed consistent evidence that the school self-concept of students with learning disability is more negative than that of students without disability. However, empirical support on the self-concept of children with learning disability has been less then straightforward, mainly due to methodological difficulties that are reported below.

1. Given the heterogeneity of the dyslexic population and the lack of agreement on the criteria used in identifying students with learning disability, the comparisons across studies are difficult. Furthermore, the selection criteria for the low-achievement groups are also varied, including using the 25th percentile point as a cut-off score to differentiate students with learning disability from those students without

learning disability, or simply using teachers' ratings (28). 2. The majority of studies about learning disability have examined the association between general self-esteem as opposed to specific school self-esteem and achievement. Taking into consideration the multidimensional and hierarchical models of the self (29), it has been supported that this association is stronger when school self-esteem is examined in relation to children with difficulties in literacy. School self-concept is also multidimensional, having components in several academic subjects. In addition, studies on different school settings, for example mainstream schools and special schools have demonstrated that dyslexic children in special schools typically have higher school self-concept as compared to dyslexic students in mainstream schools, consistent with the social comparison theory (30-31). However, this difference is less evident in other areas of self-concept (32).

The aim of this study was to compare dyslexic students in the experimental and control group after the Barton Intervention Program. The research questions are as follows:

1. Does the Barton Intervention Program improve the reading attitude of the dyslexic students in the experimental and control group?
2. Does the Barton intervention program improve the reading self-concept of the dyslexic students in the experimental and control group?

This study is guided by the following research hypotheses:

1. There is a statistically significant difference in reading attitude between the dyslexic students in the control group and the dyslexic students in the experimental group after the Barton Intervention Program.
   - 1.1 There is a statistically significant difference in recreational reading attitude between the dyslexic students in the control group and the dyslexic students in the experimental group after the Barton Intervention Program.
   - 1.2 There is a statistically significant difference in academic reading attitude between the dyslexic students in the control group and the dyslexic students in the experimental group after the Barton Intervention Program.
2. There is a statistically significant difference in reading self-concept (RSC) between the dyslexic students in the control group and the dyslexic students in the experimental group after the Barton Intervention Program.
   - 2.1 There is a statistically significant difference in RSC-competence between the dyslexic students in the control group and the dyslexic students in the experimental group after the Barton Intervention Program.
   - 2.2 There is a statistically significant difference in RSC-difficulty between the dyslexic students in the control group and the dyslexic students in the experimental group after the Barton Intervention Program.
   - 2.3 There is a statistically significant difference in RSC-attitude of the dyslexic students in the control group and the dyslexic students in the experimental group after the Barton Intervention Program.

2. Method and Procedure

In this study, the students in the fourth and fifth grades with dyslexia were identified by first using a questionnaire called the "Dyslexia Screening Instrument". Two 100-word passages with 10 comprehension questions from the students' textbooks were selected and were assigned to the students to read. Their marks were also scrutinized in the first semester and it was found that their marks in the reading skills were lower than the marks of the students without dyslexia. To examine their IQ, Raven's test was performed, and the students with the average IQ higher than 90 made up the population of this research. Finally, 138 dyslexic students in the fourth and fifth grades in elementary schools in Ilam, Iran were selected. The population of the dyslexic students for this study consisted of 40 male and 38 female fifth grade students, and 37 male and 22 female fourth grade students. Their age ranged from 10 to 12 years. The researcher used the table of random numbers to select 64 dyslexic students from the population and assigned them equally into a control and an experimental group, with each group comprising of 32 students. "Reading Attitude" and "Reading Self-Concept" Scales were conducted on both groups. The dyslexic students were given verbal instructions on how to complete the Reading Attitude Scale (33) and Reading Self-Concept Scale (34). The items were read aloud and the students' understanding of the instrument was observed. Assistance was provided when necessary. Demographic variables such as age, gender, and IQ were obtained as well. When the students had completed answering the questionnaire (approximately 40 minutes later), they returned to their respective classrooms.

3. Intervention

The Barton Intervention Program (35) was used in this study. The Barton Reading and Spelling System includes ten levels. Each level is broken into

lessons and each lesson, in turn, is further broken into procedures. In this study, only level one and two were taught with some adjustments. Considering the fact that in the Persian language, there are 26 consonants, 6 vowels, and one digraph, 6 lessons were specified for level two. Like Barton's (2000) program, in the adjustment program, teaching procedures started with the easy level and gradually became more difficult. Since instruction tools were not available in Persian, the researcher provided the necessary tools based on the Barton program. Instruction tools included: 1) color coded letter tiles, 2) word lists, 3) cards, on which one word is written in blue consonants and red vowels respectively, 4) whiteboard, 5) blue and red markers, and 6) a notebook for dictation along with red and blue pencils, erasers and sharpeners. According to Barton's program (2000), level one is taught first. Then, 6 consonants, and one vowel were taught in each session of level two. Sometimes, due to the difficulty of some consonants or vowels, some lessons were repeated for 2 to 4 sessions. Therefore, one by one instruction was done for 36 sessions in 12 weeks, each week with three sessions and each session lasting 45 minutes. It seems necessary to note that students received the intervention in their respective schools, one to one. Instruction time was set by the tutors. If the students could not learn a lesson properly, the lesson would be repeated till she/he learned it.

4. Pilot study

The purpose of carrying out the pilot study was to evaluate the suitability and appropriateness of the use of the instruments. For the pilot study, 30 dyslexic students from Ilam, Iran with similar characteristics were selected randomly to be the participants. The students consisted of 19 males and 11 females in the fourth and fifth grades. This study was carried out from 1st March to 5th March, 2010. Then, the data was entered into SPSS version 17 Windows software to determine the reliability of the scales. The reliability test was applied by calculating the Cronbach's alpha on the variables to measure the inter-item reliability. There was consistency in the following variables: reading attitude and reading self-concept. Internal consistency is usually measured with Cronbach's alpha, a statistic calculated from the pair- wise correlation between items. Internal consistency ranges between zero and one. Cronbach's alpha coefficient of reliability and alpha of 0.70 is normally considered to indicate a reliable set of items (36). Cronbach's alpha reliabilities of the Reading Attitude and Reading Self-Concept Scales were 0.79 and 0.80 respectively. The results of the reliability coefficient showed that there is a high reliability for these instruments, so these instruments were considered appropriate to be employed in this study.

5. Validity

In this study, to ascertain the validity of the Reading Attitude, and Reading Self-Concept Scales, ten psychology experts were asked to grade the scales from 1 to 5. The acceptable degree figures are shown in Table 1 below. Although there is no statistics for content validity, a statistical figure, namely mean was introduced in Table 1. It should be stated that what has been put forward in Table 1 is the acceptability degree criteria among the judges.

Table 1. Judges Rank

Judges	Mean Self-concept	Mean Attitude
1	4.21	4.40
2	4.22	4.40
3	4.19	4.45
4	4.23	4.50
5	4.24	4.50
6	4.29	4.40
7	4.26	4.15
8	4.27	4.35
9	4.32	4.20
10	4.29	4.30

Table 1 show that Juror Rank given by experts based on Cohen (37)

6. Measures

Five instruments were utilized in this research. They are as follows: 1) the Dyslexia Screening Instrument (DSI), 2) Reading Text, 3) Reading Self-Concept Scale (RSCS), 4) Reading Attitude and 5) Raven's Progressive Matrices.

Reading Self-concept Scale: The Reading Self-Concept Scale (RSCS) (34) was used as a measure of reading self-concept. The RSCS contained 30 questions, which were read aloud individually to the dyslexic students who responded on a 5-point Likert

scale (1. Never, 2. Seldom, 3. Sometimes, 4.Often, and 5. Always). Response requirements were taught to the students by means of 4 examples and 10 practice items, which took approximately eight minutes to complete. The RSCS was developed as part of a series of experimental studies in which previous research and theory in the areas of self-concept and reading were drawn upon. The RSCS measures reading and is suitable for ages 6 and above. The Cronbach's alpha coefficient score for the scale is 0.80. The RSCS was individually administered and administration time varied between 15 and 30 minutes for each participant. Each response was scored from 1 (low reading self-concept) to 5 (high reading self-concept) with the total score calculated as the mean value of the 30 responses. Responses to the RSC-difficulty were reverse scored; this means difficulty is actually correlated to easiness in this study. Mean scores for each of the three subscales were calculated in the same manner with a total of four scores calculated; Total-RSCS, Competence, Difficulty and Attitude. In this study, scores on all RSCS sub scales show acceptable reliability (Total-RSCS α=0.88; Attitude α=0.84; Difficulty α=0.71; Competency α=0.78).

Reading Attitude: Mckenna & Kear (33) defined the Elementary Reading Attitude Survey (ERAS) as a 20-item questionnaire that asks students to rate their attitudes toward reading; each item presents a brief, simply worded statement about reading followed by four pictures of the comic strip character, Garfield the Cat in varying pictorial poses. Percentile ranks can be obtained for two component subscales: recreational reading attitude and academic reading attitude. Recreation items focus on reading for fun outside the school setting and the academic subscale examines the school environment and reading of schoolbooks. A total reading attitude percentile rank can also be computed as an additive composite of the recreational and academic scores (33) . Cronbach's alpha, a statistic developed primarily to measure the internal consistency of attitude scales (38) was calculated at each grade level for both subscales and for the composite score. These coefficients ranged from 0.74 to 0. (33). The validity of the academic subscale was tested by examining the relationship of scores to reading ability. Teachers categorized norm-group children as having low, average, or high overall reading ability. The mean of the subscale scores for the high ability readers (M=27.7) significantly exceeded the mean of low ability readers (M=27<0.001); this gave the evidence that scores were reflective of how the students truly felt about reading for academic purposes. In this research, scores on the scale have acceptable reliability (attitude=0.75).

Dyslexia Screening Instrument (DSI): The Dyslexia Screening Instrument (DSI) designed by Coon, Waguespack, and Polk in 1994 consists of checklists of basic neuropsychological skills. This instrument is a rating scale designed to describe the cluster characteristics associated with dyslexia and to discriminate between students who display the cluster characteristics and students who do not. It is designed to measure "entire populations of students or students who exhibit reading, spelling, writing, or language-processing difficulties" (39). The DSI is designed to be used with students in grades 1 through 12 (age 6 to 21). The internal consistency reliability coefficients is 0.99 for elementary students which was determined using Cronbach's coefficient alpha; and the inter rater reliability of the DSI for elementary students is 0.86 which was assessed by determining the homogeneity of the statements and consistency of ratings across examiners. Coon et al (39), stated that "content was based on an extensive review of relevant literature and on experts in the field of dyslexia". Construct validity was supported by the discriminate analysis classifications which placed the elementary and secondary students accurately (98.2% and 98.6% respectively). The DSI scale should be completed by a classroom teacher who has worked directly with the student for at least four months. This will result in a rating that will be more accurate because the teacher has observed the student over a longer period of time and can compare the student's performance to that of the students' classmates. For an elementary student, the preferred rater is the teacher who has instructed the student in a variety of subjects. The teacher should complete the DSI form based the questionnaire answers: Never exhibits, Seldom exhibits, Sometimes exhibits, often exhibits and always exhibits. In this study, the Cronbach's alpha reliability of the scale was 0.89.

Raven's Progressive Matrices test: Raven's Standard Progressive Matrices (RSPM) test was constructed to measure the educative component of g (general IQ) as defined in Spearman's theory of cognitive ability (40). Kaplan and Saccuzzo (41) stated that "research supports the RSPM as a measure of general intelligence. The advanced form of the matrices contains 48 items, presented as one set of 12 (set I), and another set of 36 (set II). Items are presented in black ink on a white background, and become increasingly difficult as progress is made

through each set. These items are appropriate for those aged 5 to 65. Lynn and Vanhanen (42) summarized a number of studies based on normative data for the test which has been collected in 61 countries. The internal consistency reliability estimate for the Raven Progressive Matrices' total raw score was 0.85 in the standardization sample of 929 individuals. This reliability estimate for the revised RSPM indicates that the total raw score on the RSPM possesses "good" internal consistency reliability as provided in the guidelines of the U.S.Department of Education (43) for interpreting a reliability coefficient. The RSPM has been widely used for decades as a measure of educative ability, which is "the ability to evolve high level constructs which make it easier to think about complex situations and events" (44) . In an extensive analysis of the cognitive processes that distinguishes between higher scoring and lower scoring examinees on the Standard Progressive Matrices and Advanced Progressive Matrices, Carpenter, Just and Shall (45) described the Raven's test "a classic test of analytic intelligence". In this research, the Cronbach's alpha reliability of the scale was 0.83.

Reading text: The reading texts were developed by the researcher based on the contents of the fourth and fifth grade textbooks. During the administration of the research, only 80 percent of the textbooks had been taught, and as such, the developed test was based on only 80 percent of the Persian text books. The tests were evaluated by the fourth and fifth grade teachers and after 3 times revisiting they evaluated it as convenient. The test included a story of one-hundred related words understandable to each education level and was followed by 10 questions which indicated the students' level of understanding. The students were required to read out the test aloud and answer the questions. , The Cronbach's alpha was employed to determine reliability. The reliability coefficients for the fourth and fifth grades' reading tests are 0.87 and 0.90 respectively.

7. Findings

SPSS (version 17) was utilized for the analysis of the data. The findings of the study are presented in two parts: descriptive findings and findings related to the hypotheses. In Table 2 and 4, the means, standard deviations, and variables of attitude and self-concept are presented. In Table 2, the means and standard deviations for attitude, recreational reading attitude and academic reading attitude are shown for both the experimental group and control group, before and after the Barton Intervention Program. The findings pertinent to the first research hypothesis are shown in Table 2.

Table 2. Mean and standard deviation for attitude

	Experimental Group		Control Group	
Test	Pretest	Posttest	Pretest	Posttest
Attitude				
M	47.25	67.51	47.66	48.06
SD	6.99	5.02	7.56	12.25
Recreational reading attitude				
M	10.71	35.45	10.73	24.63
SD	3.17	3.38	2.79	5.64
Academic reading attitude				
M	22.45	32.06	22.73	23.43
SD	4.16	2.81	4.87	6.87

The result in Table 2 shows the means and standard deviations to reading attitude, recreational reading attitude, and academic reading attitude, pre and post intervention program. This table shows that there is a significant difference in the posttest means of reading attitude, recreational reading attitude and academic reading attitude for the experimental group and the control group of students with dyslexia after the Barton Intervention Program.

Table 3. t-test results for attitude

	Test	t-value	df	sig
Pretest	Attitude	-0.219	59	0.828
	Recreation	-0.031	59	0.975
	Academic	-0.243	59	0.809
Posttest	Attitude	8.05	59	0.000
	Recreation	9.11	59	0.000
	Academic	6.45	59	0.000

The findings related to the first research hypothesis are shown in Table 3. The first hypothesis is: There is a statistically significant difference in attitude between the dyslexic students in the control group and the dyslexic students in the experimental group after the Barton Intervention Program. Independent t-test was employed to test the first

research hypothesis. As can be seen in Table 3, attitude and its subscales (Recreational and Academic Reading) after the intervention program are statistically significant (t (-0.219, -0.031, -0.243) =8.05, 9.11, 6.45 and ρ<0.000).

Table 4. Mean and standard deviation for self-concept

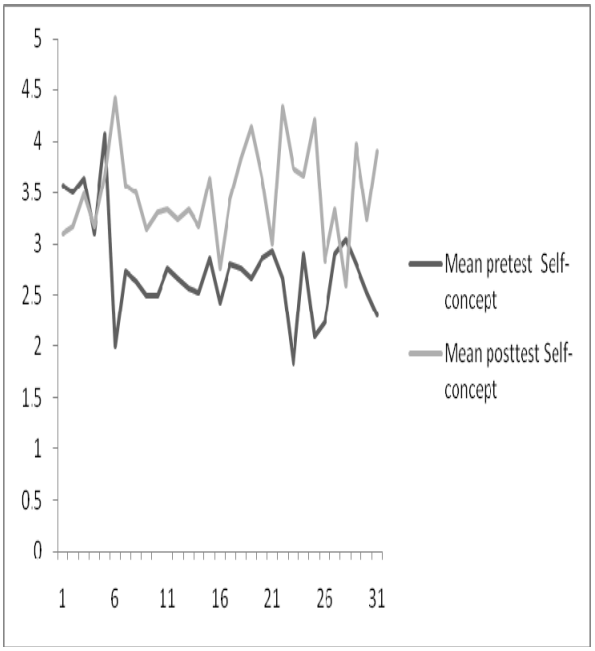
	Experimental Group		Control Group	
Test	Pretest	Posttest	Pretest	Posttest
self-concept				
M	82.64	104.06	83.63	86.63
SD	14.21	13.12	13.71	26.06
Competence				
M	28.74	35.45	28.86	29.56
SD	5.11	5.56	7.13	8.16
Difficulty				
M	26.35	29.79	26.43	27.63
SD	5.48	5.96	3.83	9.14
Attitude				
M	27.54	38.77	27.76	29.41
SD	6.77	5.70	5.39	9.71

Table 4 shows the means and standard deviations for self-concept, competence, difficulty, and attitude pre intervention program and post intervention program. This table shows that there is a significant difference in the posttest means of self-concept, competence, difficulty, and attitude for the experimental group and the control group of students with dyslexia after the Barton Intervention Program.

Table 5. t- test results for self-concept and self-concept subscale

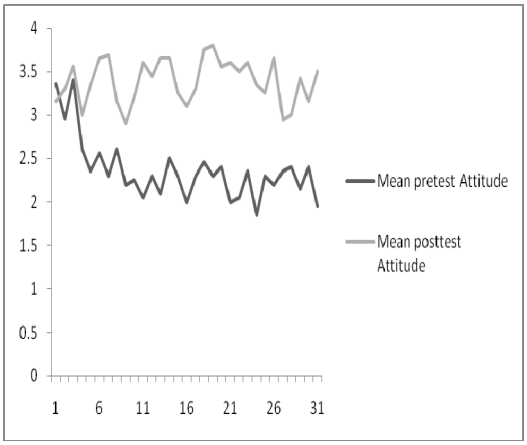
		t-value	df	sig
	Self-concept	-0.276	59	0.783
	Attitude	0.747	59	0.458
Pretest	Competence	-0.227	59	0.821
	Difficulty	-1.888	59	0.064
Posttest	Self-concept	3.316	59	0.002
	Attitude	4.776	58	0.000
	Competence	3.307	58	0.002
	Difficulty	0.396	58	0.694

The findings for the second research hypothesis are presented in Table 5. The second research hypothesis is: There is a statistically significant difference in self-concept between the dyslexic students in the control group and the dyslexic students in the experimental group after the Barton Intervention Program. As can be seen in Table 5, self-concept, competence, difficulty, and attitude are statistically significant [Self-concept (t(0.276=3.316 and ρ<0.002))], [Competence (t(-0.227=3.307 and ρ<0.002))], [Difficulty(t(-1.88=0.396 and ρ<0.694))], and [Attitude(t(-0.747=4.77 and ρ<0.000))]. Based on these results, the second research hypothesis is accepted but the subscale of difficulty is not accepted.



Reading Self-Concept

Figure 1. The pretest and posttest mean scores for self-concept. The mean score for self-concept in the pretest is lower than that of the posttest in the Standard Self-Concept Scale (Chapman & Tunmer, 1995).



Reading attitude.

Figure 2. The pretest and posttest mean scores for reading attitude. The mean score for reading attitude in the pretest is lower than that of the posttest in the Standard Reading Attitude (McKenna & Kear, 1990).

8. Discussion

The present study aimed to investigate the effect of the Barton Intervention Program on the attitude and self-concept of dyslexic students studying at fourth and fifth grades in Ilam, Iran in the academic year 2010. The first research hypothesis is: There is a statistically significant difference in attitude between the students with dyslexia in the control group and the students with dyslexia in the experimental group after the Barton Intervention Program.

The first research hypothesis is confirmed at $\rho<0.000$. The results of the study showed that the intervention program has been effective in increasing the dyslexic students' attitude towards reading. The results of this study are in line with researches such as (35, 46-47) that show intervention programs increase the academic skills of dyslexic students. Such studies show that attitude is an important factor in academic achievement.

According to Gage and Berliner (48), achievement is influenced by attitude as well as ability. "It is a well-known psychological principle that attitude influences a person's choice of activities as well as effort and persistence at tasks" (48). Alexander and Filler (49) identified several variables that seem to be associated with attitudes toward reading. These variables are achievement, the teacher and classroom, special programs and so on. As teachers attempt to improve students' attitudes toward reading, they should keep these ideas in mind; in other words, teachers need to have a positive feeling toward their students, and the students need to be commended for their efforts. The teacher's awareness of the student's attitude toward reading is essential. A student's attitude toward reading materials affects comprehension of those materials. Teachers should be well-informed that students' attitudes toward reading are formed by parents and their home environment. Studies show that reading attitude is affected by academic achievement. As such, having a positive attitude toward reading may ensure a student's success in his academic endeavor.

According to Johnson (50), attitudes toward reading are arguably formed as a result of success achievement or failure with the task of reading; therefore, students with good reading ability may have positive attitudes toward reading, while students who are poor readers often have to overcome negative reading attitudes in order to improve their reading skills. The finding of the study suggests that since the intervention program results in academic achievement of the dyslexic students, therefore, participation of the dyslexic students on a one-to-one basis in the intervention program would increase the individual capabilities of this group of students.

The second research hypothesis is: There is a statistically significant difference in self-concept between the students with dyslexia in the control group and the students with dyslexia in the experimental group after the Barton Intervention Program. The second research hypothesis is confirmed at $\rho<0.000$. In this study, it is shown that the use of the intervention program increased the self-concept of the dyslexic students; in comparison to the students with dyslexia in the control group, the dyslexic students in the experimental group performed better after the intervention program. This study is in line with researches (35, 46-47, 51-53) that show intervention programs would increase the skills and academic performance of dyslexic students. The result of the meta-analysis by Elbaum and Vaughn (54) showed that the intervention program could lead to beneficial changes in the self-perception of students with learning disabilities. The investigators noted that these findings are particularly important in light of the fact that the intervention lasted less than 12 weeks with sessions held only two or three times a week.

Studies such as Elbaum and Vaughn (55),; Davis (47); Barton (35); Torgesen (46), have shown that academic failure of students with learning disability would result in negative feelings in these students. Since the intervention program increased the academic achievement of dyslexic students (35, 46-47, 51) and since academic achievement is related to self-concept (56), it is necessary to use the intervention program in order to increase the

academic achievement and consequently, the self-concept of dyslexic students. As mentioned above, dyslexic students need a special educational program to acquire sufficient skills to complete their school assignments. Therefore, it is suggested that before running any educational program, they should be investigated regarding their ability to use the Barton educational program.

9. Recommendation for future research

Future researchers are recommended to investigate the role of such variables, for instance perception, visual memory, auditory memory, movement harmony, finding spatial direction, accuracy, creativity, and innovation on dyslexic students. Since this study was conducted on dyslexic students only and its sample was just the fourth and fifth grade students, therefore, a similar study is suggested to be carried out on other groups of students with learning disorders and other school grades. Finally, it is recommended that education officials familiarize themselves with the Barton program and carry out this method with larger groups and in several educational centers so that if positive results are observed, this method could be utilized to overcome the learning difficulties faced by dyslexic students.

10. Conclusion

The data displayed showed that the Barton intervention program does increase the students' attitude and self-concept as a result of participation and, therefore, the hypothesis is accepted. The multisensory Barton Reading and Spelling System were used on the dyslexic students in the experimental group and it improved the attitude and self-concept of these students in comparison to those students in the control group. In the final analysis, the researcher advocates the use of Strategic Barton instruction and training programs for teachers because it would be beneficial for all students.

Abstract: This study was conducted to compare between two self-tapping, self-drilling tapered one-piece implant designs used for immediate post-extraction placement with the immediate loading protocol.

Materials and Methods: Ten patients (6 males and 4 females), with a mean age of 28.5 years (range 18-39 years) were included in this study. All selected patients had two or more maxillary unrestorable hopeless anterior or premolar teeth indicated for extraction. Each patient received two implants of different designs (The OsteoCare™ Midi and Maxi-Z implants) which were placed in fresh extraction sockets and immediately loaded. Clinical criteria were survival rate, papillary bleeding index, probing depth, gingival index, Periotest M values, crestal bone level and bone density. An overall survival rate of 100% was attained. **The results** showed no significant difference in both the bleeding index and gingival index scores and also in the probing depth values, bone density measurements and crestal bone level for both implant designs after 3 and 6 months. The mean and the standard deviation of the Periotest M values (PTMV) for the Midi and the Maxi-Z implants immediately post operative were (-1.83±0.8) and (-2.57±0.9) and after 6 months were (-3.06±0.7) and (-3.11±0.7) showing a significant difference immediately postoperative and no significant difference after 6 months. Surface area analysis revealed that there is a direct relation between the initial stability and the surface area. **Conclusion**: It can be concluded that the immediate implant placement and loading using both designs is a successful treatment modality and the prognosis depends on proper case selection and treatment planning.

Keywords: Dental implants, immediate implant, immediate loading, two implant designs

1-Introduction:

One of the most important significant scientific breakthroughs in clinical dentistry was undoubtedly the introduction of osseointegrated implants 40 years ago (Fischer 2008). The original protocol was described by Branemark who described the two-stage surgical protocol which involves the surgical placement followed by the surgical uncovering of an implant. A healing period of 3-6 months after tooth extraction to allow for bone filling and contouring before implant placement was required, (Branemark 1977; Adell et al.; 1981).

Investigations showed that significant bone volume changes of the alveolar process take place following tooth extraction (Denissen et al.; 1994; Araujo and Lindhe 2009). It was reported that there is a 50 % reduction in bucco-lingual width of the extraction socket over a period of twelve months with two thirds of the reduction taking place during the first three months and a reduction of crestal bone level ranging from 0.7 to 1.5 mm after four to six months (Schropp et al.; 2003).

Thus, immediate post extraction implant placement into fresh extraction sockets is considered a predictable and accepted procedure of preserving the alveolar dimensions, with its consequences of better crown-implant ratio, improved soft tissue esthetics and favourable inter-arch relationship (Schulte et al.,1978; Rosenquist and Grenthe 1996; Sclar 2003; Oh et al.; 2006 and Lee et al.; 2009). Immediate implant placement has also been reported to have the advantage of reducing the treatment time required with the reduction of the number of surgeries (Gapski et al., 2003; Lorenzoni et al.; 2003; Testori et al.; 2004; Tsirlis 2005 and Wang et al.; 2006).With the improvement of implant design regarding the surface treatments and thread designs which has the purpose of achieving better primary stability and osseointegration, immediate loading became more popular and many authors have reported a high success rate with this

technique (Kahnberg 2009 and Guirado et al.; 2010).

Recent researches reported that there are three options for implant loading: conventional staged loading protocol in which the implant is loaded after insertion by 3-8 months (Esposito et al.; 2007) immediate loading protocol in which the implants are immediately loaded after insertion or within a week after placement, (Glauser et al.; 2001; Degidi et al.; 2003; De Bruyn and Collaert 2002) while early loading protocol allows the implant to be loaded after insertion by 1 week to 2 months (De Bruyn and Collaert 2002; Attard and Zarb 2005).

The combination of immediate post-extraction placement with immediate loading of dental implants has the advantage of shortening the treatment time and increasing case acceptance and reported to be safe in terms of survival rates and esthetics (Cooper et al.; 2002; Crespi et al.; 2007 and Oh et al.; 2007). An overall survival rate of 97.5 % to 98 % was reported for implant immediately loaded after placement (Calandriello et al.; 2003; Lorenzoni et al.; 2003; Drago and Lazzara 2004; Degidi et al.; 2005 and Zahran 2008).

Both the Midi and the Maxi-Z implants are machined from a piece of titanium alloy that incorporates both the implant body and an integral post or ball fixed abutment in a single component. These implants are designed with a "Buttress" thread design that has the advantage of allowing for the compression and expansion of the implant site to achieve high stability in even poor quality bone. They have grit-blasted and acid-etched (GBA) surface treatment. The conical macro-design of the Mini implants allows their placement in limited tooth-to-tooth spacing and atrophic ridges (Zahran 2008). Maxi-Z implants have a tapered body geometry which has the ability to distribute forces into the surrounding bone, thereby creating a uniform compaction in adjacent osteotomy walls when compared with parallel-walled implants. The unique design of both implants allows their placement with minimally invasive flapless procedures. Both designs the Midi and the Maxi-Z implants are tailored for immediate loading and allow for the provision of same day restorations following the concept of "a tooth in a day" (Zahran and Gauld 2007).

2.Material and Methods

2.1. Materials:

2.1.1. Subjects:

Ten patients (6 males and 4 females), with a mean age of 28.5 years (range 18-39 years) were consecutively included in this study.

All selected patients had two or more maxillary unrestorable hopeless anterior or premolar teeth indicated for extraction due to root fracture, endodontic failure or unrestorable crown fracture. The patients were required to be in good health, and had no condition that might affect the outcome of the treatment.

All patients participated in the study were thoroughly informed of the immediate loading protocol and all the risks associated with this type of procedure and signed an informed consent form.

2.1.2. Implants

Ten Midi implants (strictly, conical in shape) and ten Maxi-Z implants (tapered in shape) (OsteoCare™ Implant System, London, United Kingdom) were used in this study and placed in ten patients so that each patient received both designs.

2.2. Methods:

2.2.1. Pre-surgery evaluation:

Pre-surgical radiographic evaluation with panoramic and periapical radiographs (using standardized parallel techniques) was carried out.

All patients received oral hygiene instructions and periodontal treatment if needed.

2.2.2. Surgical Protocol and implant placement

After administration of local anaesthesia, periodontal ligament was excised using periotome, followed by careful a traumatic tooth extraction using the forceps to deliver the tooth out. After extraction, the integrity of the buccal plate of bone was checked using an osteotomy probe through the fresh extraction socket as intact buccal plate of bone was considered crucial.

The extracted roots were measured in bucco-palatal and mesio-distal dimensions at the middle third using a digital calliper and the readings were averaged, to determine the correct implant diameter. The length of the implant was obtained from the panoramic radiographs using radiographic stents.

Under copious saline irrigation to prevent heat generation and damage of bone, the 1.3 mm profile pilot drill was used to give needle point accuracy for position, angle and depth.

The osteotomy preparation extended three to five millimetres beyond the base of the extraction socket to achieve good primary stability for the implant. While for the Maxi-Z implant, when harder bone density was met, sequential drilling was performed using the 2.2 mm and the 2.75 mm drills to facilitate easier insertion of the implant without exerting undue pressure on the bone.

The type of implant was selected according to the size of the extraction socket:

-The Maxi-Z implants were always selected for the larger socket.

-In cases of equally sized sockets the implants were selected randomly.

The implant was removed from its sterile protective pouch and held using the attached plastic carrier and placed into the prepared socket and screwed

manually until a resistance was met. The plastic carrier was removed and the ratchet wrench and the hex driver were used for complete seating of the implant into its final position. Both the collar of the Midi implant and the first thread of the Maxi-Z implant were placed 3 mm below the crestal bone level confirmed by the periapical radiographs.

Establishment of primary stability of over 30N/cm was considered crucial with all the placed implants in the extraction sockets to allow for the immediate loading protocol. Primary stability of the implants was evaluated by the torque wrench.

2.2.3. Abutment Preparation and Provisional Restoration:

Immediately after implant placement, the abutment was prepared using either carbide or diamond burs with copious water irrigation to avoid overheating. Then, a temporary crown was fabricated and cemented to be completely out of functional occlusion in centric and eccentric position. The patients were instructed to avoid direct biting on the provisional restoration.

2.2.4. Post-operative care:

Oral hygiene instructions were given to the patients. Analgesics were subscribed to prevent post-surgical pain when necessary. Finally, a periapical radiograph was taken to check the final implant position and to estimate the initial bone level around the implant.

Final restorations:

The provisional acrylic resin restorations were removed after a healing period of 6 months. Final porcelain-fused-to-metal restorations were constructed and permanently cemented and checked for shade matching, marginal fitness and occlusion.

2.2.5 Post operative follow-ups and evaluation

2.2.5.1. Clinical records

Clinical records were obtained at 3 and 6 months post-operatively.

- Bleeding on probing was evaluated using papillary bleeding index (PBI) described by Muhlemann (1977) using a periodontal probe.
- Infection, swelling and gingival inflammation were assessed using the gingival index (GI) according to Loe and Silness (1963).
- Probing Depth was measured according to a standard procedure described by Glavind and Loe (1967) using periodontal probe with Williams' calibrations.
- Mobility was tested using the Periotest M (Medizintechnik Gulden, Bensheim, Germany). Loose implants show high Periotest M values, while osseointegrated implants have low Periotest M values. Periotest M values (PTMV) of (-8 to 0) were considered the ideal values that denote successful osseointegration.

2.2.5.2. Radiographic evaluations:

Standardized periapical x-rays films were taken immediately after implant insertion, three and six months post operatively to detect any change in crestal bone level and bone density around the implant using the linear measurement system of Digora software (Orion Corporation, Sordex, Finland).

2.2.5.3. Implant surface area measurements:

The surface area of the Midi and the Maxi-Z implants was measured using a 3D scanner to perform a 3D image which is then analyzed and the surface area was calculated using another program (AutoCAD 2004), to compare between the two different geometric features of the two implant designs and evaluate its effect on the primary stability.

2.2.6. Statistical Analysis

Data were presented as mean and standard deviation (SD) values. Data were explored for normality using D' Agostino and Pearson normality test. Paired t-test was used to compare between the two implant designs. The significance level was set at $P \leq 0.05$. Statistical analysis was performed with GRAPHPAD PRISM 5 for Windows.

3. Results

3.1. Complete soft tissue healing had occurred in all patients without any postoperative inconveniences during the study period.

3.2. The provisional acrylic resin restoration became loose in one patient in the fourth month after implant placement and was re-cemented in the same day.

3.3. All the 20 implants were successfully osseointegrated as revealed by clinical and radiographic examinations.

3.4. Implant survival rate of 100% was attested.

3.5. Clinically:

Results showed that the mean and the standard deviation of the papillary bleeding index after 3 months was (1.65 ±0.2) for the two implant designs and then after 6 months it was (1.4 ±0.2). There was no significant difference found, P_3months = 1.0000 and P_6months = 1.0000.

The mean and the standard deviation of the probing depth for the Midi and the Maxi-Z implants after 3 months were (3.6 ± 0.4) and (3.65 ± 0.4) respectively then at 6 months were (3.5±0.5) and (3.3 ± 0.4) with no significant difference found, P_3 months = 0.8144 and P_6 months = 0.9074).

The mean and the standard deviation of the Gingival index scores for the Midi and the Maxi-Z implants after 3 months were (1 ± 0.3) and (1.1 ± 0.3) respectively, then after 6 months were (0.82 ± 0.3) and (0.87 ± 0.3). There was no significant difference found, (P_3months = 0.6193 and P_6months = 0.6193). This means that the difference in implant design does not affect the bleeding index scores, the gingival index scores

and the pocket depth values after 3 months and also after 6 months.

The mean and the standard deviation of the Periotest M values (PTMV) for the Midi and the Maxi-Z implants immediately post-operative were (-1.83 + 0.8) and (-2.57 + 0.9) and after 6 months were (-3.06 + 0.7) and (-3.11 + 0.7). There was a significant difference found in the Periotest M values immediately post-operative which means that the difference in implant design does affect the PTMV immediately post-operative (P_immediate post-operative = 0.0122). There was no significant difference found after 6 months which means that the difference in implant design does not affect the PTMV in the second stage, P_6months = 0.8553).

Table (1): Correlation coefficients for the two implant designs.

Correlation coefficients	Initial stability	After 6 months
Surface area of Midi implant	0.8920912	0.7340346
Surface area of Maxi-Z implant	0.7824797	0.6114319

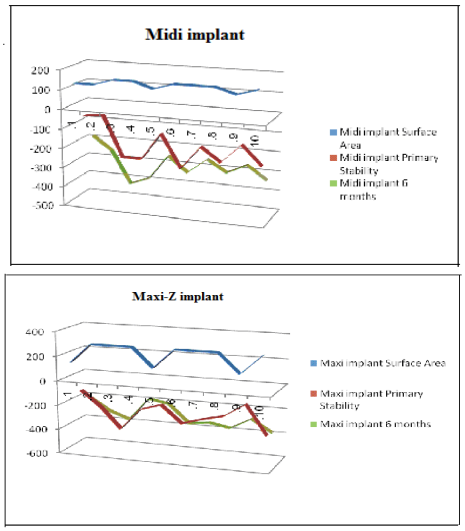

Diagram (1): showing the Midi and Maxi-Z implant surface areas, initial stability and stability after 6 months.

3.6. Radiographic evaluation:

Results revealed that the mean and the standard deviation of the crestal bone resorption for the Midi implants versus the Maxi-Z implants were (0.5 ± 0.3) and (0.6 ± 0.3) after 3 months, and was (0.67±0.3) after 6 months for the two implant designs. There was no significant difference found which means that the change in the bone level around the two implant designs was nearly the same after 3 months and after 6 months (P_3months = 0.1217andP_6months = 0.2848).

The mean and the standard deviation of the bone density values for the Midi and the Maxi-Z implants were (89.7 ± 2.1) and (88.1 ± 1.3) immediately post-operative, and after 3 months were (75.1 ± 0.84) and (76.4 ±1.6), and finally were (76.4 ± 0.7) and (76.9 ± 1.3) respectively after 6 months. There was no significant difference found which means that the difference in implant design does not affect the bone density immediately post-operative, after 3 months and after 6 months (P-immediate post-operative = 0.1075, P_3months = 0.0801, P_6months =0.3691).

Fig 1: Checking of the integrity of the socket using the osteotomy probe

Fig 2: Clinical photograph showing implant immediately after placemen

Fig 3: Checking of the integrity of the second socket using the osteotomy probe

Fig 4: Clinical photograph showing both implants immediately after placement

Fig 5: Final ceramo-metal restoraton

Fig 6: Immediate postoperative panoramic radiograph

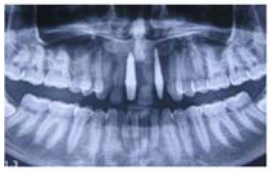

Fig 7: 3 months post operative panoramic radiograph

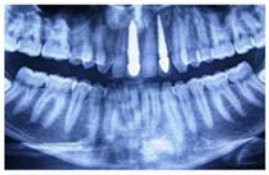

Fig 8: 6 months post operative panoramic radiograph with final crowns.

Surface area analysis showed that the calculated correlation coefficient range for the two implant designs was between 0-1 which indicated that the two variables tended to increase or decrease together. This means that there was a direct relation between the initial stability and the surface area.

4. Discussion

Success of osseointegrated implants has been validated for over 30 years as a viable alternative to fixed or removable prosthetic restorations (Albrektsson et al.; 1988; Buser et al.; 1997 and Szmukler-Moncler et al.; 2000). It has been advocated that after implant placement, surgical site should be undisturbed for at least 3-6 months depending on bone quality to allow for osseointegration. This waiting period may cause

functional and psychological problems to the patients (Chiapasco et al.; 1997 and Andersen et al.; 2002).

Several studies documented the success of the protocol of immediate implant placement in fresh extraction sockets in conjunction with immediate loading (Muhlemann 1977 and Oh et al.; 2006). Research during the last 20 years has increasingly focused on immediate loading of dental implants (Fischer 2008).

The immediate loading procedure has become a routine in the treatment of totally or partially edentulous patients and permits delivery of provisional fixed restorations the same day of implant placement (Barzilay 1993; Hahn 2000; Gapski et al.; 2003; Lorenzoni et al.; 2003 and Misch et al.; 2004a). A number of factors may influence the results of immediate implant loading. These factors could be related to the surgical procedures, patient, implant design or occlusion-related factors (Gapski et al.; 2003; Misch et al.; 2004 a,b and Zahran 2008) .

This technique is increasingly gaining popularity as an attractive advantage for both patients and clinicians alike. Today, quick delivery of implant-supported restorations immediately after extraction can be considered the standard of care in case of a missing tooth or teeth.

The present study was conducted to compare between two different implant designs for immediate placement and loading in fresh extraction sockets. All the implants were successfully osseointegrated over the six months follow-up period with a success rate of 100% with insignificant change in the crestal bone level.

The current results showed nearly similar results as that reported by (Kaj et al.; 2007) in which three implants were lost resulting in a cumulative survival rate of 97.9% after up to two years. The higher success rate which was noticed in the current study was probably attributed to the smaller sample size or the strict case selection. The results were also in agreement with those presented by Lorenzoni et al.; 2003, who evaluated the clinical outcomes of immediately loaded implants after one year of placement in the maxillary incisor region, resulting in a 100% survival rate. The results are also in agreement with Zahran et al., 2010 which evaluated the flapless immediate implant placement in fresh extraction sockets using the one piece Maxi-Z implant.

In the present study, the mobility of all implants was measured using the Periotest M immediately after placement (base line) and at 6 months post-operatively in the two implant designs. There was a significant difference between the mean Periotest values for the two implant designs at the base line but the difference was insignificant after the 6 months follow up period. This is in agreement with Orenstein et al.; 2007, who performed a study evaluating the stability of the immediately placed and immediately loaded implants using the Periotest. It was concluded that the stability of the implant through the period of the study followed the sequence of socket healing and bone remodelling.

It was observed in the present study that the initial stability attained by the Maxi-Z implant was higher than that of the Midi which was measured by the Periotest M. This could be due to the surface area of the Maxi-Z implant which is higher than that of the Midi implant. This difference in the surface area could be attributed to the modification in the body geometry of the Maxi-Z or its wider range of diameters. This coincides with the study of Langer et al.; 1993, who proposed the use of wide diameter (5.0 mm) self tapping implants to gain initial stability in the jaw bone region where low-density bone is common. The authors hypothesized that the increased contact obtained with a wider implant improved the engagement of bone and reduced the initial mobility. Increasing the diameter in a 3 mm implant by 1mm increases the surface area by 35% over the same length in overall surface. More contact area provides increased initial stability and resistance to stresses as reported by Misch 1999.

In the present study the Maxi-Z implants attained higher initial stability in wide extraction sockets than the Midi implants which in agreement with the results reported also by Jae et al.; 2005.

In the present study the bone density changes around the implants was measured. It was found that there was no significant difference in the bone densities around the two implant designs. This may be attributed to the compression of the bone trabecluae around the implants which is nearly the same for the Midi versus the Maxi-Z implants which is in similarity with a comparative study performed to evaluate implants placed in healed bony sites versus extraction sites (Diago et al.; 2008).

The first thread of the implants used in this study was placed 3 mm below the crestal bone level of the extraction sockets and this could be the reason for the minimal crestal bone resorption that occurred during the 6 months follow-up period of this study. Other studies recommended placement of the implants with their platforms below the level of the socket by 1-2mm (Lazzara 1989; Becker 2006 and Orenstein et al.; 2007).

Conclusion

Both the Midi implant and the Maxi-Z implant can be placed immediately after extraction and immediately loaded showing a 100% clinical success. The Maxi-Z implant is more suitable for bigger extraction sockets due to its wide range of diameter and its body geometry that nearly fills all the jumping gaps with better primary stability.

There is a direct correlation between the surface area and the initial stability.

Abstract: Natural dietary antioxidants are studied for their ability to protect cells from miscellaneous damage. Grape seed extract (*Vitis vinifera* L., Vitacease) is a potent antioxidant. The present study aimed to investigate the protective effect of grape seed extract (GSE) against the possible testicular dysfunction caused by aluminium chloride ($AlCl_3$) in male rats. Twenty sexually mature male albino rats were divided into four equal groups, the first served as negative control, the second received $AlCl_3$ (20 mg/kg bw, 1/ 20 LD 50), the third administered GSE (75 mg/kg bw), and the fourth received $AlCl_3$ and treated with GSE. Doses were given once daily via gavage for 70 consecutive days. The results revealed that, $AlCl_3$ induced significant decrease in final body weight, sex organs relative weight, sperm concentration, motility and viability, serum testosterone concentration and superoxide dismutase (SOD) activity, with significant increase in sperm abnormalities and thiobarbituric acid reactive substance (TBARS) concentrations. Moreover, $AlCl_3$ induced apparent alteration in the histological structure of the testis. Treatment with GSE ameliorated the harmful effects of $AlCl_3$, this was also proved histopathologically by the noticeable improvement in the testis tissues. It may be concluded that GSE may be promising as a natural therapeutic agent in $AlCl_3$-induced reproductive toxicity and oxidative stress in the male rat testes.

1. Introduction

Aluminium absorption and accumulation in humans can occur via the diet, drinking water, ingestion with fruit juices or citric acid causes a marked increase in both gastrointestinal absorption and urinary excretion of aluminium in healthy subjects (Venturini-Soriano and Berthon, 2001). Different forms of aluminium are environmental xenobiotics that induce free radical-mediated cytotoxicity and reproductive toxicity. Aluminium ingestion in excessive amount leads to accumulation in target organs and has been associated with damage of testicular tissues of both humans and animals (Yousef and Salama, 2009). $AlCl_3$ showed reproductive toxicity on rabbit sperm in vitro Yousef *et al*. (2007). Testicular aluminium accumulation, necrosis of spermatocytes/spermatids and significant decrease in fertility were found in male mice (Guo *et al*., 2005 a,b).

Grapevine (*Vitis Vinifera*), is cultivated today in all temperature regions of the world (Gruenwald *et al*., 2004). Its seeds contain several active components including flavonoids, polyphenols, anthocyanins, proanthicyanidins, procyanidines, and the stilbene derivative resveratrol. The grape seed extract has been reported to possess a broad spectrum of pharmacological and therapeutic effects such as antioxidative, anti-inflammatory, and antimicrobial activities, as well as having cardioprotective, hepatoprotective, and neuroprotective effects. The seeds of the grape are used in herbal medicine and as a dietary supplement (Shenoy *et al*., 2007). Chedea *et al*. (2010) reported that GSE considered as a powerful antioxidant nutritive supplement that prevent premature ageing and diseases. Maier *et al*. (2009) stated that oil produced from grape seeds is considered a rich source of polyphenolics with strong antioxidant activity.

Grape seed extract is a natural extract from the seed of grape (Asl and Hosseinzadeh, 2009). It is a rich source of one of the most beneficial groups of plant flavonoids and pro-anthocyanidins oligomers (El-Ashmawy *et al*., 2007). It has a protective effect on oxidant-induced production and deposition of extracellular matrix components (Dulundu *et al*., 2007). GSE contains mainly flavonoids, which involved in ameliorating the oxidative stress in vitro and in vivo (Martinez-Florez *et al*., 2002). Several studies have indicated that extracts obtained from grape seed inhibit enzyme systems that are responsible for the production of free radicals, and that they have antimutagenic and anticarcinogenic

effects (Li *et al*., 2001 and Maier *et al*., 2009). Aysun *et al*. (2008) reported that GSE is widely consumed as a dietary supplement and could be useful in synergizing the efficacy of chemotherapeutic agents in cancer treatment. Therefore, the present study was designed to investigate the role of GSE against $AlCl_3$- induced oxidative stress and reproductive toxicity in rat testes.

2. Material and Methods

Chemicals:

Aluminium chloride ($AlCl_3$) was obtained from Sigma Chemical Co. (St Louis, Mo, USA). Casein (> 85% protein) was obtained from Misr Scientific Company, Dokki, Giza, Egypt. Cellulose and D-L methionine were purchased from Morgan Company, Cairo, Egypt. Minerals and vitamins constituent, sucrose, glucose and ethanol absolute were obtained from El-Gomhoriya Pharm. and Chem. Ind. Co. Cairo, Egypt. Corn oil was obtained from the local market. Corn starch was obtained from Starch and Glucose Company, Helwan, Egypt.

Animals:

Twenty sexually mature male albino rats, *Sprague Dawley* strain, weighing (160 ± 10 gm) were purchased from the animal house of Ophthalmic Research Center, Giza, Egypt. The animals were housed in plastic cages, maintained on a natural light-dark cycle at room temperature of 26 ± 2º C and fed standard diet according to Reeves *et al*. (1993) and water ad libitum. Rats were kept for one week as acclimatization period before the start of the experiment. All rats were handled in accordance with the standard guide for the care and use of laboratory animals. The experiment was conducted at Faculty of Veterinary Medicine, Cairo University.

Preparation of grape seed extract:

Ripe grapes (*Vitis vinifera* L., Vitacease) were obtained from El-Behira government, Egypt. Undamaged and disease-free berries were snipped from clusters. Following manual separation of the seeds from whole berries, seeds were oven dried at 30 - 40 º C. Dried grape seeds were ground to fine powder with a grinder. The ethanolic extract was prepared by soaking 100 gm of grape seeds powdered in 300 ml ethanol (95 %) with daily shaking and kept in refrigerator covered by a piece of aluminum foil. The infusion was filtered by a piece of double gauze and the filtrate was centrifuged at 3000 rpm for 10 minutes, then the ethanol was evaporated using a rotatary evaporator apparatus (Switzerland) attached with vacuum pump. The 100 gm of dried grape seeds powder yield 26.7 gm ethanol extract.

Experimental design:

After the acclimatization period, rats were divided into four equal groups, each of five rats. **First group;** was negative control administered 3 ml distilled water orally once daily. **Second group;** was positive control group ($AlCl_3$ group) administered aluminium chloride (20 mg/kg bw, 1/ 20 LD50) dissolved in 3 ml distilled water, the LD 50 of ($AlCl_3$) when administered orally to rats was reported to be (380 - 400 mg/kg bw (Krasovskii *et al*., 1979). **Third group;** was administered grape seed extract (GSE) (75 mg/kg bw) which dissolved in 3 ml distilled water orally once daily according to El-Ashmawy *et al*. (2007). **Fourth group;** was co-administered with $AlCl_3$ and GSE in the same doses in 2nd and 3rd groups. Doses were given once daily via gavage for 70 consecutive days, for completion of the spermatogenic cycle and maturation of sperms in epididymis (Sarkar *et al*., 2003).

Blood sampling:

At the end of the experimental period, animals were fasted overnight, with free access to tap water. Rats in each group were anesthetized with diethyl ether for blood sampling by puncturing the inner canthus of the eye using heparinized microhematocrit tube. Collected blood was stored for 15 min at room temperature, then centrifuged with 3000 rpm for 20 min., and stored at - 20ºC till analysis.

Sex organs weight:

The testes and accessory sex organs (seminal vesicles and prostate glands) were dissected out, trimmed off the attached tissues and weighed. The index weight of the organ was calculated by (Index weight) = organ weight/ body weight x 100.

Determination of testosterone assay:

Serum testosterone level was estimated using method of Ismail (1986).

Semen characteristics:

Seminal content of epididymis was obtained by cutting of cuda epididymis using surgical blades and squeezed in a sterile clean watch glass. This content was diluted 10 times with 2.9 % sodium citrate dehydrate solution and thoroughly mixed to estimate the progressive motility and sperm concentration (Bearden and Fluquary, 1980). One drop of the suspension was smeared on a glass slide and stained by Eosin-nigrosin stain to determine the percentage of sperm cell viability and morphological abnormalities (Miller and Pass, 1952). Abnormal head and tails were evaluated according to (Nahas *et al*., 1989, Mori *et al*., 1991 and Okomura *et al*., 2005).

Determination of testicular antioxidant enzymes:
Preparation of testicular homogenate:

One testis of each sacrificed rat was used for estimation of oxidative enzymes and lipid peroxidation. One gram of testicular tissue was weighed after ice water washing of testes and homogenized in 9 volume buffered saline 0.9 %, centrifuged at 4000 rpm at 4 º C for 15 min., the supernatant was collected and kept at -20 º C till further investigation.

Determination of testicular thiobarbituric acid reactive substance formation (TBARS):

According to the method of Esterbauer and Cheeseman (1990), the extent of lipid peroxidation in terms of thiobarbituric acid reactive substances (TBARS) formation was measured. Tissue supernatant was mixed with 1 ml trichloroacetic acid (TCA) (20%), 2 ml thiobarbituric acid **(**TBA) (0.67 %) and heated for 1 h at 100 °C. After cooling, the precipitate was removed by centrifugation. The absorbance of the sample was measured at 535 nm using a blank containing all the reagents except the sample. As 99% of TBARS was malondialdehyde (MDA), so TBARS concentrations of the samples were calculated using the extinction co-efficient of MDA, which is 1.56 × 105 M−1 cm−1.

Determination of testicular superoxide dismutase activity (SOD):

Superoxide dismutase (SOD) activity was measured using assay kit (Cayman, MI, USA) according to (Giannopolitis and Ries, 1977). This kit utilizes a tetrazolium salt for the detection of superoxide radicals generated by xanthine oxidase and hypoxanthine. One unit of SOD was defined as the amount of enzyme needed to produce 50% dismutation of superoxide radical. The SOD assay measures all the three types of SOD (Cu/Zn, Mn, and Fe SOD). Enzyme activity was determined as the amount of the enzyme to reach an inhibition of 50 % nitro-blue tetrazolium (NBT) reduction rate.

Histopathological examination:

Sections were taken from testis tissues from different animals in each group immediately after sacrificed. The tissues were washed with the normal saline solution to remove blood, fixed in 10% neutral formalin for a period of at least 24 hrs, dehydrated in different grades of alcohol, and processed for paraffin embedding. Sections of 5 µm thickness were cut using a rotary microtome. The sections were processed and passed through graded alcohol series, stained with Haematoxylin and Eosin, cleared in xylene and examined microscopically according to Bancroft *et al*. (1996).

Statistical analysis:

The data were analyzed statistically by analysis of variance, for statistical significance ($p \leq 0.05$) using L.S.D. test**,** one way ANOVA, post hoc multiple comparisons according to Snedecor and Cochron (1989). An IBM computer with a software system SPSS version 16 was used for these calculations.

3. Results
Body and sex organs weight:

The effect of grape seed extract (GSE) on final body weight and weight gain in $AlCl_3$ toxicity of male rats is represented in Table (1). Oral administration of GSE had no effect on body weight gain of rats, indicating its safe use under the experimental conditions, while there were highly significant decrease in final body weight and body weight gain ($p < 0.01$) in $AlCl_3$ group (+ve) as compared with negative control group (-ve). On the other hand, there were highly significant elevation in final body weight and weight gain in $AlCl_3$ group treated with GSE as compared with untreated $AlCl_3$ group (+ve).

Table (1): Effect of grape seed extract (GSE) on body weight of $AlCl_3$ intoxicated male rats.

Experimental groups	Initial body weight (g)	Final body weight (g)	Body weight gain (g)
Control (- ve)	165.6 ± 1.21	269.2 ± 1.77	103.6 ± 2.06
$AlCl_3$ (+ ve)	166.0 ± 1.41	202.0 ± 2.43 [a**]	36.0 ± 3.61 [a**]
GSE	167.8 ± 2.65	270.8 ± 3.31	103.0 ± 3.66
$AlCl_3$ + GSE	164.4 ± 1.63	253.0 ± 1.64 [a** b**]	88.6 ± 2.23 [a** b**]

- Each value represents the mean of 5 rats ± SE.
- [a] Significant difference from control group at $p < 0.05$* and highly significant difference from control group at $p < 0.01$**.
- [b] Significant difference between $AlCl_3$ group and $AlCl_3$ group treated with GSE at $p < 0.05$* and highly significant at $p < 0.01$**.

Results indicated significant decrease in the index weights of testes and prostate ($p<0.01$ and $p<0.05$, respectively), and non-significant decrease in index weights of seminal vesicle in $AlCl_3$ group as compared with negative control group (Table 2). Treatment with GSE ameliorated the toxic effect of $AlCl_3$, the index weights of testes recorded highly significant elevation as compared with untreated $AlCl_3$ group. While, oral administration of GSE alone did not cause any significant effect on the weights of the tested tissues as compared with negative control group.

Table (2): Effect of grape seed extract (GSE) on index weights (IW) of testes and sex organs of $AlCl_3$ intoxicated male rats.

Experimental groups	Sex organs (g / 100 g body weight)		
	Testes	Seminal vesicle	Prostate
Control (-ve)	0.922 ± 0.041	0.415 ± 0.023	0.130 ± 0.006
$AlCl_3$ (+ ve)	0.488 ± 0.018 ^{a**}	0.384 ± 0.013	0.118 ± 0.004 ^{a*}
GSE	0.918 ± 0.019	0.423 ± 0.012	0.124 ± 0.0036
$AlCl_3$ + GSE	0.68 ± 0.023 $^{a**\ b**}$	0.404 ± 0.011	0.121 ± 0.002

- Each value represents the mean of 5 rats ± SE.
- ^{a} Significant difference from control group at $p < 0.05$* and highly significant difference from control group at $p < 0.01$**.
- ^{b} Significant difference between $AlCl_3$ group and $AlCl_3$ group treated with GSE at $p < 0.05$* and highly significant at $p < 0.01$** .

Sperm characteristics:

Epididymal sperm concentration, sperm motility, viability and abnormal sperm are reported in Table (3) for $AlCl_3$ and/or GSE groups. GSE group did not differ significantly from the control (-ve) in terms of sperm motility, sperm viability and abnormal sperm rates, but had highly significant elevation in sperm count ($p <0.01$) as compared with negative control group (-ve). $AlCl_3$ group (+ve) had significantly lower sperm count, motility and viability than the control group (-ve).

when total sperm abnormalities (head and tail) were analyzed, the $AlCl_3$ group (+ve) had significantly the highest level of abnormalities as compared with negative control group . On the other hand, treatment with GSE in combination with $AlCl_3$ significantly alleviated the decline in sperm count, motility, and viability, and significantly decreased the percent of dead and abnormal sperm compared to $AlCl_3$ untreated group, and this means that GSE minimized the toxicity of $AlCl_3$.

Table (3): Effect of grape seed extract (GSE) on sperm character of $AlCl_3$ intoxicated male rats.

Experimental groups	Sperm character			
	Count (10^6/ ml)	Motility (%)	Viability (%)	Sperm abnormalities (%)
Control (-ve)	62.0 ± 3.63	82.4 ± 4.53	89.6 ± 4.31	6.6 ± 0.51
$AlCl_3$ (+ ve)	28.6 ± 1.29 ^{a**}	42.0 ± 3.73 ^{a**}	52.0 ± 3.65 ^{a**}	18.4 ± 0.93 ^{a**}
GSE	75.2 ± 3.84 ^{a**}	80.6 ± 3.92	90.0 ± 4.73	5.6 ± 0.24
$AlCl_3$ + GSE	43.2 ± 3.22 $^{a**\ b**}$	58.4 ± 2.16 $^{a**\ b**}$	68.8 ± 2.85 $^{a**\ b**}$	12.0 ± 0.71 $^{a**\ b**}$

- Each value represents the mean of 5 rats ± SE.
- ^{a} Significant difference from control group at $p < 0.05$* and highly significant difference from control group at $p < 0.01$**.
- ^{b} Significant difference between $AlCl_3$ group and $AlCl_3$ group treated with GSE at $p < 0.05$* and highly significant at $p < 0.01$**.

Serum testosterone and testicular antioxidant enzymes:

Results in Table (4) showed highly significant decrease in serum testosterone concentration ($p < 0.01$) in $AlCl_3$ group compared to control group (-ve), while orally treatment with GSE induced highly significant elevation in serum testosterone concentration ($p < 0.01$) and alleviated the negative effects of $AlCl_3$ as compared with untreated $AlCl_3$ group.

On the other hand, $AlCl_3$ caused highly significant decline in SOD accompanied with highly significant elevation in TBARS compared to control group (-ve). While co-administration with GSE and $AlCl_3$, improved the toxic effect of $AlCl_3$ as manifested by highly significant increase in SOD accompanied with highly significant decrease in TBARS as compared with untreated $AlCl_3$ group.

Table (4): Effect of grape seed extract (GSE) on serum testosterone level and testicular oxidative state of $AlCl_3$ intoxicated male rats.

Experimental group	Serum testosterone (ng/ ml)	Testicular oxidative	
		SOD (u/mg protein)	TBARS (n mol/mg protein)
Control (-ve)	1.86 ± 0.049	0.068 ± 0.003	0.074 ± 0.002
$AlCl_3$ (+ ve)	0.936 ± 0.046 [a**]	0.031 ± 0.001 [a**]	0.116 ± 0.001 [a**]
GSE	1.846 ± 0.043	0.073 ± 0.003	0.066 ± 0.002
$AlCl_3$ + GSE	1.356 ± 0.05 [a** b **]	0.044 ± 0.001 [a** b **]	0.103 ± 0.004 [a** b **]

- Each value represents the mean of 5 rats ± SE.
- [a] Significant difference from control group at $p < 0.05$* and highly significant difference from control group at $p < 0.01$**.
- [b] Significant difference between $AlCl_3$ group and $AlCl_3$ group treated with GSE at $p < 0.05$* and highly significant at $p < 0.01$**.

Histopathological results:

Microscopical examination of the testis of normal negative control group (-ve) revealed the normal histopathological structure of seminiferous tubules (Fig 1). Meanwhile, testis of rat group orally administered $AlCl_3$ (+ve) showed congestion of interstitial blood vessel (Fig 2), marked degeneration and necrosis of germ cells lining seminiferous tubules (Fig 3), as well as interstitial odema and testicular degeneration with complete absence of germ cells (Fig 4). Testis of rats group received GSE showed no histopathological changes (Fig 5). In rats group received $AlCl_3$ and treated with GSE, improvement in histopathological examination was noticed in testis sections as shown in (Fig 6), where examined sections revealed no histopathological changes.

Fig (2): Testis of $AlCl_3$ group (+ve) showing congestion of interstitial blood vessel as well as marked degeneration and necrosis of germ cells lining seminiferous tubules. (H&E x 200)

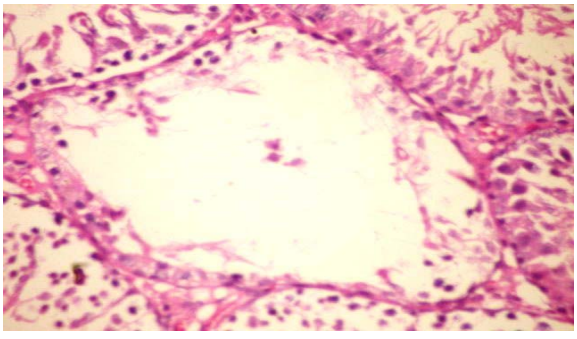

Fig (3): Testis of $AlCl_3$ group (+ve) showing marked degeneration and necrosis of germ cells lining seminiferous tubules. (H&E x 200)

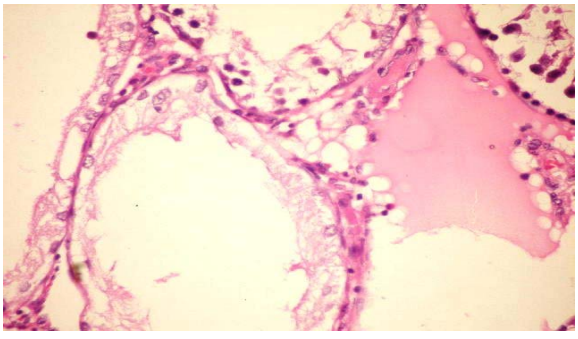

Fig (4): Testis of $AlCl_3$ group (+ve) showing interstitial odema and testicular degeneration with complete absence of germ cells. (H&E x 200)

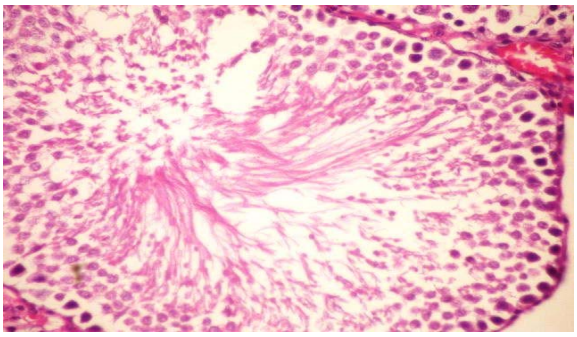

Fig (5): Testis of GSE group showing no histological changes. (H&E x 200)

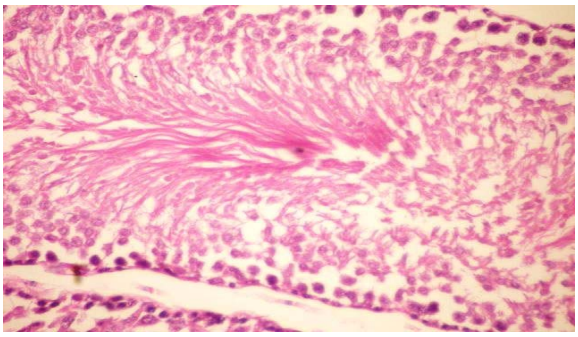

Fig (6): Testis of $AlCl_3$ + GSE group revealed no histopathological changes. (H&E x 200)

4. Discussion:

Grape seed extract is an extract by-product obtained from the seed of *Vitis vinifera*, it contains a variety of biologically active species used for protection against oxidative stress induced by free radicals and reactive oxygen spices (ROS) (Sharma *et al*., 2004). Aluminum is considered to be a non-redox active metal, it promotes biological oxidation both in vitro and in vivo because of its pro-oxidant activity (Turner and Lysiak, 2008). Testicular oxidative stress appears to be a common feature in much of what underlies male infertility, which suggests that there may be benefits to develop better antioxidant therapies for relevant cases of hypospermatogenesis (Turner and Lysiak, 2008 and Yousef and Salama, 2009). GSE has antioxidant and free radical scavenging activity (Jayaprakasha *et al*., 2003 and Caillet *et al*., 2006). Most of the beneficial health effects of GSE are attributed to their antioxidant and free radical scavenging properties (Faria *et al*., 2006).

The present results showed that oral administration of GSE had no effect on body weight gain and index weights of sex organs of rats, this confirmed its safe use and agreed with Clifton (2004) who mentioned that GSE is widely marketed as a dietary supplement and is considered safe for human consumption. Moreover, GSE- containing flavonoids are currently used as nutritional supplements, and have been shown to exert antioxidant, chemopreventive and anticancer effects (Singletary and Meline, 2001, Shi *et al*., 2003 and Mosaad *et al*., 2006). On the other hand, our results indicated significant decrease in the body weight gain and the index weights of testes and prostate ($p< 0.01$, $p <0.01$ and $p < 0.05$, respectively) in rats group received $AlCl_3$ as compared with control, and highly significant decrease in the body weight gain and the relative weights of testes ($p < 0.01$) compared with $AlCl_3$ treated with GSE.

The majority of studies that utilized chronic doses of aluminium reported significant reduction in weight gain, particularly in studies initiated in male animals, Kowalczyk *et al*. (2004) found that during three months observation of rats receiving aluminium chloride, decrease in water and food intake and transient diarrhea occurred, which resulted in lowering of final body mass of animals in comparison to the controls (differences statistically significant). The physiologic basis for this outcome is unclear, but it was reported that animals exposed to chronic doses of aluminium consumed less food. Whether general effects of aluminium on metabolic processes depress metabolism or reduce nutritional efficiency remains to be resolved. The obtained results were in agreement with Yousef *et al*. (2005) and Guo *et al*. (2005 a,b). In addition, (Bataineh *et al*., 1998) found decrease in absolute and relative testes weights and seminal vesicles weights after aluminum chloride ingestion. The decrease in the reproductive organs weights could be due to the decrease in testosterone level which was observed in the current study, that may be resulted from the oxidative damage induced in rat testes (El-Ashmawy *et al*., 2007). The amelioration effect of GSE may be due to grape seeds which are rich sources of monomeric phenolic compounds such as catechin, epicatechin, dimeric, trimeric and tetrameric proanthocynidins (Escribano-Bailon *et al*., 1992). These molecules possess a structure that confers on them an antioxidant property, which has been demonstrated to exert a novel spectrum of biological, pharmacological, therapeutic, and chemo-protective effects against oxygen free radicals and oxidative stress (Bagchi *et al*., 1997).

$AlCl_3$ induced highly significant decrease in sperm count, motility (%) and viability (%), with increase in dead and abnormal sperm count as compared to both control group (-ve) and $AlCl_3$

group treated with GSE, this means that GSE minimized the toxicity of $AlCl_3$. Moreover, rats orally administered GSE alone showed highly significant increase in sperm count, but had no effect on the other sperm character determined. Previous studies showed that, sexual behavior of male rats was suppressed after ingestion of aluminum chloride (Bataineh *et al*., 1998). Necrosis of spermatocytes/ spermatids was observed in the testes of mice exposed to aluminium (Llobrt *et al*., 1995). Yousef *et al*. (2007) showed also that $AlCl_3$ declined semen quality in vivo and vitro, and induced significant decrease in ejaculate volume, sperm concentration, total sperm output, sperm motility, total motile sperm per ejaculate, packed sperm volume, normal and live sperm, while dead and abnormal sperm were increased. The current results may be explained by aconitase, a protein that binds citrate and catalyzes its isomerization to isocitrate via the intermediate cis-aconitate in Krebs cycle, which showed decreased activity in the presence of aluminium, thus influence mitochondrial enzymes, consequently, changes in mitochondrial functions may be reflected in sperm motility and viability (Yousef *et al*., 2007). Moreover, the observed decrease in sperm motility could be attributed in part to the concomitant reduction in testosterone production following aluminium treatment (Guo *et al*.,2005a and Yousef *et al*., 2005).

Testosterone is a key hormone that regulates spermatogenesis. $AlCl_3$ induced significant ($p < 0.01$) decrease in serum testosterone concentration and SOD activity, with significant increase in TBARS levels compared to control rats. However, it was found that, GSE was capable of restoring the SOD activity and serum testosterone level in rats group administered $AlCl_3$ and treated with GSE, there were significant differences as compared with untreated $AlCl_3$ group (+ve). Also, GSE significantly reduced TBARS levels compared to $AlCl_3$ group, this means that GSE increased the process of steroidogenesis and hence testosterone production and improved sperm production and the process of fertility. These results were in line with the results reported by Yousef (2004) who showed that aluminium chloride was able to generate reactive oxygen species in rabbit's testes. Yousef *et al*. (2005) found that aluminium enhanced lipid peroxidation in plasma, testes and liver. Guo *et al*. (2005a) demonstrated also that, exposure to aluminum lowered plasma and testicular testosterone levels in mice. The authors suggested that the severe reduction in male fertility following aluminium administration might result from excessive aluminium accumulation in the testes and low testosterone concentrations. Moreover, Turner and Lysiak (2008) found over productive of ROS, which can be detrimental to sperm and associated with male infertility, and thus spermatoxic effect might be due to $AlCl_3$ induced free radicals.

There is evidence implicating androgenic hormones involved in mechanisms of aluminium toxicity on male reproduction. Guo *et al*. (2005a) found that aluminium administration significantly increased nitric oxide (NO) production and decreased both testicular adenosine 3′, 5′-cyclic monophosphate (cAMP) and testosterone levels. Excessive NO activated inducible NO synthase (NOS) which may be involved in reproductive toxicity of aluminum, hence reducing rate and motility of sperm cells, increasing their morphological abnormalities, and suppressing testosterone secretion in male rats. Moreover, these effects of $AlCl_3$ may be attributed to aluminium ability to cross the blood-testis barrier, after inducing oxidative stress and lipid peroxidation that damages the biological membranes in the testes, this in turn causes the degeneration of the spermatogenic, which disrupts spermatogenesis and reduces sperm counts (Latchoumycandane *et al*., 2002). Also, the increase in TBARS can bring negative effects on motility and sperm-oocyte fusion (Kim and Parthasarathy, 1998), which was found in the present study. Moreover, increased ROS subsequently attack almost all cell components including lipid membrane and producing lipid peroxidation (Flora *et al*., 2003). The protective effect of GSE treatment agreed with Aysun *et al*. (2008) who reported that oral intake of GSE reduced the oxidative stress. In addition, GSE treatment considerably increased the formation of antioxidant products which may be regarded to the phenolic constituents of GSE and its antioxidant activity. Flavonoids have been shown to alleviate the oxidative stress by increasing the endogenous antioxidant status, protecting cells against free-radical damage by increasing resistance to oxidative stress (Perez *et al*., 2002).

Histopathological examination of rats group orally administered $AlCl_3$ (+ve) showed apparent alteration in the testes, where it induced marked degeneration and necrosis of germ cells lining seminiferous tubules, as well as interstitial odema and complete absence of germ cells. Meanwhile, treatment of $AlCl_3$ group with GSE showed noticeable improvement in histopathological changes induced by $AlCl_3$ in testis sections. The histological changes in testes of rats administered $AlCl_3$ are in agreement with Khattab (2007) who studied the effect of $AlCl_3$ on the rat's testes. Also, Guo *et al*. (2005b) observed deleterious effects and histopathological changes in testicular tissues after 2 weeks of aluminium treatment, as well as noticeable spermatogenetic loss as necrosis in the spermatids

and spermatozoa at the 5th week of aluminium treatment. This damage effect may be explained by Yousef and Salama (2009) who reported that oxidative stress results from the production of oxygen radicals in excess of the antioxidant capacity of the stressed tissue. Many conditions or events associated with male infertility are inducers of oxidative stress, which leads to an increase in germ cell apoptosis and subsequent hypospermatogenesis, such stress condition, can cause changes in the dynamics of testicular microvascular blood flow, endocrine signaling, and germ cell apoptosis. Moreover, reactive oxygen species and oxidative damage of bimolecular may contribute to male infertility by reducing sperm function (Atessahin *et al*., 2005). Minimizing the hazard effects of $AlCl_3$ by GSE treatment may be due to the flavoniods in GSE, which exert many health-promoting effects, including the ability to increase intercellular antioxidant levels, decrease capillary permeability and fragility and scavenge oxidants and free radicals (Singth *et al*., 2004).

In conclusion, $AlCl_3$ caused fertility disturbances and testicular dysfunction, decrease in antioxidant enzymes and increase in lipid peroxidation in testes. Treatment with GSE showed protective effect against its reproductive toxicity and this may be attributed to the activity of GSE as a natural antioxidant. Oxidative stress is one of the mechanisms of $AlCl_3$ reproductive toxicity and GSE has protective effect against such oxidative damage. Additional studies are needed to demonstrate GSE efficacy in humans.

Abstract: Objective: To determine the relationship between body compositions, fat distribution and blood lipid profile in obese school children aged 7 to 18 years. Methodology: In this cross-sectional study, 150 pupils between the ages of 7 to 18 years were included. Anthropometric measures of adiposity (BMI, waist circumference, waist-to-hip ratio, peripheral adiposity: as the sum of triceps and biceps skinfold thickness, central adiposity: as the sum of sub scapular, suprailiac and abdominal skinfold thickness), body composition and serum total lipids profile were assessed. Results: There are significant sex differences in ages 7 -18 years regarding BMI, abdominal skinfold thickness and TC/ HDL-C, and in peripheral adiposity at young age (7-11 years) and central one at adolescents (12-18 years). Body composition and fat distribution showed significant sex differences in adolescent period only; and in fat distribution in young age period. For young age, triglycerides and HDL-C are correlated to most of the body composition and anthropometric parameters in boys and not in girls. For adolescents, there is no correlation between any one of the lipid profile and the body composition and anthropometric parameters in either gender. Conclusion: This study has shown that in comparison to girls, the correlation of body composition, fat distribution and lipid profiles were higher in boys aged 7 – 11 years only, with a tendency to develop the higher risk level of cardio vascular disease. Particular attention should be focused on the time prevention of childhood obesity.

Keywords: Body composition, Anthropometry, fat distribution, lipid profile, School children, Risk of cardiovascular disease.

1. Introduction:

Obesity; which is an excessive amount of body fat; is currently a global pandemic, and represents an important health problem both in developed and developing countries [1] and Egypt is not spared.

According to the Centers for Disease Control and Prevention (CDC), the prevalence of childhood obesity in 2006 reached 27.5% in USA, 25.5% in Europe and 12.5% in Egypt and North Africa [2]. In 2008, the rate of overweight and obese children in the United States was 32% [3].

With a growing incidence of obesity in childhood, this problem is even more alarming when its progression and associations are considered because metabolic changes and the consequence of obesity, formerly observed in adults, are now observed in younger individuals [4]. The multiple associated co- morbidities increase the cardiovascular mortality risk and reduce the quality of life in adulthood. Among the different situations associated with adult obesity, hypertension, dyslipidemia and alterations in glucose metabolism have also been found in children with excess weight [4, 5]. In the school age group, early vascular complications have also been detected, and they are as feared as those in adults, particularly when their progressive character is considered [6].

The relationship of obesity to risk factors is not only defined by the level of obesity but also by distribution of fat [7]. Anthropometric measurements; including body weight , height, circumferences and skin fold thickness; can be used to assess body size and proportions as well as total body and regional body compositions especially fat distribution. The anthropometric indices of adiposity include body mass index (BMI), waist circumference, waist-to-hip ratio, peripheral adiposity; as the sum of triceps and biceps skin fold thickness; central adiposity; as the sum of sub scapular, suprailiac and abdominal skin fold thickness; and body composition [8, 9]. Waist circumference reflects central adiposity as well as general adiposity, based on waist circumference which uniquely related to disease risk [10]. The use of BMI to classify children and adolescents as overweight and obesity is well established [11].

Prospective and retrospective studies have shown that risk factors related to cardiovascular diseases (CVD) namely obesity, lipid profiles, unhealthy diets and sedentary lifestyle, have their

roots in childhood and tend to track into adulthood [12]. In childhood, obesity is associated with high levels of blood pressure, very low-density lipoprotein cholesterol (VLDL-C) and insulin, lower levels of high density lipoprotein cholesterol (HDL-C), increased heart rate and increased cardiac output [13]. Abnormal serum concentrations of lipids such as total cholesterol (TC) and low- density lipoprotein-cholesterol (LDL-C) are strongly correlated with early atherosclerotic lesions [14]. Lima et al., 2004 [15], stated that serum lipid levels may be affected by obesity or body fat distribution patterns.

Few studies have tested whether fat distribution is associated with cardiovascular risk factors irrespective of the total amount of fat in children [10, 16]. None of these studies analyzed genders separately.

The present study was planned and performed with the aim of identifying and determining the relationship between body composition, fat distribution and the serum lipid profile in obese school-aged children (aged 7 to 18 years) for each gender separately.

2. Subjects and Methods

Subjects

This research was a cross-sectional one, conducted in 6 public schools (two Primary Schools, two preparatory and two secondary schools) situated in Giza governorate, Egypt; during the period of October, 2007 to April 2009. With parental consent, 150 obese pupils (70 boys, 80 girls), were recruited for this research. These pupils were required to meet the following inclusion criteria: age, 7–18 years and BMI, greater than the 95th percentile for age and gender based on the Egyptian Growth Reference Charts [17]. Pupils were excluded if they had a prior major illness, including type 1 or 2 diabetes, recieve medications or had a condition known to influence body composition, insulin action or insulin secretion (e.g. glucocorticoid therapy, hypothyroidism and Cushing's disease). The sample was divided into 2 groups according to their age:

Group (I): including 62 pupils (32 boys and 30 girls) of the primary school, aged 7 -11 years $\pm$ 6 months.

Group (II): including 88 pupils (38 boys and 50 girls) of the preparatory and secondary schools, aged 12 -18 years $\pm$ 6 months.

Permission to perform the study was granted by the Ministry of Education, and the directors of the school included in the research. Parents were informed about the purpose of the study and their permission in the form of written consent was obtained. Approval to conduct this survey was granted by the "Ethical Committee" of the "National Research Centre".

Anthropometric measures:

Each pupil underwent a complete physical examination, including anthropometric measures. The height, weight, waist and hip circumferences and skinfold thickness were measured following the recommendations of the International Biological program [18]. The height was measured to the nearest 0.1 cm on a Holtain portable anthropometer, and the weight was determined to the nearest 0.01 kg on a Seca Scale Balance, with the subject wearing minimal clothing and no shoes. Waist circumference (central adiposity) was measured at the level of the umbilicus with the subject standing and breathing normally, hip circumference at the level of the iliac crest, using non-stretchable plastic tape to the nearest 0.1 cm. Skin folds thickness were taken at five sites: triceps, biceps, sub scapular, suprailiac and abdominal. Each skinfold was measured three times on the left side of the body; with Holtain skin fold caliper to the nearest 0.2 mm, and the mean was recorded. The following adiposity indices were calculated:

- Body mass index (BMI): as weight (in kilograms) divided by height (in meters) squared.
- Waist/ Hip ratio (cm/ cm).
- Peripheral adiposity: as the sum of triceps and biceps skinfold thickness.
- Central adiposity: as the sum of sub scapular, suprailiac and abdominal skinfold thickness.

Body Composition:

Whole body resistance and reactance (capacitance) were measured using a Bioelectrical Impedance Analyzer (HOLTAIN LIMITED). As specified by the manufacturer, the unit was calibrated before testing using 400-ohm resistor, and electrodes were placed on right wrist and ankle. By using pupil sex, age, weight and height approximated to the nearest unit, the percentage body fat (Fat %), fat mass (FM) and fat free mass (FFM) were derived.

Plasma Lipid profile:

Early morning venous blood samples were taken from each pupil for biochemical screening tests after 12-hours overnight fasting. Professional staff performed venipuncture. The blood samples were left to clot; sera were separated by centrifugation for 10 minutes at 5000 rpm then stored at –80ºC until assays. Serum concentrations of total cholesterol (TC) [19], triglycerides (TG) [20] and high-density lipoprotein-cholesterol (HDL-C) [21] were measured

using commercially available kits provided by STANBIO Laboratory Inc.(1261 North Main Street Boerne Texas 78006 USA). LDL-C was calculated according to an equation developed by Friedewald et al., 1972 [22] as follows:

LDL-C= Total cholesterol –Triglycerides/5+ HDL-C.

The ratio between total cholesterol and high-density lipoprotein-cholesterol (TC/HDL-C) was calculated.

Statistical Analysis:

All values are reported as the mean ± SD. Statistical evaluation of the results was performed with the SPSS 9.05 computer program. Student's *t test* was used to examine the sex differences. Pearson's correlation coefficients were used to assess relationships between independent variables. The level of significance was set at a probability of less than 5% ($p<0.05$).

3. Results:

The total sample included 150 students, 46.7% were boys (n: 70) and 53.3% were girls (n: 80). Descriptive data for the anthropometric measures, body composition and lipid profile for boys and girls are shown in tables I and II. Analyses of the pupils of group (I) aged 7- 11 years ± 6 months (table 1) revealed significant differences between gender for body weight, BMI, biceps, sub scapular and abdominal skinfold thickness, peripheral adiposity and TC/HDL-C ($p<0.05$). Girls had significantly higher mean values of body weight, BMI, and sub scapular skinfold thickness than boys, while skinfold thickness at the biceps and abdominal areas, peripheral adiposity and TC/HDL-C mean values were significantly higher in the boys. Insignificant sex differences were recorded regarding the body composition in this age.

Group (II) aged 12- 18 years ± 6 months (table 2) had significant differences between gender for, BMI, abdominal skinfold thickness, central adiposity, body composition parameters (fat % , fat mass , fat free mass) and TC/HDL-C ($p<0.05$). Girls had significantly higher mean values of BMI, fat %, fat mass and TC/HDL-C while abdominal skinfold thickness, central adiposity and fat free mass mean values were significantly higher in the boys. There is insignificant sex difference in TG, TC, HDL-C and LDL-C for both groups.

Correlation of lipid profiles to body composition and fat distribution for both groups by gender are presented in tables III and IV. For boys in group (I) aged 7- 11 years ± 6 months (table III) , a highly significant positive correlations were observed between triglyceride and all the anthropometric measures and indices; body composition parameters except waist/ hip ratio which show insignificant positive correlation. HDL-C showed highly significant positive correlations with weight and fat free mass, and significant positive correlations with BMI and fat%, while highly significant negative correlations were found in HDL-C and skinfold thickness at the biceps and abdominal areas, peripheral and central adiposity. Both TC and LDL-C showed significant positive correlations with suprailiac skinfold thickness, while TC only showed highly significant positive correlation with fat %, and LDL-C had significant negative correlation with fat free mass. Moreover, TC/ HDL-C showed significant negative correlations with body weight, BMI, hip circumference and fat free mass. However, none of the parameters under study showed any correlation in girls of this group, except triglyceride which had significant positive correlations with body weight, and highly significant positive correlations with hip circumference.

For group (II) aged 12- 18 years ± 6 months (table IV), none of the parameters under study showed any significant correlation in both gender except triglyceride which had significant negative correlation with biceps skinfold thickness.

4. Discussion:

Childhood obesity represents a high risk of morbidity and mortality, and it perpetuation into adulthood strongly increases the risk of cardiovascular disease [7, 23]. This constellation is caused by excessive food and decrease in physical activity which leads to accumulation of body fat [5, 24].

Obesity and changes in blood lipid profile during childhood increases cardiovascular disease risk (CVD) in adulthood. Therefore in CVD examination, one of most important parameters is the analysis of total lipid profiles [25].

BMI increase lipid mobilization leading to increase in triglycerides and LDL. Obesity appears to influence the accumulation of fat, which in turn related to the development of major risk factors. Once thought to only be inactive energy storage area in which excess calories were stored as fat, it is now known that adipose tissue also functions as an endocrine gland [26, 27]. Fat cells secrete free fatty acid, which may stimulate hepatic triglyceride and low density lipoprotein cholesterol (LDL) production in adults [28].There is evidence to suggest a similar relationship in youth [9]. So, the purpose of this research is to identify and determine the relationship between body composition, fat distribution and the serum lipid profile in obese school-aged children (aged 7 to 18 years) for each gender separately.

In the current research, there are significant gender differences in ages 7 -18 years regarding BMI, abdominal skin fold thickness and TC/ HDL-C, and in peripheral adiposity at young age (7-11 years) and central one at adolescents (12-18 years). Body composition showed significant sex differences in adolescent period only. In young age (7-11 years), in spite of girl's recorded significant higher values of BMI, boys had significant higher values of abdominal and peripheral adiposity. In adolescents (12-18 years), in spite of girl's recorded significant higher values of BMI, fat%, and fat mass, boys still recorded significant higher values of abdominal subcutaneous fat but with central adiposity. Regarding lipid profile, for young age, triglycerides and HDL-C are correlated nearly with all measures of adiposity (body composition and anthropometric parameters) in boys and not in girls which might have been influenced by frequency of pubertal stages in girls. Hormonal changes, found at this stage, may act as a protective factor against changes in lipid profile. Before and after menarche, changes in lipid profile are sensitive to the influence of sex hormones, especially estrogen, which has a favorable effect on lipoprotein by increasing HDL and reducing LDL [15]. This can be explained by such study found that trunk skin folds predicted cardiovascular disease risk factors to the same extent as total fat mass by DXA, and in some cases independently of total fatness [10]. In another study, Daniels et al., 1999 [29] , studied

both the percent body fat and fat distribution in a stepwise multiple linear regression analysis and found that fat distribution was a more important independent correlate of cardiovascular risk factors (high triglycerides, low HDL cholesterol, high systolic blood pressure, high left ventricular mass) than percent fat mass. The associations found only in boys between the sum of skin folds and cardiovascular risk can be due to the fact that a central fat distribution is considered as a male specific pattern and an explanation for the high prevalence of cardiovascular disease in men compared to women [30].

This study assumed that the fat distribution is more homogeneously centrally distributed in boys and its effect on cardiovascular risk factors would not be distinguished from that of subcutaneous fat mass. Conversely in girls, there is more variability in the fat distribution, from a gynoid to an android pattern, for a given level of total fat mass. The subcutaneous fat mass has a role in the relation between fat distribution and cardiovascular disease risk in these young boys.

For adolescents, there is no correlation between any one of the lipid profile and the body composition and anthropometric indices in either gender.

Our results are in partial agreement with a previous report of Hu et al 2000 [31], who found that in boys, BMI was positively correlated with triglyceride and negatively correlated with HDL-cholesterol. Triglycerides increased with waist circumference and HDL cholesterol decreased with waist circumference. Flodmark et al 1994 [32] found also that BMI was significantly correlated with serum triglycerides. Chu et al., 2001[33], proved that TG was positively associated with most anthropometric parameters. Also Okada et al, 1998 [34] found that the distribution of central-type fat accumulation was inversely correlated with the HDL-C level in both boys and girls, and showed a stronger correlation with both the triceps and the sub scapular skin fold thicknesses.

In this study both TC and LDL-C showed significant positive correlations with supra iliac skin fold thickness, while TC only showed highly significant positive correlation with fat %, TC/ HDL-C showed significant negative correlations with body weight, BMI, hip circumference and fat free mass. This coincides with the result of Takahashi et al., 1996 [35], who recorded that overweight and obese boys had significantly higher levels of total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C). Okada et al., 1998 [34] found also that the degree of obesity and the body mass index (BMI) were more strongly correlated with serum levels of lipids and apolipoproteins in boys than in girls. In boys, atherogenic lipoproteins, such as LDL-C, showed a stronger correlation with the thickness of the triceps skin fold.

5. Conclusion:

In young boys abdominal fat distribution is associated with cardiovascular risk factors, independently of overall adiposity. International definition of abdominal obesity in children is required to standardize studies and progress in the evaluation of childhood obesity and its consequences.

Evaluate of Head Loss, Sediment Value and Iron Removal in Rapid Sand Filter

Hossein Banejad [1], Reza Pirtaj Hamedany [1], Navab Daneshi [1]

[1.] Department of Water Engineering, Faculty of Agriculture, Bu-Ali Sina University, Hamedan, Iran
Hossein_banejad@yahoo.com

Abstract: Quality and appropriate quantity of water is necessary for human kind to survive. Along with the technology development and increasing consumption of water resources, we are experiencing low qualities in the mentioned resources. Iron is the fixed element found in the crust of the earth. This metal found variously in water resources and industrial activities. Therefore, it needs to treat the water resources from these excessive amounts. Different methods have used for this reason but the most used method during recent years has been the absorption by economic absorbers such as sand. Rapid sand filters usually used in water treatment plants for water clarification. In this research, a single layer gravity rapid sand filter has used to reduce different concentrations of iron. sediment value and head loss arising from it specially oxidized iron sediments in filter media is simulated by using combination of Carman-Kozeny, Rose and Gregory models in different discharges of rapid sand filter. Results have shown that with increasing in discharge and decreasing in input iron concentration, arriving time to given head loss, is increasing. In addition, results demonstrated that with increasing in iron concentration in influent, removal efficiency is decreasing somewhat. Results of this research can applied in (1) appropriate design of rapid sand filter to iron removal, (2) prediction of rapid sand filter ability to iron removal and (3) estimation of arising head loss during filter work thus evaluating of time interval backwash. 1. Introduction

1.1. Iron content in water and its removal

In the past few decades using of heavy metals lead to increasing the concentration of this metals in water supply and environment. Discharge increasing of heavy metal from wastewater, their poisonous identity, Detroit effect on water supply (Nuhoglu et al., 2003) and indegradable in environment has caused to their special importance (saxena et al., 2006). Considering the increasing of industrial activity and problems due to the existence of heavy metals, removal or reduction of their concentration for achieving the acceptable level before discharge in environment is essential.

Iron is of the metals that found in many water supplies and they could be considerably troublesome. Soluble of iron is colorless but in exposure with air or known chemical materials convert to insoluble form and create the colors in water. Some of problems that create by high concentration of iron in water can refer to interfere in disinfection process, slime formation in piping, taste and color**.** Removal the metal ions of industrial wastewater has been achieved by ion exchange, membrane separation (Katsumata et al., 2003), evaporation (Mouflih et al., 2005) electrolysis, absorption processes and reverse osmosis (Sarioglu et al., 2005, Pehlivan, et al., 2006). Choosing the best method to water treatment depends on the concentration of heavy metals in the wastewater and the treatment expenses. Depositing has used extensively for removal of heavy metals due to low performance expenses. However, default of this method is production of high volume of sludge (Raju., 2003). On the other, hand absorption method such as ion exchange method in easy for removal of metals but ion exchanging resins are expensive (Katsumata el al., 2003, Aslam el al., 2004). Among the mentioned methods, we should look for a method that is economic and easily applicable for developing countries and can use efficiently. Adsorption method has suggested for removal of heavy metals because it is cheaper and more effective than other technologies (Pehlivan et al., 2006). A method for metal removal can be applied to industrial wastes without prior treatment using solid adsorbents such as sand and silica (Yabe et al., 2003). In recent years, liquid content iron filtration through granular media such as silica is very considerable (Aklil el al., 2004, Mouflih el al., 2005). Effluent iron concentration is an important water quality criterion used for the assessment of the performance of rapid sand filters, in addition to other criteria (Cakmakci et al., 2010).

1.2. Rapid sand filter and head loss

Filtration is the process in which the suspended particles removed from a flow by passing through a prose media (hamoda et al., 2004, vissman et al., 2004, Tebbutt, 1998, iritani, 2003). During the filtration process, water passed trough the bed under pressure or gravity. Removal of particle will vary due to size and identity of them (classen, 1998). Rapid sand filter used extensively for treatment of water and wastewater (Raju, 2003). Two factors, effective size and uniformity coefficient should consider for filter media. Usually the effective size and uniformity coefficient are considered 0.45 – 0.7 (mm) and 1.3 – 1.7 respectively in rapid sand filters (Punmia et al., 1995).

Different parameters involved in filtration affect the efficiency of these filters. Studies have shown that if the filter has smaller grains, lower rate and is deeper, the removal of manganese will be more efficient.

In drinking water treatment, granular media or rapid gravity filter is used. Filters clogged with deposits and this event lead to head loss in through of filter media. Therefore, filter backwashing have been necessary. To design an appropriate rapid sand filter utilizable effectively in removal of specific pollutant, head loss prediction before establishing is essential. Because of this, the equations that show relationship between involved hydraulic parameter must used.

1.3. Granular media hydraulic equations

During filtration, the clogging of the pores increases thus the resistance in the filter bed. When the filter reaches to the maximum available head loss, the filter needs to backwash to avoid a decrease in the filtration velocity**.** Head loss effective factors presented by below equation.

$$H_L = f(L, d, V_S, g, e, \upsilon)$$

Where H_L = head loss in L depth of filter; d= filter media diameter; V_s = flow velocity across media; g= gravity acceleration; e= filter porosity; υ = cinematic viscosity.

To calculate head loss the most common equation are (1) Carman-Kozeny, (2) Rose and (3) Gregory

1.3.1. modified Carman-Kozeny equation

The Carman-kozeny equation is a semi-empirical relationship and its extension to the particle deposition phase has to be based on experimental data because no theoretical description of the processes governing the head loss development have been developed to described the head loss as a function of time or increasing solids deposits. Summarizes of the wide variety of head loss development model during filtration by Herzig et al. (1970) and Sakthivadivel et al. (1972) also show that all head loss models have used on modifications to the Carman-Kozeny equation. The change of various parameters as probity decreases, and the internal surface and the tortusity of the flow increases during solids deposition is incorporated into the Carman-Kozeny equation (Boller et al., 1995). Must be attention that Carman-Kozeny equation can be applied to estimate head loss, but can only be applied to clean filter beds. Therefore, this promoted and modified along the time.

Most of the models lead to an equation relating the head loss gradient I at the certain floc volume deposit σ_v to the initial head loss gradient I_0 given by the general form (equation 1)

$$\frac{I}{I_o} = \left(1 + P.\frac{\sigma_V}{f_0}\right)^x . \left(1 - \frac{\sigma_V}{f_0}\right)^y \qquad (1)$$

Where *p, x, y* are empirical constant that are 35, 1.5 and -1 respectively. f_0 is the clean bed porosity (in the other word initial porosity involved in filtration).

$$I = \frac{h}{L} \qquad I_o = \frac{h_o}{L}$$

Where h, h_o and L are head loss, initial head loss and depth of purification layer respectively.

1.3.2. Rose equation

Rose equation in order to use for rapid sand filter in state that the filter bed considered homogeneous is shown as a equation 2:

$$\frac{h_0}{l} = 1.067 C_D \frac{v^2}{g \cdot d \cdot \psi} \frac{1}{f_0^4} \qquad (2)$$

Where g = gravity acceleration; h_0 = head loss between up and down of porous media; l = length of path that fluid travel through media; d = effective size of bed particles; f_o = initial porosity involved in filtration; and C_D = Newton drag coefficient.

C_D is the function of Reynolds number. Amount of C_D can achieve from equation 3:

$$C_D = (24 / R) + (3 / \sqrt{R}) + 0.34 \qquad (3)$$

R is the Reynolds number by below equation:

$$R = \frac{v\, d}{\upsilon}$$ v and υ are apparent velocity and

cinematic viscosity, respectively. ψ is the particle shape factor that achieve from below equation:

$$\psi = \frac{A_0}{A}$$

Where A_0 = area of sphere that have a same volume with filter media particle; A = real area of filter media particle. Amount of this parameter suggested between 0.79 and 1 for sand (Tebbutt., 1998).
After filter backwashing and start of filtration, due to fluid velocity in porous media, initial pressure gradient $\left(I_0 = {h_0}/{l}\right)$ produce between up and down of porous media. With gradient entrance to Rose equation, initial porosity involved in filtration (f_0) is attainable.

1.3.3. Gregory equation (Tebbutt, 1998)

Gregory equation presented by as equation 4:

$$h = h_0 + \frac{K v C_0 t}{(1 - f)} \qquad (4)$$

Where v = apparent fluid velocity; f = involved porosity in filtration with respect to head loss (h); t = time (minute); C_0 = concentration of substance in fluid that lead to lead loss; and K = Gregory equation coefficient that variable in each of condition.
In this study by combination of modified Carman-Kozeny, Rose and Gregory equation the time that head loss in granular media reach to premises level, estimated. This method is a benefit way to design the filter.

2. Materials and methods

To do this study, a single layer rapid sand filter by below characteristics is constructed. Filter surface size is 17*17 cm; length of effective layer in treatment is 70 cm that included sand with 0.42-1.8 mm diameter, actual density is 2.65 ${gr}/{cm^3}$, 0.6 mm effective size and uniformity coefficient is 1.5.

The filter media supported on base material consisting of graded gravel layers (table 1). The gravel should be free from clay, dirt, vegetable and organic matter, and should be hard , durable and round, its total depth is 120 cm and laid in the following layers (figure 1).

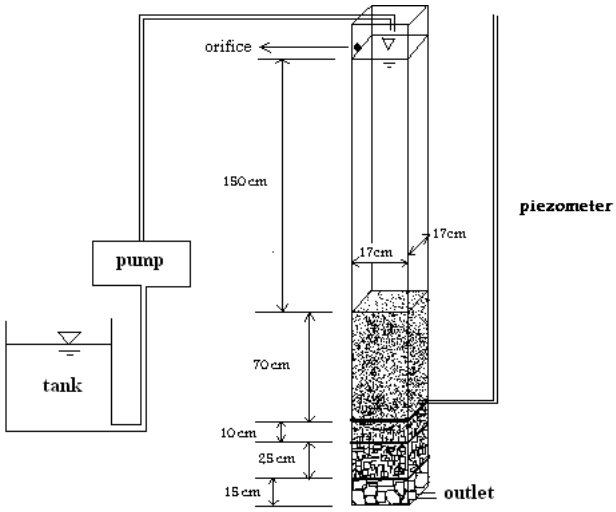

Fig 1. Schematic of filter

In order to achieve different iron concentration (25, 75, 125 and 175 ppm), nitrate salt of iron is used. Then solution separately sent to top the filter and they to passed trough the granular media in various discharge (1.5, 2, 2.5 and 2.9 ${lit}/{min}$) separately.

The characteristics of used water to making solution have shown in table 2.
Sampling carried out from established tap under filter drain. Given samples acidified immediately by nitric acid. Then iron concentration in effluent perused by atomic emission spectrometer with ICP source.

Table 1. Layer of filter

	Layer	Depth	Grasde size	Manometer below layer
1	Top most	700 mm	0.6-1.18 mm	h_1
2	Intermediate	100 mm	2.36-4.75 mm	h_2
3	Intermediate	250 mm	6.7-13.2 mm	h_3
4	Bottom most	150 mm	26-52 mm	h_4

Table 2. characteristics of used water to making solution

Unit	Amount	Characteristic
-	7.2-7.5	pH
NTU	1.5	Turbidity
mg/L	0	Chlorine
mg/L	0	Iron
mg/l	0	Manganese
mg/L as carbonate calcium	185	Hardness
$\frac{\mu mho}{cm}$	457	Electrical conductivity
^{0}**C**	23-25	Temperature

2.1. Initial porosity involved in filtration (f_0) calculating

One of most important factors in modified Carman-Kozeny equation is the f_0. Since that recognizing the amount of porosity that participate in filtration is impossible specially when deposits by complex morphology formed in granular media and f_0 will varied with each discharge to other, estimating of this factor is a hard work.

To do above aim for each discharge, initial head loss (h_0) was perused from installed piezometer at the purification layer (upper layer) below. Then C_D calculate from equation 3. In this study ψ considered equal to 0.85. f_0 calculate from Rose equation. Noticeable attention in Rose equation is on l. In the case of granular media l is length of path that fluid travel through filter. Because of this, purification layer height multiplied to tortuosity coefficient. Carrier (2003) explained that this amount is two.

2.2. Head loss in filter and porosity amount relationship with emphasis on different passed discharge

In this step, the range between initial head loss (h_0) and permissible headloss was assumed. For any discharge and assumed head loss, σ_v calculated from modified Carman-Kozeny equation. Needed f_0 in modified Carman-Kozeny equation, be achieved from step 2.1 for any discharge.

2.3. Gregory equation adaptation

Unknown parameters in Gregory equation are K and f. In each step of experiment f will be achived from below equation.

$$f = f_0 - \sigma_V$$

σ_v available from step 2.2.

To achieve K, following steps must perform.

A: Calculate iron removal efficiency by filter in various steps then figure out the concentration of trapped iron that lead to lead loss in filter (C_0).

B: h_0 peruse from installed piezometer at the beginning of filtration for each of discharges. h peruse from piezometer at certain time after filtration (in this case 50 minute) for each of discharges and inlet concentration of iron,

C: entrance C_0, f, h, h_0, v and t in Gregory equation for each of experiments step. Therefore K is available in each step of experiment.

2.4. Time estimation of certain head loss arriving

In this step, assumptive range of head loss (h) (between initial head loss and permissible head loss) is considered. Now from 2.2, decreased porosity respect to assumptive head loss (f) is available. By entrance f, h_o, C_o, v, h and K in Gregory equation for all of the situations (assumptive range of head loss, varied discharge and different concentration of inlet iron), time of reach to certain assumptive head loss (t in Gregory equation) will be accessible.

3. Results

3.1. Hydraulic parameters for different discharge

Achieved amounts for initial head loss, initial head loss gradient, Reynolds number, drag coefficient and initial porosity shown in table 3. As observed all of the Reynolds number have amount of less than one. Thus, laminar flow dominates on filter bed.

3.2. Assumptive head loss versus f diagrams for all of the discharges

Figure 2 describe relationship between head loss and decreased porosity (f) in different discharge. With attention on fig. 2 and table 2, these points figure out that with increase in discharge f_0 decreased. In addition, slop of lines in fig. 2 approximately is same. Then can be expected that porosity decreasing trend in different discharge be similar. In other word, increasing deposit rate in discharge range is similar.

Table 3. Initial head loss, initial head loss gradient, Reynolds number, drags coefficient and initial porosity amounts respect to apparent velocity .

f_0	C_D	R	I_0	h_0(cm)	v(m/sec)	Q(lit/min)
0.477130201	51.03696	0.515905	0.15714	22	0.000865	1.5
0.493656059	38.9537	0.685885	0.185	25.9	0.00115	2
0.509767521	31.5216	0.858847	0.2064	28.9	0.00144	2.5
0.519388408	27.44179	0.996024	0.224	31.4	0.00167	2.9

3.3. K (Gregory coefficient) amounts in different condition (table 4) and estimated time to arrive given head loss (minute) in different iron concentration and different discharge (fig. 4, 5, 6, 7)

To achieve C_0 in Gregory equation, removal efficiency of iron by rapid sand filter (E %), must calculate (fig. 3). Then by using below equation, C_0 be accessible.

$$C_0 = C_1 - C_2 = C_1 - (E\%) \times C_1$$

Where C_1 and C_2 is inlet and outlet concentration of iron, respectively.

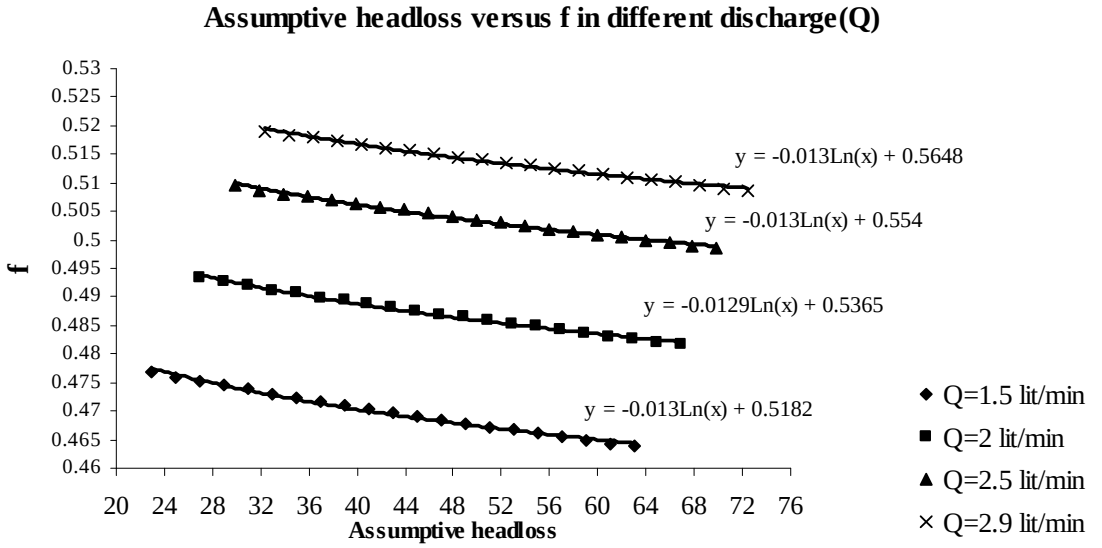

Fig.2. Assumptive head loss versus f

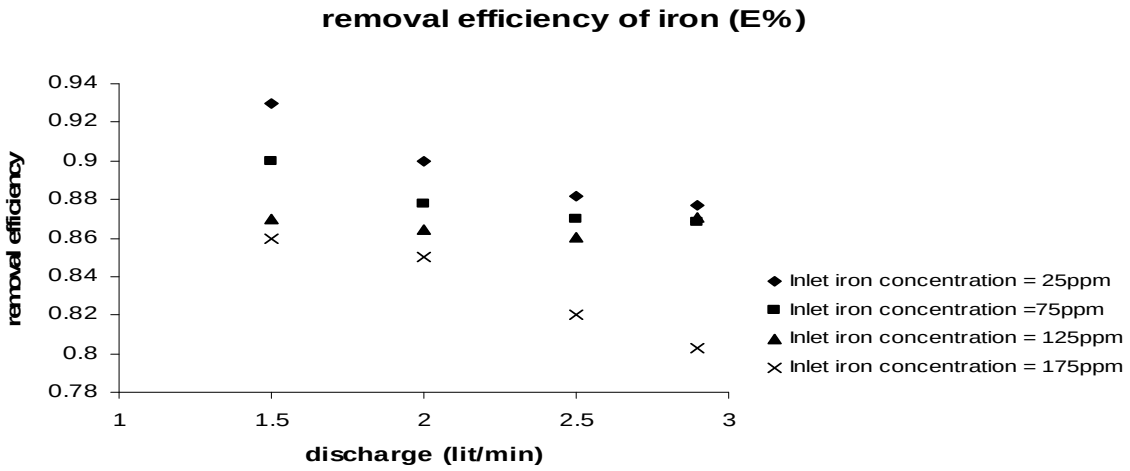

Fig.3. Removal efficiency of iron by filter

Table 4. K amounts in different condition

	Inlet iron concentration (mg/L)			
Discharge (lit/min)	**25**	**75**	**125**	**175**
1.5	0.036058668	0.01317152	0.008362015	0.00617717
2	0.010762841	0.004235695	0.002854978	0.002369632
2.5	0.006683628	0.002780231	0.002004233	0.001660144
2.9	0.003943624	0.001623595	0.001148426	0.001094495

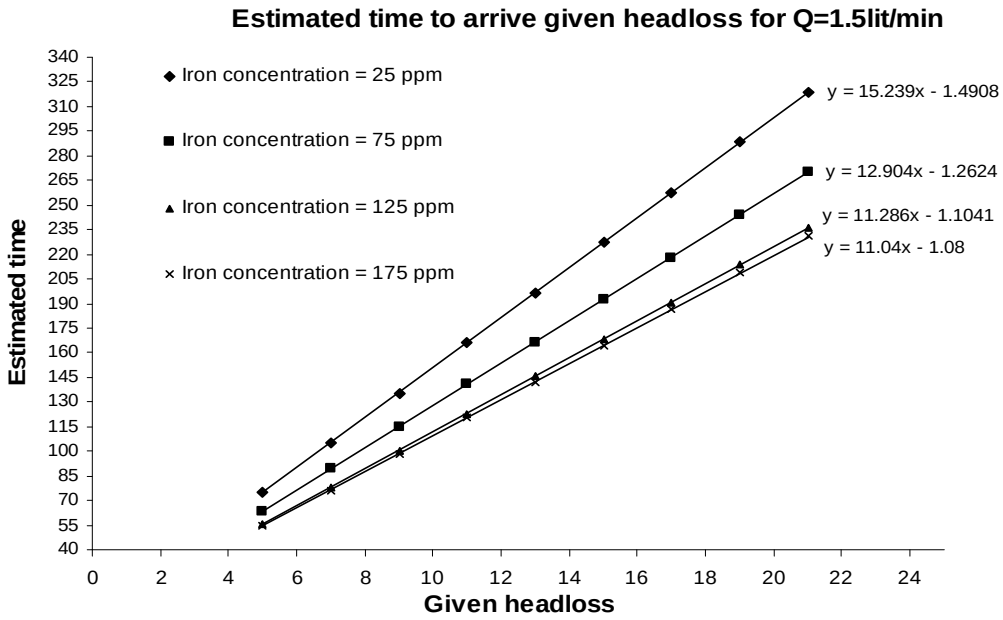

Fig.4. Time (min) versus head loss (cm) for discharge equal 1.5 (lit/min)

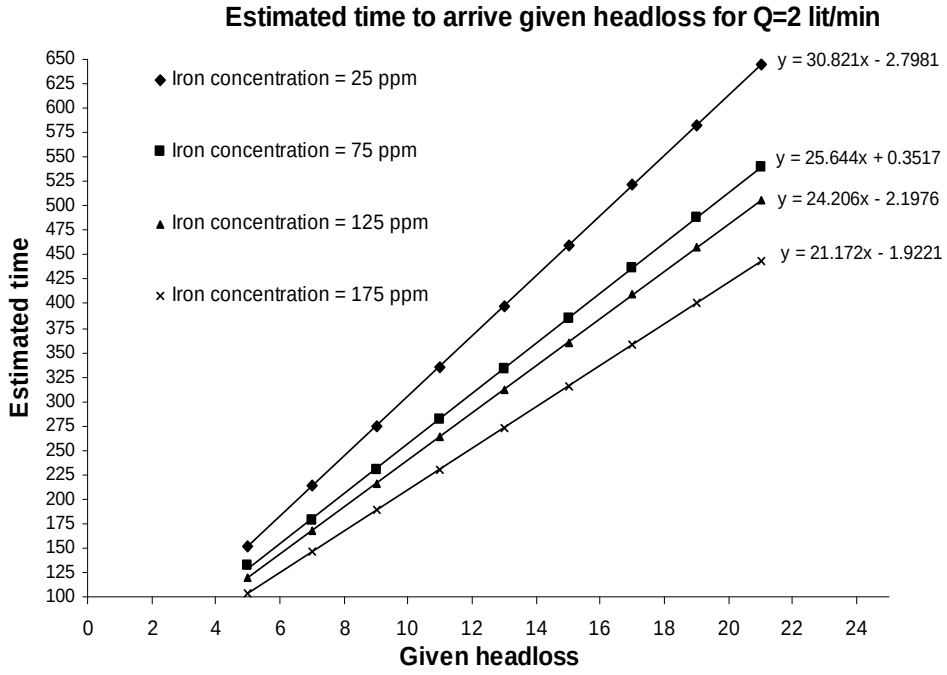

Fig.5. Time (min) versus head loss (cm) for discharge equal 2 (lit/min)

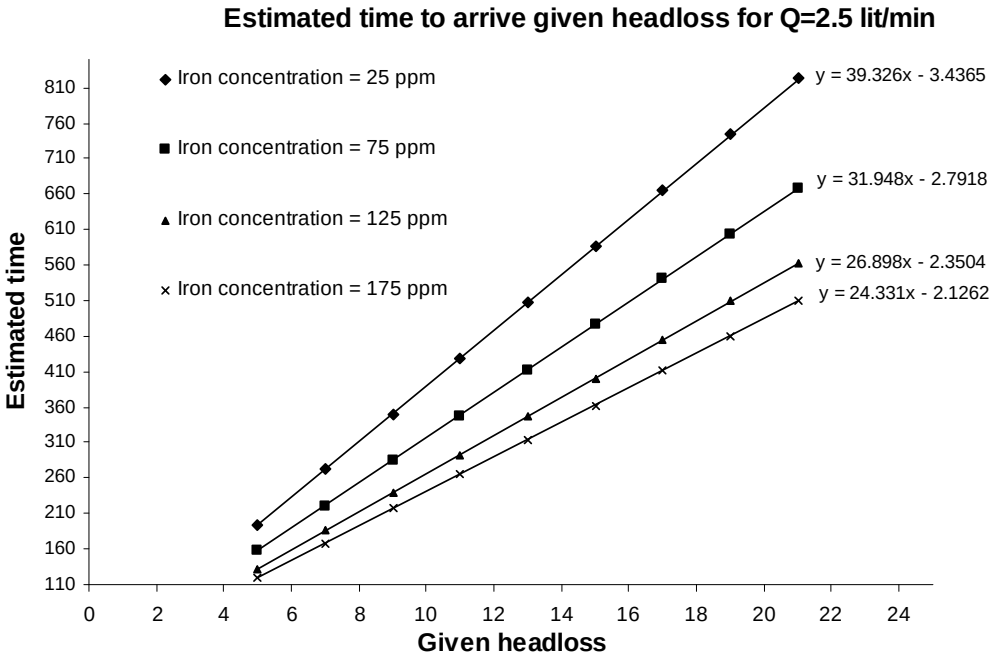

Fig. 6. Time (min) versus head loss (cm) for discharge equal 2.5 (lit/min)

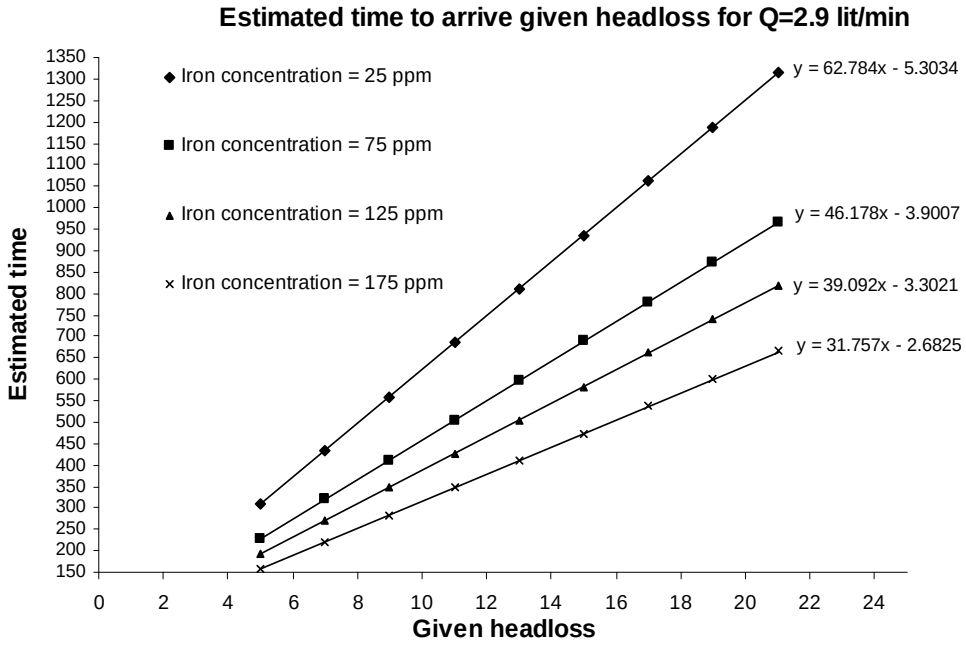

Fig 7. Time (min) versus head loss (cm) for discharge equal 2.9 (lit/min)

R^2 in figures 4, 5, 6 and 7 by linear regression is closely to 1. In addition figures 4,5,6 and 7 show that with decreasing in inlet iron concentration and increasing in discharge, arriving time to same given head loss ($h - h_0$) is increased.

Although increasing in discharge lead to entrance iron to filter is increased, the higher rate of water in bed causes that removal efficiency decreased, in addition deposit that is more compact form in granular media (because of more hydrodynamic force). Thus in same circumstance (same inlet iron concentration and given head loss), increasing in discharge lead to decreasing in σ_V . In other world, hydrodynamic force of water in iron filtration is more effective on head loss rather than inlet volume of iron.

Line slope comparison in same discharge for any of the figures 4, 5, 6 and 7 shows that in lower inlet iron concentration slope is greater. Therefore, expect that in lower inlet iron concentration, deposit distribution in depth of bed is more homogeneous. However, in higher inlet iron concentration most of deposit formed in upper layers of bed.

4. Discussions

Increasing in iron concentration lead to removal efficiency decreased. Then if high concentrations of iron exist, a series of rapid sand filters must used. Considering that rapid sand filter has relatively establishing and reclamation low cost rather than other method for iron removal, its recommend that this type of filter used for iron removal from water.

In lower inlet iron concentration, deposit distribution in depth of bed is more homogeneous. Therefore, if high concentrations of iron exist, rapid sand filters series consequence must be from filter by less depth to filter by more depth.

With increasing in discharge and decreasing in inlet iron concentration, arriving time to given head loss increased.

Following trend of this study can be useful to better rapid sand filter design (depth of filter, discharge, and grain size of filter media)

Determining of arising head loss during filtration by presented method in this research lead to more exact estimation time interval for rapid sand filter backwashing.

Using of filter media variable size in calculation and following of mentioned methodology, can aid to appropriate rapid sand filter particle size select.

Comparative Study Of Isocratic And Gradient Elution Chromatography In Stability Indicating Assay Of An Antihypertensive Drug Combination.

M. Abdel Kawy*, A.E. El-Gendy**, E.S. Shokry**

* Faculty of pharmacy, Cairo university

** Faculty of Pharmacy, Misr International University

ABSTRACT: Inspite that chromatographers are cautioned to avoid gradient elution when isocratic elution will do. In this work, the analytical properties of gradient and isocratic elution applied to separation of a complex sample of (fosinopril, hydrochlorothiazide and their degradation products) which can be done under isocratic condition are compared. Procedures were developed for determining fosinopril and hydrochlorothiazide in presence of each other and their degradation products by HPLC in the gradient elution mode using methanol- 20 mM KH_2PO_4 (PH 2.4) containing 0.1% triethyl amine. In the isocratic mode, the same mobile phase composition was applied in a constant ratio of 60: 40 (Buffer: methanol). Separation was achieved on a cyanopropyl column (4 x 250 mm, 5 μm) known for its high selectivity for polar and hydrophilic compounds and the least retentive of hydrophobic compounds which do not normally elute on standard C18 or C8 columns. The present work shows that gradient elution gave a shorter overall analysis time with similar resolution of the critical pair without sacrificing repeatability in parameters, so many of the reasons given to avoid gradient elution deserve serious reconsideration especially for those samples that can be separated isocratically.

I. INTRODUCTION

Fosinopril (FOS) and hydrochlorothiazide (HCTZ) are administered as a drug combination used in treatment of hypertension marketed under the name Monozide®. Stability studies confirm that both FOS and HCTZ are liable to hydrolysis yielding fosinoprilat (FOS-at)[1-3] and 6-chloro-2,4-disulfamoyl aniline (DSA)[4-5] respectively. FOS was successfully determined in presence of its degradate in synthetic mixture and biological fluids by chromatographic[1-3,6-13] and CE[14] methods. On the other hand, spectrophotometric[15,16] and HPLC[17,18] methods were applied for determination of HCTZ in presence of its degradate or in its pharmaceutical drug combinations.

Several methods have been also presented for the analysis of pharmaceutical preparation containing mixtures of FOS and HCTZ but the analysis of a quaternary mixture of the two active ingredients simultaneously in presence of their process degradates is considered a challenge.

The complexity of this mixture arises from the great difference in hydrophobicity and physiochemical properties of the analyzed compounds, FOS (being of highest lipophilicity and excessive retention time) and HCTZ (least retentive) in addition to their degradates whose presence lead to the problem of critical pairs of almost similar chromatographic behavior which makes the separation process even more complicated.

Two approaches have been presented in this work for the analysis of this mixture, the first one is based on isocratic elution utilizing the cyanochemistry of cyanocolumns which provides a different selectivity from both phenyl and standard aliphatic (C_4, C_8, C_{18}) reversed phases, having a dual nature with both polar and hydrophobic properties. They therefore can be used as the least polar alternative of NP in normal phase applications and the least hydrophobic alternative to RP-8 in reversed

phase applications. Separations using reversed and normal phase can be carried out using this material, where combination of weak hydrophobic interactions and polar interactions enable successful separation of complex samples of compounds of different physicochemical properties[19].

In the second approach, another modulation is introduced by the use of gradient elution, which involves gradual change in the mobile phase composition by increasing the concentration of the organic modifier during the course of separation. This maintains separation of the critical pair and in the sometime decreases the retention time of the late eluting peaks by reducing the retarding strength of the aqueous component.

Combining the benefits of cyanopropyl column with gradient elution provides a complete separation of the present mixture in a much shorter runtime.

II.EXPERIMENTAL

II.1. Instrumentation

An HPLC unit equipped with an autosampler, thermostated column department, diode array detector IG1315A), quaternary pump (G13154A) and a vacuum degasser from Agilent technologies, USA. The chromatographic column from Merck KGaA, Dermstadt, Germany was lichrospher® 100 CN (4x250 mm i.d., 5µm particle size). Data acquisition was performed on Agilent LC chemstation software. All determinations were performed at 45^{o}C.

II.2. Samples and reagents

II.2.1. Samples

II.2.1.1. Authentic samples

FOS and HCTZ certified to contain 100.50% and 99.50% respectively by the manufacturer method were kindly supplied by Bristol Myers Squib. 4-amino-6-chlorobenzene-1,3 disulphonamide (DSA) certified to contain 99.25% by the manufacturer method as supplied by Sigma-Aldrich chemie, GmbH, Germany.

II.2.1.2. Market samples

A commercial pharmaceutical preparation (Monozide® tablets manufactured by (Bristol Myers Squib, Egypt, Batch no. L 93731) labeled to contain 20 mg/10 mg FOS/ HCTZ was obtained from the local market.

II.2.2. Reagent

- Methanol used was HPLC grade (Sigma – Aldrich Co., USA)
- Potassium dihydrogen phosphate (BDH, Poole, UK), triethylamine (BDH) and orthophosphoric acid used were analytical grade.
- Distilled water was used throughout the whole work.

II.2.3. Standard solutions

II.2.3.1. Standard stock solutions

II.2.3.1.1. Standard stock solutions of FOS, HCTZ and DSA

Portions equivalent to 500.00 mg of FOS and 100.00 mg of each of HCTZ and DSA were accurately weighed and transferred into separate 100 ml volumetric flasks and dissolved in the minimum amount of methanol, sonicated for 10 minutes and the volume was made up to the mark with methanol to give stock solutions of concentrations 5.0 mg.ml^{-1} and 1 mg.ml^{-1} respectively.

II.2.3.1.2. Standard stock solution of FOS -at

It was prepared by mixing a portion equivalent to 500.0 mg of FOS with 1.0 M NaOH, heated under reflux for 1 hour at 100^{o}C the solution was then cooled and neutralized with a calculated volume of 1.0 M HCl. The obtained precipitate was filtered, washed, transferred quantitatively into 100 ml volumetric flask and the volume was made up to the mark with distilled water to give a standard stock solution of concentration 5.0 mg.ml^{-1}.

II.2.3.2. Standard working solutions of HCTZ and DSA

A portion equivalent to 10.0 mg of HCTZ and DSA was accurately transferred from their standard stock solution into two 100 ml volumetric flasks. The volume was made up to the mark with methanol to give standard working solutions of concentration 100 µg.ml^{-1}.

III. Procedure

III.1. Chromatographic conditions

** For isocratic elution:*

Isocratic elution technique was utilized with the column maintained at 45°C. The mobile phase used was a mixture of 20 mM potassium dihydrogen phosphate containing 0.1% triethylamine adjusted at PH (2.4) using orhtophosphoric acid and methanol in a ratio of (60:40). The mobile phase was filtered thorough a 0.45 μm membrane filtration system (Millipore Corp., Milford, MA, USA) to remove any particulate matter then degassed by sonication for 20 minutes. The flow rate was 1.5 ml/min. samples of 20 μl, were injected onto the column and scanned at 210 nm and 220 nm and the mixtures were scanned over the range of 200-400 nm. All the chromatographic determinations were performed 3 times at 45°C.

** For gradient elution:*

Simultaneous separation and quantification of FOS, FOS-at, HCTZ and DSA was performed by the use of gradient elution with the column maintained at 45°C. The gradient was prepared from 40:60 (v/v) methanol-20 mM aqueous potassium dihydrogen phosphate containing 0.1% triethylamine adjusted at PH 2.4 (component A) and 90:10 (v/v) methanol-20 mM aqueous potassium dihydrogen phosphate containing 0.1% triethylamine adjusted at PH 2.4 (component B). The gradient elution program is presented in the following table. All the changes in gradient were linear and the re-equilibration time was 15 minutes. The mobile phase flow rate was 1.5 ml/minute. Diode array detection was performed for optimum selection of wavelengths used in quantification of the selected compounds.

Time	Component A (%)	Component B (%)
0	100	0
4	100	0
10	0	100

III.2. Method validation

III.2.1. Linearity

Aliquots equivalent to (2.0- 30.0 μg) of HCTZ and (40.0- 1000.0μg) and (6.0-600.0 μg) of FOS for isocratic and gradient elution respectively were accurately transferred from their stock and working solutions respectively into 10 ml volumetric and diluted to the volume with mobile phase. Each of those dilutions were then chromatographed by injecting an aliquot of 20 μl of each into the chromatographic system five times and processed according to the method described in this work. The mean peak areas of five determinations of each concentration were plotted against the same concentration and the regression equations were then computed.

III.2.2. Laboratory prepared mixture

A laboratory prepared mixture containing 500 $\mu g.ml^{-1}$ of FOS and FOS-at and 10 $\mu g.ml^{-1}$ of HCTZ and DSA was prepared and chromatographed by adopting the procedures mentioned under linearity. The concentrations were determined by referring to the regression equations. The percentage recoveries and the standard deviations were then calculated.

III.2.3. Accuracy

The previously mentioned procedures under linearity were applied for different concentrations of FOS, HCTZ, DSA and FOS-at. The concentrations of the studied compounds were calculated from their corresponding regression equations. The mean percentage recoveries and standard deviations were then calculated.

III.2.4. Precision

III.2.4.1. Intraday precision (Repeatability)

The previously mentioned procedures under linearity were used for the analysis of freshly prepared solutions of concentrations, (2.0, 18.0, 30.0 $\mu g.ml^{-1}$) of HCTZ, (40, 400, 1000 $\mu g.ml^{-1}$) and (6.0, 100.0, 600.0 $\mu g.ml^{-1}$) of FOS by isocratic and gradient elution respectively for the determination of intraday precision (n=5) and the relative standard deviations (R.S.D %) were calculated.

III.2.4.2. Interday precision (Intermediate precision)

The previously mentioned procedures under linearity were used for the analysis of freshly prepared solutions of concentrations, (2.0, 18.0, 30.0 $\mu g.ml^{-1}$) of HCTZ, (40, 400, 1000 $\mu g.ml^{-1}$) and (6.0, 100.0, 600.0 $\mu g.ml^{-1}$) of FOS by isocratic and gradient elution respectively for the determination of interday precision (n=5) and the relative standard deviations (R.S.D %) were calculated.

III.2.5. Application to pharmaceutical preparations

Twenty tablets of Monozide tablets were accurately weighed, and finely ground in a mortar. A portion of the powder equivalent to 100 mg of each of

FOS and HCTZ was separately extracted with the minimum amount of methanol, sonicated for 30 minutes, centrifuged for 10 minutes. The precipitate was then filtered through a micropore filter, washed into two volumetric flasks and the volume was made up to the mark with the same solvent.

An appropriate dilution was made to prepare working solutions of the studied drugs, the aliquot was then chromatographed by adopting the procedures mentioned under linearity. The concentrations of FOS and HCTZ were then calculated from their corresponding regression equations and the mean percentage recoveries were then calculated.

III.2.6. Validation by standard addition technique

This study was performed by adding known amounts of the studied compounds from their working standard solutions to a known concentration of the commercial preparations. The resulting mixtures were chromatographed by adopting the procedures mentioned under linearity.

IV. RESULT AND DISCUSSION:

When working with mixture of analytes in different compound classes, with different structures, physicochemical properties and polarities, selectivity can be a factor of many variables as type of stationary phase used, percentage of organic modifier, temperature of analysis, PH of mobile phase and flow rate.

Developments in column technology have been mainly responsible for the advances in these directions[19,20]. A chemical modification that was made to the surface functional groups by introduction of cyanobonded phases led to development of cyanocolumns which are much less hydrophobic, less sterically restricted and have lower hydrogen bond acidity and considered the least retentive of all reversed phases as discussed earlier[20-24].

Fosinopril is a phosphonate containing ACE inhibitor which is the most hydrophobic (lipophilic) and retentive among all ACE inhibitors due to the hydrophobic side chain added to fosinoprilat to modulate its ionization characteristics and promote its poor oral bioavialbility[25-29] therefore a major difficulty was faced during analysis of a mixture of not only FOS, FOS-at but also HCTZ and its degradate (DSA) due to the diverse nature in the polarity of the investigated compounds.

Method development started with the use of different columns including C8, C18 and CN columns with different lengths (15 cm and 25 cm) and CN column (25 cm) was the only one capable of eluting FOS under the chromatographic conditions which resolve the rest of the mixture isocratically but the problem faced was the very long retention time of FOS which makes the runtime very long and it being eluted as a broad peak with extensive tailing. This means that the selectivity of the stationary phase was not enough for solving this analytical problem, there arises the need for manipulating another parameters which is the column temperature.

Operation at elevated temperatures decreases the mobile phase viscosity, the column back pressure allowing the use of not only higher flow rates but also longer columns thus offers better separation for complex mixtures[19,20].

In the present work, a long cyanocolumn, 25 cm long was under being operated at 45^{o}C, where significant reduction in the column back pressure allowed the use of a flow rate of 1.5 ml/min which was considered a limitation when being used the same column at room temperature and in the same time led to faster elution of FOS as a sharp peak instead of the broad peak obtained by operating at room temperature.

Several mobile phase compositions of methanol-water were investigated but no peaks were obtained, water was then replaced by 20 mM potassium dihydrogen phosphate with subsequent adjustment of PH at different values. It was found that very minor changes in PH can have a major effect on the peak shape and the chromatographic behavior of FOS and FOS-at at where at PH 3.0, distorted or irregular shaped peaks were obtained while at PH 2.4, sharp and symmetrical peaks were obtained instead.

The composition ratios of buffer and methanol were varied to study the effect of the % of organic modifier. It was found that minor changes lead to either:

1. Complete retention of FOS, where there exists a critical concentration of methanol below which FOS is retained on the column.

2. Overlapping of the critical pair (HCTZ and DSA).

Therefore fine tuning of the mobile phases composition is considered a must in order to establish good resolution of the critical pair and elution of FOS from the column with a reasonable retention time. Triethylamine (0.1%) was added to minimize peak tailing and enhance peak symmetry. Thus the mobile phase used was a mixture of 20 mM potassium dihydrogen phosphate containing 0.1% TEA and methanol in a ratio of 40: 60 (v/v) and a representative chromatogram of the mixture is presented in figure (2).

In gradient elution:

A further refinement made to HPLC by changing the mobile phase composition during the coarse of separation termed a solvent gradient elution was generally utilized for separation of complex mixtures with a wide retention range with no loss of resolution and applied specially in the case presented here to decrease the overall runtime and in the same time the cost of analysis.

Successful separation of the investigated compounds (FOS, FOS-at, HCTZ and DSA) was carried out but with an important limitation which is the prolonged analysis time where each run lasts about 30 minutes, therefore a modification was introduced to the method which involves gradual increase in the mobile phase strength as the separation proceeds in such away that the elution of the late elute compounds (FOS and FOS-at) was continuously reduced.

The model of gradient solvent profile applied was linear, gradient shown in figure (1) where the rate of the change in methanol is linear overtime because it permits greater separation selectivity between the earlier peaks (HCTZ and DSA) as well as later peaks (FOS and FOS-at).

It starts with an isocratic mode of 60% buffer: 40% methanol for the first 4 minutes of the run to ensure complete separation of the critical pains (HCTZ and DSA) followed by linear gradient over the next 6 minutes where methanol reaches 90% by the end of the run and this produces early elution of FOS-at and FOS with no loss of their resolution.

The column was allowed to re-equilibrate for 10 minutes with less than two column volumes of the initial eluent before the next run. The detector was operated on the DAD mode, allowing scanning of the absorption of the investigated compounds for confirmation of their identity and for selection of optimum wavelength for measurement.

The main problem faced during the analysis was that the wavelength chosen for quantitative determination of HCTZ and FOS was 210 nm which is close to the cut-off λ of the solvent used (methanol) which cause slight drift in the baseline in the positive direction, therefore the linear gradient model was chosen because it involved small change in the eluent strength relative to time which helped minimize the baseline disturbance. The same flow rate (1.5 ml/min) was applied throughout the whole run for the same season. Representative chromatograms of the laboratory prepared mixture of the investigated compounds by the gradient mode are shown in figure (3).

It was found that gradient elution gave a shorter overall analysis time with similar resolution of the critical pairs compared to the isocratic elution without sacrificing repeatability in retention time, peak area, peak height or linearity of the calibration curve and this was confirmed by the values of the correlation coefficients of calibration curves constructed for Fos and HCTZ which are close to 1. The regression equations were

P.A = 18.961 C + 574.070 r =0.9999 for FOS (by isocratic elution)
P.A = 24.028 C + 11.039 r =1
for FOS (by gradient elution)
P.A = 71.534 C + 13.348 r =1
for HCTZ.

Linearity was obtained over the range of (2.0-30.0 $\mu g.ml^{-1}$) for HCTZ and (40.0 -1000.0 $\mu g.ml^{-1}$) and (6.0-600.0 $\mu g.ml^{-1}$) for FOS by isocratic and gradient elution respectively.

The results obtained from the determination of accuracy are listed in table (1). The good recoveries and low standard deviation values indicate that the method is accurate. The mean percentage recoveries ±SD were found to be 100.14±0.530 for HCTZ and 99.96±1.227 and 100.51±0.962 for FOS using isocratic and gradient elution respectively.

The methods were found selective and valid for the determination of the two intact drugs simultaneously in presence of their degradates with mean percentage recoveries 100.14±0.894 for HCTZ, 99.59±1.917 and 100.05±1.012 for FOS by isocratic and gradient elution respectively.

Satisfactory results were obtained for the recovery of the analyzed drugs in its pharmaceutical preparation (Monozide®) and were in agreement with the labeled claims. Results indicate there was no interference from the excipients used in the formulation of tablets.

The results of the assay validation parameters are discussed in table (3). The data revealed that the proposed method was found suitable for the determination of the drugs in pure powder form, pharmaceutical preparation and was proved to be precise, accurate and suitable for quality control laboratories where economy and time are essential provided that the instrument with the right specification is available. The results of the proposed method presented in table (2) were compared with the reported method, student's t- and F tests at 95% confidence level were applied and the results showed that the calculated t- and F-values didn't exceed the theoretical ones indicating no significant difference between the results obtained by the proposed method and these obtained by the reported method.

Table (1): Accuracy of the proposed HPLC method for the analysis of pure samples of fosinopril and hydrochlorothiazide.

V. CONCLUSION

Delivering competent analytical judgment on samples in a timely manner is becoming more difficult as the sample load in quality control laboratories continues to increase. These economic pressures prompted the development of analytical technologies which can deliver high qualitative and quantitative information in a high throughout environment. Cyanopropyl columns combined with elevated temperature was presented as an approach for this purpose as well as gradient elution. Gradient elution technique was found to present tremendous chemical selectivity as well as precise retention time data under well controlled conditions. It was successful in separation of a complex mixture of fosinopril, hydrochlorothiazide and their degradates in less than 1/2 the time consumed in isocratic elution with no loss of accuracy or precision of data.

Abstract: *Rhazya stricta* plants have always played a major role in the treatment of human and animal diseases. The aim of this study was to study the effect of different doses of *Rhazya stricta* extract administered orally to rats, treatment period, effect on adiponectin protein, insulin resistance and finally its effect on exon 3 of adiponectin gene. Oral administration of aqueous leaves extracts of *Rhazya stricta* evoked fluctuations in adiponectin levels during eighteen weeks period of treatment. Serum adiponectin levels showed a significant increase after 2 and 4 weeks of treatments. Also a highly significant increase in adiponectin level, compared with the control group, was detected in rats treated with 0.125 gm/ml and 0.150 gm/ml after eighteen weeks of treatment. Insulin resistance is an important risk factor for type II diabetes mellitus and cardiovascular disease. Therefore, we performed HOMA-IR to check the degree of insulin resistance in rats. The results showed an inverse highly significant correlation between adiponectin levels and insulin resistance degrees after two weeks of treatment with *Rhazya stricta*. Studies published to date indicate that polymorphisms at the adiponectin gene (exon 3) are indeed predictors of circulating adiponectin levels. However, our results showed a significance increase in adiponectin levels, we did not detect any rare mutation in this locus using CSGE technique. The effects of *Rhazya stricta* extract on the increase of adiponectin levels concentrations could be promising issue (after avoiding its possible mutagenic effects) in treating diabetes, carbohydrate metabolism, hypertension, as well as inflammatory conditions.

Keywords: *Rhazia stricta*; rat adiponectin gene, exon 3; insulin resistance; mutagenicity

1-Introduction

Rhazya stricta plants have always played a major role in the treatment of human and animal diseases. The effect of an alkaloidal isolated from *Rhazya stricta* leaves (rhazimine) on arachidonic acid metabolism in human blood was described by Saeed *et al*. (1993). The alkaloid has been shown to be a dual and selective inhibitor of platelet activating factor (PAF)-induced platelet aggregation and arachidonic acid metabolism. It was concluded that these effects might provide additional beneficial anti-inflammatory and anti-PAF effects by comparison with classical non-steroidal anti-inflammatory drugs.

In addition, the lyophilized extract of *Rhazya stricta* was shown to relax isolated intestinal muscles of rats (Tanira *et al*., 1996a). The plant may have potential as an antispasmodic drug. This seems to corroborate the folk medicinal use of the plant in certain localities.

The effect of the lyophilized extract of *Rhazya stricta*, on some indices of the antioxidant status, was studied in rats (Ali *et al*., 2000a). It was found that the high doses were effective in significantly increasing the hepatic and renal concentrations of reduced glutathione (GSH) and ascorbic acid, and significantly reducing the degree of lipid peroxidation. The low doses were ineffective in significantly altering these indices.

A lyophilized extract of *Rhazya stricta* leaves was found to be of low toxicity in rats. In this species, the oral lethal dose (LD_{50}) has been estimated to be 16 g/kg in rats and 2.36 g/kg in mice. Subchronic treatment of rats with *Rhazya stricta* extract at doses of 0.5-2.0 g/kg/day did not significantly affect the body weights, food, water intake, urine, and faecal output during 28 days of treatment (Tanira *et al*., 1996b). Subchronic treatment also had no significant effect on haematological and plasma biochemical constituents. However, Adam, (1998) dosed Saudi Arabian sheep with powdered *Rhazya stricta* leaves in water and reported that the higher doses produced body-weight depression, bloating, diarrhea, dyspnoea and weakness of the hind limbs. Histologically, there were entero-hepatonephropaty, pulmonary congestion, haemorrhage and emphysema.

An intravenous dose of 80 mg/kg of *Rhazya stricta* extract administered to dogs, produced intense salivation, and rigor, followed by respiratory failure, convulsions and death within 15 minutes (Siddiqui and Bukhari, 1972).

Several studies were performed by Baeshin's team to assess the mutagenic potential of *Rhazya stricta* (Decne) leaf extract: It was first evaluated by using the Saccharomyces cerevisiae auxotrophic mutant test (Baeshin *et al*., 2005) then on Aspergillus terreus (Baeshin *et al*., 2009a). Also, the cytogenetic status and DNA integrity of human lymphocytes were studied after exposure to an aqueous extract of *Rhazya stricta* leaves in Vitro (Baeshin *et al*., 2009b) and its effect on plant cells were also studied on Allium cepa root tip meristem (Baeshin *et al*., 2009c). The results of this battery of tests indicated a mutagenic potential of *Rhazya stricta* Leaf extract on different organisms and tissues.

Subsequently, the biochemical parameters such as Blood Lipid Profile Concentrations, Liver Enzyme Activities and Kidney Functions in Rats were the subjects for detecting the effect of this extract in these respects and results indicated that, aqueous extract of the *R. stricta* leaves significantly decreased concentrations of TGs, LDL-c, cholesterol, uric acid and creatinin, but increased concentration of HDL-c. It triggered all these activities without affecting liver enzyme activities or kidney functions. These findings may have a positive impact on the cardiovascular patients and may provide a new therapeutic strategy to reduce hypertriglyceridemia. (Baeshin *et al*., 2010)

As far as we are aware, the effects of *Rhazya stricta* on adiponectin concentrations have not been identified yet. However, from the literature reviewed, there are similarities in the effects of *Rhazya stricta* and adiponectin on diabetes, carbohydrate metabolism, hypertension, as well as inflammatory conditions. The leaves of *Rhazya stricta* have been used, among other aliments, for the treatment of diabetes mellitus. Diabetic patients in the Arabian Gulf region commonly use water extracts of the leaves (Ali *et al*., 2000b). Tanira *et al*. (1996b) reported that acute oral treatment with the extract at a dose of 4 g/kg produced a significant and short-lived increase in plasma insulin concentration, accompanied by a significant reduction in plasma glucose concentration. On the other hand, animal studies have demonstrated that adiponectin reduces hyperglycemia in different models of obesity/diabetes mellitus (Yamauchi *et al*., 2001; Berg *et al*., 2001). In addition, multiple animal and human studies have shown a correlation between adiponectin levels and insulin sensitivity (Berg *et al*., 2001; Combs *et al*., 2002). One of the most interesting findings is that, a decline in adiponectin levels seems to identify insulin resistance before the development of diabetes (Oh *et al*., 2007).

In many studies, relatively large doses of the plant extract were used to determine the pharmacological and toxicological actions (Tanira *et al*., 1996b and Adam *et al*., 2002). Therefore, it was necessary to study the effects of this plant using doses, almost near that is used by humans in the folk medicine.

2.Material and Methods

The experimental work was conducted at the biochemistry lab of King Abdul-Aziz University Hospital (KAUH) and at King Fahd Medical Research Centre (KFMRC), Jeddah, Saudi Arabia.

2.1. Materials

2.1.1 *Rhazya stricta* plant

It was collected from the nearby areas of Jeddah, KSA. The leaves were washed, shade-dried and ground to a fine powder with a blender and the resulting powder were diluted in distilled water.

2.1.2.Experimental design (Samples)

Fifty five locally bred adult male Wistar rats initially weighing 150- 200 gm were used. They were housed in groups of five animals at a temperature of 22 °C under a 12 h dark- light cycle. They were fed standard pelleted diet (Grain Soils and Flourmills Organization Jeddah, KSA) and drinking water.

The animals were divided into four groups: Group 1 (n= 10) was the control and was dosed orally by gavage with distilled water (0.5 ml). Group 2 , 3 and 4 (n= 15), were treated orally by gavage with 0.5 ml *Rhazya stricta* extract at single doses of 0.1 gm/ml, 0.125 gm/ml and 0.150 gm/ml respectively for 18 week.

Blood samples were obtained from rats (after an overnight fast) by penetrating the retro-orbital plexus with a glass capillary tube or Pasteur pipette. Blood samples were collected after one, 2, 4, 8, 12 and 18 weeks from all treated and control groups.

2.2.Methods

2.2.1.Preparation of plasma:

Few drops of rat's whole blood were collected in an EDTA tube. The blood was centrifuged for 10 minutes at 3000 rpm. Plasma was separated carefully in a number of ependroof tubes and then stored at-80˚C.

2.2.2.Preparation of serum:

Blood was collected in a plain tube, allowed to stand to clot for one hour at room temperature and centrifuged for 10 minutes at 3000 rpm. After centrifugation, serum was separated carefully in a number of Ependrof tubes and then stored at -80˚C.

2.2.3.Determination of adiponectin levels:

Rat adiponectin kit was used in an enzyme-linked immune-sorbent assay (ELISA) for quantitative determination of adiponecin in rat serum. The intensity of color was measured at 450 nm in a plate reader.

2.2.4.Determination of insulin levels:

Rat insulin ELISA kit was purchased from Linco research and was used as recommended by the manufacturer.

2.2.5.Determination of glucose levels

Glucose was determined using enzymatic methods on automated chemical analyzer (Dimension R Clinical Chemistry System, USA). The glucose kit was used as recommended by the manufacturer.

2.2.6.Assessment of Insulin Resistance:

According to Matthews *et al*. (1985), insulin resistance can be estimated from fasting blood glucose and insulin concentrations. In the present study, degree of insulin resistance was measured by Homeostasis Model Assessment of Insulin Resistance (HOMA-IR), which was calculated with the formula: Fasting serum insulin (µ U/ml) x fasting plasma glucose (m mol/l)/ 22.5. High HOMA-IR scores denote low insulin sensitivity (insulin resistance).

2.2.7.DNA extraction:

Few drops of rat's whole blood were collected in tubes containing EDTA and genomic DNA was extracted using QIA amp DNA mini kit according to manufacturer's instructions. DNA Samples were obtained from both treated and control rats.

2.2.8.Primer design and PCR amplification:

PCR primers were designed (for exon 3 of adiponectin gene) with the computer program Primer 3.0 (Rozen and Skaletsky, 2000) and were synthesized commercially (Tib Molbiol Syntheselabor Berlin, Germany). The forward primer sequence is 5'-taa ggg tga ccc agg aga tg-3' and the reverse primer sequence is 5'-gcg gag act agg gag tgc tt-3'.

The PCR mixtures were prepared using ready to use HotStar TaqTM Master Mix as recommended by the manufacturer (Qiagen, Germany). The PCR program consisted of initial activation step for 15 minute at 95°C, followed by 35 cycles at 94°C for 30 seconds, 54°C for 1 minutes, and 72°C for 1 minute, and a final extension at 72°C for 10 minutes.

Few µl of PCR products were electrophoresed on 0.8 % agarose gel in 1X TBE buffer.. The relative size of the PCR products were determined using 100–1500 bp DNA ladder (Qiagen, Inc. USA). A visual image was obtained using Gel Documentation System (UVP Products Ltd, Cambridge, UK).

2.2.9.Conformational sensitive gel electrophoresis (CSGE):

To generate heteroduplexes for analysis by CSGE, 5µl of both control and treated PCR product (*Rhazya stricta* extract, 0.150 gm/ml) were mixed and incubated at 68°C for 30 minutes. Prior to electrophoresis, 4 µl of each PCR product was mixed with 4 µl of 20% ethylene glycol/30% formamide containing 0.025% (wt/ vol) each of Xylene Cyanol FF and Bromphenol Blue. Samples were separated by electrophoresis on a standard DNA sequencing gel apparatus [1-mm-thick gel prepared with 10% polyacrylamide made from 40% stock of acrylamide containing 99:1 acrylamide to bis-acrolylpiperazine (BAP)] using 0.5 ×TTE (Tris base, Taurine, EDTA) as the electrode buffer. The gel was pre-electrophoresed at 400V for 45 min and the samples were electrophoresed at 750 volts for 16 hr at room temperature.

After electrophoresis, one glass plate was removed and the gel on the second glass plate was stained with 1µg/ml ethidium bromide for 10 min followed by destaining in distilled water for 10 min. The bands were visualized with a UV light and the gel was then photographed under standard conditions.

3.Results

3..1 Relation between adiponection and insulin levels

Oral administration of aqueous leaves extracts of *Rhazya stricta* evoked fluctuations in adiponectin levels during eighteen weeks period of treatment with *Rhazya stricta* leaves (Table 1). Serum adiponectin levels were significantly ($p < 0.05$) lower (15.77±3.84 µg/ml) than control after one week of treatment in rats receiving 0.150 gm/ml *Rhazya stricta* aqueous extracts, On the other hand, serum adiponectin levels showed a significant increase ($p < 0.05$) after 2 and 4 weeks of treatments. This increase was clear in rats of group 4 receiving 0.150 gm/ml *Rhazya stricta* (33.40±8.38) and after 4 weeks of treatment in group 2 receiving 0.1 gm/ml *Rhazya stricta* (33.89± 5.46). Also a significant ($p < 0.01$) increase in adiponectin level, compared with the control group, was clear in rats of group 3 (20.77± 7.03 µg/ml) after eighteen weeks of treatment with *Rhazya stricta*. A highly significant ($p < 0.001$) increases in adiponectin concentration was recorded with the same dose in group 4 (24.06± 4.65 µg/ml).

NS: Not significant
Values were represented as the mean ± SD.
(a: control vs. group 2, b: control vs. group 3,
c: control vs. group 4).
p- value ≤ 0.05 was used as a criterion of significance.
p- value ≤ 0.01and ≤ 0.001were used as a criterion of highly significance.
($p < 0.01$, r = -0.35).

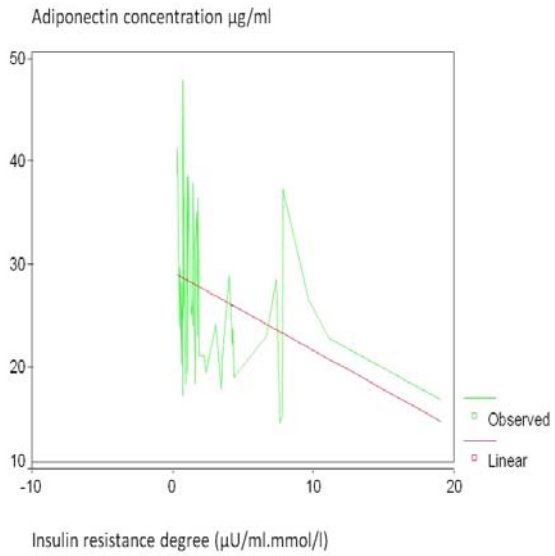

Figure 1: Correlation of adiponectin and insulin resistance degree after 2 weeks of treatment with *Rhazya stricta*

3.2.The Relationship between Adiponectin and Insulin Resistance:

Interestingly, analysis of data using Pearson correlation showed an inverse highly significant correlation between adiponectin levels and insulin resistance degrees after two weeks of treatment with *Rhazya stricta.* ($p < 0.01$, $r = -0.35$) as shown in figure 1.

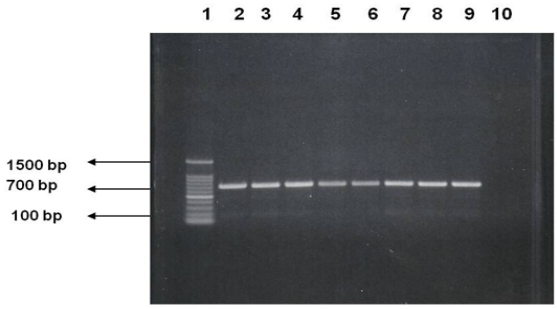

Figure 2: Gel electrophoresis image of PCR products separated on 0.8% agarose gel. Lane 1 is the DNA ladder, Lane 2-9 the 713-bp PCR products containing sequences for exon 3 (680-bp) of *Adipoq* gene. Lane 10 is the negative control (without DNA)

3.3.PCR and Gel Electrophoresis

The PCR amplification products were analyzed on 0.8% agarose gel. The electrophoresis of the PCR products is shown via an image of the ethidium bromide-stained agarose gel visualized under ultraviolet using Gel Documentation System (Figure 2). The figure shows PCR amplified bands of 713-bp containing sequences for exon 3 (680-bp) of the *Adipoq* gene.

3.4.Conformational Sensitive Gel electrophoresis (CSGE)

The PCR products were screened for mutations by conformation sensitive gel electrophoresis (CSGE). Figure 3 shows CSGE image of a 713-bp PCR product that contains the sequence for exon 3 of the *AdipoQ* gene. Lane 15 contains the control sample and Lane 1-14 contains PCR products from rats treated orally for 18 weeks with *Rhazya stricta* extracts mixed with PCR products from control rats after heteroduplexing. The CSGE analysis of the PCR products showed that there is no single-base mismatches (heteroduplexes) were detected by CSGE in a 713-bp PCR product that contains sequences for exon 3 of the *AdipoQ* gene. The results obtained showed that there is no mutation or polymorphism in exon 3 of AdipoQ genes.

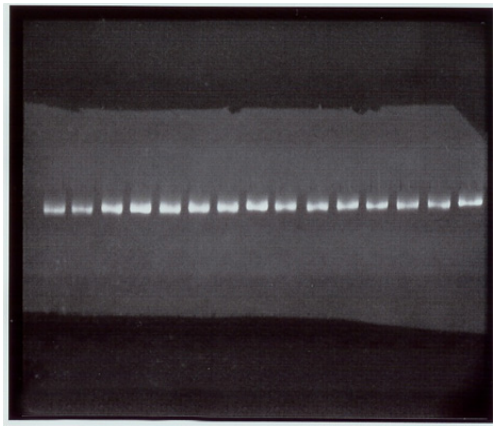

Figure 3: **CSGE image** of **a 713-bp PCR product that contains sequences for exon 3 of the *AdipoQ* gene. Fifteen lanes, lane 1-14 (from left to right) are PCR products from rats treated with the plant extract. Lane 15 is the control sample.**

4.DISCUSSION

Rhazya stricta is commonly used in folk medicine for the treatment of many diseases. In many studies, relatively large doses of the plant extract were used to determine the pharmacological and toxicological actions (Tanira *et al*., 1996b and Adam *et al*., 2002).

Recently, adiponectin has been identified as one of the adipocytokines with important metabolic

effects. It plays an important role in the development of insulin resistance and atherosclerosis. (Ekmecki and Ekmecki, 2006). It was important to realize that adipocytokine is circulating in concentrations exceeding the concentrations of any other known hormone, though still there is much uncertainty with regard to its primary physiological role especially in healthy subjects (Lihn *et al*., 2005).

The biochemical effects of *Rhazya stricta* aqueous leaves extract were examined in liver and kidney of rats by Baeshen *et al*. (2010). The same condition of the previous experiment was conducted in the present experiment to determine the effects of oral administration of aqueous leaves extract of *Rhazya stricta* on serum adiponectin concentrations and to study its molecular effects on exon 3 of adiponectin gene in rats. Also the relationship between serum adiponectin and insulin resistance after treatment with aqueous leaves extracts of *Rhazya stricta* in rats were estimated.

Oral administration of aqueous leaves extracts of *Rhazya stricta* evoked fluctuations in adiponectin levels during eighteen weeks period of treatment with *Rhazya stricta* leaves (Table 1). This increase in adiponectin concentration induced by the *Rhazya stricta* extract show the importance of using this plant as a medicinal treatment. However, the mode of modulating adiponectin concentration by *Rhazya stricta* is not clear till now.

Moreover, our results showed inverse significant correlations between adiponectin levels and serum insulin levels after week 1 and 2 of treatment with the plant extract. In agreement with our results, Wasim *et al*. (2006) reported an inverse significant correlation between adiponectin levels and insulin levels in a British South-Asian population with a high incidence of type 2 diabetes, cardiovascular disease, central obesity and metabolic syndrome.

Insulin resistance is an important risk factor for type II diabetes mellitus and cardiovascular disease (DeFronzo and Ferrannini, 1991). Therefore, we performed HOMA-IR to check the degree of insulin resistance in each rat. This method has been supported by other studies as a precise method for the assessment of insulin resistance (EL-Midaoui and de Champlain, 2002; Bonora, 2000).

The present work showed an inverse significant correlation between adiponectin and insulin resistance degrees in all treated rats after one week of treatment with *Rhazya stricta* leaves. Our finding is in consistent with previous studies that observed inverse correlation between adiponectin levels and insulin resistance (D'Anna et al., 2006; Farvid *et al*., 2006).

To our knowledge, this work is the first to study the effects of treatment with *Rhazya stricta* leaves on adipoQ gene (exon 3) and its protein (adiponectin). This study clearly shows that oral administration of *Rhazya stricta* leaves for eighteen weeks produced highly significant increases in adiponectin concentrations in treated rats especially on rats that were treated with the highest dose of the plant extract.

The adiponectin gene was shown to be associated with adiponectin levels in healthy Caucasians (Mackevics *et al*. 2006). It was reported that the presence of at least 1 non-synonymous mutation in exon3 showed evidence of association with adiponectin levels. (Cancello *et al*., 2004). The significance of the genetic variations in human adiponectin gene on its plasma concentrations and obesity were examined in Japanese subjects (Takahashi *et al*. 2000). Mutations in the adiponectin gene were screened by direct sequencing or restriction-fragment polymorphism. The levels of plasma adiponectin were determined by the enzyme-linked immunosorbent assay (ELISA). The results showed that, two nucleotide changes have been identfied in the adiponectin gene. G=T polymorphism in exon 2 was associated with neither plasma adiponectin concentrations nor the presence of obesity. A subject carrying missense mutation in exon 3 (R112C) showed markedly low plasma adiponectin concentration.

The frequency of adiponectin gene mutations in exon 3 of Polish origin patients with type 2 diabetes was 3.9%, while in the control group 0.98% and this difference was not statistically significant. It was also observed that adiponectin level is significantly lower in patients with C.331 TC mutation (Krętowski *et al*., 2005)

In summary, the studies published to date indicate that polymorphisms at the adiponectin locus (exon 3) are indeed predictors of circulating adiponectin levels, insulin sensitivity, and atherosclerosis, highlighting the pivotal role of this adipokine in the modulation of metabolism and atherogenesis (Menzaghi *et al*. 2007).

The technique of CSGE was developed for Detection of mutations in double-stranded DNA by gel electrophoresis (Ganguly and Prockop, 1995). Under the initially described conditions, no single-base mismatches (heteroduplexes) were detected by CSGE in a 713-bp PCR product that contains sequences for exon 3 of the AdipoQ gene. Since mean adiponectin levels were significantly higher ($p < 0.01$- $p < 0.001$) than the control group after 18 weeks of treatment with *Rhazya stricta* leaves extracts, and molecular analysis showed that no single base mismatches were

detected, these results indicated that no mutagenic action was practiced by *Rhazya stricta* extracts on exon- 3 of adipoQ gene . This does not exclude the possibility that it is mutagenic elsewhere in the genome of the rat since it was reported previously by Baeshin's team that it is mutagenic (Baeshin *et al*., 2005: 2009 a, b, c).

Therefore, a screening of the total genome of the rat for mutagenic action of *Rhazya stricta* liquid leaf extract will be revealing and this what it is being done in a current work in our laboratory. Furthermore a knockout mutation of the adipoQ gene will be more revealing in this respect and will be considered in future work. Adiponectin has drawn much attention because of its insulin-sensitizing and antiatherogenic actions, suggesting that genetic deficits in its production or action may contribute to insulin resistance and coronary artery disease (CAD) (Lacquemant *et al*., 2004). Diabetes is categorized into: Type 1- Insulin Dependent Diabetes Mellitus (IDDM) – which is an autoimmune destruction of Pancreatic β cells: Type 2: Non-insulin Dependent Diabetes Mellitus (NIDDM) – which is characterized by Insulin resistance in target tissues. The current focus of drugs discovery research in diabetes includes exploration of alternative medicines, discovery of new synthetic anti-diabetic agents as well as isolation of active compounds from plants which have been the source of traditional herbal medicines and have been documented and described for their anti-diabetic properties. A number of bioactive compounds have been isolated from plants which are potent α-glycosidase and /or α-amylase inhibitors and show good antidiabetic properties. The main phytochemicals with reported anti-diabetic activities were flavonoids, polyphenolic compounds, tannins, glycosides, alkaloids and terpenoids. A potent α-glycosidase inhibitor which helps in prevention of diabetes was isolated from water extract of leaves of mulberry trees (*Morus alba* L.) (Day, 2005). It is known that *Rhazya stricta* leaves extract contains the main phytochemicals with reported anti-diabetic activities such as: alkaloids, glycosides, flavonoides, tannins and triterpenes (Al-yahya *et al*., 1990: Badreldin *et al*., 2000: Szabó, 2008).

The possibility that some of the claimed therapeutic actions of *Rhazya stricta* extract may be due to immunomodulatory capacity. The alkaloidal fraction of *Rhazya stricta* significantly increased the production of IL-1 and TNF-α (Tanira *et al.,* 1998). On the other hand, it was reported that there is a highly significant correlation between IL-1 and TNF-α levels and adiponectin concentrations (Lihn *et al.,* 2003).

The effect of *Rhazya stricta* leaves extract on rat adiponectin level concentration could be a promising issue (after avoiding its possible mutagenic effects) in treating human diabetes, coronary artery disease, as well as inflammatory conditions. Future studies will be conducted for studying the mode of action of separated alkaloids of *Rhazya stricta* extract on whole adipo Q gene, adiponectin receptor loci and the identification of additional genes which might be involved in the regulation of serum adiponectin levels.

shailendra.b.sharma@gmail.com

ABSTRACT: The "biological monitoring" has been widely used to assess the environmental impact of pollutant discharges. The methodology must be evaluated in terms of false positives and false negatives. A false positive is an indication that an excursion beyond previously established quality control conditions (i.e., unacceptable conditions) has occurred when, in fact, one has not. A false negative is an indication that conditions are acceptable when, in fact, they are not. Statistics must play a more important role in biological monitoring because they are capable of explicit statements of confidence in the biological monitoring results. With appropriate statistical evaluation of the data, professional judgment on whether to initiate immediate action or wait for more confirming data will be more objective and reliable. In order to optimize the usefulness of biological monitoring, the selection of biological monitoring methodology shall not be based on the investigator's favorite organism or group of organisms. Neither can be a convenient methodology adopted by regulatory agencies. The selections must be based on the compatibility of data generated with the decision making process, including the statistical establishment of confidence in the result obtained.

INTRODUCTION:

In recent years, the environment has been put to serious threat due to the discharge of harmful and toxic chemicals of various types which are primarily the byproducts of developmental activities like industrialization, urbanization, use of chemical fertilizers as well as pesticides and burning of fossil fuel emitting green house gases. Huge oil spills in the oceans and radioactive fallout are contaminating air, water and soil. In the event of large scale eco-degradation, it is necessary to monitor the nature and degree of change in environment so that the consumers may be warned and appropriate preventive and specific corrective measures may be adopted. After the UN conference on the Human Environment in Stockholm in 1972, the global Environmental Monitoring System (GEMS) has been set up. Literature is missing today. Environmental monitoring requires authentic data base and is considered as an useful tool in assesses the health of the environment. Furthermore, it is an indispensable prerequisite for Environmental Impact Assessment (EIA). Biomonitoring is an important exercise in the assessment of water quality. The present paper aims to discus the concept scope and procedure of biomonitoring. The concept of indicator species has been explained, species can be classified in tolerant facultative and sensitive groups. A holistic approach for water quality assessment has been suggested.

CONCEPT OF BIOMONITORING

Environmental monitoring is a systematic method of collecting qualitative & quantitative information about the status of environment by physico-chemical and biological methods. Monitoring by biological methods i.e. as "biomonitoring" is 'an ecological exercise where various kinds of biota are considered in ascertaining the extent of pollution in a water body'. These biota are known as bioindicators.

OBJECTIVE OF BIOLOGICAL MONITORING

Biological monitoring can be used for the following purposes:

1) To provide an early warning of a violation of quality control systems in time to avoid deleterious effects to ecosystems.
2) To detect episodic events such as accidental spills, failure of predictive models, failure of early warning systems or illegal disposal of wastes at night, etc.
3) To detect trends or cycles.
4) To determine information redundancy
5) To evaluate environment effects associated with the introduction of make it or concise part of introduction genetically engineered organisms into natural systems.

SCOPE OF BIOMONITORING

Biomonitoring has ample scope in ecology where biologists can play a meaningful role in environmental management. The idea of using appropriate organisms in the assessment of environmental quality originated at the beginning of twentieth century. It has been emphasized that nature and degree of pollution of any water body may be judged from the occurrence, abundance and composition of the inhabiting organisms. According to Forbes (1913) it is quite possible to arrange the plants and animals of a stream in order of their preference for or tolerance of organic impurities in such a way that their graded list may serve as an index to the level of contamination". Wilhm (1975) reported that environmental stresses eg. pollution induce changes in the structure and function of biological systems. Such changes may occur from the molecular to community level. In recent years biochemical, cytological and histological analysis are conducted with sophisticated instruments to assess the extent of pollution with much accuracy. Mason (1980) further stated that biological assessment of water quality involves three sequential steps: Suvey, surveillance and monitoring or research. The survey is the first step that apprises one about ecological condition of a given spot where the biomonitoring programme is to be followed. For example, In case of a lake, its geomorphology, ecogeography, nutrient status, inflow and outflows, point and non-point sources of pollution as well as biotic community may be known through survey. which should also take into account the anthropogenic influences such as socio-demographic, economic and cultural on the lake. The surveillance is vital practice of repeated measurements of the variables dependent or independent, of a particular habitat. The final step is monitoring the pollution status of the habitat concerned. The vast amount of data produced during surveillance is subjected to critical analysis for the final analysis & interpretation. The programme objective should be clearly defined and the sampling strategy outlined at the beginning of biomonitoring programme. Aquatic biota which can be are classified as follows:

1. **Plankton**: Microscopic organisms having either relatively small / one power locomotion and drift in the water due to the subject to the action of waves, currents and other forms of water motion".
2. **Periphyton:** Periphyton are assemblage of minute organisms (both plants and animals) growing on free surfaces of submerged substrata, natural (e.g. plant parts) or artificial (e.g. rocks).
3. **Nekon** includes the organisms (animals) of larger size moving freely and independently, in aquatic environment.
4. **Neuston** are the organisms resting or swimming on the surface film of water.
5. **Pleuston** are floating / submerged in higher plants water.
6. **Benthos** organisms which live in or on the bottom sediments.

SPECIES AS INDICATORS

Using of indicator organisms for the assessment of water quality a thorough knowledge of the ecological tolerance of the organisms concerned. Depending on the sensitivity to pollution Gaufin (1958) categorized species as (1) intolerant or sensitive, (2) facultative and (3) tolerant. With the onset of pollution or stress, intolerant species are either eliminated or migrate to other places, if is scopes there. Facultative species are able to withstand moderate pollution, whereas the tolerant species can endure severe pollution. It has however been postulated that through the existence of tolerant species indicate the presence of pollution but the absence of intolerant or sensitive species also indicates the occurrence of pollution. Some examples of indicator species are cited as below:

Ephemera simulans (may fly) *Acroneuria evoluta (stone fly)*	Intolerant or sensitive species
Hydropsyche bronta (caddis fly) *Agabus stagninus (beetle)*	Facultative species
Chironomus riparium (true fly) *Limnodrilus sp.* *Tubifex sp.*	Tolerant species

Further say few words how benthic involucrate are different from the above species and why they are grouped. Richardson (1925) categorized benthic Macro invertebrates into three groups on the basis of their degree of tolerance to pollution:

Pollution Level	Type of macroinvertebrates
1. Pollutional or more or less tolerant species	Tubificid worms, midge larvae etc.
2. Cleaner preference species	Current loving snails, insects, crustaceans etc.
3. Clean water species	Snails of Viviparidae, insects or insect larvae or

	nymphs of Hemiptera, Odonata, Neuroptera, Coleoptera etc.

Kolkwitz and Marsson (1908, 1909) propounded saprobien system based on the observation that a river receiving a heavy input of sewage shows zones of decreasing pollution. These zones are polysaprobic, α - mesosaprobic, β - mesosaprobic and oligosaprobic and their sequence reflects self purification. Fzerdingstand (1963) proposed nine stream zones as follows: (i) Coprozoic (ii) α - polysaprobic (iii) β - Polysaprobic (iv) χ - polysaprobic (v) α - ,mesosaprobic (vi) β - mesosaprobic (vii) χ - mesosaprobic (viii) Oligosaprobic and (ix) Katharobic. Organisms are graded into four groups on the basis of tolerance to organic enrichment as follows: Fecal coliforms, especially *Escherichia coli* is a better indicator of sewage pollution than total coliform count. The count is made by the most probable number (MPN) technique. Fecal coliform count <5000 cells / 100 ml is the minimum standard.

1.	Saprobiontic species	Occurring only in heavily polluted waters (tolerant species)
2.	Saprophilic species	Occurring generally in polluted waters but may also be found in other communities (facultative species)
3.	Saproxenous species	Generally found in unpolluted waters but are able to survive in presence of pollution (facultative species)
4.	Saprophobous species :	Unable to tolerate presence of pollution (sensitive or intolerant species)

BIOMONITORING WITH COLIFORM BACTERIA

It has been estimated that average adult excretes about 2000 000 000 coliform each day and its number is a reliable measure of fecal pollution. The presence of fecal coliforms in a water body indicates that the fecal pollution has occurred. Earlier total coliform count was used as an indicator. It is now proved that the presence in water of

BIOMONITORING BASED ON TOXICITY TEST

The presence of toxic substance in aquatic medium may be determined by toxicity test. In which suitable organisms are placed in water containing toxic chemicals and observations are made on the mortality of the test organisms. The toxicity may be acute, chronic, lethal, sublethal and cumulative. Lethal concentration is considered as the criterion of toxicity. The percentage of experience are expressed with a number, say LC_{50} which indicates the percentage (50% in this case) of animals killed at a particular concentration. The time of exposure is also important in toxicity. Eg. 48-hour $LC_{50,}$ means the concentration of a toxic substance can kill 50% of the test organisms in 48-hours. Instead of ex *situ* observation, an in *situ* continuous flow system has been devised. In such cases, caged organisms are placed in the field. In toxicity test, various organisms like algae, protozoa, rotifers, insects, microcrustaceans etc. can be used.

FISH ALARM SYSTEMS

It is well established that fishes show distinct physiological and behavioral responses to pollutants. The behavioral responses can be seen and observed by various techniques. An automatic fish monitor tank with required gadgets has been devised. If the polluted water is allowed to enter such a tank, recording of movement and other

responses will be automatically done from which the quality of water can be assessed.

BIOCHEMICAL OXYGEN DEMAND AND BIOMONITORING

The BOD values serve as good indicator of organic pollution. Although often considered as a component of chemical monitoring but in reality, it is based on a biological process and therefore, it may be regarded as an aspect of biomonitoring.

Water quality according to BOD values
(as followed in UK)

Water quality	**BOD_5 at 20^0c (mg/l)**
Very clean	<1
Clean	1-2.5
Fairly clean	2.5-4
Poor	6-10
Bad	10-15
Very bad	15-20

MISCELLANEOUS METHODS OF BIOMONITORING

Weber and McFarland (1969) used ash-free weight of periphyton and concentration of chlorophyll a in assessing the water quality. They proposed the following index (I_q) to characterize water quality I_q =

$$\frac{ash-free\ weight\ of\ perphyton\ (gm^{-2})}{Chlorophyll\ a\ (gm^{-2})}$$

According to the author the index values in unpolluted or slightly polluted waters contain mostly populations of algae and therefore, the index value should be lower than in polluted areas having large populations of filamentous bacteria and non-chlorophyll bearing organisms.

Odum (1956) found that the ratio between production and respiration (P/R) might serve the purpose of biomonitoring. According to him in the septic (polluted) zone of a stream, the respiration fax exceeds production and obviously the P/R ratio would be less than one. In the recovery zone, production increases and exceeds respiration and as a result P/R ratio would exceed one.

1.0 – 1.5	Oligosaprobic	No pollution
1.5 – 2.5	β - mesosaprobic	Weak organic pollution
2.5 – 3.5	α - mesosaprobic	Strong organic pollution
3.5 – 4.0	Polysaprobic	Very strong organic pollution

The ratio between production and biomass (P/B) may also serve as an indicator of environmental conditions. It is now known that pollution by organic phosphorous insecticides can be assessed by determining the brain acetylcholinesterase of the experimental fish. Analysis of serum and other blood components are also useful in the detection of pollution. Radioactive pollution can be determined by studying banding patterns in chromosomes.

MATHEMATICAL APPROACH IN BIOMONITORING

A large number of mathematical formulations (or indices) have been developed in biomonitoring. Surveillance programme over time produces voluminous data on various aspects of environment. Such data must be analysed to make the surveillance worthwhile. The analysis of surveillance data may be done by multivariate analysis or by using biotic or diversity indices. Multivariate analysis can be carried out on both qualitative (presence/absence) and quantitative data. Green (1979) strongly recommended that Principal Component Analysis (PCA) should from the basis of multivariate analysis. However, some biotic and diversity indices are briefly given below:

BIOTIC INDICES

A biotic index takes into account the sensitivity of tolerance of individual species or groups to pollution and assigns them a value, the sum of which gives an index of pollution for a site. The data may be qualitative (presence/absence) or quantitative (relative abundance or absolute density). These indices are designed mainly to assess the organic pollution in water bodies.

The saprobien system of Kolkwitz and Marsson (1908, 1909) is the earliest biotic index. Polysaprobic, α - mesosaprobic, β - mesosaprobic and oligosaprobic zones from the higher organic enrichment to decreasing state in a river are recognized and the presence or absence of indicator species in the said zones are recorded. This information is used to monitor pollution. Pantle and Buck (1955) also developed the saprobien system to take into account the relative abundance of organisms in a sample. They assigned a value (h) to express the abundance of each organism in the different Saprobien groups as well as a value (s) for the saprobic grouping.

The saprobic index of Pantle and Buck

The saprobic index ranges are

Saprobien groups		**Relative abundance**	
	s value		h value
Oligosaprobic	1	Occurring incidentally	1
β - mesosaprobic	2	Occurring frequently	3
α - mesosaprobic	3	Occurring abundantly	5
Polysaprobic	4		

Mean saprobic index (S) = $\frac{sh}{h}$

Trent biotic index (TBI)

Considers the presence and absence of species and species richness, but animals does not need counting. The sensitivity to organic pollution of different species or groups is used in determining the index. In grossly polluted waters, where no macro-invertebrates are present, a TBI of zero is obtained.

The maximum score in unpolluted water with a species rich invertebrate fauna is 10.

Chandler Biotic Score (CBS) –

According to Chandler Biotic Score (1970), the abundance of organisms within the community as well as the species richness, is of value assess the degree of pollution. This index has five levels of abundance, the score of each indicator species being weighted in relation to its abundance. If a species intolerant of pollution is abundant, it is given a high score of 100, whereas an abundant, pollution tolerant species is given us a lower score of 4. The allocation of scores is somewhat arbitrary because the lower limit of the score is zero while there is no upper limit when no macro-invertebrates are present,

Community Similarity Indices (Plafkin *et al*, 1989):

These indices are used in situations where a reference community exists either through sampling or through prediction for a region. Data sources or ecological data files may be available to predict a reference community to be used for comparison. These indices are designed with either species level identifications or higher taxonomic levels. Three of the many community similarity indices available are discussed as below

(Sample A = reference station [or mean of reference database]
Sample B = station of comparison)

- Community Loss Index- it measures the loss of benthic taxa between a reference station and the station of comparison. This is an index of compositional dissimilarity with values increasing as the degree of dissimilarity with the reference station

Increases. Values range from 0 to ∞. This index seems to provide greater discrimination than either of the following two community similarity indices. The formulae for the Community Loss Index is:

$$Community\ Loss = \frac{d-a}{e}$$

Where
a = number of taxa common to both samples
d = total number of taxa present in Sample A
e = total number of taxa present in Sample B

- Jaccard Coefficient of Community Similarity- Measures the degree of similarity in taxonomic composition between two stations in terms of taxon presence of absence. The Jaccard Coefficient discriminates between highly similar collections. Coefficient values, ranging from 0 to 10, increase as the degree of similarity with the reference station increases.

The formulae for the Community Loss Index and the
Jaccard Coefficient are:

$$Jaccard\ Coefficient = \frac{a}{a+b+c}$$

where
a = number of taxa common to both samples
b = number of taxa present in Sample B but not A
c = number of taxa present in Sample A but not B

- Pinkham and Pearson Community Similariy Index- Incorporates abundance and compositional information and can be calculated with either percentages or numbers. A weighting factor can be added that assigns more significance to dominant taxa. The formula is:

$$S.I._{ab} = \sum \frac{\min(x_{ia}, x_{ib})}{\max(x_{ia}, x_{ib})} \left[\frac{x_{ia}}{x_a} \cdot \frac{x_{ib}}{x_b} \div 2 \right]$$

(Weighting factor)

where

x_{ia}, x_{ib} = number of individuals in the i^{th} taxon in Sample A or B

DIVERSITY INDICES

Mason (1980) stated that biotic indices have been developed to measure responses to organic pollution and may be unsuitable for detecting other forms of pollution. Diversity indices are used to measure stress in the environment. It has been seen large number species are found in unpolluted environment, with no single species making up the majority of the community and a maximum diversity is obtained when a large number of species occur in relatively low number in a community. When an environment becomes stressed, species sensitive to that particular stress tend to disappear. As a result species richness will be reduced, and the density of the surviving species will increase. Species diversity indices usually take account of both the number of species (species richness) and their relative abundance (evenness). There are number of diversity indices but the most widely used is Shannon index of general diversity, which is based on information theory. According to Southwick (1976) "Information theory is a branch of science and mathematics which deals with measurable and quantifiable units of information". It involves the numerical analysis of

systems which transmit, process, or store information". Southwick (*op cit.*) further emphasized that "information theory provides the numerical basis for analyzing systems of all types, living as well as non-living".

Shannon index $(\bar{H})$

Where ni = importance value for each

$$\bar{H} = -\sum\left(\frac{ni}{N}\right)\log\left(\frac{ni}{N}\right) (Odum,\ 1971)$$

Where ni = importance for each species and N = total of importance values

$$H' = -\sum_{i=1}^{S} pi \log pi\ (Mason, 1980)$$

where pi is estimated from ni/N as the proportion of the total population of N individuals belonging to i^{th} species (ni)

On the basis of observation of the diversity index in a range of polluted and unpolluted streams Wilhm and Dorris (1968) reached at the following eonclusion.

H (Shannon index of diversity)	**Condition of water quality**
> 3	Clean water
1 - 3	Moderately polluted

BMWP Biotic Index (Armitage *et al,* 1983; Friedrich *et al,* 1996; Hynes, 1998; Mackie, 1998)

In order to limit the taxonomic requirement of earlier biotic indices to identify organisms to species level, some alternative indices have been developed which use only the family level of identification. An example is the Biological Monitoring Working Party-score (BMWP) which has been published as a standard method by an international panel (ISO-BMWP, 1979). This score was devised in the UK but was not specific to any single river catchment or geographical area. The new BMWP score attempted to take the advantages of earlier biotic indices. The Biological Monitoring Working Party (BMWP) score is calculated by adding the individual scores of all indicator organisms present (family level, except order Oligochaeta) (Friedrich *et al*, 1996).

The organisms are identified to the family level and then each family is allocated a score between 1 and 10. The score values (Table II-15) for individual families reflect their pollution tolerance; pollution intolerant families have high scores and pollution tolerant families have low scores. Mayfly nymphs score 10, molluscs score 3 and the least sensitive worms score 1. The number of taxa gives an indication of the diversity of the community (high diversity usually indicates a healthy environment, Friedrich *et al*, 1996).

Table II-15: Pollution sensitivity grades for families (higher levels in a few cases) of river macroinvertebrates for SIGNAL (S) and BMWP (B) scores. Families not occurring in North America have been omitted. N represents families found in N. America and are graded according to the inverse of Bode et al (1991) and Plafkin et al (1989) tolerance values to correspond to SIGNAL and BMWP scores (modified from Mackie, 1998)

Family	**Grade**			**Family**	**Grade**			**Family**	**Grade**		
	N	**B**	**S**		**N**	**B**	**S**		**N**	**B**	**S**

Ephemeridae	8	10	-	Odontoceridae	10	10	8				
Ephydridae	4	-	2	Oedicerotidae	4	-	-				
Erpobdellidae	3	3	3	Oligochaeta	2	-	-				

Note: The grades under (N) above should be used in the said indices (there is some question as regards the grades of the taxa which have been noted along with a `?')

BIOLOGICAL WATER QUALITY CRITERIA (BWQC)

To assess the actual health of water bodies, CPCB has derived a Biological Water Quality Criteria (BWQC) for water quality evaluation. This system is based on the range of saprobic values and diversityof the benthic macro-invertebrates families with respect to water quality. The system has been developed after making calibration study on the saprobic score and diversity score data on the presence of different taxonomic groups of benthic macro-invertebrate families in few lakes, ponds and reservoirs. To indicate changes in water quality to different grades of pollution level, the entire taxonomic groups, with their range of saprobic score from 1 to 10, in combination with the range of diversity score from 0 to 1 has been classified in to five different classes of water quality (Table 3). The abnormal combination of saprobic scorer and diversity score indicates sudden change in environmental conditions.

Table: 3 Biological Water Quality Criteria (BWQC) for Lakes/Ponds and Reservoirs

S.No. Score	Range of saprobic score	Range of diversity class	Water Quality Indicator	Water Quality	Colour
1.	7-10	0.5-1	A	Clean	Blue
2.	6-7	0.5-1	B	Slight pollution	Light blue
3.	3-6	0.3-0.9	C	Mod. Pollution	Green
4.	2-5	0.4 & less	D	Heavy pollution	Orange
5.	0-2	0-0.2	E	Severe pollution	Red

WHY BIO-MONITORING?

1. Animals and plant communities respond to intermittent pollution, which may be escaped in a chemical sampling / monitoring programme.
2. Biological communities may respond to new or unsuspected pollutants in the environment, which are difficult to analyze chemically. It would be uneconomic and impracticable to regularly determine concentration of 1500 or so known pollutants.
3. The chemical analysis is relatively expensive in terms of equipment needed and number of analysis required to achieve results with comparable reliability, to those achieved by bio-monitoring.
4. Biological monitoring can reflect the environmental pollution levels as some chemical species are accumulated in the bodies of biotic organisms.

Table 1: Comparison of Physico-chemical monitoring with Biological monitoring.

S.No.	Characteristic	Physico-chemical Monitoring	Biological Monitoring
1.	Pollutant concentration	Good	Poor
2.	Assessment of intermittent, irregular pollution discharge	Not possible unless continuously monitored	Possible without continuous monitoring
3.	Kind of pollution assessment	Good	Poor
4.	Reliability (representation of data)	Poor	Good
5.	Measure of ecological effect	Not possible	Possible
6.	Monitoring	Relatively high	Relatively low

ADVANTAGES OF BIOLOGICAL ASSESSMENT

1. The biological methods are quite quick, economical and can be integrated with other relevant studies.
2. Much less equipments are required and large area can be surveyed in less time resulting in large amount of information suitable for assessment.
3. Provide cheaper option in comparison to physico-chemical assessment, where chemical analytical equipment, manpower and operational cost are very high.
4. Biological assessment methods do not eliminate the need for chemical analysis of water samples, however, these may provide information, which may be integrated with physico-chemical information.
5. The integration of biological method with physico-chemical method may provide a system, which is not too expensive and generate necessary information with maximum efficiency.

INFORMATION GENERATED BY BIOLOGICAL BIO-ASSESSMENT

Biological assessment relies on the fact that pollution of water body will cause changes in physico-chemical environment of water and that those changes will disrupt the ecological balance of the system. The measure of extent of ecological upset will depict the severity of pollution. The extreme kind of ecological upset may be clearly visible, such as – unusual color in water, increased turbidity, or presence of dead fishes or mortality, however, many form of ecological damage cannot be assessed without detailed examination of aquatic biota.

Biological assessment of often able to indicate an effect on ecosystem arising from a particular use of the water body. It can determine and depict the general effect of anthropogenic factors on ecosystem as well as the presence and effects of common pollution problems (eutrophication, toxicity and industrial inputs etc.) Biological assessments exhibit deleterious changes in aquatic communities and provide systematic information on water quality. The pollution transformation in water and in organisms can be determined through biological surveillance. The long-term effects of polluting substances in water body may be reflected by study of bio-accumulation and bio-magnification. The biological surveillance may depict the conditions resulting from disposal of wastewater, its character and dispersion as well as assess the effectiveness of environmental protection measure. Quantify the toxicity of substances under controlled, defined laboratory conditions (e.g. toxicity studies).

1. The biological systems used as water quality indicators should have following characteristics:

2. The sampling, sorting, identification and data processing should be as simple as possible involving minimum time and manpower.

SELECTION OF BIOLOGICAL ORGANISMS AS WATER QUALITY INDICATOR

1. It is impossible to study the entire biota present at a sampling area due to constraints of time and wide variety of sampling method required for different group of organisms.
2. The biomonitoring / surveillance must therefore be based on those organisms, which are most likely to provide right information regarding pollution effects.
3. The use of single species as water quality indicator is usually avoided because individual species depict high degree of temporal and spatial variation due to habitat and biotic factors.
4. The indicator species must be able to be used to detect subtle rather than gross and obvious effect of pollution.

CONCLUSION

The term "biological monitoring" has been widely used in this discussion to include almost any type of data gathered to assess the environmental impact of discharges. In our opinion, biological monitoring is limited to a continue collection of data to establish whether explicitly stated quality control conditions are being met. If these conditions are not being met, there will be an immediate decision to take corrective action. Purpose of biological monitoring include providing early warnings of hazards, detecting spills, detecting environmental trends or cycles, determining the best and least redundant information for monitoring, and evaluating the environmental effects associated with the introduction of genetically engineered organisms into natural systems. One design will not serve each purpose, but if the researchers have clearly defined goals for the monitoring program, powerful designs are possible.

Abstract: Among all the elements required by a plant, phosphorus (P) is one of the most important nutrients for crop production and emphasis is being given on the sufficient use of P fertilizer for sustainable crop production. A pot experiment was conducted in green house at the Department of Soil Science and SWC, Pir Mehr Ali Shah Arid Agriculture University, Rawalpindi during Rabi season, 2007. Phosphorus was applied at the rate of 40 and 80 kg P ha^{-1} in the form of SSP, TSP, NP and DAP. A basal doze of 100 kg N and 60 kg K ha^{-1} was applied as urea and murate of potash (MOP) respectively. All the growth parameters of wheat were significantly improved by addition of P application. It was concluded from the study that phosphorus application at the rate of 80kg P ha^{-1} as single super phosphate (SSP) showed better results as compared to triple super phosphate (TSP), nitrophos (NP) and diammonium phosphate (DAP) on phosphorus deficient soil of Balkasr area of Tehsil Chakwal.

Key Words: Phosphorus, Wheat, Growth Attributes, P Fertilizer, calcareous soil

1. Introduction

Phosphorus is critical in the metabolism of plants, playing a role in cellular energy transfer, respiration, and photosynthesis. It is also a structural component of the nucleic acids of genes and chromosomes and of many coenzymes, phosphoproteins and phospholipids. Early season limitations in P availability can result in restrictions in crop growth, from which the plant will not recover, even when P supply is increased to adequate levels. An adequate supply of P is essential from the earliest stages of plant growth (Bertrand *et al.*, 2003). A growing plant may experience different stages in mineral nutrition, based on the balance among internal and external nutrient supplies and crop demand for nutrients. Initially, plants will live on their seed reserves, with external supply having little effect on plant growth. A second stage occurs when growth rate is determined by nutrient supply through a dynamic balance between internal plant factors and external (soil) supply (Grant *et al.*, 2001). In a final stage, the relative growth rate may decline for reasons other than inadequate nutrition. At this point, the growth rate of deficient and sufficient plants may converge, since the factor most limiting to growth is not nutrient supply. The length of time required for a P deficiency to show an effect on plant processes depends on the extent of P reserves in the plant. In tissues of higher plants, the majority of the P is present as inorganic P (Holloway *et al.*, 2001).

Among different factors, the role of nutrients is well recognized in crop production. The inadequate supply of the essential plant nutrients in soil is growth limiting factor towards its production. Among all the elements required by a plant, phosphorus (P) is one of the most important nutrients for crop production and emphasis is being given on the sufficient use of P fertilizer for sustainable crop production (Ryan, 2002). It is an expensive nutrient as compared to nitrogen (Nisar, 1996). Therefore it is imperative to manage it properly to achieve its maximum use efficiency. Among other factors, lack of proper balance between nitrogen (N) and phosphorus (P) is considered important as it remained mostly in favor of N and has increased to as high as 4.7:1 against the recommended ratio of 2:1 or lower (Ahmed, 2000).

Soils of Pakistan are alkaline and mostly calcareous in nature and P fixation is a serious problem in these soils (Sharif *et al.*, 2000). According to NFDC (2003), 93 percent of Pakistani soils are P deficient. When P fertilizer is added, the soil can rapidly and firmly adsorb a large amount of P from the soil solution. When P is adsorbed, it becomes unavailable to the plants and with time is difficult to release from the soil (Huang, 1998). At present DAP

(18:46:0) is the principle phosphate fertilizer used in Pakistan, with somewhat less quantities of NP (23:23:0) and much smaller amounts of SSP and TSP. The phosphorus fertilizer use can help to reduce the adverse effect of drought under rainfed conditions. The Potash and Phosphate Institute (PPI, 1999) reported that phosphorus, in balanced soil fertility program, increase water use efficiency and helps crop to achieve optimal performance under limited moisture conditions. As wheat is staple food of Pakistan, the present study was undertaken to compare the effect of different phosphatic fertilizers on wheat crop in Balkasr soil series.

2. Materials and Methods

A pot experiment was conducted to compare the effect of different phosphatic fertilizers on wheat crop in Balkasr soil series of Tehsil Chakwal. The study was conducted in green house at the Department of Soil Science and SWC, Pir Mehr Ali Shah Arid Agriculture University, Rawalpindi during Rabi season, 2007. For this, bulk soil sample from 0-30 cm depth was brought from farmer's field of Balkasr area of Tehsil Chakwal. Soil sample was air dried, ground, passed through a 2 mm sieve and mixed thoroughly. Ten kg of the prepared soil was packed in each earthen pot having height and diameter of 18 and 12, inches respectively. The pots were lined with polythene bags. Eight seeds of wheat (cv. GA 2002) were sown on 20th November, 2007. Phosphorus was applied at the rate of 40 and 80 kg P ha^{-1} in the form of SSP, TSP, NP and DAP. A basal doze of 100 kg N and 60 kg K ha^{-1} was applied as urea and murate of potash (MOP) respectively. Thinning was conducted on 22nd December, 2007 and four plants per pot were grown. Distilled water was used to bring the soil to 50 percent of maximum water holding capacity by weighing the pots as and when required. One plant per pot was harvested at 80 days growth while three plants were harvested at maturity on Saturday, May 5, 2007 at 137 days growth. Experiment was laid out in completely randomized design (CRD) with three replications.

Soil sample collected from the farmer's field of Balkasr soil series was air dried, ground, passed through a 2 mm stainless steel sieve and mixed thoroughly. This soil sample was used for physio-chemical analysis like soil texture, macronutrients (P, K), electrical conductivity (EC_e), soil pH_s, and organic matter (OM) at the beginning of experiment (Table 1). The soil used for the experiment was sandy loam in texture, alkaline in reaction (pH=7.92), poor in organic matter (0.40%), adequate in potassium (92 mg kg^{-1}) and low in available phosphorus (4.6 mg kg^{-1}). Particle Size Analysis was done by Bouyoucus Hydrometer Technique (Bouyoucus, 1962). Soil paste was prepared and saturation extract was obtained. Then the pH was determined with a pH meter (Page *et aI.*, 1982) and Electrical conductivity was measured by using electrical conductivity meter (Page *et al.*, 1982). Organic matter was determined by using Walky and Blake method (Page *et al.*, 1982). Available Phosphorus was measured by spectrophotometer (Olsen, 1982). Extractable potassium was determined by using flame photometer (Knudsen *et al.*, 1982).

2.1 STATISTICAL ANALYSIS

The data collected for various parameters were subjected to Analysis of Variance (ANOVA) and the means obtained were compared by LSD at 5 percent level of significance (Steel and Torrie, 1980).

3. RESULTS

3.1 Effect on Number of Tillers per Plant

The yield of a crop is dependent upon the combined effect of many factors. Among these factors, the number of tillers per plant has a vital position, controlling yield of wheat. The more the number of tillers, the better will be the stand of crop, which ultimately increases the yield (Jamwal and Bhagat, 2004). The data presented in Table 2 show the effect of different phosphorus sources and levels on number of tillers per plant of wheat crop (cv. GA 2002). The results revealed that the maximum numbers of tillers per plant (6.67) were found in the treatment T_6 (80 kg ha^{-1} P as SSP) and minimum numbers of tillers per plant (3.00) in treatment T_1 (control). Different P sources showed significant effect on number of tillers per plant while the number of tillers per plant increased with the increased level of phosphorus application. At both P fertilizer levels applications, Single Super Phosphate (SSP) resulted in maximum number of tillers per plant as compared to Triple Super Phosphate (TSP), Nitrophos (NP) and Diammonium Phosphate (DAP).

3.2 Effect on Plant Height (cm)

Plant height is a genetic character of a variety but its potential can be achieved by adequate crop management. The data on the effect of different P sources and levels on plant height is given in Table 2. The results showed that the maximum plant height (91.67 cm) was recorded in treatment T_6 (80 kg P ha^{-1} as SSP), while it was minimum (75.33 cm) in treatment T_1 (control). Plant height was significantly affected among all the various P sources application. It also increased linearly with the increased level of phosphorus application. Hence, among low level of various phosphorous fertilizer application,

Diammonium Phosphate had enhanced more plant height while at high level SSP resulted in maximum plant height as compared to TSP, NP and DAP.

3.4 Effect on Spike Length (cm)

The data in table-2 pertaining to spike length indicated that it was maximum (10.00 cm) in treatment T_6 (80 kg P ha^{-1} as SSP) while recorded minimum (5.00 cm) in farmer practice. Various P sources and levels application to wheat spike length varied significantly. The data concluded from the results that among low P level application, Nitrophos had enhanced more spike length. Among all high P level application, Single Super Phosphate had produced more spike length as compared to TSP, NP and DAP.

3.5 Effect on Number of Grains per Spike

Number of grains per spike is one of the easily determinable characters, which has a positive co-relation with the yield. The effect of different P sources and levels on number of grains per spike along with statistical interpretations is presented in Table 2. The results showed that maximum numbers of grains per spike (39.67) were observed in treatment T_6 (80 kg P ha^{-1} as SSP) and minimum numbers of grains per spike (33.33) were observed in treatment T_1 (control). Different P sources showed significant effect on number of grains per spike. Number of grains per spike increased with the increased level of phosphorus application. At low P level applications, DAP increased more number of grains per spike while at high P level applications, SSP had produced maximum number of grains per spike as compared to TSP, NP and DAP.

3.6 Effect on Grain Yield (g pot^{-1})

The data regarding grain yield (g pot^{-1}) shown in table-2 differed significantly in all treatment. Maximum grain yield (32.20 g pot^{-1}) was observed in T_6 (80 kg P ha^{-1} as SSP) while it was found minimum (12.00 g pot^{-1}) in treatment T_1 (control). Grain yield was significantly affected by different P sources and increased with the increased level of phosphorus application. Among low level of P application, DAP had produced maximum grain yield. Hence among all high P level applications, SSP resulted in maximum grain yield as compared to TSP, NP and DAP.

3.7 Effect on Straw Yield (g pot^{-1})

The data on the effect of different P sources and levels on straw yield (g pot^{-1}) along with statistical interpretations were shown in table-2. The straw yield also showed the similar response like the grain yield. The findings showed that the maximum straw yield (61.24 g pot^{-1}) was observed in the treatment T_6 (80 kg P ha^{-1} as SSP) while it was observed minimum (25.20 g pot^{-1}) in the treatment T_1 (control). Different P sources and levels showed significant effect on straw yield. Hence, among all P applied levels, SSP had produced maximum straw yield as compared to TSP, NP and DAP.

4. Discussion

The result of this research indicated that there existed a significant impact of P containing fertilizers on the various growth attributes of wheat crop. The crop yield is much important for enhancing the farmer and country economy. It is specifically correlated with many growth factors like number of tillers per plant, plant height, spike length, number of grains per spike and straw yield. These had lingering role to enhance or lemmatize the crop productivity. Therefore more number of tillers per plant (6.67) was found in the treatment (table-2) where 80 kg ha^{-1} P as SSP was applied while farmer practice produced very minimum numbers of tillers per plant (3.00). However, our findings showed that the number of tillers per plant increased with the increased level of phosphorus application. Among all P containing fertilizers, SSP application had produced more number of tillers per plant as compared to TSP, NP and DAP. It might be due to maximum availability of phosphorous which established more root establishments. This fact would ultimately maximum availability of mineral nutrients for optimum cell growth, reproduction, photosynthesis and transformation of sugars and starches. The results are in line with the findings of Jamwal and Bhagat (2004) who reported that basal application of the recommended dose of DAP produced significantly higher number of effective tillers m^{-1} row length which ultimately increased the grain and straw yields. Renu *et al.* (2005) also found that the number of tillers per plant was less where no fertilizer was applied as compared to phosphorus fertilizer application in case of wheat crop. Various other scientists (Baon *et al.*, 1992; Bertrand *et al.*, 2003; Glassop *et al.*, 2005) also responded similar to our findings. They also found that phosphorous had a significant impact on various cereal crops growth attributes as these are paradox for the yield enhancing factors. They also suggested for application of phosphatic fertilizers at early growth stages to support the lateral growth stages for enhancing crop productivity as per their potential.

Number of tillers per plant depicted in table-2 also elucidated the similar trend number of tillers per plant. Therefore, our findings do match to Jamwal and Bhagat (2004) who reported that basal application of the recommended dose of DAP produced significantly higher number of effective tillers m^{-1} row length which ultimately increased the grain and straw yields. Renu *et al.* (2005) also found that the number of tillers per plant was less where no fertilizer was applied as compared to phosphorus fertilizer application in case of wheat crop. Various other scientists (Baon *et al.*, 1992; Bertrand *et al.*, 2003; Glassop *et al.*, 2005) also responded similar to our findings. They also found that phosphorous had a significant impact on various cereal crops growth attributes as these are paradox for the yield enhancing factors. They also suggested for application of phosphatic fertilizers at early growth stages to support the lateral growth stages for enhancing crop productivity as per their potential.

In addition to them, plant height also contributed a significant impact on enhancing the straw yield. The table-2 showed that plant height higher plant height (91.67 cm) was also noted in treatment where80 kg P ha^{-1} as SSP, while farmer practice had attained minimum (75.33 cm) plant height. Hence DAP and SSP had enhanced higher plant height as compared to TSP, NP and DAP. Our findings are in line with the accordance of Holloway *et al.*, 2001; Khan 1975; Li *et al.*, 2005) who also reported the similar findings.

Spike length in table-2 was recorded maximum (10.00 cm) in 80 kg P ha^{-1} as SSP application and was noted minimum (5.00 cm) was found in control treatment. Different P sources and levels significantly affected spike length. However, amongst low level, NP resulted in maximum spike length while at high level SSP resulted in maximum spike length as compared to TSP, NP and DAP. Some other scientists (Lombi *et al.*, 2004; McBeath *et al.*, 2005; Mohammad *et al.*, 2004) showed the similar trend for phosphorous application to various crops. They also found that spike length of the cereal crops are the major factor to feed the livestock for the sustainability of the food web. They observed that basal application of the recommended dose of DAP produced significantly taller spike length that ultimately increased the grain and straw yields.

Number of grains per spike shown in table-2 reflected that control practice had produced minimum number of grains per spike while were noted more in treatment T_6 where 80 kg P ha^{-1} as SSP applied. However, DAP and SSP had produced more number of grains per spike as compared to other P containing fertilizers. Poulsen *et al.* (2005) recommended the phosphatic fertilizer application enhanced significantly higher number of grains per spike which ultimately increased the grain and straw yields. Various scientists (Ravnskov *et al.*, 1995; Reuter *et al.*, 1995) also showed the similar results.

In table-2, higher grain yield (32.20 g pot^{-1}) was observed in T_6 (80 kg P ha^{-1} as SSP) while it was found minimum (12.00 g pot^{-1}) in treatment T_1 (control). Grain yield was significantly affected by different P sources and increased with the increased level of phosphorus application. At low level, DAP resulted in maximum grain yield but at high level, SSP resulted in maximum grain yield as compared to TSP, NP and DAP. The results are in line with the findings of Reddy and Sigh, (2003) who observed that among the different phosphatic fertilizers, single super phosphate resulted in the highest grain yield (50.27 q ha^{-1}), followed by nitrophos (43.96 q ha^{-1}) and diammonium phosphate (43.13 q ha^{-1}). Grain yield was higher; where phosphorus fertilizer was applied as compared to that where no P fertilizer was applied in case of wheat crop (Yaseen *et al*., 1998). Highest grain and straw yields were observed where P was applied as nitrophos (Alam *et al., 2002*). Rashid *et al.* (2002) observed that substantial crop yield increases as well as plant P concentration enhancements were observed with applied P. The findings of various scientists (Schweiger and Jakobsen 1999; Smith and Smith 2005; Smith *et al.*, 2003) also responded similar to our results.

The straw yield (table-2) also showed the similar response like the grain yield. SSP had produced more straw yield as compared to TSP, NP and DAP. Straw yield was higher; where phosphorus fertilizer was applied as compared to that where no P fertilizer was applied in case of wheat crop (Yaseen *et al*., 1998). Highest grain and straw yields were observed where P was applied as NP (Alam *et al.*, 2002). Various other scientists (Rashid *et al*, 2002; Smith *et al.*, 2004; Zhu *et al.*, 2001) observed that substantial crop yield increases as well as plant P concentration enhancements were observed with the application of phosphorus.

Above discussion stated that P containing fertilizer like DAP and SSP fertilizer should be applied at the early growth stages. Hence, these would have significant affect on the lateral growth stages of the wheat crop. Hence, this study would act as a paradox for other scientist to verify this fact at large field scale for it implication.

Table 1: Basic Soil Analyses of the Selected Soil

Parameters	Units	Values
Sand	%	90.14
Silt	%	7.92
Clay	%	1.94
Textural Class		Sandy Loam

- The means having different letter are significantly different from each other at 5% level of probability.

5. Conclusion

It was concluded from the study that phosphorus application at the rate of 80kg P ha^{-1} as single superphosphate (SSP) showed better results as compared to triple superphosphate (TSP), nitrophos (NP) and diammonium phosphate (DAP) on phosphorus deficient soil of Balkasr area of Tehsil Chakwal. This superiority of SSP over the other three sources could be due to presence of more Ca content and better water solubility of phosphate compound. Single super phosphate can be used on all crops and soils as a basal dressing. Its use for ailing saline/sodic soils is, however, preferred because of the ameliorative effect ascribable to its 46% gypsum content and highly acidic nature (pH 2.0). This product is also manufactured locally and easily available to farmers. However as it contains less

percentage of phosphorus therefore its storage and transportation cost is high as compared to other sources.

[1,2,3,4] *Department of Industrial Management, Faculty of Management, University of Tehran*

parsanejad@ut.ac.ir

Abstract: Construction industry is an important part of any economy. But it does not have an appropriate performance especially in the productivity of materials. Statistics show production of billions of tons of construction waste per year in the world, and these issues threaten all beneficiaries of this industry. Thus, convenient strategies should be founded for improving waste production. This will not be achieved unless we recognize waste sources across construction supply chain. Also each material has its own source of waste, therefore exact identification of any material and after that its source will help to develop waste minimization strategies. In this research 30 questionnaires were distributed between experts. At first we prioritized waste sources, and by following the question about impact of sources on selected material, using binominal test, it observed that a category of sources had impact on some of material and another sources on another materials. Analysis of these two types of materials showed us that this result was not accidental and those materials when use in building, their dimensions is important (like brick, block, tile and etc.), those sources have impact on their waste that emphasize design parameters of building. Those material when use in building, their weight are important (like cement, gypsum, sand and etc.), those sources have impact on their waste that emphasize purchasing level of ordering and purchasing. Therefore materials categorized by their sources of waste across supply chain.

[Mohamad Reza Parsanejad, Mansor Momeni, Ahmad Jafarnejad, Ali Mohaghar. **A new categorization of construction materials Based on sources of waste across supply chain**. Journal of American Science 2010; 6(12):1263-1273]. (ISSN: 1545-1003). http://www.americanscience.org.

Keywords: Waste, Source of waste, Construction supply chain, Non-coordination, Dimensional, Weight based.

1) Introduction:

Statistics shows us at 2008, 16.7 million tons of wastes were disposed in Tehran landfills. Also since year 1995 to 2008 it was estimated that 150 million tons of wastes were produced in Tehran and transported to wastes centers. (Report of material section of construction and housing research center, 2008), (Report of Tehran municipal recycles organization, 2008), (Omrani et al., 2008)

Based on Tehran municipal reporters, construction wastes are transported to some places like ABALI, TELO, ARDIB and so on. The most popular of these places is ABALI that 900 thousands of construction wastes are disposed there every month. This area is more than 700 square kilometers, it means as wide as Tehran city. By growing population and flourishing demands for building, lots of problems will generate near these high amounts of wastes. (Report of environmental committee of consoling Tehran city, 2008)

These statistics shows that the amount of waste production is high in Iran but with a review it could be seen that this amount is high in another countries too. Here are some researches that show this subject:

- The amount of waste is about 1 to 10% of purchased material with average of 9% (Ekanayake and Ofori, 2004),
- The amount of waste in Brazil is between 20 to 30% of material weight entered a construction site (Pint and Agapyan, 1994),
- Construction waste in Australia is from 4% for glass to 19.6% for plaster (McDonald and Smithers, 1998),
- In USA, waste in most of buildings is 20 to 30 kilograms (Chun-Li et al., 1997),
- Average waste of block in Singapore is about 13% of purchased weight (Kang, 2000),
- The amount of waste cost is about 3 to 40% of total project cost. (Katz and Baum, 2010)
- 25% of materials in construction process waste (Hamassaki and Neto ,1994),
- 20% of material entered the site are wasted (Formoso et al., 1993),
- Construction waste is about 30% of all material weight in site. (Fishbein, 1998),
- Construction waste as a percent of solid wastes entered to the site in some countries are as below: Netherlands 26%, Australia 20-30%, USA 10-29%, Germany 19% and Finland 13-15% (Bossink and Brouwers, 1996),

These statistic excited researchers to sick and develop some solutions for management and prevention of construction wastes. Among various methodologies of waste management, a categorization is more popular. It classifies waste management

solutions to four categories : minimization, reuse, recycle and disposal. (Gavilan and Bernold, 1994; Franiran and Gaban, 1998; Begum et al., 2007; Silva and Vithana, 2008)

However material waste management leads to higher level of productivity in this business, but almost all researchers emphasize that minimization and elimination of waste is the best solution. (Gavilan and Bernold, 1994; Skoyles and Skoyles, 1987; Begum et al., 2006).

For development of waste strategies in construction, the waste and their types should be identified. Inherent properties of any material such as methods of usage, important parameters when use, how to supply and how to maintain, are effective in process of changing a material to final product. Since this process and properties are different for various materials, the trends of waste production and waste sources are different too. Many researchers have done so many studies about waste sources but there are no categorization based on inherent properties of materials until now. The purpose of this research is to identify material types which will be used for developing waste minimization strategies for any type of materials. For solving this problem we should find out that the sources across supply chain will effect on waste production in any material or not? After that, by this method the materials can be categorized.

2) Literature review

2-1) Waste

After categorizing waste to seven types by ohno (1994), Womack and jones (1996) defined waste as any activity that absorbs sources and does not have any value adding. In another word waste is the loss of any kind of sources-materials, time (labor and equipment), and capital- produced by activities that generate direct or indirect costs but do not add any value to the final product from the point of view of the client (Formoso et al., 2002).

2-2) Construction materials waste

Construction material wastes refer to materials from construction sites that are unusable for the purpose of construction and have to be discarded for whatever reason (Yahya and Boussabaine, 2006).

In another research construction waste was defined as any material apart from earth materials, which needed to be transported elsewhere from the construction site or used on the site itself other than the intended specific purpose of the project due to damage, excess or non-use or which cannot be used due to non-compliance with the speci6cations, or which is a by-product of the construction process. (Ekanayake and Ofori, 2004)

2-3) Types of Construction materials wastes

There are many studies about kinds of materials waste that have so many overlaps.

Bossink and Brouwers (1996) first intimated to waste measuring by pinto (1989) and solbeman(1994) and pinto and agopayan(1994). They compared these studies in waste of 11 materials. Next they studied material waste in five building project in Germany in three views:

1. Construction waste of a specific material as percentage of total construction waste,
2. Construction waste of a specific material as percentage of its total amount,
3. Cost of construction waste of a specific material as percentage of total waste costs. (Bossink and Brouwers, 1996)

A study in Malaysia shows, composition and percentage of material wastes: Soil 27%, wood 5%, brick and blocks 1.16%, metal product 1%, roofing material 0.20% and plastic and packaging materials 0.05% concrete and aggregate 65.80% (Begum et al., 2006).

Jones and greenwood (2003) obtained percentage of waste in ten materials as below: plaster board 36%, packaging 23%, cardboard 20%, insulation 10%, timber 4%, cateen waste 20%, chipboard 2%, plastic 1%, electric cable 1%, and rubber 1% (Yahya and Boussabaine,2006).

In another research in 2009, material wastes have been gathered in 100 building material. It contains Earthmoving transport, Concrete reinforcement ,Piles ,Reinforced concrete foundation ,Concrete ,Concrete foundation ,Catch basins ,Collectors ,Downpipe ,Concrete slabs ,Steel reinforcement ,Reinforced concrete ,Wall(chambers) ,Wall(partitions) ,Brick exterior ,Brick interior ,Roof ,Circuits ,Electric lines and derivations ,Light points ,Electric sockets ,Ground connection, Hot water pipes ,Drains ,Cold water pipes ,Tap ,Toilet, basin and bathtub ,Thermos/heaters ,Thermal insulation ,Tiling ,Plaster ,Whitewash ,Screed, Floors, Ceiling ,Finishing ,Steel frames ,Wood doors, Shades ,Glass ,Exterior paints ,Interior paints (Guzman et al., 2009).

2-4) Waste sources

It is important to know the waste sources for applying correct waste minimization methods. There are many studies about waste sources that we mention them here briefly.

Skoyles (1987) makes a distinction between direct and indirect material waste and Gavilan and Bernold(1994) grouped the causes of direct and indirect wastes into six categories, including design, procurement, material handling, operation, residual and others such as theft (Silva and Vithana, 2008).

Bossink and Brouwers (1996), based on Gavilan and Bernold (1994) and Cranen et al. (1994), classified materials wastes to seven categories and

investigated source of them. Finally they combined six sources with seven materials and reached to a table that shows any material with its sources.

Based on this categorization, among great contractors in Singapore waste sources were categorized to four categories and many subcategories. Then were scored in a likert spectrum and finally the rank of any sub category have been found. The three top subcategories in any category are as below:

- Design related:
  1) Design changes while construction is in progress,
  2) Designers' inexperience in method and sequence of construction,
  3) Lack of attention paid to dimensional coordination of products,
- Operational related:
  1) Errors by trades persons or laborers,
  2) Damage to work done due to subsequent trades,
  3) Required quantity unclear due to improper planning,
- Material handling related:
  1) Inappropriate site storage,
  2) Materials supplied loose,
  3) Use of materials which are close to work place,
- Procurement related:
  1) Ordering errors (too much or too little),
  2) Lack of possibility to order small quantities,
  3) Purchases not complying with specifications (Ekanayake and Ofori, 2004).

In another study formoso et al. (2002) extensively studied seven material wastes and their sources. They investigated waste sources for steel reinforcement, Premixed Concrete, cement, Sand and mortar, Bricks and Blocks, Ceramic Tiles, and Pipes and Wires.

In a study in china, a widespread investigation about material wastes has been implemented. A questionnaire survey was conducted to investigate the compositions of these construction waste and their sources. One hundred and ten copies were sent to governmental officers, designers, engineers, and contractors and 84 responses are received. Findings shows concrete, cement, brick, timber, tile, steel, and aluminum wastes are the main waste sources produced on construction sites and the sources of these wastes are varied (Wang et al., 2008).

In another research waste sources investigated and categorized in seven types: 1) Lack of planning 2) unclear information 3) source quality problem 4) late information 5) lack of control 6) sources misused 7) information quality problems (Serpell and Alarcon, 1998).

Design problems in many researches are known as one of waste sources. Designers think often many wastes are because of operation in sites, whereas about one third of wastes are because of design.

Keys et al (2000) explain waste production process in design period is complicated, because of many different materials have used in building and many stakeholders that impact on waste production.

Some researchers (Bossink and Brouwers, 1996; Faniran and Caban, 1998; Chandrakanthi et al., 2002) emphasis that lack of knowledge about construction technique in design process lead to waste production. Many studies (Baldwin et al., 2006; Coventry and Guthrie, 1998; Greenwood, 2003; Poon et al., 2004a) describe that designers and architectures have an important role in waste minimization (Osmani et al., 2008).

3) Methodology

In this research for categorizing of construction materials, their sources of waste across supply chain are used.

From literature review and based on interview with experts, 32 sources of waste identified. Because of research limitations all of them cannot be investigated. Thus they ranked by specialists, by First Step questionnaires, in a five options likert spectrum, and so five top sources of waste selected for more investigations.

Through interviews, 18 most important materials have been gathered and categorized considering their waste production in 12 categories. Then impact of selected sources on material waste can be surveyed. This impact can be calculated by many methods. In this research binominal test are used. Second step Questionnaire also had five options and the question was amount of impact of source on material waste .Options "very low" and "low" impact, had been located in a group, and "mediocre", "high" and "very high" impact, in another group.

Hypothesis have been designed as below:

$$\begin{cases} H0: p \leq 0.60 \\ H1: p > 0.60 \end{cases}$$

H0 shows high level of impact and H1 shows that there is no meaningful impact. The calculations were done by SPSS 15, and with amount of significant validity of questionnaires were tested.

The whole questionnaires were sent to 30 specialists in two steps. Then with analysis of impact of source on material waste categorization will be done.

4) Results and discussion

4-1) First Step Questionnaires

Analysis of data's obtained from questionnaire are presented in this section. In this research questionnaires were sent and gathered in two steps.

First Step Questionnaires Contain respondent's properties and waste sources ranking. Second Step Questionnaires Contain impact of selected sources on material waste.

Every Questionnaires will Analyzed and the results will be used in next steps.

4-1-1) Respondents' properties

The results of Questionnaires show that 73.3 % of respondents were bachelor, 23.3 % were master and 3.3 % were PHD. Also 76.7 % of them were construction engineer, 23.3 % architectural engineer and 10% mechanical engineer, and 23.3% of them had a related background between 20-30 years, 66.7% between 10-20 years and 10% between 3-10 years.

4-1-2) Ranking sources of material waste

From literature review and interviews, 32 sources of material waste were derived.

These sources of waste were ranked by questionnaire, Fig.1 shows the results.. It exhibits that the five sources have the highest rank as below:

1. Traditional construction methods,
2. Lack of design commensurate with materials exist in market,
3. Lack of coordination between supply chain,
4. Lack of proportionate material ordering of purchasing section,
5. Lack of production of material with variant dimensions,
6. Other sources were omitted because of research limitations.

4-2) Second Step Questionnaires

Whereas investigation of all construction materials and their sources of waste are higher than the capacity of this research, by using expert's opinion, some materials which had higher importance in waste, were selected for another steps. Selected materials are: Cement, gypsum, sand, tile, mosaic, ceramic, stone, gypsum board, cement board, shard, brick, block, glass, steel, reinforcement steel, water, paint, and pipe.

Then in this section result from questionnaires were entered to SPSS. It was intended to investigation of impact of sources, so the test proportion was assumed 0.6 and cut point 2.5. This is because of the options "very low" and "low" was in one side and options "average", "high" and "very high" were in another side. Using binominal test for any material a matrix was acquired that shows significants and acceptance of assumptions. Finally Table 2 shows effective sources of waste for any material. All significants are lower than 0.05 and so all of them are valid.

4-3) Analyses of Second Step Questionnaires

Here impact of five below sources on material waste are analyzed.

- Source number1 (S1): lack of design commensurate with materials exist in market,
- Source numbe2 (S2): traditional construction methods
- Source numbe3 (S3): lack of coordination between supply chain
- Source numbe4 (S4): lack of proportionate material ordering of purchasing section
- Source numbe5 (S5): lack of production of material with variant dimensions.

Some new results were achieved with observation of questionnaire as demonstrated below.

- First result: new classification of material based on waste sources, weight based material and dimensional material,
- Second result: presence of source number 3, lack of coordination between supply chain in both categories of materials effective waste sources,
- Third result: presence of source number 3, lack of production of material with variant dimensions, in both categories of materials effective waste sources,
- Forth result: presence of two incongruous sources number 1 and 4 with source number 5 in waste sources of one material, named pipe.

4-3-1) Result 1:

It was achieved that, there are separate effective sources of waste for any kind of materials. In another word in some materials the weight is the most important parameter while using.

In these materials sources number 2, 3 and 4 affect waste production. Also in some other kind of materials the dimensions is the most important parameter while using. In this case the sources number 1, 2, 3 and 5 affect waste production.

When the material is type1, source 1 and source 5 (traditional construction methods, lack of design commensurate with materials exist in market) are not effective on their waste production, and another sources like lack of proportionate material ordering of purchasing section, is effective instead of that. Vice versa if a material be type1, lack of proportionate material ordering of purchasing section is not effective.

Fig 1: Ranking of 32 sources of waste

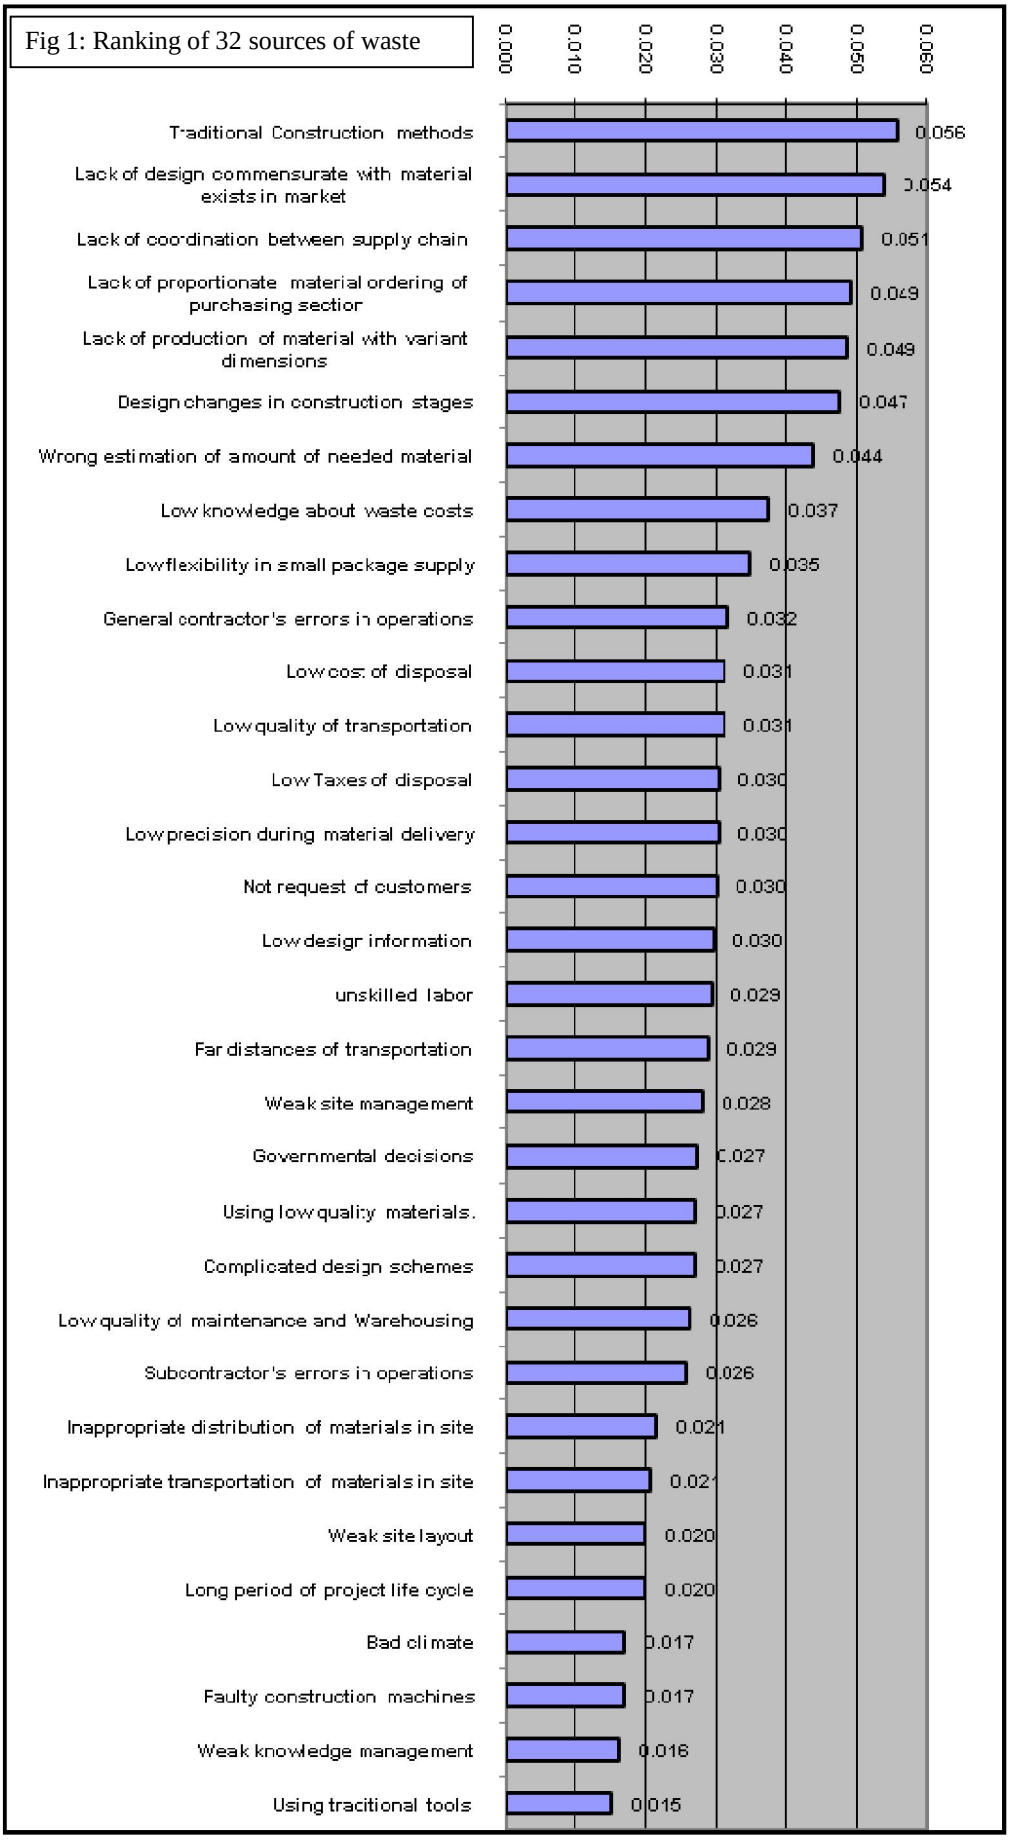

Table1: weight based and dimensional materials

Materials types	Important parameters when use	Effective sources	Non-Effective sources	Measurement units	Example of materials
Weight based materials	Material weight	2,3,4	1,5	kilogram	Cement, gypsum, sand, water and paint
Dimensional materials	Material dimensions	1,2,3,5	4	Meter	Brick, adobe , block, Tile, mosaic, ceramic, stone , steel, reinforcement steel, glass, gypsum board, cement board

Table3: questionnaire results about Impact of selected sources on waste production of Pipes

pipes	Important parameter when used	Non-Effective sources Of waste	Effective sources Of waste	Materials type
Looped pipes	dimensions	3,4	1,5	Type1
Branch pipes	dimensions	1,3,5	4	Type2

It is important in explanation of locating two sources 1 and 5 close to each other, that these two sources are inherently similar. These two sources are two side of a subject and their both goal is description of non alliance between design and products of market.

If materials with variant dimensions be available in market, contractors can build any complicated design without any waste. Because they can reach to the design with selection of a module and correspond materials, and therefore there is no need to cutting and breaking materials in end of building items and elements.

In another hand if designer accepts that suppliers cannot produce materials in any variant dimensions because of economies of scale, contractors will not be enforced to do cutting works on material on site. Hence it is emphasized that sources 1 and 2 are supplement.

Thus with these analysis new categorization of material are obtained. The First category is weight base material that sources 2, 3 and 4 affect their waste, and second category is dimensional materials that sources 1, 2, 3 and 5 affect their waste. This categorization can be summarizing in Table 1.

Weight based material are materials like cement, gypsum, sand, water and paint that from contractors view, their weight are important when using them in building, and basically their dimensions are not important in their usage. For example in foundation concreting of a building, A kilogram sand with B kilogram of cement and C kilogram of water should be mixed and never be told A meter of cement or B meter of sand. Because their unit is kilogram not meter and effective parameter of their usage is their weight, not their dimensions.

In a good condition these materials are purchased in pallets or sacks and are transported to site. Often purchaseing department does not buy the required amount of material in the site and its amount is more than need. In this case some part of sacks that are semi used or none used, will be mixed with the site floor soils and will be wasted often as a powder, because of lack of packaging, poor maintenance and traditional mixing methods. Since this act repeat several times in project lifecycle, role of purchasing department is very important in coordination between orders and needs.

In a bad condition that takes place more often in projects, some of these materials are bought in mass volumes, and transported to the site with big trucks and spilled in a corner of site. Unusing materials confidently will be mixed with site floor soils and wasted. Thus source 4 is one of the effective waste sources of weight based material and sources 1 and 5 that are involved with design term are not effective in their waste.

Dimensional materials are materials like brick, shard, block, tile, mosaic, ceramic, stone, steel, reinforcement steel, and glass that in the view of contractors, when using in building, their dimensions are important and their weights don't have significant role. For example in walls it is used bricks with dimensions A*B*C meters and it isn't apply F kilogram brick, because its unit is meter not kilogram and effective parameter of its usage are its dimensions not their weight.

In usage of these materials, contractors will use products available in market and if dimensions and their modules were not accordant with building dimensions, need for cutting will browse. Here two works can be done, production of material with variant dimensions, requisition from designer to design commensurately with market's products. Thus source1 and 5 are effective sources of waste in dimensional material and sources4 are not effective in their waste.

4-3-2) Result 2:

This result is supplement of result1. It was observed that source3, lack of coordination between supply chain, is in two categories of sources of both weight based and dimensional materials. It should be noted that source3 are a general state of sources 1, 4 and 5. In another word when designers don't design commensurate with material available in market; failure happens in coordination between supply chain. This failure itself can be because of lack information, lack of willing or lack of experience and knowledge in coordination of sketch with materials available in market.

In another hand when purchasing section of a project does not coordinate with construction section of project, indeed failure in supply chain has happened. This failure also itself can be due to lack of willing or lack of experience and knowledge or lack of accurate calculation of need amount. Also when producers and suppliers cannot produce any variant dimensions of materials, failure in coordination happens between supply chain, and this failure is itself due to economic of scale. Indeed with above analysis it can be known that source3 is a general concept of all sources 1, 4 and 5.

Source3 is along with source1 and 5 in production of waste in dimensional materials, and contemporary with source4 in production of weight based materials waste. The reason is that respondents believe coordination between design section and suppliers between many coordinations in supply chain, is effective in production of waste inmaterial type2, and coordination between purchasing section and construction section is effective in production of waste in material type1. Thus source3 conceptually are effective in production of both material type1 and.

2. With summering above analysis Fig .2 and 3 will be achieved

There is some important point about Fig.2 and 3: First point is that Fig .2 and 3 shows position of any sources in supply chain, conceptual relation between sources 1 and 5, partition between sources 1 and 5 with source 4, and position of sources 1, 4 and 5 under general source3.

Another point is non-effectiveness of other non-coordination in production of waste.

Another important point is that, source4 have also its supplement like source 1 and 5. Its supplement is miss-approximation of amount of need for materials. This source had seventh rank in production of waste in material and was deleted from interring to another step. Its inducement is construction section. It means that source4 is happen in the side of purchasing section and source7 in the side of construction side.

The final point is that, source1 and 5 are kind of non- coordination between organizations and source1 and 5, are kind of non- coordination among an organization.

4-3-3) Result 3:

Presence of source2 in production of waste in both two material types should be described in other way. This presence is not similar to presence of source3. Presence of source3 was due to generality of that in comparison with sources 1, 4 and 5.

But source2 are effective in waste of all types of materials because of change in the production paradigm. In traditional construction methods amount of pre-engineering is low and often building activities are done in the construction site. But using industrialized methods, many activities are done in factory and building parts are produced in production line and transported to site to install and Montage. In this method project managers can increase portion of pre- engineering and also quality control can be done in factory.

Over above cases, since parts are produced in firm and all of them are distinct where will be used, design Sketch is completely compatible with produced parts. Thus every part are produced by contractor orders and based on design Sketch and are known where it will be used. **(**Jaillon et al., 2009; Silva and Vithana, 2008;Tam, 2008; Tam et al. 2007). In this way there are no needs to lots of adjustments in construction site.

Therefore changing production paradigm from traditional to industrialized construction will hold feasibility of mistake occurrence. Sometimes if it be happened any mistake in production line or in ordering, the part will not be used in that project never, because of non-feasibility of correction or cutting works. In this case all of building part that has produced is waste unless using that in another project and because of cost and transportation problem it is not rational. For example in prefabricated concrete elements there is no chance for correction if there is any misalliance.

Hence until the construction is in traditional paradigm, feasibility of waste production is high in any material. With these analyses presence of source2 among sources of waste in both material types is reasonable.

4-3-4) Result 4:

A new result was presence of source 1, 4 and 5 with source3 in production of waste in one material, named pipe. From result 4 it was shown that S4 is specific for waste production of material type1 and S2 and S5 are specific for waste production of material type2. Question is that how they can be among sources of waste in both material waste sources. The single reasons are that some kinds of pipe are material type1 and some others are type2. With a watchful observation it can be seen that there are two kind of pipe.

Pipes for transmission of water are in loop form in the market. Contractors can cut it in any size. In these pipes there will be no waste because of cutting works and indeed S1 and S5 are ineffective in their waste and just S4 are effective. In another word in purchase section over order, more than need, remain part will be unused and because this ordering will happen so many times in a project, feasibility of control, maintenance and management of these remained part is not easy.

In another word although important parameter in usage in these pipes are their dimensions, but because their waste sources is S4 and S1 and S5 are not effective, it will be material type1.

In another hand Pipes for transmission of sewerage and city gas are in branch form in the market. If designer does not design commensurate with existing materials in market or there are not variant materials in market, Contractors should cut pipes. In this kind of pipes remained parts of cutted pipes are waste. It cannot be used again because of technical consideration and leakage. So S1, S5 are effective waste sources thus branch pipes because of important parameter in usage of them are their dimensions, and because their waste sources is S1 and S5, and S4 are not effective, it will be material type2.

Also S3 is a generality state of S1, S4 and S5 then it will be among effective sources. By these analysis it will known that why S1 and S5 are contemporary waste sources of pipes. Table 3 summaries these analyses.

5) Conclusions

Construction wastes have a great spread, and any of them have its source . To recognize that sources, impact of selected sources on waste of selected

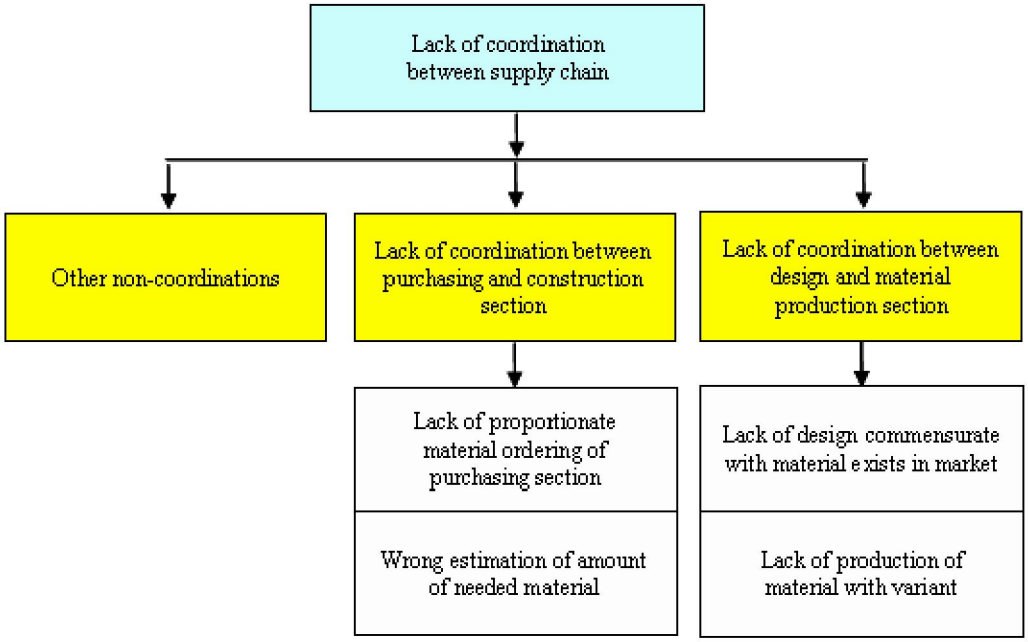

Fig. 2: non-cooardinations between supply chain

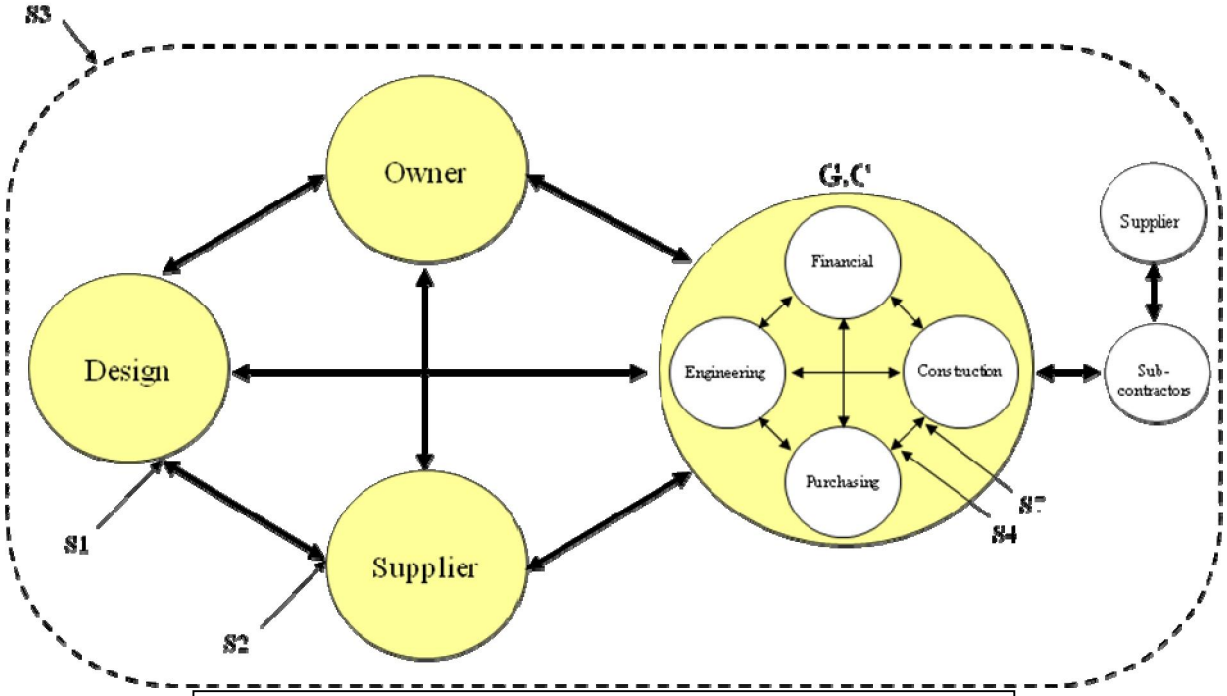

Fig.3: Position of waste sources in a typical construction supply chain

materials were investigated. Some new results were yielded. First it was clarified that materials have their specific waste sources based on their inherent properties.

Materials inherent properties are such as, methods of usage, important parameters when use, how to supply and how to maintain, measurement units, that impact on process of row material conversion to final product and therefore impact on methods that wastes are produced in any material.

With investigation of questionnaire it was identified that those material which their dimensions are important in their usage, some sources are effective in their waste that related to building design. In these materials if there were no coordination between design and materials exist in market, it will lead cutting in dimensional non-coordinations and thus waste will be produced. Whereas dimensions are the main aspect of inherent properties in these materials, their names will be dimensional materials.

Also in weight based materials, that their weight is important in their usage, some sources are effective in their waste that related to amount of purchasing. In this materials if exist any non-coordination between site need and amount of purchasing material, because of remaining material and repetition of this act in project life cycle, and lack of protection of material in site, it result in waste production. Whereas weight is the main aspect of inherent properties in these materials, their names will be weight based material. Non-coordinations between supply chain, cover both

Non- coordination between design and materials exist in market, and Non-coordination between site need and amount of purchasing material, it is effective in waste production of both two types of materials. Using traditional construction methods in contrast with industrialized methods is effective in both two types of materials too. If construction managers change their paradigm to industrialized methods, because of non-feasibility of errors in design and amount of purchasing, the feasibility of waste production will reach zero.

Acknowledgements

The authors like to thank Mapsa Company for providing relations between us and practitioners to contribute them through questionnaire and Interview. We would particularly like to acknowledge all practitioners and specialists that help us in making a good framework for data gathering and their rapid responses to questionnaires.

We also gratefully thank the comments from Dr.Jahangir Darvish and Ahmad Ghanaatian for their helpful comments in the research process.

Abstract: The study was conducted to investigate the antitumor activity of miso, storage at different period or prepared with different starters, on human cell lines {HEPG2 (liver carcinoma), MCF7 (breast carcinoma), and HCT116 (colon carcinoma)}. The highest inhibitory effect on liver and breast carcinoma was seen when miso used after fermentation/aging zero time without storage period. Miso with different storage period (zero, 6 months and 5 years) has the same effect on colon carcinoma. Preparation of miso with different mixture of starters was also investigated on the same human tumor cell lines in culture. Miso prepared with *A. oryzae* and *Bacillus subtilis* starters inhibited the proliferation of human tumor cell lines culture with a wide variation in LC_{50} values (2.97, 3.37 and 3.37 µg/ml for MCF7, MCT116 and HEPG2, respectively). Miso prepared with *Aspergillus oryzae* and *Pleurotus ostreaus* starters inhibited human tumor cell line cultures with different LC_{50} values (10.9, 17.5 and 24.3 µg/ml for MCF7, MCT116 and HEPG2, respectively). The miso prepared with *A. oryzae* and *Rhizopus oryzae* effect only on MCF7 and HEPG2 with high LC_{50} values (25.5 and 35.8 µg/ml, respectively). We can conclude that the mixture of *A. oryzae* and *Bacillus subtilis* has the best effect among the other mixture of starters. The results indicated that all of fermented soybeans products with different mixture of starters contained higher isoflavones compounds than unfermented cooked soybeans. Moreover, soybean fermented with *B. subtilis* showed highest amount of isoflavones. Therefore, miso can be used as anticancer.

1. Introduction

Soybeans (*Glycine max* (L.) Merr.) are highly regarded as a healthy food in several Asian countries and are widely consumed as soymilk, tofu and fermented products. Fermented soy foods, such as *paste*, are important components of the Korean diet in much of the world. *Soy paste (Doenjang)* has been traditionally manufactured from *Koji*, which is a fermented rectangular block of crushed cooked soybeans. The primary microorganisms involved in *Koji* fermentation are *Bacillus subtilis* and molds such as *Rizopus*, *Mucor*, and *Aspergillus* species (Park and KO 2005; Dajanta et al., 2009). Soy paste fermented with various filamentous fungi including *Aspergillus awamori, Aspergillus oryzae, Aspergillus sojae, Rhizopus azygosporus and Rhizopus sp.* lead to the increased antioxidant activities, total extractable phenolic compounds and anthocyanins content after fermentation (Lee et al., 2007; 2008). Fermentation of soybean and other ingredients by microbial starters is the most important step during manufacturing of soybean fermented products. During fermentation and due to excretion of hydrolytic exoenzymes by microbial starters, precursors such as phenolic compounds (genistin and diadzine) are converted by β- glucosidase into more biologically active forms of isoflavones such as genistein and daidzein (Hsiang et al., 2005). Protein and fats are also converted into amino acids and bioactive peptides, and fatty acids by proteases and lipases respectively (Dziuba et al., 2003).

In the past several years, soy and its constituents have garnered considerable attention, from both

researchers and health practitioners. Epidemiological data which indicated people from Asian cultures have lower rates of certain cancers, including cancer of the breast, prostate and colon, sparked an interest in soy as a contributing factor. Numerous epidemiological, human, animal, and *in vitro* studies have demonstrated that soy isoflavones are effective chemopreventive agents for certain types of cancer (Head, 1997). *In vitro*, high concentrations of the isoflavone genistein inhibit most types of cancer cells and some animal studies suggest that genistein inhibits metastases (Menon et al., 1998). Further controlled human trials are needed to confirm the preliminary findings reported in these studies. Jung et al. (2006) reported that miso could prevent cancer by decreasing tumor formation and increasing natural killer cell activity in spleens. Miso goes a long way towards providing people with their daily needs for the trace minerals zinc, manganese and copper. Miso has antioxidant properties and it has the ability to decrease the lipid peroxidation (El-Shenawy and Abu Zaid, 2011).

In the present study, we have tested the effect of miso that prepared with single starter (*Aspergillus oryzae*) and stored for different period (Zero, 6 months and 5 years) on three human tumor cell lines. In addition, the effects of three different mixture of starters were examined on cell proliferation of the same cell lines [HEPG2 (liver carcinoma), MCF7 (breast carcinoma) and HCT116 (colon carcinoma)].

2. Materials and Methods

2.1 Microorganisms and Media

The microorganisms included in this investigation are commonly used as starters in the fermentation of many traditional, oriental food products. The mold *Aspergillus oryzae*, is used to make traditional doenjang, a Korean fermented soy paste (Kim et al., 2009), *Rhizopus oryzea*, used in preparation of temper, Indonesian fermented food (Haron et al., 2009) and the bacterium *Bacillus subtilis* was found among the microbial community in doenjang (Yoo et al., 1999). Potato dextrose agar was used for growth and maintenance of all mold strains, and nutrient agar medium was used for the bacterium *Bacillus subtilis.*

2.2 Preparation of miso

Miso was prepared in two major steps. In the first step, microbial starters were prepared as follows: wheat bran seeded with *Aspergillus oryzea* fungi as singly at approximately 1-2 X 10^6 cfu/g. Then, it was spread at the surface of a layer of 20 Kg of boiled and steamed wheat at a ratio of 1% and incubated at 25 ºC for 3 days in order to encourage growth and multiplication of microbial starters. Secondly, the growing starter was added to 40 Kg of boiled and steamed soybean mixed thoroughly in presence of 16% salt and moisture content was controlled at approximately 12.5%. The resulting paste represents the miso at zero time. If the paste was stored in jars for fermentation and aging, the resulting miso represents 6 months or more (ISO, 2006). During all the experiment, fermentation/aging for 6 months has been used except for antitumor activity experiment; three different times of fermentation/aging [zero (1), 6 months (2) and 5 years (3)] have been investigated. Miso was also prepared with different mixture of starters; *Aspergillus oryzae* and *Pleurotus ostreaus* (4) or *A. oryzae* and *R. oryzae* (5) or *A. oryzae* and *B. subtilis* (6) (Abu Zaid *et al.* 2010). The bacteria were routinely cultured on nutrient agar and their stock cultures were maintained at -80°C in 20% glycerol. For inoculums preparation, the bacteria were grown in nutrient broth at 37°C for 24 h. The cells were then harvested, re-suspended in sterile distilled water and properly adjusted to obtain a concentration of 10^4 CFU/mL. The suspension was served as the inoculums for soybean fermentation.

2.3 Determination of miso total fatty acid and amino acids

Gas liquid chromatography was applied to identify the fatty acids present in different types of miso. Lipids were extracted by a modified method described by Xu and Beardall (1997). Amino acid determination was performed according to the method of the Official Journal of the European Communities 19-9-98 (AOAC, 1995).

2.4 Determination of miso Isoflavones

The method described by Coward et al. (1993) was used after modification. After freeze drying, samples were extracted using 80% aqueous methanol (10 ml/g) and stirred for 1.0 h at 60 °C. The mixture was centrifuged at 2500 g for 10 min and the supernatant was decanted into a round bottom flask. The pellet was re-suspended in 10.0 ml of 80% aqueous methanol and centrifuged. Then, both

supernatants were combined and taken to dryness using rotary evaporator. Then, dried extract was re-dissolved in 5.0 ml of 50% aqueous methanol, and the lipid fraction was removed by partitioning in hexane (4 X 20 ml). The aqueous methanol phase was evaporated to dryness using rotary evaporator and the dried residue dispersed in 10 ml of 80% aqueous methanol. The mixture was centrifuged using an eppendorfed by microfuge just prior to analysis by HPLC. Separation of isoflavones was achieved by high-performance liquid chromatography (HPLC) on a 30 cm x 0.45 cm, Aquapore C8 reversed – phase column with mobile phase consisting of a gradient of 0- 46.4% acetonitril in 0.1 % (v\v) aqueous trifluoracetic acid at flow rate of 1.5 ml/min. The eluting components were detected from their absorbance at 262 nm. Concentrations of the isoflavones were calculated from standard curves of area responses for authentic isoflavones standards normalized to the constant amount of fluorescein as internal standard was added to each sample.

2.5 Antitumor activities of miso on human cell lines

Antitumor activity of a colorimetric cytotoxicity assay (Skehan et al., 1990). Cell lines: HEPG2 (liver carcinoma), MCF7 (breast carcinoma) and HCT116 (colon carcinoma) were harvested from exponential phase cultures by trypsinization, counted and plated as cell monolayer in 96-multiwell plate (10^4 cells/well) for 24 h. Cells were cultured in Dulbecco's modification of Eagle's medium (DMEM) supplemented with 5% heat-inactivated fetal calf serum (FCS) and 1 mM L-glutamine. Then different concentrations (0, 1, 2.5, 5 and 10 µg/ml in DMSO for HEPG2 and MCF7) or (0, 5, 12.5, 25, and 50 µg/ml in DMSO for HCT116) of miso after fermentation/aging for zero, 6 months and 5 years were added to the wells in triplicate. After 48 h of incubation, cells were fixed, washed and stained with Sulfo-Rhodamine-B (SRB) stain. Excess stain was washed with acetic acid and the attached stain was recovered with Tris–EDTA buffer. Color intensity was measured in an ELISA reader. The relation between survival fraction and extract concentration was plotted to give the survival curve of each tumor cell line after the specified dilution of the extract, and the LC_{50} was calculated.

2.6 Statistical analysis

Results are expressed as mean ± SE, and were obtained from at least 5 samples. Statistical analysis was performed using one-way analysis of variance (ANOVA) followed by the Bonferroni's *post-hoc* test (level of significance; $P \leq 0.05$) using SPSS version 15, statistical program (Hill, 1971).

3. Results

3.1 Total fatty acid, total amino acid and total isoflavones

The highest level of fatty acid and total amino acid (Table 1) were detected in the miso that prepared with *A. oryzae* and *R. oryzae* (5) (102.55 ± 7.29 and 30.2 ± 0.27, respectively). However, the highest level of total isoflavones was determined in miso that prepared with *A. oryzae* and *B. subtilis* (6). The concentration of isoflavones in unfermented soybean was too low as compared with all other types of miso.

3.2 Effect the storage time of miso on human tumor cell lines

The survival fraction of HEPG2 and MCF7 cell line was plotted against the different concentrations (1-10 µg/ml) of miso with different storage period (0, 6 months, 5 years). The concentrations of miso that reduced survival of carcinoma cell line of liver (HEPG2) to 50% were 1.96, 2.88 and 3.5 µg/ml for zero, 6 months and 5 years of fermentation, respectively (Fig. 1). The concentrations of miso that reduced survival of breast (MCF7) carcinoma to 50% were 0.982, 1.3 and 1.14 µg/ml for zero, 6 months and 5 years, respectively (Fig. 2). The highest inhibitory effect on liver and breast carcinoma was seen when miso used immediately after fermentation (zero time). However, the survival fraction of carcinoma cell line of colon (HCT116) was plotted against the different concentrations (5-50 µg/ml) of miso (Fig. 3). Effect of different storage periods of miso on colon carcinoma was approximately the same; 14.4, 13.0 and 14.3 µg/ml for zero, 6 months and 5 years of fermentation, respectively.

3.3 Effect of different methods of miso preparation on human tumor cell lines

The survival fraction of MCF7, MCT116 and HEPG2 cell line was plotted against the different concentrations (5-50 µg/ml) of miso that prepared with different mixture of starters. The concentrations

of miso that reduced survival of breast (MCF7) carcinoma to 50% were 2.97, 10.9 and 25.6 µg/ml for 6, 4 and 5, respectively (Fig. 4). The concentrations of miso that reduced survival of carcinoma cell line of liver (HEPG2) to 50% were 3.73, 24.3 and 35.8 µg/ml for 6, 4 and 5, respectively, (Fig. 5). The highest inhibitory effect on liver and breast carcinoma was seen when miso prepared using mixture of *A. oryzae* and *B. subtilis* (6). However, effect of different preparations of miso on colon carcinoma was 3.73 and 17.5 for 6 and 4, respectively. The miso prepared by *A. oryzae* and *R. oryzae* (5) did not effect on the HCT116 (Fig. 6).

Table 1: Effect of different starters on total fatty acid, total protein and total isoflavones of miso

Miso starters	Total fatty acids (mg/ 100g)	Total amino acids (%)	Total isoflavones (mg/100g)
Raw materials (unfermented soybean)	----	----	71.46 ± 6.5
Aspergillus oryzae and *Pleurotus ostreaus* (4)	93.88 ± 6.66*,**	28.6 ± 0.23	571.02 ± 5.12**
A. oryzae and *R. oryzae (5)*	102.55 ± 7.29***	30.2 ± 0.27***	562.73 ± 4.95***
A. oryzae and *B. subtilis* (6)	77.24 ± 4.3	26.52 ± 0.24	1090.95 ± 9.69

The data presented as mean ± SE (n=5). Statistical analyses were performed with SPSS version 11.5 (SPSS Institute, Chicago, IL). One-way analysis of variance (ANOVA) was used to assess the statistical significance of the continuous variables. --- Not detected. $^{*}p < 0.01$, (4) compared with (5). $^{**}p < 0.05$, (4) compared with (6). $^{***}p < 0.05$, (5) compared with (6).

4. Discussion

This study describes the *in vitro* antitumor activity of Miso, a fermented soybean food, on liver, breast and colon cancer human cell lines. Different types of miso, prepared with three starter culture mixtures and of different fermentation periods, were evaluated and their fatty acid, amino acid and isoflavone contents were determined. Finally, the effect of different miso on the inhibition of proliferation of cancer cell lines was studied.

Traditionally fermented soybeans contained higher concentration of Isoflavones than unfermented cooked soybeans. However, *B. subtilis* fermented soybeans appear to be
a better source of bioavailable soy isoflavones as it has been reported (Kano et al., 2006; Dajanta et al., 2009**).** Miso may be of particular interest for using as antitumor agents against liver, breast and colon carcinoma. The present finding indicates that miso storage for different period were able to inhibit the liver, breast and colon carcinoma. Miso has the ability to inhibit the carcinoma of liver and breast with low concentration at zero time (without storage period) after preparation. However, there is no significant different in the LD_{50} of miso that effect on colon carcinoma by using different storage fermentation period. However, Jung et al. (2006) demonstrated that prolonging the fermentation period (24 months) when making soy paste increases its antitumor effects *in vivo*. The longer storage period of miso over three years led to increase isoflavones concentrations (Yamabe et al., 2007). The time course of the isoflavone composition during the fermentation/aging process of rice-koji miso indicated that glycosides decreased from 86.4% to 44.9% after 6 months but aglycones increased from 9.6% to 53.3% (Yamabe et al., 2007). Soy

isoflavones have also been reported to reduce the risk of prostate cancer by acting as anti-cancer agents blocking the growth of hormone dependents cancers (Heald et al., 2007).

The present study proved that fresh prepared miso in better than miso after storage periods against liver and breast cancer. This result confirmed by the observation of Weed et al., 1985 and Park et al., 2003. They reported that the cooked soybeans showed less inhibition of the mutagenicity than raw soybeans, probably due to the destruction of the trypsin inhibitor by heat treatment (Weed et al., 1985). Park et al. (2003) also noted a marked antimutagenic activity in doenjang, For example, miso, tempeh and natto, fermented soybean products prepared with A. oryzae, showed an antimutagenic activity 2.5-fold more than that of unfermented milk. Soybeans inhibit mammary tumors in models of breast cancer. The lower antimutagenic activity of miso is probably due to the smaller portion of soybeans used and short fermentation period (Park et al., 2003).

In this study, the relationship between two types of starts that could be bacteria or fungi was evaluated for preparation of miso. Human cell lines have not been used as an *in vitro* model for studying the potency of miso that prepared with mixture of starters as anticancer. There is no data concerning the influence of miso on the cancer human cell lines MCF7, MCT116 and HEPG2 and for this reason it is very difficult to compare our results with those reported by other authors. Miso was prepared from *A. oryzae* and *B. subtilis* (6) has more potent effect on human tumor cell line MCF7 and reached almost plateau level at all tested concentrations (5-50 µg/ml), causing 50% cell death. There was a dose-dependent relationship of increased number of dead cells (MCF7) with increasing concentration of *A. oryzae* and *R. oryzae* (5). The concentration of miso that prepared with mixture of starters (6) has the most potent effect of the human cell lines HEPG2 and MCT116 as compared to other mixtures (4) and (5). These results could be due to the highest level of isoflavones that detected in miso that prepared with the mixture (6). This present study suggests a promising use of *Bacillus* starter cultures in improving isoflavone compounds especially the isoflavones which would benefit for novel functional food development. This result is in agreement with Dajanta et al. (2009).

We can conclude that miso decreased growth of various human cancer cells and its effect depends on the storage time of miso and the type of the starters. The results indicated that isoflavones suppressed tumor growth of the human cell lines *in vitro*. These results suggest that these different types of miso could induce inhibition of human cell lines in dose-dependent manner.

Oxidative Stress in Brains of Male Rats Intoxicated With Aluminum and the Neuromodulating Effect of Some Forms of Sage (*Salvia officinalis*)

EL-Kholy, W.M.; EL-Habibi, E.M. and Mousa, A.T.
Zoology Dept., Faculty of Science, Mansoura University, Mansoura, Egypt
eelhabibi555@yahoo.com

Abstract: The present study was designed to investigate the role of oxidative stress and the status of antioxidant system in the management of aluminum chloride (AlCl3) induced brain toxicity in rats and further to elucidate the potential role of three forms of *Salvia officinalis* (sage) in alleviating such negative effects.
The results revealed that the levels of thiobarbituric acid reactive substances (TBARS) and protein carbonyl (PC) were significantly increased, however, the activities of superoxide dismutase (SOD) and catalase (CAT) as well as the reduced glutathione (GSH) content were significantly decreased in the cerebral cortex (Co) and hippocampus (Hip) of rats intoxicated with $AlCl_3$. In addition, the lipid profile, total lipids (TL), total cholesterol (TC) and triglycerides (TG) were significantly increased in serum and the mentioned brain regions, while phospholipids (PL), total protein (TP) and serum HDL-C were significantly decreased in $AlCl_3$ group. Additionally, serum and brain regions acetylcholinesterase (AChE) as well as alkaline phosphatase (ALP) and acid phosphatase (ACP) activities were significantly increased. On the other hand, the results exhibited that, sage when given in any form along with $AlCl_3$ was able to regulate the mentioned parameters and the values returned close to the normal ones. It can be concluded that Al-induced neuronal oxidative stress and inhibition of the antioxidant system, accompanied with disturbed lipid profile, total protein and enzyme activities could be the cause of $AlCl_3$ neurotoxicity. In addition three different sage forms, by their antioxidant constituents, could be able to antagonize Al neurotoxicity perhaps by reducing the oxidative stress and improving the antioxidant status and particularly by inhibiting the acetylcholinesterase activity, thus may improve memory and other brain cognitive activities.

Key words: Aluminum neurotoxicity- Alzheimer's disease- *Salvia officinalis* - Lipid peroxidation - Antioxidants-acetylcholinesterase

1. Introduction:

Aluminum has been implicated in many human neurodegenerative diseases; various investigations have suggested that Alzheimer's disease (AD) is more common in areas where Al content in water supplies is the highest (Lynch *et al*., 2000). Alzheimer's disease is a complex, multifactor, heterogeneous mental illness, which is characterized by an age-dependent loss of memory and an impairment of multiple cognitive functions (Mattson, 2004) and has been shown to be associated with both plaques and tangles in the brain. Indeed, the brain is a target of Al toxicity which can alter blood-brain barrier (BBB) mediating Al transport to the brain (Zatta *et al*., 2002a) and gets deposited in the cortex (Platt *et al*., 2001) and hippocampus (Struys-Ponsar *et al*., 1997). This can be occurring by altering the physiological ligands present at these barriers in states (Yokel, 2001).

Possible mechanisms of Al induced neurotoxicity have been related to cell damage via free radical production and oxidative stress (Kumar *et al*., 2009a, b). High aluminum levels exposure leads to increased central nervous system (CNS) Al concentrations that altered CNS concentrations of the essential trace elements; iron and manganese and increased the susceptibility of CNS to lipid peroxidation (LPx) (Oteiza *et al*., 1993).

Oxidative stress, caused by reactive oxygen species (ROS), is known to cause the oxidation of biomolecules leading to cellular damage. Increased lipid peroxidation (LPx) is the major consequence associated with oxidative stress. It is also speculated to be pathologically important in various neurodegenerative processes including cognitive deficits that occur during normal cerebral aging, Alzheimer's (AD), and Parkinson's diseases (Gray *et al*., 2003). Alternatively, the most remarkable biochemical change in AD patients is a reduction of acetylcholine (ACh) levels in the hippocampus and cortex of the brain (Jaen *et al*., 1996). Therefore, inhibition of acetylcholinesterase (AChE), the enzyme responsible for hydrolysis of ACh at the cholinergic synapse, is currently the most established approach to treating AD (Akhondzadeh *et al*., 2003).

On the other hand, *Salvia officinalis* (sage) specially the oil had apparent dual cholinergic activity, as it was active on both, AChE and

butyrylcholinesterase (BuChE) (Savelev *et al.*, 2004). Besides the cholinergic activity, there has already been a wider range of activities reported for the genus *Salvia*, which may be relevant for CNS disorders. These include antioxidant (Celik and Isik, 2008 and Carla *et al*., 2009), nicotinic activity (Wake *et al.*, 2000), anti-inflammatory properties (Moretti *et al*., 1997), and glutamergic activities (Kuang and Xiang, 1994). The essential oils of the plant, also, tested for its memory-enhancing effect (Akhondzadeh *et al*., 2003). Therefore, the main goal of the present study was to examine the possible mechanisms by which Al exposure could induce Alzheimer-like condition related alterations in brain of male rats, and extend to investigate the beneficial effects of sage in preventing or modulating these risks.

2. Materials and methods

Material and methods

Chemicals:

Aluminum Chloride ($AlCl_3$) was obtained from agents of Sigma Chemicals (St. Louis, MO, USA). *Salvia officinalis* (sage) oil was obtained from (NATURE'S ALCHEMY) distributed by LOTUS BRANDS, USA. Dried leaves of sage, for preparations of sage tea (water extract and ethanolic extract), were purchased from a local herb market. The taxonomic identity of the plant was confirmed by the botanist of the Department of Botany, Faculty of Science, Mansoura University, Mansoura, Egypt. All other chemicals were purchased locally and were of analytical reagent grade.

Sage extracts preparation:

1- Sage water extract (sage tea): was routinely prepared by pouring 150 ml boiling water onto 2 g of dried grounded leaves and allowing it to steep for 5 min. (Lima *et al*., 2005).

2- Sage ethanolic extract: was prepared according to the method described by Eidi *et al*. (2006). Dried grounded leaves of *Salvia officinalis* (60 g) were subjected to extraction with 300 ml of ethanol (80%) in a glass container for 72 h. The extract was decanted and filtered through Whatman No 1 filter paper into a clean flask. The same procedure was repeated a further two times. The solvent was evaporated using a rotary evaporator, and then the flask was weighed to determine dried weight of extract. The supernatant was reconstituted using 53% ethanol and assayed using serial dilutions and the dose was calculated according to Ghosh, (1971)

3- Sage oil: diluted 1:2 in sunflower oil according to Perry *et al.* (2002).

Experimental animals:

This study was carried out on 48 adult male albino rats weighing 130 ±10 g b.w., supplied by The Urology & Nephrology Center; Mansoura University. The rats were maintained under controlled humidity; temperature (25 ± 2˚C) and light (12h light/ 12h dark). They were fed standard commercial rodent pellet diet and water *ad libitum* (free access to water and food).

Experimental Protocol:

After one week of acclimatization, the rats were divided into 8 groups consisting of 6 animals each. All treatments were continued for 90 days as follows:

1. Normal control
2. Sage water extract (given instead of drinking water) according to Lima *et al*. (2005).
3. Sage ethanolic extract (given orally by stomach tube as 0.1 ml/kg b.w.) (Akhondzadeh *et al*., 2003).
4. Sage oil group (given orally by stomach tube as 100 µl/ kg b.w.) every other day (Perry *et al*., 2002).
5. Aluminum (Al) treated group (mixed with diet as 100mg $AlCl_3$/ kg b.w.) (Bilkei, 1993).
6. Al + sage water extract group (given as in groups 5&2 respectively).
7. Al + sage ethanolic extract group (given as in groups 5&3 respectively).
8. Al + sage oil group (given as in groups 5&4 respectively).

Sample preparation:

At the end of the experimental period, overnight-fasted animals were decapitated, blood samples were collected and sera were separated and stored at -20°C until biochemical assay. The brain was then gently removed; the cerebral cortex and hippocampus were separated on an ice-chilled glass plate as described elsewhere (Nayak and Chatterjee, 2001). The tissue samples were quickly frozen on dry ice, weighed, and stored at -80°C until biochemical assay. Cortex and hippocampus were chosen for the present study because; aluminum affects more severely the cortex and hippocampus regions than any other area of the central nervous system (Urano *et al*., 1997). Also, these brain regions are known to be particularly susceptible in Alzheimer's disease, and have an important role in learning and memory functions (Bihaqi *et al*., 2009).

Biochemical analysis:

Determination of lipid peroxidation product thiobarbituric acid reactive substances (TBARS) was carried out according to the method of Ohkawa *et al*., (1982). Meanwhile, protein carbonyl was

measured spectrophotometrically according to the method of Smith *et al*., (1991). On the other hand, superoxide dismutase (SOD) and catalase (CAT) activities were determined following the methods of Nishikimi *et al*., (1972) and Bock *et al*., (1980), respectively. Additionally, reduced glutathione (GSH) content was determined spectrophotometrically according to the method of Prins and Loose, (1969) as well as Acetylcholinesterase (AChE) activity was measured according to the method of Ellman *et al*., (1961). Alkaline phosphatase (ALP), acid phosphatase (ACP), total protein (TP), total lipids (TL), phospholipids (PL), triglycerides (TG), total cholesterol (TC) in (serum, cortex and hippocampus) and serum HDL cholesterol were determined by using commercial kits from (Biodiagnostic, 29 Tahreer Str., Dokki, Giza, Egypt).

Statistical analysis:

Data were presented as means ± standard error (SE). The statistical analysis was performed with one-way analysis of variance (ANOVA) using SPSS (version 17) software package for Windows followed by *Dunken test*. A p-value of less than o.o5 was considered statistically significant.

3. Results:

Cortex and Hippocampus Lipid Peroxidation (LPx), Protein Carbonyl (PC) and Antioxidants:

As observed in table (1), the statistical analysis showed that the level of cortex and hippocampus TBARS and PC were significantly ($p<0.05$) increased by Al intoxication in comparison with the control value.

Concerning sage only, there were significant ($p<0.05$) decreases and increases in hippocampus TBARS level and catalase activity respectively in the groups administered (ethanolic extract and oil) comparing to the normal control group. Regarding the antioxidants, the data indicated that, Al group exhibited significant ($p<0.05$) reduction in cortex and hippocampus SOD, CAT activities as well as GSH content compared to normal control group.

Sage administration to rats intoxicated with Al caused a significant ($p<0.05$) reduction in the elevated cortex and hippocampus TBARS and PC concentrations compared to Al intoxicated group. The reduction in hippocampus TBARS reached levels below the normal ones and was significant ($p<0.05$), only, in (Al + sage ethanolic extract) group. On the other hand, daily administration of sage preparations to Al intoxicated animals revised the decreases in the cortex and hippocampus SOD and CAT activities as well as GSH contents to marked increases compared to Al intoxicated group.

Indeed, the modulating effects of sage preparations on both the oxidative stress markers (LPx and PC) and the antioxidant system (SOD, CAT and GSH) arrived them to values within the normal ranges where non significant ($p<0.05$) alterations were seen in comparison with the normal group except a significant ($p<0.05$) reduction in Hip LPx of (Al + sage ethanolic extract) and a significant ($p<0.05$) increase in Hip CAT of (Al + sage water extract) and (Al + sage oil) groups as well as in Hip GSH of (Al + sage oil) group.

Serum, Cortex and Hippocampus Total Lipids (TL), Total Cholesterol (TC), Triglycerides (TG) and Phospholipids (PL) Concentrations:

The data presented in table (2), exhibited that, serum, cortex and hippocampus total lipids (TL), total cholesterol (TC), and triglyceride (TG) contents showed significant ($p<0.05$) increases, but phospholipids (PL) exhibited significant ($p<0.05$) reductions in Al intoxicated animals in comparison with normal control.

Concerning sage only, cortex phospholipids content was significantly ($p<0.05$) increased in the groups administered (sage water extract and oil) and in hippocampus of (sage ethanolic extract and oil) groups comparing to the normal control group. But, significant ($p<0.05$) decreases were observed in TC of cortex in (sage water extract and ethanolic extract) as well as Hip TC and TG in the groups administered (sage oil). Such results referred to the benefits of sage preparations, specially the oil for reducing TC and increasing brain PL.

On the other hand, concomitant administration of sage (different preparations) with Al reduced the elevation of serum, cortex and hippocampus TL, TC and TG contents and enhanced serum, cortex and hippocampus PL approaching most of them to the normal values except in case of cortex PL only of (Al + sage water extract) which showed a non-significant ($p<0.05$) increase compared to Al intoxicated animals indicating no protection.

However, the reduction in serum, cortex and Hip TL levels reached to values within normal levels, except Hip TL in Al + sage ethanolic extract which, still, exhibited a significant ($p<0.05$) reduction compared to normal control group. Regarding TC, the reduction was, still, significant ($p<0.05$) in both, cortex of Al + sage ethanolic extract and hippocampus of Al + sage oil groups comparing to control one. Concerning TG, the reduction arrived to values significantly ($p<0.05$) lower than normal in serum TG of Al + sage ethanolic extract and Hip TG of Al + all sage preparations groups comparing to control one.

On the other hand, the enhancement in serum and cortex PL by sage was non-significantly ($p<0.05$) changed in (Al + all sage preparations) compared to normal control. But in the Hip, PL reached to values that still significantly ($p<0.05$) lower than normal in all Al + sage different preparations groups.

Serum HDL-C, Serum, Cortex and Hippocampus Total Protein (TP) Content:

As seen in table (3) serum, cortex and hippocampus total protein content and serum HDL-C showed highly significant ($p<0.01$) decreases in Al intoxicated animals compared to the normal control group. Concerning sage only, total protein exhibited a significant ($p<0.05$) increase in hippocampus of the groups administered all sage preparations compared to the normal control group.

Administration of different preparations of sage to Al intoxicated animals reversed the decrement in serum, cortex and hippocampus total protein contents and serum HDL-C to significant ($p<0.05$) increases compared to Al group. But, there were non-significant ($p>0.05$) elevations in serum HDL-C concentration of Al + all sage preparations except Al + sage water extract group which exhibited a non-significant ($p<0.05$) reduction compared to normal control group. Interestingly, the elevation in TP arrived to the normal levels except hippocampus total protein in Al + sage water extract and Al + sage ethanolic extract which showed significant ($p<0.05$) increases compared to the normal control group. These results indicated pronounced ameliorating effects of sage oil, followed by sage ethanolic extract, the water extract showed the lowest protective effect

Serum, Cortex and Hippocampus Acetylcholinesterase (AChE), Alkaline phosphatase (ALP) and Acid Phosphatase (ACP) Activities:

As shown in table (4), in Al intoxicated rats, there were significant ($p<0.05$) elevations in serum, cortex and hippocampus AChE, ALP and ACP activities compared to normal control ones. Concerning sage only, ALP and ACP activities were significantly ($p<0.05$) decreased in hippocampus of (sage oil) group only compared to normal control one.

On the other hand, significant ($p<0.05$) reductions were seen in all Al + sage treated groups serum, cortex and hippocampus AChE, ALP and ACP activities comparing to Al intoxicated group, arriving the values within the normal levels, with the exception of AChE activity, which was still significantly ($p<0.05$) higher than normal control in cortex of Al + sage ethanolic extract group and hippocampus in (Al + sage oil) group in comparison with normal control.

Regarding ALP activity, it was still significantly ($p<0.05$) higher than the control activities in all Al + sage preparations groups except serum (Al + sage water extract) and cortex Al + sage ethanolic extract groups which showed non-significant ($p<0.05$) elevations (within normal ranges) when compared to control.

Concerning serum, cortex and Hip ACP activities, marked ameliorations were seen, where non-significant ($p<0.05$) decreases and increases were shown respectively compared to normal control animals except hippocampus ACP activity of Al + sage ethanolic extract and Al + sage oil groups which were still, significantly ($p<0.05$) declined comparing to the normal control.

3. Discussion:

Aluminium has an association with the etiology of Alzheimer's disease and some other neurodegenerative diseases. It exerts its toxic effect on nervous system especially at high concentration, causing loss of memory, speech disturbances, dysparaxia, tremors, jerking movement's impaired muscular coordination and paralysis (Drago *et al*., 2008). *Salvia officinalis* (common sage) is a medicinal plant that has strong antioxidant properties (Baricevic and Bartol, 2000). For that reason, the present study aimed to look into the antioxidant potential of various sage preparations against Al neurotoxicity.

In the present study, there were significant increases in the oxidative stress markers lipid peroxidation (LPx) and protein carbonyl (PC) contents following Al exposure for 90 days in both cerebral cortex and hippocampus regions of rats. Such results are in harmony with those obtained by Deloncle *et al*. (1999) and Johnson *et al*. (2005) who reported that the neurotoxicity of Al may be a result of LPx.. Furthermore, Nehru and Anand (2005) reported a significant increase in brain thiobarbituric acid reactive substances in rats after stimulation by Al salts which was known to be bound by the Fe^{3+} carrying protein transferrin, thus reducing the binding of Fe^{2+} and increasing free intracellular Fe^{2+} that causes the peroxidation of membrane lipids and consequently membrane damage. Aluminum, being an inert metal, has been suggested to induce oxidative damage indirectly by potentiating the peroxidative effect of Fe^{2+}. It promotes reactive oxygen species (ROS) formation. ROS subsequently attack almost all cell components including membrane lipids thus producing lipid peroxidation (Christen, 2000).

The findings of the present study, also, showed that the rise in LPx in Al treated rats was accompanied by concomitant decrease in the activity of some antioxidant enzymes involved in the detoxification of

ROS, namely SOD, CAT as well as the level of GSH in the cortex and hippocampus tissues comparing with the control declaring the prooxidant effect of Al. These findings agreed with the antecedent studies of Savory *et al*. (2003) and Johnson *et al*. (2005) whom showed that Al exposure enhanced the neuronal lipid peroxidative damage with concomitant alterations in the enzymatic antioxidant defense status, thus having serious bearing on the functional and structural development of the central nervous system (Dua and Gill, 2001). Similar data recorded a decrease in the antioxidants such as GSH (Wu and Cederbaum, 2003) and SOD activity (Yousef, 2004) in the brain of Al exposed rats (Chainy *et al*., 1996) and human (Dua and Gill, 2001).

Moreover, such results are consistent with the studies indicated that Al intake produced an oxidative stress-related change, contributed to its neurotoxicity (Flora *et al*., 2003). However, in rats, a significant relationship between Al exposure and the presence of oxidative stress was established also by Gómez *et al*. (2005). This could be caused by inflicting damage to membrane lipids, proteins and antioxidative enzyme defense system (Jyoti *et al*., 2007).

The elevation of LPx in the cortex and hippocampus in the present study and other ones (Dua and Gill, 2001) suggested participation of free-radical-induced oxidative cell injury in mediating neurotoxicity of Al. Lipid peroxidation of biological membranes results in the loss of membrane fluidity, changes in membrane potential, an increase in membrane permeability and alterations in receptor functions (Nehru and Anand, 2005 and Albendea *et al*., 2007).

However, the increased Al concentration could deleteriously affect the neurons, leading to depletion of antioxidants and metal ions (Kumar *et al*., 2008) through the induction of free radicals, that exhausting SOD and CAT which function as blockers of free radical processes. These results are in accordance with (Nehru and Anand, 2005) who recorded a significant decrease in the activities of SOD and CAT in brain of rats after Al treatment. Alternatively, the decreased enzyme activities could be related to a reduced synthesis of the enzyme proteins as a result of higher intracellular concentrations of Al (Albendea *et al*., 2007).

The data obtained by the present study illustrated, further, that administration of water, ethanolic extracts of *S. officinalis* as well as sage essential oil to Al treated rats caused a significant decrease in the level of TBARS and protein carbonyl in the cerebral cortex and hippocampus and elevated the SOD and CAT enzymes activities and GSH contents when compared with Al intoxicated rats. Moreover, the plant extracts and oil significantly, improved or restored the normal activities of the antioxidant enzymes (SOD and CAT) and GSH in both of the cortex and hippocampus regions as compared to normal control.

Generally, the antioxidant effects of sage extracts have often been attributed to phenolic and monoterpenic compounds (Ren *et al*., 2003). Flavonoids are a diverse group of polyphenols (Havsteen, 2002) rosmarinic acid being the most representative that possess several modulatory effects, either inducing or decreasing the expression of SOD and CAT enzymes depending on structure, concentration, and assay conditions. Rosmarinic acid is the predominant phenolic compound in sage (Lima *et al*., 2005) and its effects was attributed to the compound's antioxidant properties acting as scavenger of reactive oxygen species (Zheng *et al*., 2004).

In point of fact, all of the tested forms of sage have previously shown to potently suppress hydroxyl radical formation (Kosar *et al*., 2005). Additionally, the protection of cell viability conferred by sage extracts seemed to be due, mainly, to their ability to prevent GSH depletion by their main phenolic compounds, rosmarinic acid and luteolin-7-glucoside. Nevertheless, unknown compounds other than phenolics also seem to contribute to the antioxidant effects of sage on basal GSH levels (Lima *et al*., 2007). However, the later authors (Lima *et al*., 2007) besides other ones Brandstetter *et al*. (2009) showed the ability of sage (mainly the methanolic extract) to increase basal GSH levels, probably by the induction of glutathione synthesis. However, sage ethanolic extract strongly decreased the level of lipid peroxidation compared to Al intoxicated rats, such effect which may be due to its free radical scavenging potential induced by ethanol where various species of Salvia has inhibitory and quenching impact on lipid peroxidation along with enhancement of antioxidant defense system in brain tissue of rats treated with Aluminum (Zupkó *et al*., 2001).

In fact, the glutathione peroxidase system consists of several components, including GSH that effectively remove (hydrogen peroxide) and serves as a cofactor for glutathione transferase, which helps remove certain drugs and chemicals and other reactive molecules from the cells. Moreover, GSH can interact directly with certain ROS (hydroxyl radical) to detoxify them, as well as performing other critical activities in the cell. So, GSH is probably the most important antioxidant present in cells. *Salvia officinalis* had a potent increasing effect on GSH content in brain compared to Al treated rats. Also, the enzymatic antioxidant defense system including SOD

and CAT which can decompose superoxide and hydrogen peroxide in the cells are the main defense against oxidative injuries. The decreased level of these biomolecules may lead to increased severity of Al toxicities in the brain (Tripathi *et al.,* 2009). Most likely, the sage tea effects observed, herein, was a result of interactions and synergisms among the different compounds and metabolites present, which makes it difficult to attribute them to any particular compound or family of compounds (Lima *et al*., 2005).

2- Lipid profiles

The present data indicated that serum, cortex and hippocampus total lipids (TL), total cholesterol, (TC) and triglycerides, (TG) were significantly increased by aluminum ingestion, while phospholipids (PL) and serum HDL-C levels were decreased; such results are in accordance with the results reported by Yousef (2004). Similarly, Wilhelm *et al*. (1996) suggested that long-term exposure to Al specifically altered the brain lipid/phospholipid metabolism and/or their transfer to various membrane systems and resulted in significant changes in phospholipid classes and in cholesterol contents of the rat brain. Alternatively, studies in monkeys revealed the chronic effects of Al exposure on brain physiology, including alteration of the lipid composition and the activities of various membrane-bound enzymes; Al was found to decrease significantly the total lipid, glycolipid, and phospholipid concentrations in the primate brain (Sarin *et al*., 1997). In addition, cholesterol and cholesterol/phospholipid ratios were shown to be remarkably increased, indicating a relevant loss of membrane integrity, and consequently a strong effect of Al on the activity/functionality of various membrane-bound enzymes, including AChE (Atack *et al*., 1983). Similarly, the long-term exposure to $AlCl_3$ was shown to result in a 60 % decrease in the total phospholipids content while total cholesterol content increased by 55 %. It is possible that this altered lipid /phospholipid content and composition could affect the insulation properties of the myelin. The finding may thus have some bearing on loss of short-term memory in Alzheimer's disease.

The increase in serum cholesterol and total lipids due to Al administration indicated, also, a loss of membrane integrity (Sarin *et al.*, 1997). This was further confirmed when Al was found to have a significant effect on the various membrane-bound enzymes (Newairy *et al*., 2009). One possible way to explain the relatively more intense lipid peroxidation due to Al is that the susceptibility to catalyze oxidative cascades which is much easier for lipids than it is for proteins. Moreover, Al exhibited high affinity for phosphate groups and binds to the phospholipid head groups through electrostatic forces, which may disturb the order as well as the other dynamic parameters of the lipid bilayer (Martin, 1986). From the foregoing results it is clear that Al resulted in significant reduction in the phospholipid content accompanied by major compositional changes, which is consistent with membrane hypothesis of AD. According to this hypothesis, in order to make up for the choline deficiency, the neurons try to extract choline from choline containing phospholipids. These results leads to the disruption of cell membranes and ultimately to neuronal cell death (Roth *et al*., 1995). Such elevations in TL, TC together with the reduction of HDL-C following Al intoxication shown herein, represent risk factors for atherosclerosis and decreased blood flow to the brain (ischemia) which may be added to the mechanisms involved in Al-induced neurotoxicity.

On the other hand, the present study showed that treatment of rats with $AlCl_3$ plus different preparations of sage decreased serum and brain total lipids, total cholesterol and triglycerides and enhanced phospholipids and serum HDL-C levels compared to $AlCl_3$ intoxicated group. These results are in agreement with Ninomiya *et al*. (2004) and Carla *et al*. (2009) who found that oral administration of sage significantly lowered total cholesterol, triglycerides in serum of rats; and increased serum levels of HDL-C. Also, Akram and Maryam (2009) showed that oral administration of sage water extract significantly decreased serum cholesterol and triglycerides. These results suggested that *S. officinalis* tea consumption is accountable for the improvement of the lipid profile inducing an increase in the HDL-C particles, contributing, therefore, positively to the control of the dyslipidaemia observed in Type 2 diabetes but also related to other diseases (Nesto, 2005). However, sage modulating results may attributed to several sage natural components have been shown to act on cholesterol metabolism by reducing its absorption or its synthesis, such as catechins (Plana *et al*., 2008). This is in addition to the polyphenols, especially, phenolic rosmarinic acid in sage which has potent antioxidant effects protecting membrane lipids of fatty acids and phospholipids from oxidative stress (Lima *et al*., 2005).

3-Total protein content

The data of the present work showed that Al intoxication caused a significant decrease in the protein contents of serum, cortex and hippocampus protein. These results are in accordance with those

obtained by Nayak *et al*. (2006) and Newairy *et al*. (2009).

Thus, the observed alterations could be attributed to direct or indirect effects of aluminum on protein synthesis and breakdown and interaction with neurotransmitter synthesis and degradation, through a series of reactions that depends on many enzymatic pathways and regulatory mechanisms (Goncalves and Silva, 2007).

The decline in the levels of protein in Al-treated rats is in agreement with Chinoy and Memon (2001) and might be due to changes in protein synthesis and/or metabolism and could be, also, attributed on one hand to an under nutrition and on the other hand to a reduction of the protein synthesis in the liver resulted from Al intoxication as well as to reduced enzymes of protein synthesis as a result of higher intracellular concentration of Al (Tripathi *et al*., 2009).

Alternatively, since GSH has been reported to be involved in protein and DNA biosynthesis so, the reduction in its content and in the antioxidant enzymes (SOD and CAT) resulted from Al intoxication may partly explain the decline in the total protein content. Additionally, Al induced reactive oxygen species (ROS) formation and promoted oxidative stress (Exley, 2004 and Kumar *et al*., 2009 a,b) enhancing peroxidative damage to lipids and proteins of the cellular membranes (Julka and Jill, 1996) is another suggestion for protein decline. Such an explanation, which was confirmed by Jyoti *et al.* (2007), indicated that Al exposure caused oxidative stress inflicting damage to membrane lipids, proteins and antioxdative enzyme defense system. Exposure of proteins to free radicals leads to gross structural and functional modifications including protein fragmentation, formation of cross-links and aggregates, protein peroxides generation, and enzymatic oxidation and degradation or clearance (Albendea *et al*., 2007).

On the other side, the results, herein, indicated that all sage preparations enhanced the protein contents in serum and cerebral cortex and hippocampus of Al intoxicated rats reached them within or near the normal levels comparing to the control group. Regarding the protective mechanisms of sage, it has been speculated that antioxidative properties of sage components may be primarily involved, since changes related to the oxidative stress, where lipid peroxidation and oxidative DNA damage, were shown to be eliminated by sage tea consumption; possibly due, in part, to scavenging the nitrogen oxide or their radical derivatives (Lima *et al*., 2005). Since the antioxidants play an important role in the regulation and maintenance of metabolism in the body against oxidative stress. So, sage constituents with their antioxidant properties overcame the lower in the total protein content perhaps by preventing oxidative stress and protein breakdown and enhancing protein synthesis and antioxidant system. Not only phenolic (Durling and Catchpole, 2007) or other flavonoids (Wang *et al*., 2001), but all other sage components known to be participating in the series of reactions, hence the observed improvement in the present results may be due to all those components.

4- Acetylcholine system:

Cholinesterases are a large family of enzymatic proteins widely distributed throughout both neuronal and non-neuronal tissues. In Alzheimer's disease (AD), analytical as well as epidemiological studies suggested an implication of an abnormal focal accumulation of Al in the brain (Zatta *et al*., 2002b). In this devastating disease, Al may interfere with various biochemical processes including acetylcholine metabolism, and can thus act as a possible etiopathogenic cofactor. Aluminum is known to interfere with cholinergic (Amador *et al*., 2001), glutamatergic and gamma-aminobutyric acid neurotransmission. A disturbance in the enzyme activities involved in the acetylcholine metabolism has, also, been reported following Al exposure (Cordeiro *et al*., 2003).

In the present work, the data obtained showed that Al intoxication caused significant activation of AChE in the serum, cortex and hippocampus. Prior studies have reported the influence of Al on the metabolism of acetylcholine (Jankowska *et al*., 2000). They exhibited that, specifically, there was a selective loss of acetylcholine releasing neurons in the basal forebrain, hippocampus and cortex. However, impaired cholinergic function in AD has been correlated with loss of memory.

Generally, there have been some hypotheses to explain pathogenesis of the disease such as "cholinergic hypothesis" and "amyloid formation hypothesis". Nowadays, the most accepted treatment strategy in AD has been accepted as "cholinesterase inhibitors" that can inhibit acetylcholinesterase (AChE) enzyme in order to increase acetylcholine level in the brain (Akhondzadeh *et al*., 2003). In fact, the most remarkable biochemical change in AD patients is a reduction of acetylcholine (ACh) levels in the hippocampus and cortex of the brain. Therefore, the inhibition of AChE (the enzyme responsible for hydrolysis of AChE at the cholinergic synapse), is currently the most established approach to treating AD (Tariot *et al*., 2000). Al interacts with the cholinergic system, acting as a cholinotoxin According to (Kaizer *et al*., 2005) the alterations in

the lipid membrane could be a decisive factor in changing the conformational state of the AChE molecule. However, another explanation for increased AChE activity following Al exposure could be the allosteric interaction between the cation and the peripheric anionic site of the enzyme (Gulya *et al*., 1990).

On the other hand, the results of the present study showed that sage administration alone or to Al-intoxicated rats led to AChE inhibition. However, it has been reported that *Salvia officinalis* has CNS cholinergic receptor binding activities that may be relevant to enhance or restore mental functions including memory (Wake *et al*., 2000). Similar effects are also observed *in vivo* (Howes *et al.*, 2003), at least for AChE, suggesting that relevant components of *Salvia* can cross the blood– brain barrier and increase cholinergic transmission via cholinesterase inhibition (Perry *et al*., 2002).Similarly, up to date, a number of studies on AChE inhibitory activity of several *Salvia* species have been reported. Among these, the essential oil and ethanolic extract of S. officinalis have been shown to possess anti-cholinesterase activity (Perry *et al*., 1996). This finding is consistent with recent reports established sage benefits to memory following administration of the essential oil in healthy young adults (Andrew *et al*., 2008). Moreover, the essential oil as well as its major components, α-pinene, 1, 8-cineole, and camphor were determined to have uncompetitive and reversible acetylcholinesterase inhibitory activity (Perry *et al*., 2000). Additionally, the constituents contained within *Salvia* oil may combine non-linearly to produce cholinesterase inhibition. A combination of the major monoterpenoid constituents (camphor, 1,8-cineole, borneol, α-pinene and β-pinene) reconstituted in a naturally occurring ratio was significantly less potent than that of the whole oil (Perry *et al*., 2003 and Savelev *et al*., 2004). The monoterpenoids may therefore act synergistically to inhibit AChE.

The activity of the essential oils was concluded mainly to be due to its monoterpenoids. The data indicated that the terpenoids, monoterpenes in particular, may have anticholinesterase activity (Orhan *et al*., 2007). Alternatively, the ethanolic extract of *Salvia officinalis* potentiated memory retention and it has also, an interaction with muscarinic and nicotinic cholinergic systems involved in the memory retention process but to less extent than oil (Eidi *et al*., 2006).

5- Alkaline and acid phosphatases:

The present study illustrated that Al ingestion led to significant elevation in alkaline phosphatase (ALP) and acid phosphatase (ACP) activities in sera, cerebral cortex and hippocampus. Alkaline phosphatase is a membrane-associated enzyme, which predominantly concentrated in the vascular endothelium in the brain. There is a more or less continuous sheath of ALP covering all internal and external surfaces of the central nervous system including the spinal cord and thus it may functionally be part in the blood-brain barrier mechanism. On the other hand, intracellular ACP is largely confined to lysosomes, which primarily respond to cellular injury. Within the brain, the ACP is found to be concentrated in the gray matter, although it shows the activity in the white matter, also, to some extent. However, significant contribution by Al was observed to induce changes in ACP activity (Dasgupta and Ghosh, 1993).

The increased activity of ALP and ACP enzymes in serum & brain of animals treated with $AlCl_3$ are in accordance with the findings of Ochmanski and Barabasz (2000). Also, El – Demerdash (2004) found that the activities of these enzymes were increased in serum of mice fed on wheat containing Al residue of 0.2 g /kg b.w. The present results are further, in consistent with the recent findings of Esmaeili *et al*. (2009) who showed that chronic Al consumption caused significant increases in the activities of ALP and ACP enzymes which could be due to severe damage to tissue membranes.

In addition, the increase in the activity of ALP or ACP in blood might be due to the necrosis of liver, kidney and lung (Sallam *et al*., 2005). Our own interpretation for increased levels of ALP and ACP is the disruption of the blood brain barrier and oxidative damage of tissue membranes, releasing membrane bound enzymes following Al intoxication which is also confirmed previously by Exley (2004) and recently by Esmaeili *et al*. (2009).

Moreover, regarding Al enhanced serum, cortex and hippocampus ACP activities of rats, herein, it was in agreement with the earlier observations recorded altered activities of specific lysosomal hydrolytic enzymes in neuronal tissues (Suzuki *et al*., 1988) due to Al administration. From these observations it can be suggested that Al induced an increase in ACP activity of the brain may be an indication of lysosomal proliferation and increasing catabolic rate. The increased ACP activity may result in phosphate accumulation within the lysosomes, and this in turn may lead to decreased plasma inorganic phosphate concentration (Hussain *et al*., 1990).

In the present work, administration of sage tea, ethanolic extract and oil caused marked reduction in the elevated activities of ALP and ACP in Al

treated rats. Such decrease could be due to the antioxidant properties of sage constituents as polyphenols (carnosol, carnosic acid, and rosmarinic acid) and flavonoids (apigenin) that protect cellular membranes integrity from Al-induced oxidative damage and repair the antioxidant system (Carla *et al.*, 2009), consequently, improve brain structure and function against Al toxicity.

4. Conclusion:

Aluminum plays a pivotal role in the neuropathology of many neurodegenerative diseases including AD and validate the fact that chronic exposure to aluminum causes oxidative damage to the membranes and neural cells affecting memory loss and other cognitive dysfunction and exhaust the antioxidant system. Moreover, it is clearly evident that sage (all forms) has a neuroprotective effect against neuronal structural dysfunction caused by aluminum which may be attributed, mainly, to their high ability to scavenge ROS and augment the repair of the antioxidant system as well as its anti-ChE activity, thus it has been suggested that sage has shown promise in the treatment of many neurodegenerative diseases including Alzheimer's disease.

No fixed pattern of protection was seen specific for the different preparations of sage, but, we can arrange them in the following order: sage oil> ethanolic extract> water extract Future study may be designed and further warrants the need for molecular studies to elucidate the mechanisms underlying the protective effects of sage and its active components.

First Record of Microsporidium *Neonosemoides* Sp. and some Ciliates Infecting *Chrysichthus Auratus* (Bagridae) from the Damietta Branch of River Nile, Egypt

Enayat Salem Ahmed Reda

Department of Zoology, Faculty of Science, Mansoura University, Mansoura, Egypt
enayatSalem40@yahoo.com

Abstract: The present study was carried out as a general survey for the possible ectoparasites that can infect the Nile fish *Chrysichthus auratus*. A total of 52 fish specimens were collected from Damietta branch of River Nile. Examination of the investigated fish revealed that, fish were infected with four ectoparasitic species belonging to three genera. These species were: *Neonosemoides* sp., *Scyphidia* sp. 1, *Scyphidia* sp. 2 and *Ichthyophthirius multifillis*. The first three species were recorded for the first time in Egypt. The recovered parasites have pathological effects on the host fish with subsequent economic losses were discussed.
[Enayat Salem Ahmed Reda. First Record of Microsporidium *Neonosemoides* Sp. and some Ciliates Infecting *Chrysichthus Auratus* (Bagridae) from the Damietta Branch of River Nile, Egypt. Journal of American Science 2010;6(12):1298-1305]. (ISSN: 1545-1003). http://www.americanscience.org.

Key words: *Neonosemoides* sp., Ciliates, *Chrysichthus auratus*, River Nile. Egypt.

1. Introduction:

Microsporidia are obligate intracellular parasites. Infected cells usually enlarge to accommodate the proliferating parasite. In 1968 Wiessenberg coined the term "xenoma" on the host cell with completely changed structure and the parasite proliferating inside it. According to Klaus (2005) microsporidia infect most invertrbrate phyla and all classes of vertebrate. As mentioned by Klaus (2005) there are 17 genera are known to infect fishes; 13 genera infect marine fishes and 4 genera infect freshwater fishes: *Heterosporis* (Schubert, 1969), *Nosemoides* (Vinckier, 1975), *Neonosemoides* (Faye, Toguebaye and Bouix, 1996) and *Pseudoloma* (Matthew, Brown, Larison, Bishop-Stewart, Rogers and Kent, 2001).

Genus *Neonosemoides* is one of microsporidian genera parasitizing freshwater fishes and at the same time produce xenoma which is an important agent of diseases in commercial fishes.

Although there is considerable information on the species of microsporidia (Lom and Dykova, 1992; Sprague *et al*., 1992; Lom, 2002; Lom and Nilsen, 2003), little is known about those from Africa. (Sakiti and Bouix, 1987) recorded *Neonosemoides tilapia* in *Tilapia zillii* from Benin and Faye and Toguedaye, (2005) recorded 4 unidentified species in carangid fishes from Senegal.

External protozoa are cited as major problem in freshwater fishes; sessilines ciliates like genus *Scyphidia* utilize gills and skin as a substrate for attachment.

On the other hand mobilina ciliates like genus *Ichthyophthirius* which is an obligate parasite of gills, skin and fins has a worldwide distribution (Paperna, 1980). It also has been found to cause the white spot disease which is accompanied by severe morbidity and eventually end with fish mortality (Hoffman, 1970). Abu-El Wafa, (1988) and Koura *et al*., (1997), described *I. multifiliis* from some freshwater fishes.

This study aims to contribute to the ciliates fauna infecting *Chrysichthys auratus* with special emphasis on genus *Neonosemoides* as a first record in Africa and to establish a background for further studies.

2. Materials and methods

A total of 52 fish of *Chrysichthys auratus* were collected from Damietta branch of River Nile near El-Mansoura. The collected fishes were transported to the laboratory in tank with good aeration. Fishes were kept alive until required in aerated glass aquaria. Fishes were identified according to Bashai and Khalil (1997).

Fish skin, fins and gills were firstly examined by the naked eye for detection of any macroscopically visible lesions. Samples of mucus were scraped gently from the skin, fins and gills, then spread on a clean slide and freshly examined under phase-contrast microscope for the presence of ectoparasitic protozoans. Some of the positive slids were air-dried and stained according to Klein;s dry silver impregnation method. Other positive slides were also air-dried, fixed with absolute methanol and stained with 10% Giemsa stain.

Detected protozoa were examined freshly, stained and identified according to Shulman (1984) and Lom and Dykova (1992 & 2005). All measurements were taken in micrometers (µm) mean ± SD (range). Figures were drawn with aid of camera lucida.

3. Results

The detected protozoan parasites were classified into two main phyla; Microsporidia and Ciliophora as following:

Phylum: Microsporidia
Genus: *Neonosemoides*
Neonosemoides sp.

Xenomas are white spherical, inhabiting gills range in size from 50-70 µm (mean 60 µm) in diameter. Xenoma consists of a simple lamellar wall measures 2.2 µm, contains only 16 mature macrospores in direct contact with the cytoplasm of the host cells and the three lobes hypertrophic nucleus of host cell. All spores in generally are surrounded by a light zone. Fully formed xenoma appears as "a bag of spores". (Figs. 1A & 3A)

Spore description

Spores are egg-shaped with bluntly rounded poles (Fig. 1B). It measures 3.2±0.2 (3.0-3.4) µm in length X 1.6±0.3 (1.3-1.8) µm in width. The spore has a thin outer finly corrugated layer (exospore), thin inner layer (endospore) and an inner most simple cell membrane. The spore consists of three parts which determine the anterior-posterior polarity of the spore (Fig. 1C).

The anchoring disc (polar cap) is mushroom cap like-shaped and stained as a red granule by Giemsa stain (Lom & Dykova,1992) , which is highly characteristic of the group (Fig. 3A). It is eccentric (subapically) located.

The polar tube; is the first part and is inserted into the base of the polar cap. The manubrium part of the polar tube extends from the cap obliquely backwards. There is an outer sheath around the polar tube, acting as a sleeve, through which the tube slides while extruding.

The isofilar polar filament forms 4 regular and helically arranged coils around the surface of the posterior vacuole in the posterior half of the spore. The second part is the polaroplast; lamellar organelle consisting of an anterior region of closely packed membranes and posterior region of more loosely packed membranes that surrounding the basal part of the polar tube. The third part, is the posterior vacuole, that lies inside the coils of the polar tube and occupies more than one-third of the spore cavity.

The remaining space within the spore and between the polaroplast and the posterior vacuole is occupied by the infective germ itself, the sporoplasm. The nucleus is single, spherical and centrally located between the polaroplast and the posterior vacuole.

Phylum: *Ciliophora*
I-Genus: *Ichthyophthirius*
I. *multifiliis*

This parasite appears as a rounded-shaped ciliated organism (Figs. 2A, 3B & 4A). In heavily infested fish, this parasite could be easily detected by the naked eye inhabiting the gills, skin and fins. It is white in colour, tiny dots, exhibits a sluggish movement and measures 44.2-90.6 µm in diameter (mean 67.4). The body is uniformly covered by dense rows of cilia. The number of meridional kineties are ranged from 77-98 (mean 88), converging anteriorly and apically raised into a pointed elevation. The cytoplasm appears to be grossly granulated containing many small food vacuoles, the horse-shoe macronucleus measures (32.3-44.6) µm in length (mean 38.5) and lies in middle of the body. A rounded micronucleus is almost adhering to the macronucleus. There are many contractile vacuoles.

II-Genus: *Scyphidia*
Scyphidia sp. 1

This ciliate is solitary large parasite, inhabiting gills with cup-shaped body measures 57.6±3.6 (54-61.2) µm in length X 49.9±3.1 (46.8-53) µm in width. Epistomial disc is vaulted and slightly elevated above the peristomial disc. The peristomial disc is narrow and encircles the epistomial disc. The macronucleus is ribbon shaped, sinuous and measures 48.4±4.4 (44-52.8) µm in length. Micronucleus is very small. There are some scattered contractile vacuoles. Transverse striations of pellicle conspicuous and ranged from 80-110 (mean 95). There is non ciliated groove near the narrow scopula (Figs. 2B, 3C& 4B).

Scyphidia sp. 2

This peritrich is solitary parasite, inhabiting gills with cup-shaped body and measures 35.2±2(33.1-73.2) µm in length X 36.3 ±2(34.4-38.1) µm in width. Peristomial disc is narrow. Both epistomial disc and peristomial lips are at the same level. The macronucleus is ribbon-shaped, sinuous, occupies almost all the body cavity and measures 33.6±5(28.6-38.5)µm in length X 5.5±0.8(4.6-6.2). The giant micronucleus situated in close contact with the macronucleus and measures 11.3±1.4(9.9-12.6) µm in length X 2.2±0.4(1.9-2.7) µm in width. Scopula attacted to the host skin directly by a secretory layer of sticky material. Infundibulum is small and extends between the two nuclui by cytopharynx. There is a non ciliated groove situated anteriorly (Figs. 2C & 3D).

Table (1): Comparative description of *Neonosemoides tilapiae* with the present species. (Measurements are in micrometers).

Parameter	*N. tilapiae* Sakiti and Bouix, 1987	Present Species
Xenoma size	120-800	50-70
Xenoma spores number	Many micro and macrospores	16 macrospores
Nucleus	Multinuclei	One with three lobes
Spore length	2.5-3	3-3.4
Spore width	1.5-2	1.3-1.8
Polar filament coils	4-5	4
Host	Cichlid *Tilapia zillii*	Bagrid *Chrysichthys auratus*
Site	Gills	Gills
Locality	Benin (West Africa)	Egypt

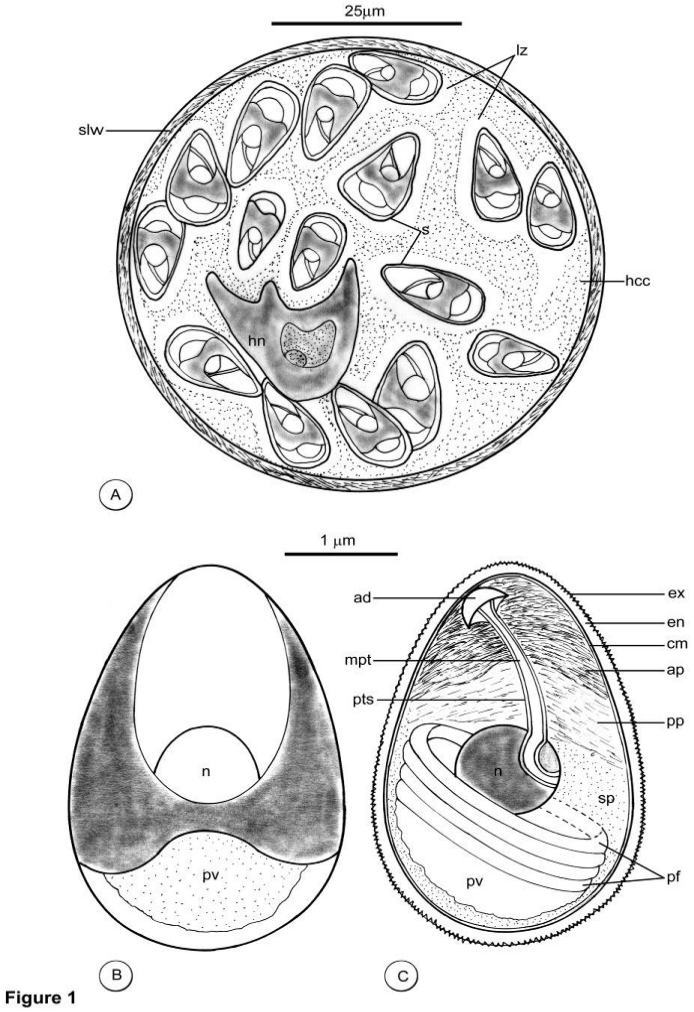

Figure 1

Fig. (1). Diagram of zenoma of *Neonosemoide* sp. (A) showing 16 macrospores, three lobes of hypertrophic nucleus and light zones. Mature spore (B) with characteristic egg-shaped and posterior vacuole. Mature spore (C) in details.

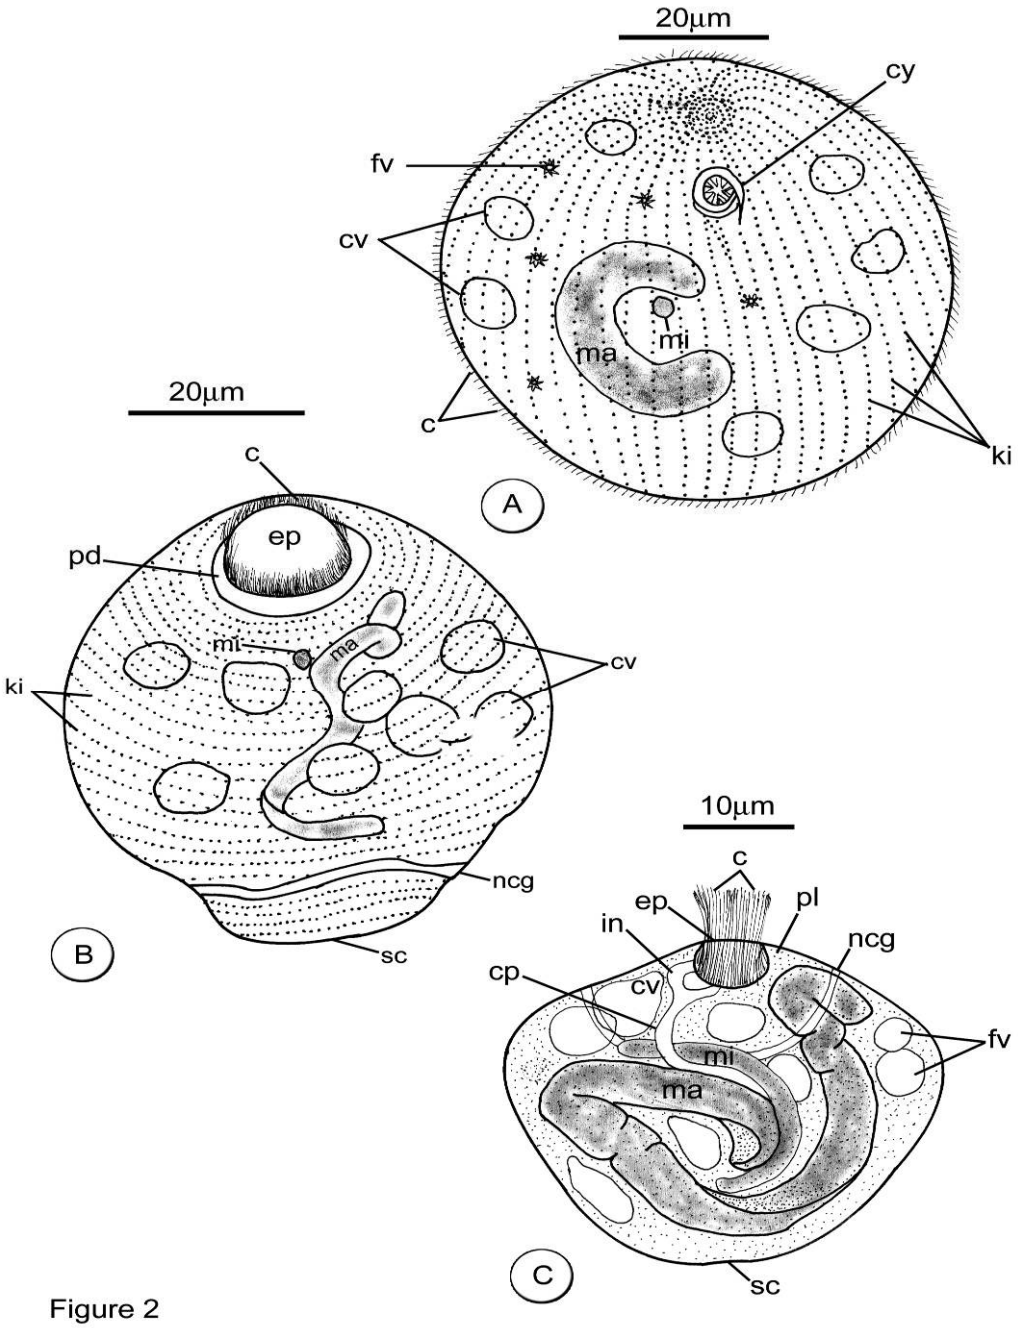

Figure 2

Fig. (2). Diagram of *Ichthyophthirius multifiils* (A). with characteristic round-shaped, horse-shoe macronucleus and meridional kineties. *Scyphidia* sp. 1(B) with transverse striation of pellicle. *Scyphidia* sp. 2(C) with cup-shaped body. Note the ribbon-shaped and sinuous macronucleus and giant micronucleus.

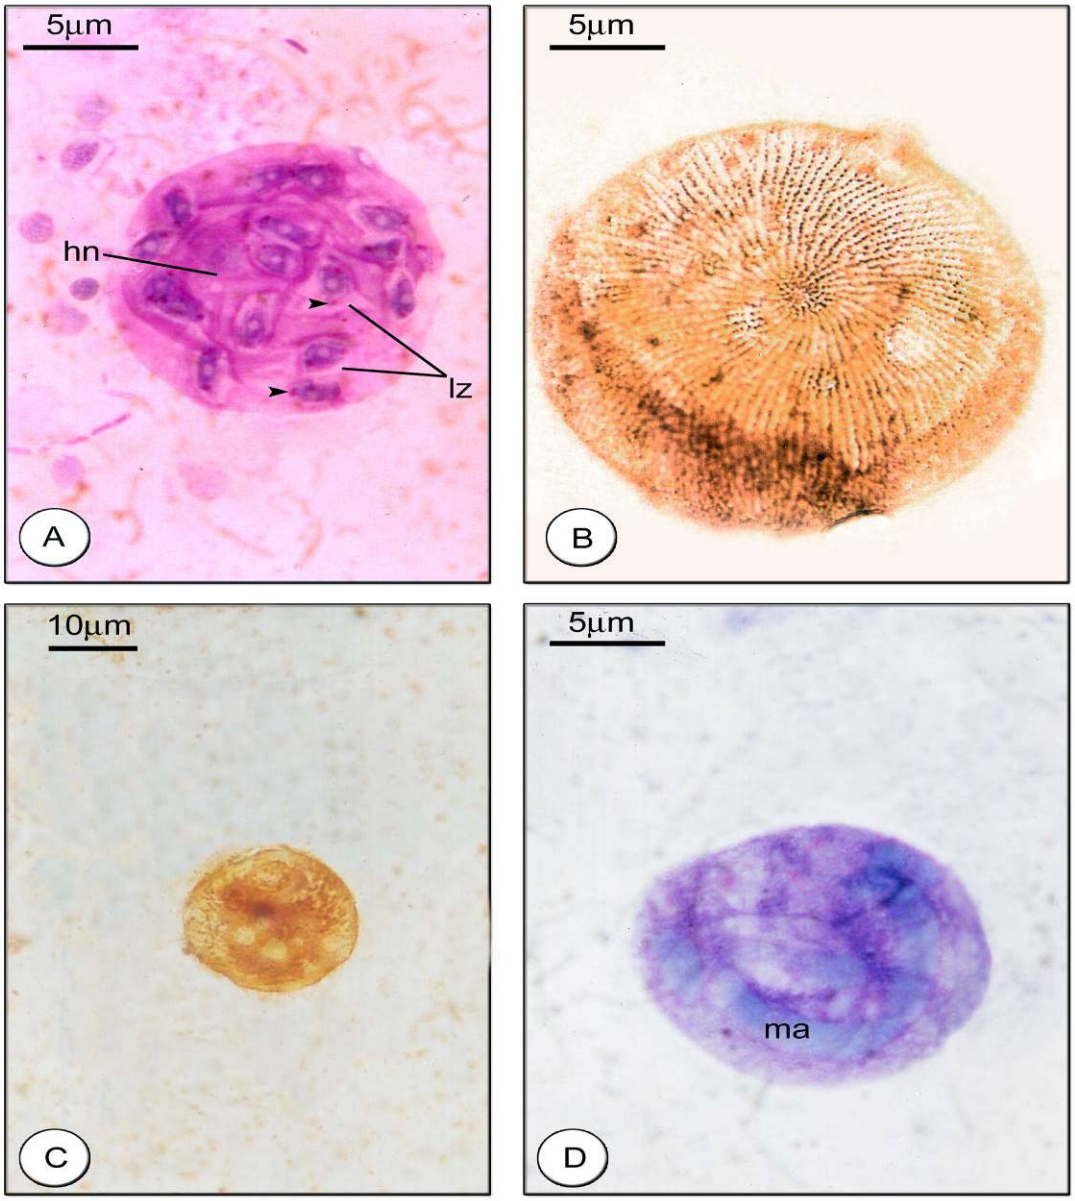

Figure 3

Fig. (3). Giemsa stain zenoma (A). Note the presence of anchoring disc as a red granule (arrowhead), silver impregnation Ichthyophthirius *multifillis* (B) and *Schyphidia* sp. 1(C) and Giemsa stain *Schyphidia* sp. 2(D). Not the sinuous ribbon-shaped macronucleus.

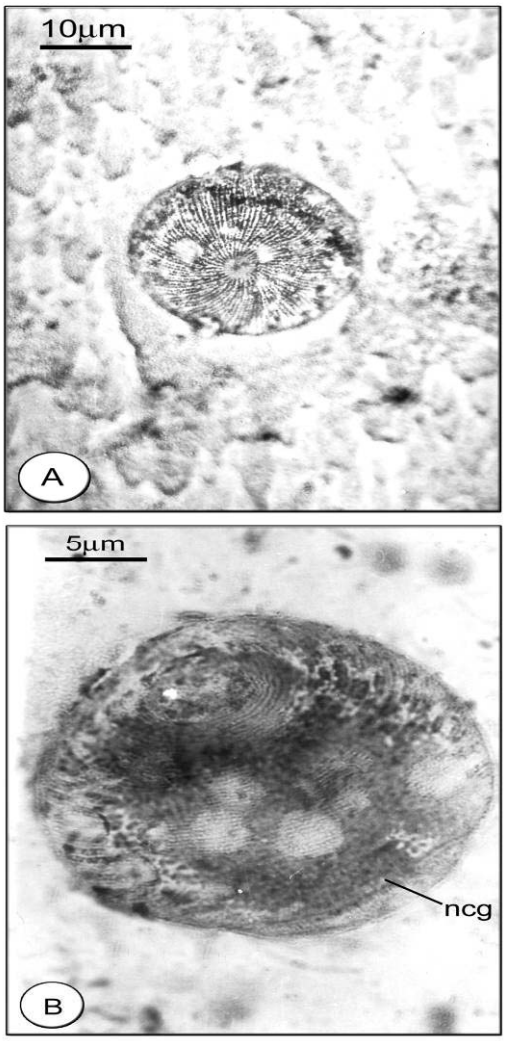

Figure 4

Fig. (4). Phase contrast microscope photograph of living specimens of *I. multifillis* (A) and *Schyphidia* sp. 1(B). Note the non ciliated groove.

4. Discussion:

1-Genus *Neonosemoides*

Neonosemoides sp.

The more conspicuous characteristics of the spore; the shape, wall, polaroplast, polar filament and posterior vacuole are used to distinguish microsporidia from other taxonomic group (Sprague *et al*., 1992). According to the site of infection the present xenomas were found on the gills of freshwater fish *Chrysichthys auratus*, so it belongs to genus *Nosemoides* (Lom and Dykova, 1992). Recently (Lom and Dykova, 2005) reported that genera of microsporidia that comprise xenoma-forming species can be grouped in several categories according to xenoma wall, hypertrophic nucleus and type of spores inside xenoma. Accordingly the present investigated xenomas belong to genus *Neonosemoides*. Type and only species recorded in this genus is *Neonosemoides tilapiae* from *Tilapia zillii* (Sakiti and Bouix, 1987 and Faye *et al*., 1996) from Benin (West Africa). Comparing the present species with *N. tilapiae*, it was found many differences as listed in Table (1). So the present species assigned to the same genus but further ultrastructure and molecular study need to reveal the exact taxonomic assignment of this species.

The pathogenic effects induced by Microsporidia in host include physical disruption of cells due to occupation of intracellur space, host cell hypertrophy, change to host cell metabolism and reorganization of host cell components. The direct effects include increased mortality (Klaus, 2005). In the present work parasites are generally surrounded by a light zone the existence of which, is to be explained by the action of their proteolytic enzymes, which dissolve the host protoplasm around parasites and render it suitable for assimilation.

2- Genus: *Ichthyophthirius*

I. multifiliis

The parasite is identified by its characteristic horse-shoe shaped macronucleus in addition to the coarsely granular and vacuolated cytoplasm. Abu El-Wafa (1988) described *I. multifiliis* from different species of fishes but with smaller measurements (28 µm in diameter). He also found the same species in the grass carp *ctenopharyngodon idella* with the measurements much larger (about 710 µm in diameter). The present study (67.4 µm) is similar to Koura *et al.* (1997) described the parasite from *Oreochromis niloticus* (57.5 µm).

The first symptom of heavy infection is the presence of white spots appear over the entire body “white spots disease”. Fins begin to fray, skin starts being eroded, gills are pale (anemia). Scales may detach, eyes sunken, fish hardly move followed by death (Lom and Dykova, 1992).

3- Genus: *Scyphidia*

Scyphidia sp. 1

The present investigated parasite is resemble in shape and measerments to *Scyphidia doliaris* Chernova, 1977 (cited in Schulman 1984), but the latter has one contrctile vacuole, epistomial disc is below the peristomial disc level and there is no non ciliated groove. This species is first record in Egypt.

Scyphidia sp. 2

Scyphidia sp. investigated during this study was characterized by the cup-shaped body, ribbon-shaped irregularly twisted macronucleus, occupies almost all the cell cavity. The most characterized feature was the detection of the giant micronucleus. The present *Scyphidia* sp. 2 is similar in shape and macronucleus to *Scyphidia* sp. described by Ahmed *et al*. (2000), but the present parasite have-smaller size and has giant micronucleus. The present parasite is closely resemble *S. globularis* described by Solomatova, 1977 (cited in Shulman, 1984), but the latter has a smaller macronucleus besides the micronucleus not detected. This species is first record in Egypt.

The pathogenicity of genus *Scyphidia* is attributed to disturbance in the respiratory process of the infected fishes, leading to asphyxia. (Paperna, 1980).

shrose22@yahoo.com

ABSTRACT: The main objectives of the current investigation are to compare some chemical constituents, mainly cell wall components (cellulose and lignin), of stalks of five Egyptian cotton cultivars, as a step to convert a low valued bio-wastes of cotton plant stalks into highly value product as pure cellulose, which will, also, contributed in solving major environmental and health problem in Egypt. Lignocellulosic raw material cultivars; Giza 80, Giza 85, Giza 89, Giza 86, and Giza 90 were used in this study. They were obtained from Cotton Research Institute experimental fields. As first stage, chemical analysis comparison among aforementioned cultivars was conducted. The results showed that, there were significant differences among the five studied cultivars in moisture, Lipids, wax, crude fibers and β cellulose contents. As coincides, ash, protein, holocellulose, hemicellulose, α cellulose and lignin percentages exhibits no significant differences among cultivars. The highest percentages of moisture estimated in Giza 89 (7.74%), also in ash and lignin (3.39% and 25.75%, respectively), but it was the lowest cultivar in wax percentage (2.43%). Giza 86 showed the highest percentage in lipids and crude fibers (1.96% and 46.92, respectively), also in protein and holocellulose percentages (5.12 and 77.26 %, respectively), but it was the lowest cultivar in β cellulose (1.11%) as well as ash (2.95 %). The highest percentage in wax and β cellulose estimate (3.67% and 2.72%, respectively) was in Giza 90, but it was the lowest cultivar in Lipids (0.96%) and hemicellulose (40.04%). The highest percentages in α cellulose (49.21%) was in Giza 80 which reflected the lowest percentage in the crude fibers (38.75%). The second stage was the preparation of cellulose by removing the waxes, lignin, and hemicellulose, since cotton stalk consists of 75±2% holocellulose percentage and 44±5% α cellulose %. The third stage was conducting physical test by analyzing the sample that was prepared by X-ray, then comparison with standard cellulose sample chart to confirm its structure as cellulose.

INTRODUCTION

In Egypt, crop residues are by-products of common crops such as cotton, wheat, maize and rice, with total amount of about 16 million tons of dry matter per year (El Saeidy, 2004). The Egyptian cotton is a unique descender of cotton that is characterized by high quality, it gained worldwide reputation for more than century and half as being of the highest lint quality among the world cottons for textile industry, beside seeds use in oil production (Bailey, 1958 and Simpson and Ogorzaly, 2001). Cotton crop area accounts for about 5% of the cultivated area in Egypt (El Saeidy, 2004). Cotton stalks produced annually as agricultural residues reached 1.9 million tons (Mona, *et al.*, 2001). These post-harvest by-product cause many severe problems; fires causing significant environmental and health disorders, in addition, eggs and larvae of harmful pink boll worm lays inside it (Amal *et al*., 2010). The cotton stalks are rich in cellulose and close to the fibrous structure of hard wood (Metcalfe and Chalk, 1950). Commercially, this material is being used as fuel in rural areas and for raising edible mushroom crops (Balasubramanya, 1981 and Pandey and Shaikh, 1987).

The largest share in cotton plant dry weight is for stem which comprises 23.15 % (Mcbryde, 1891). Cellulose comprises the major part of all plant biomass, and the source of all cellulose is the structural tissues of plants. Cellulose often occurs in close association with hemicellulose and lignin (Farone *et al*., 1998)

Brown (1927) found that cotton stalk consist of ash 3.09%, protein 4.00%, fibers 45.31% and fats

1.11% (percentage of constituents in water-free material). It was found that, as average chemical compositions of pulping woods, waxes, holocellulose, alphacellulose and lignin percentages are 1%-5%, 70-73%, 42-44% and 27%-31%, respectively (Grant, 1958). Rizk (1970) mentioned that the cotton stem fibers contained cellulose 65.43%-69.28%, lignin ranged from 21.19% to 22.93 % , wax from 1.91% to 2.06%., and ash content percentage was ranged from 1.89% to 2.53%. Kebeasy (1988) found that, the value of lipids in methanol benzene solution is (4.24%) which, mostly, belong to the waxes, whereas petroleum ether extract reflect lower values (2.93%). The estimations on cotton stalk of ash, crude protein, crude fibers, lignin, and cellulose were 2.94%, 3.48%, 47.35%, 23.6% and 35.6%, respectively. Paralikar and Bhatawdekar (1987) found that moisture content of raw cotton stalk was 9.5%. Silverstein, *et al*. (2007) reported that, the estimated percentage of acid-insoluble lignin was (27.9%), acid-soluble lignin was (2.2%) and ash was (6.0%).

Lignin is an integral part of plant cell walls and makes up one-quarter to one-third of the dry mass of wood, along with hemicellulose, is nature's cement which exploits the strength of cellulose and confers flexibility (Parajuli, 2006). Wassel (1985) found that, for sowing date, mean values of fiber cellulose and lignin were significantly increased as the time of sowing was delaying (between 67.45%-71.63% and 24.19-28%, respectively), on the contrary wax and ash percentages were (between 1.64%-1.015%, and 2.67-1.98%, respectively). The effect of retting methods was significant on the mean values of lignin and ash percentages scoring, in stagnant water retting, 23.36% and 1.79%, respectively. In 1.2% ammonium oxalate solution at 100 ºC for 1-2 hours, the highest percentage values were scored in cellulose percent, wax and ash (75.75%, 1.998% and 2.71%, respectively). On the other hand, the lowest percentages of cellulose (67.29%), lignin (21.22%) and wax (1.015%) were found in 1.2% sodium carbonate at 100 ºC for 1-2 hrs.

Acidified sodium chlorite is an effective method to remove lignin; however, during the delignification process the hydroxyl groups and reducing end groups of cellulose can also be oxidized (Fengel and Wegener, 1984).

MATERIALS AND METHODS

1. **Plant materials:** The current investigation was carried out on the dry stalks for five Egyptian cotton (*Gossypium barbadense* L.) cultivars; Giza85, Giza86, Giza89, Giza80 and Giza90.
2. **Work procedures:** The work was conducted in the Cotton Seed Technology and Natural Products Laboratory, Cotton Chemistry Department, Cotton Research Institute (CRI), Agricultural Research Center (ARC), Giza, Egypt. Cotton stalks of all studied cultivars were collected from ARC experimental fields, after complete harvesting of the economic crop, in August 2006, then cut into splinters about 2.5-4 cm in length by hand, then samples milled in a mill, using 0.4 mm screen, and finally, the milled samples were subjected to compositional analysis to compare among the five studied cotton cultivars. Mixed sample of cultivars stalks was subjected to cellulose extraction method then preparing derivatives from it. The chemical comparison among five studied cultivars was statistically analyzed as Randomized Complete Block Design (RCBD) with one factor (cultivars) in three replicates to obtain L.S.D. (at alpha 0.05) among averages for each studied character.
3. **Chemical analysis** (was determined on dry weight basis).

The chemical composition of the cotton stalks *i.e.* moisture, ash, Lipids, protein, Lignin, crude fibers, wax, (holocellulose and hemicellulose) and (α and β cellulose) were determined according to (AOAC, 1984), (AOAC, 2000), (AOAC, 1990), (AOAC, 1955), (Tanaka *et al*., 1985), (A.O.A.C., 1970), (Dorée , 1947), (whistler *et al.*, 1948) , and (Whister and Wolform, 1963), respectively.

4. **Preparation of cellulose:** The method described by Chahal *et al.*, (1979) was used for preparation of cellulose as follows:

Cotton stalks (50 g) were separately extracted with ethanol– benzene (1:2 v/v) for 6 hours in soxhlet apparatus then dried at 45 ºC. The dried samples were heated with sodium chlorite solution [Blend 23.5 g of sodium chlorite ($NaClO_2$) in 1000 ml of water containing 5 g of glacial acetic acid] at 75-80 ºC for 5 hrs. to remove the lignin. This treatment was repeated twice and the solution filtered. After filteration the residual material was washed with distilled water until free from chloride ions, then treat with ethyl alcohol to give holocellulose (hemicellulose and cellulose). To obtain the hemicellulose and cellulose fractions the

holocellulose was treated with 500 ml. NaOH 10% (w/v) for 4 hr. at 25 ºC with occasional stirring then filtered. The residue was again treated with 250 ml. NaOH 10% (w/v) for 3 hr. at 80 – 90 ºC, filtered and washed with water, ethanol, acetone and ether then air dried. This fraction contained the cellulose. The obtained cellulose was used in the preparation of hydrocellulose, cellulose acetate, cellulose nitrate

5. X-ray diffraction: The prepared cellulose sample was exposure to x-ray treatment in Central Laboratories Sector, The Egyptian Mineral Resources Authoroty (EMRA), The Ministry of Petroleum. A Philips X-Ray Diffraction equipment model PW/1710 with monochromator, Cu-radiation (λ=1.542 Å) at 40 K.V., 35 m.A. and scanning speed 0.02º/sec. were used. The reflection peaks between 2Θ = 2º and 60º, corresponding spacing (d, Å) and relative intensities (I/Iº) were obtained. The diffraction charts and relative intensities are obtained and compared with ICDD files. Obtained diffraction chart of prepared cellulose was checked against chart of standard cellulose sample (Kennedy *et al*., 1992) treated by 25% aqueous ammonia at 10 ºC for 15 and 240 min.

RESULTS AND DISCUSSION

In a trial to solve major environmental and health problem in Egypt, chemical constituents, mainly cell wall components, of five Egyptian cotton cultivars were investigated as presented in Table (a,b) and illustrated by Fig. (1a, 1b).

I- Chemical analysis:

1. Moisture %:

Data in Table (a) illustrated by Fig. (1a) indicated that there were significant differences among studied cultivars. Estimated stalk moisture ranged between 7.21 to 7.74% corresponding to studied samples. Giza 89 showed the highest value for this trait, significantly differed than Giza 90 and Giza 85 by 5.59 and 7.35%, respectively.

Table (a): Chemical composition of the cotton stalks.

Characters / Cultivars	Moisture%	Ash%	Lipids%	Wax%	Protein%
Giza 85	7.21	3.25	1.13	3.26	2.55
Giza 86	7.62	2.95	1.96	3.38	5.13
Giza 89	7.74	3.39	1.24	2.43	3.09
Giza 80	7.61	3.04	1.14	2.57	3.10
Giza 90	7.33	2.98	0.96	3.67	4.05
L.S.D at 0.05%	0.332	N.S	0.502	0.601	N.S

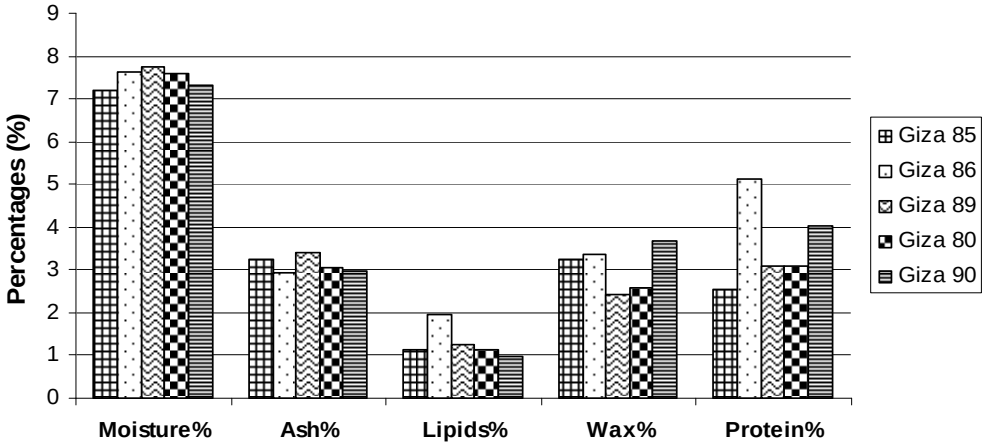

Fig. (1a): Chemical composition of cotton

2. Ash %:

No significant differences among cultivars understudied were observed, as indicated in Table (a) and Fig. (1a). Ash percentages ranged from 2.95% to 3.39%. The highest cultivar (Giza 89) increased by 14.92% than lowest one (Giza 86).

3. Lipids %:

As shown in Table (a) and Fig. (1a), there were significant differences among studied cultivars. Percentages of lipid % enclosed between 0.96% and 1.96% according to cultivar. Giza 86 showed the highest value significantly excelled Giza 89, Giza 80, Giza 85 and Giza 90 by 58.06%, 71.93%, 73.45% and 104.17%, respectively.

4. Wax %:

It was obvious of Table (a) and Fig. (1a) that, significant differences were statistically estimated among studied cultivars. Wax percentages % ranged from 2.43% to 3.67% due to cultivar. *Gossypium barbadense* cv. Giza 90 significantly exceeded Giza 80 and Giza 89 by 42.8% and 51.03%, respectively.

5. Protein %:

According to data in Table (a) and Fig. (1a), no significant differences were estimated among studied cultivars. Protein % percentages were elevates from 2.55% to 5.13% as to genotypic variations among cultivars. Giza 86 was the superior than other cultivars and exceeded Giza 85 (the lowest one) by 101.18%.

6. Crude fibers %:

Data in Table (b) and Fig. (1b.), confirmed the existence of significant differences among studied cultivars. Crude fibers % values were between 38.75% and 46.92% as to cultivar. Highest value was achieved in Giza 86 which score significant elevation by 21.08% over the lowest valued cultivar; Giza 80.

7. Lignin %:

As shown in Table (b) and Fig. (1 b), there were no significant differences among studied cultivars. Percentages of lignin % enclosed between 21.84% and 25.76% according to cultivar. Giza 89 showed the highest value exceeded Giza 85 (the lowest value) by 17.95%.

8. Holocellulose %:

It was obtained from data in Table (b) and Fig. (1b) that, no significant differences among cultivars understudied were observed. Percentages of holocellulose% ranged between 73.44% and 77.26% according to cultivar. Giza 86 showed the highest value exceeded the lowest value; Giza 85 by 5.20%.

9. Hemicellulose %:

Data in Table (b) and Fig. (1b) indicated that, there were no significant differences among studied cultivars. Estimated hemicellulose%, related to dry sample weight, ranged between 40.04% to 49.89% corresponding to studied cultivar. Giza 85 showed highest value for this trait, differed than Giza 90 which showed the least value by 24.60%.

Table (b): Chemical composition of the cotton stalks

Characters / Cultivars	Crude fibers%	Lignin%	Holo-cellulose%	Hemi-cellulose%	α Cellulose%	β Cellulose%
Giza 85	39.50	21.84	73.44	49.89	39.74	1.74
Giza 86	46.92	23.98	77.26	45.83	41.08	1.11
Giza 89	44.98	25.76	75.62	47.66	41.25	2.51
Giza 80	38.75	25.48	75.69	44.60	49.21	2.051
Giza 90	43.43	22.27	76.52	40.04	45.73	2.72
L.S.D at 0.05%	7.993	N.S	N.S	N.S	N.S	1.035

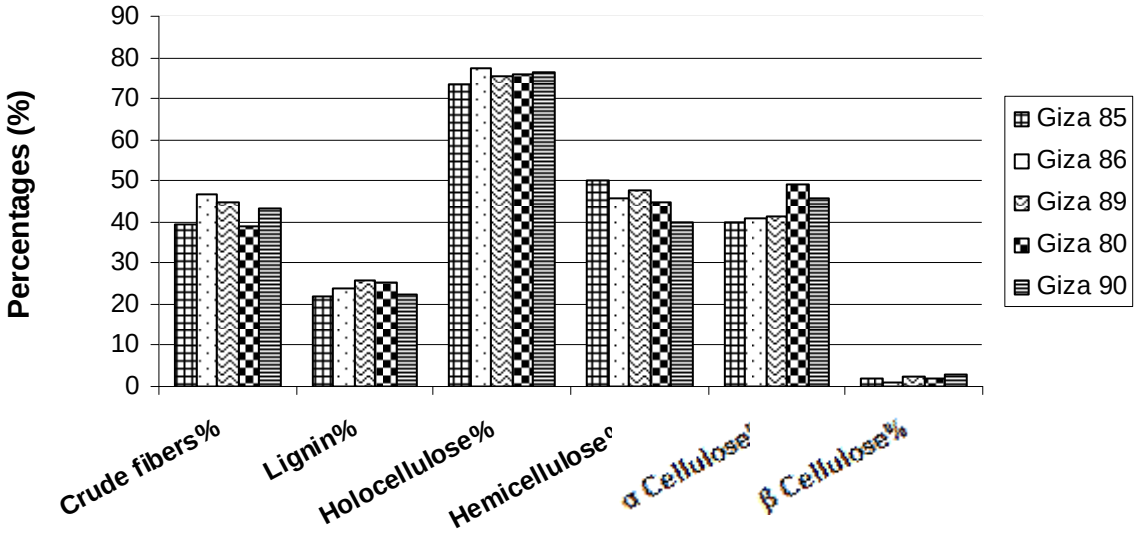

Fig. (1b): Chemical composition of cotton stalks

10. α Cellulose%

Differences among cultivars understudied were insignificant as observed in Table (b) and Fig. (1 b). Percentages of α cellulose%, related to cellulose sample weight, ranged from 39.74% to 49.21% as to studied cultivar. Highest cultivar (Giza 80) showed increment by 23.83% than lowest one (Giza 85).

11. β Cellulose%

It was obvious from Table (1 cont.) and Fig. (1 cont.) that, significant differences were statistically estimated among studied cultivars. Percentages of β Cellulose%, related to cellulose, enclosed from 1.11% to 2.72% due to cultivar. Cultivar Giza 90 significantly exceeded Giza 86 by 145.05%.

Aforementioned results are in agreement with those found by Brown, 1927, Grant, 1958 and Rizk, 1970, and partially in accordance with data estimated by Wassel, 1985 and Kebeasy, 1988. Previous results are coincides those found by Paralikar and Bhatawdekar, 1987 and Silverstein, *et al*., 2007.

II- X-ray diffraction:

Extracted cellulose sample was applied to X-Ray Diffraction equipment. Obtained diffraction chart of prepared cellulose (Fig. 3) was checked against chart of standard cellulose sample treated by 25% aqueous ammonia at 10 ºC for 15 and 240 min. (Fig 2), and this comparison showed that, the cellulose sample at D.p. (degree of polymerization) was treated with 25% aqueous ammonia for 15 and 240 min., and the tested sample, which was extracted from cotton stalks, had the same trend and enclosed in the same range. This aforementioned result confirmed that the tested extracted sample is cellulose.

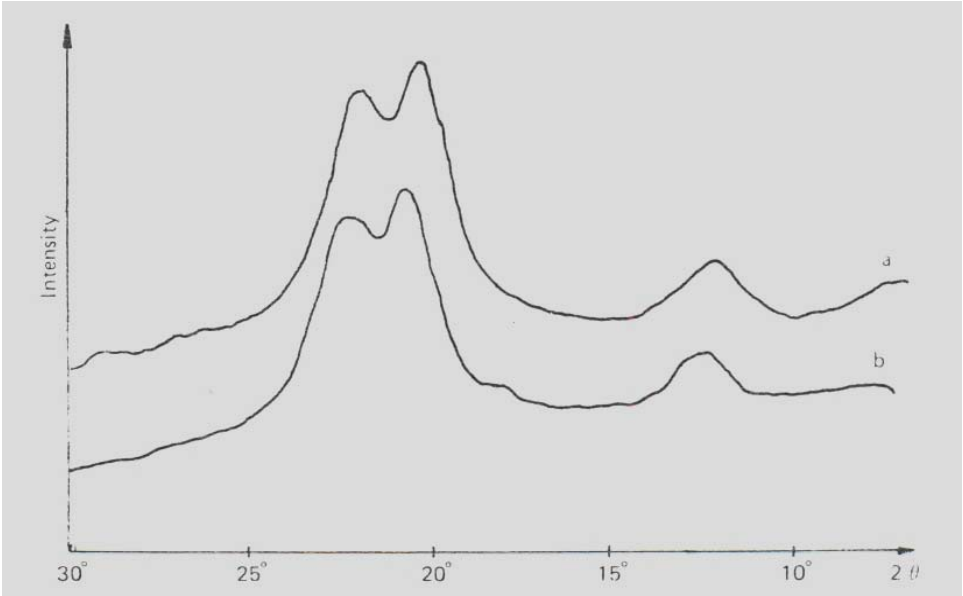

Fig. (2): X-ray diffractograms of cellulose (D.p.=425) treated by 25% aqueous ammonia at 10 ºC for :

a. 15 min.
b. 240 min.

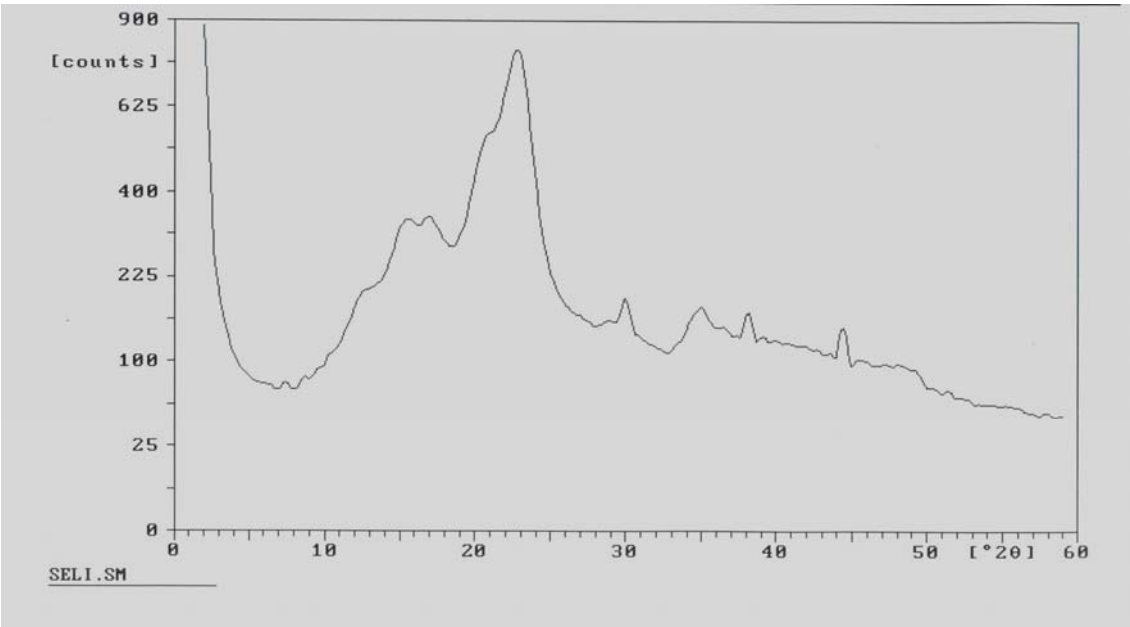

Fig (3): X-ray diffractograms of cellulose extracted from cotton stalks

CONCLUSION

Final goal of current work is achieved by extracting cellulose from cotton stalk of five cultivars understudied and use it to produce economical cellulose derivatives products. However, cultivar Giza86 has best performance for this investigation aim; it has the highest holocellulose percentage (beside some other traits) compared with other studied cultivars. Elimination of wax and lignin are prerequisite operations before cellulose extraction, thus Giza 86 has favorable (reduction in) percentage of lignin but set second (without significant difference) to Giza 90 as the highest wax percentage. Some cellulosic derivatives will be produced as future complementary investigation to current work.

دراسات كيميائية حيوية على بعض مخلفات القطن

الجزء الاول - التركيب الكيميائى لحطب القطن المصرى

فؤاد عبد الرحيم أحمد*- نادية عبد المعين الغرباوى-*أمل صابر محمد- شيماء السيد أحمد****

***قسم الكيمياء الحيوية الزراعية - كلية الزراعة - جامعة القاهرة**

****معهد بحوث القطن- معهد البحوث الزراعية- الجيزة- مصر**

تعد الأهداف الرئيسية للبحث الحالى هى مقارنة المكونات الكيميائية وبصفة أساسية مكونات الجدار الخلوى (السليلوز و اللجنين) لحطب خمسة أصناف من الأقطان المصرية، ثم تحويل المخلفات الحيوية منخفضة القيمة إلى منتج عالى القيمة الاقتصادية كالسليلوز النقى، مما سيساهم بدوره فى حل مشكلة بيئية وصحية رئيسية فى مصر. وقد استخدم فى هذه الدراسة خمسة أصناف من أصناف القطن المصرى هى جيزة 80 وجيزة 85 وجيزة 89 وجيزة 86 وجيزة 90. ولقد تم الحصول عليهم من الحقول التجريبية لمعهد بحوث القطن. تم اجراء مقارنة للتحليل الكيميائى بين الأصناف سابقة الذكر. وقد أظهرت النتائج ما يلى

1- أن هناك اختلافات معنوية بين الأصناف المستخدمة من حيث المحتوى من الرطوبة و اللبيدات و الشمع و الألياف الخام و البيتاسليلوز

2- ليس هناك اختلافات معنوية بين الأصناف من حيث المحتوى من الرماد و البروتين والسليلوز الكلى و الهيميسليلوز و الألفا سليلوز و اللجنين

3- سجلت أعلى النسب للرطوبة فى حطب الصنف جيزة89 (7,74) أيضا فى الرماد واللجنين (3,39 و 25,75% على التوالى) ، ولكنه كان أكثر الأصناف انخفاضا فى نسبة الشمع (2,43%).

4- أظهر الصنف جيزة 86 أعلى النسب فى اللبيدات (1,96%) و أيضا فى نسب البروتين والألياف الخام والسليلوز الكلى (5,12 و46,92 و77,26 % على التوالى), بينما كان الصنف الأكثر انخفاضا فى البيتا سليلوز (1,11%) وكما فى الرماد (2,95%).

5- كانت أعلى نسبة فى الشمع (3,67%) فى جيزة 90 والذى أظهر أيضا أعلى تقدير فى البيتاسليلوز (2,72%)، ولكنه كان أكثر صنف انخفاضا فى الهيميسليلوز (40,04%) واللبيدات (0,96%).

6- كانت أعلى النسب في الألفاسليلوز (49,21%) فى جيزة 80 و الذى عكس أكثر النسب انخفاضا فى الألياف الخام (38,75%).

7- تم استخلاص سليلوز الحطب بإزالة الشموع و اللجنين والهيميسليلوز (المواد المصاحبة له) كما تم إجراء الاختبار الفيزيائى للسليلوزالمستخلص بواسطة الأشعة السينية الحيودية التى أكدت المقارنة مع الرسم البيانى لعينة سليلوزقياسية أن المستخلص هو سليلوز. يصلح لاجراء عمليات التحوير الكيميائى له لانتاج المشتقات السليلوزية وذلك فى الجزء الثانى من هذه الدراسة.

Abstract: Marine fishes are suffering from continuous depletion due to bacterial pathogens infections triggered by devastating environmental changes at their native aquatic environment. Qarun Lake and Suez Gulf are among the most vulnerable areas. 600 fish samples of Six different fish species; *Epinephelus tuvina*, *Sisganus rivulatus*, and *Dedlechilus labiosus* native to Suez-gulf at Suez governorate; *Mugil capito* , *Solea vulgaris* and *Tilapia zilli* native to Qarun Lake at El-Fayoum governorate were examined throughout the different year seasons. Gram positive and negative fish pathogenic bacteria were isolated from a total of 245 fish sample. Among those samples, the following bacteria were retrieved in the following percentages respectively, 17.55% (Vibrio*. anguillarum),* 16.73% (*Vibrio. alginolyticus*), 15.51% (*Pasteurella. piscicida*), 15.91% (*Pseudomonas. fluorescens)*, 13.46% *(Streptococus. fecalis*), 11.02% (*Aeromans . hydrophila*), 6.12% (*Aeromans. sobria)* and 3.67% were infected with *Staph. aureus*. The *Siganus rivulatus* was the highest infected fish species with a prevalence of 8.33%, while *Mugil capito* was the lowest infected species (5.67 %). The highest total prevalence of bacterial infection was recorded in summer season (40.81%) while the lowest was recorded in winter (15.91%). The aforementioned bacterial isolates were successfully re-isolated from experimentally infected fish. The retrieved isolates were confirmed by semi-automated (API 20 E) and conventional biochemical tests.

Keywords: Marine fishes, Bacterial diseases ,Diagnosis, seasonal variation.

1-INTRODUCTION

Fish is considered as one of the main principal sources of the national income in Egypt. Like all animals, marine fish are subjected to numerous diseases, especially bacterial one, in which bacteria play the main role in producing the disease. Diseases are intensified by climatic changes that reflect negatively on the aquatic environment which is a good media for numerous pathogens **Wedemeyer, 1996)**.

The prevalence of bacterial pathogens have been well documented in several cultured and wild freshwater fish species, however; only a few bacteriological surveys on the prevalence of bacterial pathogens responsible for outbreaks in marine fishes **(Alicia., et al 2005).**

On the long run water resources will be the most limiting factor to be considered in aquaculture development in Egypt, especially freshwater aquaculture. Therefore, marine waters are the immediate alternative sources for water needed for mariculture **(Sadek, 2000).** One of the most promosing regions for mariculture in Egypt are The Gulf of Suez and Lake Qarun .

The present work was planned to isolate and identify the most predominant bacterial pathogens in some marine fishes native to both Suez Gulf, at Suez governorate and Lake Qarun at EL-Fayoum province. Further, work aimed to evaluate the seasonal variation of bacterial isolates among the examined fishes.

2. Materials and methods

2.1. Sampling and processing

Six hundred (600) marine fishes of Six different spp. were examined freshly from two localities in Egypt, (Suez Gulf and Lake Qarun). Through the different seasons of the year.

Twenty-five fish of each species were collected and examined seasonally. Fish species, numbers of fish, average body weights and localities are shown in table **(1).** Clinical and P.M examination were carried out using the methods described by **(Buller, 2004).**

Samples from gills, liver, spleen, kidney and external lesions from fishes were cultured on general and selective media; tryptic soy agar and tryptic soy broth (Difco) supplemented with 1.5% (w/v) NaCl, marine agar (Difco), and thiosulphate–citrate–bile

salt–sucrose agar (TCBS, Difco). aeromonas agar base medium supplemented with Ampicillin, pseudomonas agar base medium supplemented with CFC and 2 % NaCl , R-S agar supplemented with novobiocin and 2 % NaCl, and Azide blood agar supplemented with 2 % NaCl . All the inoculated media were incubated at 22 C for 2–5 days. clinically diseased fish, additional samples were taken from external lesions.

2.2. Identification of the isolates

Pure cultures of the isolates were identified by biochemical characterization following the criteria proposed by those described in the Bergey's Manual of Determinative Bacteriology, (**Holt et al., 1993).**Final confirmation of each strain was achieved using the analytical profile index of API20-E system **(Buller, 2004).**

2-3- Experimental infection

70 apparently healthy *O. niloticus* fish, weighting 50 ± 5 gram were selected after the 15 day of the acclimation period for determination of the pathogenicty of the most prevalent bacterial isolates. Fishes were divided into seven groups each contained 10 fish. The inocula prepared for bacterial isolates as I/P injections were prepared according to **(Austin & Austin, 1999).** Fish were observed daily for 15 days. Six groups were consistently inoculated I/P with bacterial suspension of (*Aeromonas hydrophila*, *Pseudomonas fluorescence*, *Vibrio anguillarum*, *Pasteurella piscicida*, *Streptococcus fecalis* and *Staphylococcus aureus*) at dose of 0.2 ml of (3 X 10^7 CFU) while the control group (group 7) were injected I/P with 0.2 ml of sterile tryptic soy broth according to **Hussain (2002)**.

3. Results

3-1Clinical examination

Symptoms detected in the diseased fish included Haemorrhages widely distributed into many parts of the body (Fig 1). Some fishes showed eye exophthalmia and opacity(Fig 2), scale detachment and darkness of the skin. gills were congested((Fig 3). while in others appeared to be pale and swollen with accumulation of excessive amount of mucus. Abdominal distention was observed in some fishes. Vent inflammation as well as prolapse was also seen in many cases.

Necropsy findings of the naturally infected marine fishes exhibited reddish serous fluid in the abdominal cavity. The liver was pale (Fig 4). in some fishes and congested, haemorrhagic with numerous randomly scattered whitish nodules throughout the parenchyma in others (Fig 5).. Spleen was congested and enlarged in some fishes, while in others appeared to be apparently normal. Kidneys were congested and slightly enlarged. In some fishes, white patches were found in kidneys. The intestines were haemorrhagic, inflamed with congestion of their blood vessels. In other samples, the intestines were seen filled with gases.

3.1. Isolation and identification of the bacterial isolates.

Biochemical characteristics of gram –ve bacterial spp. isolated from examined fishes are shown in Table (2).

Results indicated that 245 naturally collected fishes out of 600 were found to be infected with different types of bacteria. The culture results demonstrated that (203) fishes were found to be infected with Gram-negative bacteria and only (42) fishes were infected with Gram-positive bacteria. 17.50 % of the infected fishes were positive for *V. anguillarum,* (16.73%) for *V. alginolyticus*, (15.51%) for *P. piscicida*, (15.91%) for *Ps. fluorescens,* (13.46%) for *S. fecalis*, (11.02%) for *A. hydrophila*, (6.12%) for *A. sobria* and (3.67%) of the surveyed fishes were infected with *Staph. aureus.* The total prevalence of bacterial isolates is illustrated in tables (**3**)

Prevalence of different types of bacterial infections in the different examined fishes is illustrated in table (**3**). The results revealed that *Siganust rivulatus* was the most infected fish spp (50 %), followed by *E. tuvina* (42 %), *S. vulgaris* (41 %), *Tilapia spp.* (40 %), *M.sahlae* (38 %), while *M. capito* was the lowest infected spp (34 %).

The prevalence of bacterial infections for fishes collected from both Suez Gulf and Lake Qarun was illustrated in table (**4**). The results revealed that: The total Prevalence of bacterial infections for fishes collected from the Gulf of Suez (53.06%) was higher than that recorded for those collected from lake Qarun (46.93%).

The results indicated that, the highest total prevalence of bacterial infections among the naturally infected marine fishes was recorded in the summer season (40.81%), followed by autumn (25.71%), then spring (17.14%). On the other hand the minimal prevalence of infection was recorded in winter (15.91%). table (5).

The highest prevalence of bacterial infection among the naturally infected marine fishes in winter season, was recorded for *Ps. fluorescens* (7.75%) while the lowest one (0.40%) was recorded for *V. anguillarum.* on the other hand *P. piscicida*, *S. fecalis and Staph. aureus* were not recorded. For spring season, the highest prevalence of bacterial infection (3.67%) was recorded for *A. sobria* and *V. anguillarum*. while the lowest one (1.22%) was recorded for Ps. fluorescens and S. fecalis. on the other hand Staph. aureus were not detected. The highest prevalence of bacterial infection (9.38%) in summer season was recorded for *V. anguillarum*, while the lowest one (0.40**%**) was recorded for *A. sobria*. The highest prevalence of bacterial infection (5.30%) in autumn season was recorded for *V.alginolyticus* and *P.piscicida* while the lowest one (0.40%was recorded for *A. sobria*. The Prevalence of different types of bacterial infections in the different seasons is illustrated in table (5).

Results of experimental infection .

Mortality patterns in experimentally infected *O. niloticus* with the different bacterial isolates. Table (**6**).

experimentally infected O. niloticus with the different isolates were characterized by septicemic lesions nearly similar to those of naturally infected fish. Experimentally infected fish showed haemorrhagic patches distributed on different parts of the body surfaces. fin and tail rot (fig7). Some fish exhibited typical ulcers (fig8). Some cases showed inflammation of the vent (fig9).Pnecropsy findings showed, congestion of Liver; in some cases the liver was pale. Spleen and kidneys were congested and enlarged. Gall bladder was distended. The gut was haemorrhagic and filled with yellowish content. Serous to serosanguinous fluid in the abdominal cavity was noticed in some cases.

Re-isolation of all the injected bacterial isolates was obtained from dead and sacrificed experimentally infected fish. Moreover, the results of culture and biochemical characteristics of the re-isolated different bacterial isolates revealed the same morphochemical characteristics of the injected bacterial isolate.

Discussion

Septicemic bacterial infections such as vibrios, aeromonads, pseudomonads, photobacteria, streptococci and staphylococci have been observed in several fingerlings, juveniles, adults and brood stocks of some marine fish species **(Alicia *et al.*, 2005** and **Samuelsson *et al.*, 2006)**.

In regards to bacterial pathogens that have been isolated, results came in this study revealed that Gram-negative bacteria prevailed the Gram-positive ones with *Vibrio anguillarum*, *Vibrio alginolyticus*, *Pasteurella piscicida (photobacterium damsella subspp piscicida), Pseudomonas fluorescens, Streptococcus fecalis, Aeromonas hydrophila, Aeromonas sobria* and *Staphylococcus aureus* were the most common isolated spp. These results are supported by those reported by **Zorrilla *et al.* (2003)** who declared that the main pathogenic microorganisms isolated from diseased gilt-head seabream in the marine water at south western Spain were; *Vibrio* spp, *Pseudomonas* spp, *P. piscicida*, *Flavobacteria maritimus*, *Aeromonas* spp and Gram positive bacteria were also isolated but in low prevalence.

Table (1) Number and Weight

	Locality	Number	weight
E. tuvina	Suez Gulf	100	95±20
S. rivulatus	Suez Gulf	100	70±10
M. sahla	Suez Gulf	100	50±5
S. vulgaris	Lake Qarun	100	75±15
M capito.	Lake Qarun	100	85±10
Tilapia zilli	Lake Qarun	100	655

In concern to the total prevalence of bacterial infections in the naturally infected marine fishes at the present study (40.83 %) which may appear to be lower than those reported by some authors for the freshwater fishes as **Soliman (1999)** who noticed that the total bacterial prevalence was (65%). This difference might be due to the unfavorable effect of the salinity of marine water on the viability of bacterial pathogens.

In regard to the localities of isolation, results revealed that the prevalence of bacterial infections was higher (53.06%) in fishes collected from the Gulf of Suez than that (46.93%) recorded for those collected from Lake Qarun. the prevalence of Lake Qarun may be explaind as the lake Qarun is the largest reservoir of agricultural waste water drainage of Fayoum province as well as the drainage from fish farms established around the lake (**Mansour & Sidky, 2003**).

The high prevalence of isolation recorded from the Gulf of Suez may in part be attributed to the stress induced by high crude oil pollution at the Gulf water which is maintained by the low water

flow, low water exchange rates and daily crowded ship traffic crossing the gulf as well as industrial effluents from oil refineries. All these factors are compromising to the fish immune system ending up with marked increase in the magnitude of bacterial infections.

The study declared that marine fish can succumb MAS, as supported by **Larsen & Jensen (1977)** who isolated *A. hydrophila* from ulcer disease in Cod, *Gadus morhua* L., a strictly marine fish. Authors added that motile aeromonas group especially *A. hydrophila* is considered one of the most important pathogen responsible for haemorrhagic septicemia in a wide variety of marine water fish. Moreover, **Vethaak (1992**) isolated *A. hydrophila* from ulcers, lesions, and blood of ulcerated European flounder.

The results pointed out that the highest prevalence of *A. hydrophila* was recorded in winter season (5.71%) followed by spring (2.85%), in summer and autumn the results were the same (1.22%). These results supported by **Pathak *et al.* (1988)** who suggested that the highest isolation rates of *A. hydrophila* occurred during the late winter followed by a progressive decline in density during the summer and monsoon seasons. Moreover, **Popovic *et al.* (2000)** mentioned that there was clear seasonality in the prevalence of *A. hydrophila* as there were no isolates recovered in the summer months. On contrast, **Meyer (1970)** reported that the most epizootics of motile aeromonase were generally reported in spring and early summer.

In regards to the seasonal prevalence of *A. sobria*, our study recorded that the highest prevalence e of *A. sobria* septicemia was recorded during the spring (3.67%) followed by winter (1.63%) while the minimal prevalence e of infection (0.40%) was recorded during the summer and autumn. These results are in concordance with those obtained by **Wahli *et al.* (2005)** who noticed that mortalities due to *A. sobria* peaked during the low water temperatures of winter time and reached levels of 1% of the total fish on the farm per day. On contrary, the results are not in concordance with those obtained by **Kooj *et al.* (1988**) who demonstrated that the highest prevalence of Aeromonads in marine water have been obtained in the warmer months**.**

The pathogenicty of *A. hydrophila* for experimentally infected *Oeorchromis niloticus* with *A. hydrohila* may be attributed to the production of toxins and extracellular enzymes and lethal toxins including, proteases, amylases , lipases, enterotoxin, cytotoxins and haemolysin **(Saavedra *et al.*, 2004).**

In regards to the total prevalence of pseudomonas septicemia, the study recorded that (15.91%) of infected fish were positive for pseudomonas infection, These results are in concordance with those obtained by **Hussain (2002)** who reported that (15.27 %) of naturally infected marine fishes were positive for *Ps, flourescens* septicemia**.** on contrast, the results are lower than those reported by **Khan *et al.* (1981)** who reported that *Pseudomonas* spp accounted for (72 %) of the mortalities recorded in captive Atlantic cod, *Gadus morhus* L associated with fin rot disease.

The highest prevalence of *Ps. fluorescens* septicemia was recorded during the winter season (7.75%) followed by autumn (4.48%) summer (2.44%) and spring (1.22%), this reveals that *Ps. fluorescens* has certain affinity to low temperature for propagation and wide spreading infection **(El-Moghazy, 2004)**. The results are supported by **Golomazou *et al.* (2006)** who demonstrated that Pseudomonads were isolated mainly in cold months of winter. On contrary, the results are not in concordance with those obtained by **Hoda *et al.* (1999)** who revealed that the prevalence of pseudomonads was lower in winter than summer. This may be also attributed to amplified activity of proteinases produced by pseudomonads at the low temperature (10-25°C) that play the significant role in the pathogenesis of pseudomonas septicemia **(Hoshino *et al.*, 1997)**.

The pathogenicty of *Ps. fluorescence* for experimentally infected *Oeorchromis niloticus* may be attributed to the production of extracellular enzymes and lethal toxins **El-Attar & Moustaf (1996).**

In regards to the total prevalence of vibriosis recorded (34.28%), this result are in accordance with those reported by **Khan *et al.* (1981)** who recorded that vibrios accounted for (28%) of mortalities in captive Atlantic cod, *Gadus morhus* L associated with fin rot disease. the results are lower than those recorded by **Zorrilla *et al.* (2003)** who recorded that the prevalence of vibrios among diseased gilthead sea bream, *Sparus aurata* L in southwestern Spain was (69.90%).

V. anguillarum in this study was the *Vibrio* spp most frequently isolated as (17.55%) of the infected cases were positive for *V. anguillarum*. this is in accordance with **Zorrilla *et al.* (2003).** On the other hand *V. alginolyticus* was the cause of (16.73%) of the recorded cases. this high prevalence *of V. alginolyticus* indicates its importance in mariculture as supported by **Zhu *et al*. (2000)** who suggested that *V. alginolyticus* is one of the key diseases that have made great harm to a wide variety of marine fishes.

The highest prevalence e of *V. anguillarum* infection was recorded during the summer (9.38%), followed by autumn (4.08%), spring (3.67%), and only (0.4%) were recorded in winter. On the other hand the highest prevalence e of *V. alginolyticus* infection was recorded in summer (8.57%), autumn (5.30%), spring (2.04%) and (0.81%) in winter. The results of the seasonal prevalence of *Vibrio* spp are in concordance with those reported by **Roberts (2001)** who demonstrated that in wild, vibriosis normally occurs in fish in late summer when the temperatures are high. On the other hand, **(Golomazou *et al.* (2006**) reported that *V. alginolyticus* were not associated with a particular season.

The pathogenicty of *V. anguillarum* for experimentally infected *O. niloticus* may be attributed to the effect of the lethal and toxic effect of the extracellular toxins and enzymes produced by the bacterium **(Nottage & Birkbeck, 1987)**.

In concern to the total prevalence of *P. piscicida* in this study recorded that (15.51%) of diseased fish were positive for *P. piscicida*. The results are higher than those recorded by **Balebona *et al.* (1998)** who declared that (6.7%) of diseased gilt-head sea bream, *Sparus aurata* L. in southwestern Spain were infected with *P. piscicida*. On the other hand, our results are lower than those recorded by **Athanassopoulou *et al.* (1999)** who recorded that the prevalence of *P. piscicida* in diseased Cuvier, *Puntazzo puntazzo* L. collected from marine aquaculture systems in Greece was (80%).

Seasonally, the highest prevalence e of *P. piscicida* in our study was recorded during the summer season (7.75%) followed by the autumn (5.30%) followed by the spring (2.44%) on the other hand, it was not recorded in winter. These results are in concordance with those reported by **Magarinos *et al.* (1996) who** declared that *P. piscicida* has certain affinity to the high water temperature inducing fatal disease in fish but only when the water is warm and when water quality is low. On the other hand, **Mladineo *et al.* (2006)** suggested that temperature had not a strong influence on the course of pasteurellosis.

In regard to the pathogenicty of *P. piscicida* for experimentally injected fishes may be attributed to the effect of its toxic and harmful effect of the extracellular products produced by *P. piscicida* that possessed strong phospholipase, cytotoxic, and haemolytic activities (**Nakai *et al.*, 1992**).

In regards to the total prevalence of streptococcal septicemia. The present study recorded that (13.46 %) of infected fish were positive for streptococcal infection. These results higher than those recorded by **Zorrilla *et al.* (2003)** who recorded that 7% of bacterial infection affecting cultured gilthead sea bream, *Sparus aurata* L. was attributed to Gram-positive bacteria. **Hussain (2002)** recorded that (6.25 %) of naturally infected marine fish were positive for streptococcal septicemia.

In regards to the seasonal prevalence of streptococcal septicemia, the highest prevalence of the streptococcal infection was recorded in the summer season (6.16%) followed by autumn (4.08%) and spring (1.22 %) on the other hand it was not recorded during the winter. These results are in concordance with those obtained by **Varvarigos (1997)** who revealed that *Streptococcus* spp cause septicemia to all farmed species mainly during late spring and early summer when sea water temperatures are high.

In regards to the experimental infection *of O. niloticus* with *S. fecalis*. The pathogenicty of streptococci may be attributed to the effect of exotoxins produced by the bacterium **(Kimura & kusuda, 1979** and **Woo, 1999)**.

In regards to the total prevalence of *Staph. aureus*, the present study recorded that (3.67%) of infected fish were positive for Staphylococcal infection. These results were lower than those recorded by **Athanassopoulou *et al.* (1999)** who recoded that the total prevalence of *Staph. epidermidis* among diseased *Puntazzo puntazzo* in marine aquaculture systems in Greece was (10 %). Moreover, **Zorrilla *et al.* (2003)** recorded that (7%) of bacterial infections affecting gilthead sea bream

Sparus aurata L. were attributed to Gram-positive bacteria**.**

Seasonally the highest prevalence of Staphylococcal infection was recorded in the present study in the summer season (2.85%) followed by autumn (0.81%) while it was not recorded in spring nor in winter**.** These results are supported by **Varvarigos (2001)** who declared that *Staphylococcus* spp causing septicemia to all farmed species mainly during late spring and early summer during the high temperature of sea water. This may be explained by the high organic matters in water and the stress induced by the high temperature and hence the decrease in DO.

In regards to the experimental infection of *O. niloticus* with *Staph. aureus***.** The results are in accordance with **Huang (2000)** who indicates that staphylococci can be a possible cause of mortalities and losses among fish.

Table (2) Variable

Clinical Prespective Of Repeat Breeding Syndrome In Buffaloes

Ahmed W.M., El-khadrawy H.H., Emtenan M. Hanafi , Amal H. Ali , Shalaby S.A.

Department of Animal Reproduction and Artificial Insemination, National Research Centre Dokki,Cairo, Egypt. (wahidmma@hotmail.com)

ABSTRACT: Local meat production in Egypt is in continuous decrease and can not meet the local market requirement. So this study was designed to throw light on true repeat breeding syndrome (RBS) as one of the reproductive disorders that hinders the buffalo meat and milk production. A field survey was carried out on 1358 female buffaloes which were subjected to clinical and gynecological examination , and blood samples were collected for carrying out some relevant analyses. Treatment trials were practiced using different ways to control the condition and the economic impact of this syndrome has been studied. Results revealed that the incidence of clinical repeat breeding (RB) in the examined buffalo cows was 4.34 %. Typical repeat breeders represented 7.25 % of total reproductive disorders in female buffaloes. Serum progesterone level was 1.44 ± 0.39 and 3.66±0.84 in RB and normal buffaloes (NB), respectively. Oxidant/antioxidant markers in RB buffalo-cows showed increased malondialdehyde (MDA) and nitric oxide (NO) and decreased catalase (CAT), superoxide dismutase (SOD), ascorbic acid (ASCA), reduced glutathione (R-GSH) and total antioxidant capacity (TAC). Serum zinc, copper,iron and selenium values were lower in repeat breeder cows compared to normal animals. Repeat breeder buffalo-cows responded to the treatments with mineral mixture, GnRH and Lugol's solution with recovery rates; 63.64, 61.54 and 60.00%, respectively. The study concluded that special care should be paid for food additives to control this syndrome.

1. INTRODUCTION

Currently, the incidence of infertility becomes relatively increased with consequent reduction of productivity of farm animals. According to global Agricultural Information Network report for 2010, the total number of Egyptian cattle and buffalo decreased from 6.256 million head in 2008 to 6.248 million in 2009 and it is expected to decline in 2010 to level lower than 2009 because of many problems that continue to limit the growth of the animal production industry [1]. The price of domestic beef increased dramatically and the imported frozen meat and liver are still important sources of protein in domestic market. The average per capita consumption of red meat including variety meats is estimated at 8.5 kilograms per year, which is quite low compared to consumption levels in other countries. The lower consumption is mainly due to limited local production combined with lower per capita income [1].

Although buffalo constitutes 49% of the above mentioned number, it is the source for high quality milk (65% of milk production), lean meat (33.9% of meat production) and preferred by most of Egyptians. However, in Egypt and most of developing countries having buffalo population, these animals are mostly raised in small holder farms under hard socioeconomic circumstances [2].

Reproductive disorders, poor nutrition, parasitic infection are the main constraints of buffalo development. Ovarian inactivity, silent heat, endometritis and repeat breeding are the main reproductive disorders in buffaloes in Egypt [3].

Typical repeat breeding (RB) is defined as the animal that did not conceive after three or more consecutive inseminations, despite; it comes normally in heat and shows clear estrous signs with no clinical detectable reproductive disorders [4].

The objective of this study was to throw light on typical repeat breeding syndrome in Egyptian buffaloes with emphasis on the oxidative status and application of some field treatment trials. Also, economic impact of this syndrome has been investigated.

2. MATERIALS AND METHODS

Animals

The current study was conducted on 1358 mature polyparous buffalo cows randomly selected from small-scale holders at Al Sherkia governorate,

lower Egypt during 2008-2010. These animals were fed on Barseem (*Trifolium alexandrinum*), wheat or rice straw and a few amount of concentrate mixture. Based on owner complains, case history, general health condition and the gynecological examination, animals were categorized into two groups; the first group (G1) bred and conceived normally after no more than 3 inseminations. The second group (G2) was those animals which did not conceive after three or more inseminations, despite no clinically detectable reproductive disorders were observed (Typical repeat breeders). Gynecological examination was carried out through rectal palpation aided by ultrasonography machine (PiaMedical Falcs e`Saote, Netherlands) with an endorectal linear array of 8.6 M hertz to register the reproductive status and/or disorders.

Sampling and Analysis:

Blood samples were drawn from the jugular vein of each animal, in tubes with and without EDTA. Serum was separated after centrifugation and stored at −20 °C until analysis. Serum progesterone level was assayed by ELISA microwell technique using kits from DIMA (Germany). The kit had a sensitivity of 2.0 pg/ml with inter- and intra- run precision coefficient of variations of 2.9 and 4.85, respectively [5]. The concentrations of malondialdehyde (MDA) [6], nitric oxide(NO) [7], catalse (CAT))[8], ascorbic acid (ASC) [9], superoxide dismutase (SOD) [10] and total antioxidants(TAC) [11] in the serum and glutathione reduced (GSH-R) [12] in the whole blood were determined by colorimetric methods using chemical kits (Biomed Egypt) and Shimdzu UV 240 spectrophotometer. Zinc, copper, iron and selenium concentrations were determined using atomic absorption spectrophotometry (Perkin Elmer, 2380) as outlined by [13]

Treatment trials:

A total number of 34 repeat breeder buffalo cows was subjected to one of the following treatments: 1- No treatment at all and kept as the control group (n=5).

2- Lugol's Iodine solution (0.5 – 2%) as a vaginal wash for 3 successive weeks (n=5).

3- Receiving 20 g from a mixture of minerals, vitamins and Lasalocids® in their ration for 10 successive days. This mixture was prepared in the laboratory by throuogh mixing of 20 g of zinc sulphate , 6.25 g of copper sulphate, 1.5 g potassium iodide, 30 mg sodium selenite, 200 g AD3E and 5 g Lasalocids®, (F-Hoffman-La Roche,Basle, Swizerland) and sodium phosphate dibasic up to 1 kg [2] (n=11)

4- Receiving an intramuscular injection of GnRH (Receptal, Hoechst Roussel Vet GmbH) (n=13)

Treatments were carried out according to the instruction of manufacturing companies. Animals were followed up during the next weeks for conception.

Economic evaluation:

Economic losses were calculated on light of decreased calf crop, prolonged calving intervals, decreased milk production and veterinary intervention services, cost of the used drugs as well as cost of repeated AI.

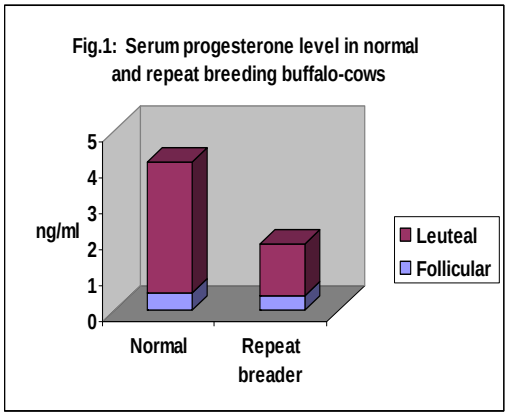
Statistical analysis:

The data were computed and statistically analyzed using PSS-10.5 software package [14].

3- RESULTS

3.1. Incidence

The present study declared that 59 (4.34%) out of 1358 examined polyparous buffalo- cows are typical repeat breeders with an average body condition and good health status. Moreover, this syndrome represented 7.25% of the total recorded reproductive disorders (813).



3.2. Reproductive aspect:

The studied buffalo cows came normally in heat inseminated in the proper time with normal proven fertile bulls and came in heat again after 20 – 22 days during the breeding season of buffaloes (September– March). Ultrasonographic examination

revealed that such animals showed no detectable clinical reproductive disorders with the corresponding normal physiological structure during the different stages of the estrous cycle. Serum progesterone level (Fig. 1) was significantly (P< 0.05) low (0.44 ± 0.39 ng/ml) during the mid -luteal phase of the estrous cycle in repeat breeder animals compared to normal animals **(**3.66±0.84 ng /ml).

3.3. Oxidative status:

Table 1 show the oxidant/ antioxidant status of the investigated animals. It was found that MDA and NO values were significantly high (P< 0.01) while, ASC, GSH-R, Zn, Cu, Fe and Se values were significantly(P< 0.01) low in repeat breeder buffalo-cows compared to normal animals.

Table (1): Oxidant / antioxidants concentrations in repeat breeder buffalo- cows (Mean ± SE).

Oxidant/antioxidant	Normal cows (N=10)	Repeat breeder buffalo-cows (N=10)
MDA (mmol/ml)	1.98 ± 0.09	3.70 ± 0.48 **
NO (mmol/L)	15.55 ± 1.58	25.17 ±0.85**
CAT (U/ml)	2.28 ± 0.4	1.99 ±0.10
ASC (µg/dl)	132.17 ± 5.12	95.16 ±2.37**
SOD (U/ml)	338.16 ± 7.11	332.12±16.14
GSH-R (mmol/L)	6.38 ± 0.11	2.66 ±0.09**
TAC (mmol/L)	1.43 ± 0.08	0.46 ±0.50
Zinc (µg/dl)	139.11 ± 2.17	120.21 ± 5.20**
Copper (µg/dl)	78.65 ± 0.13	68.33 ± 2.05**
Iron (µg/dl)	168.40 ± 4.11	152.13±2.05**
Selenium (µg/L)	144.85 ± 0.34	130.12±2.01**

** P< 0.01

3.4. Treatment trials:

Field trails to treat the typical repeat breeding syndrome using Lugol's solution, mineral mixture and GnRH indicated that 60 – 63 % of the treated animals get conceived as indicated by gynecological examination in 40 – 60 days later, while no animal from the untreated group get conceived. It was found that mineral mixture- treated group gives the highest response .

Table (2): Treatment trials for repeat breeder buffalo-cows (Mean ± SE).

Treatment	Repeat breeder-cows	Recovered animals	Recovery (%)
No treatment	5	0	00
Lugol's solution	5	3	60
Mineral mixture	11	7	63.64
GnRH	13	8	61.54

3.5. Economic evaluation

In the present study, economic losses were estimated as 1588 LE =288$ for every unsuccessful service. Moreover, such losses become greater if the animal did not get pregnant before the end of breeding season.

4- DISCUSSION

Repeat breeding is among reproductive disorders which hinder favorable productivity in buffaloes [15].

In the present study, the incidence of typical repeat breeders was 4.34% of the total examined animals and 7.25 % of all cases having reproductive disorders (813). The same result was found by [3]. Meanwhile, [16] and [17] reported a range of 8.33 - 28% for this syndrome in bovines. Variations in incidences may be attributed to the heterogeneity or multifactorial causes of the repeat-breeder syndrome as well as the effect of locality, season and year [18].

The low progesterone level that was recorded in the current study in repeat breeder buffaloes during the luteal phase was similar to the result of [19] that attributed the failure of conception in these animals to their low progesterone level. Moreover, [20] indicated that RB heifers revealed higher P4 concentrations during estrus and early metoestrus, and lower P4 concentrations during late metoestrus and onwards. In this respect, [21] suggested that the supra basal level of P4 during estrus reduced tubal contractility and delayed sperm transport to the site of fertilization and early embryonic mortality. Also, [17] mentioned that the disturbed hormone level which prolonged standing estrus and delayed ovulation causes changes in the microenvironment of the preovulatory follicle, negatively affecting the final maturation of the oocyte leading to fertilization failure in those repeat-breeder heifers. In another study, he reported a negative correlation between conception rate and skim milk progesterone level in cows artificially inseminated [22].

It is well known that in a healthy body, reactive oxygen species (ROS) and antioxidants remain in balance. When the balance is disrupted towards an overabundance of ROS, oxidative stress (OS) occurs. Also, ROS have a role in pathological processes involving the female reproductive tract, whereas, it affect multiple physiological processes from oocyte maturation to fertilization, embryo development and pregnancy [23]. This theory was confirmed in the current study where RB buffalo-cows showed increased MDA and NO and decreased CAT, SOD , ASCA, GSH-R and TAC. An endogenous NO system exists in the fallopian tubes [24].

NO has a relaxing effect on smooth muscles and it has similar effects on tubular contractility. Abnormal concentration of NO may lead to tubal motility dysfunction, resulting in retention of the ovum, delayed sperm transport and infertility. On the other hand, it was reported that increased NO levels in the fallopian tubes are cytotoxic to the invading microbes and also may be toxic to spermatozoa [24]. Moreover, [25] found that NO inhibits ovarian steroidogenesis. The presence of endothelial NO synthase in corpora lutea and its expression has been reported in the mid and early luteal phase and to a lesser extent in the late luteal phase Moreover, [26] and [27] added that NO inhibits steroidogenesis in the corpus luteum and has luteolytic action mediated through increased prostaglandins and by apoptosis.

SOD is present in the ovarian tissue and it was found that there is a correlation between SOD and Ad4BP which is a steroidogenic transcription factor that induces transcription of the steroidogenic P450 enzyme. Thus, it controls steroidogenesis in the ovaries. The correlation between Ad4BP and SOD expression suggests an association between OS and ovarian steroidogeneis [28]. The preovulatory follicle has a potent antioxidant defense, which is depleted by the intense peroxidation [29].

Glutathione peroxidase may also maintain low levels of hydroperoxides inside the follicle and thus play an important role in gametogenesis and fertilization [30]. Meanwhile, [31] reported that glutathione is present in the oocyte and tubal fluid and has a role in improving the development of the zygote beyond the 2-cell block to the morula or the blastocyst stage

Vitamin C is a chain breaking antioxidant that stops the propagation of the peroxidative process and helps to recycle oxidized vitamin E and glutathione [32].

Increase in TAC was seen in follicular fluid of oocytes that later were successfully fertilized. Therefore, lower TAC is predictive of decreased fertilization potential [33].

The low concentrations of zinc, copper, iron and selenium traced in this study coincide with [34] and [35] who recorded that serum zinc and copper

were significantly low in repeat breeders if compared to normal buffalo cows and added that when these animals were supplemented with 500 ppm zinc acetate in the drinking water and sodium phosphate 40 g/head/day in the diet for 1 month, respectively , the conception rate improved by 80%.and this explains our findings where the treatment with mineral supplementation gave the best results for conception (63.64 %) . This is in agreement with [15] who reported that 64.6 % of repeat breeder buffaloes came to estrus and 58.4 % conceived within one month after supplementation with vitamin/mineral mixture for 3 weeks. Then, he added that the hormone treatment is more effective than 3 weeks supplementation with vitamin/ mineral mixture.

Use of hormonal treatments such as GnRH or hCG, have been used by many investigators to increase the rate of pregnancy for repeat breeder cows [36, 37, 38]. It is suggested that it has a role in the expression of SOD as it is found that the Cu-Zn SOD expression in the corpora lutea paralleled with levels of progesterone and these levels rose from early to the mid luteal phase and decreased during the regression of the corpus luteum. However, in the corpus luteum from pregnant cases, the mRNA expression for Cu-Zn superoxide dismutase was significantly higher than that in midcycle corpora lutea [28]. Other investigators reported that when 36.4- 50.0 % repeat breeder buffaloes washed by 1 liter of 1% Lugol's solution conceived within one month after treatment [15].

From the economic point of view, the repeat breeding syndrome impacts the buffalo industry as it causes increased culling, reduced milk production, and reduced value of breeding stock. On the other side, the indirect costs of sound diagnosis, treatment trials, repeated artificial insemination should also be considered. RBS return the animal to service, increased time to conception and thus increased calving interval in the long-term reduced milk production or permanent infertility. The profitability of milking buffalo-cow increases with age, and culling earlier than the fourth lactation may result in net cost.Also reduced fertility is the commonest reason for culling in the UK [39], so any disease or syndrome affects fertility will have an economic impact. RBS may negatively affect milk production. Whilst an increased calving interval would reduce the number of lactations within a period of years, an RB may increase or prolong the lactation in which it happens. Thus, the impact of RB on milk production is complex and has not been fully quantified. In twenty-two Michigan dairy herds, repeat-breeder syndrome was observed in 24% of 3,309 lactations. Cost components associated with unsuccessful inseminations included costs of delayed conception, extra inseminations, extra veterinary service and losses due to culling. Lactations with repeat-breeder syndrome were associated with a loss of approximately $385. An estimated extra cost of $140 was associated with a second insemination, $279 with three inseminations, $429 with four inseminations and $612 with five inseminations [40].

It was concluded that RBS has economic impact on buffalo production and consequently, local meat and milk production in Egypt. Veterinary supervision should provide better animal health care and education to farmers regarding the risk factors that may lead to RB. Also, use of ultrasonography may help to get rapid and sound diagnosis. Great efforts should be done to catch up the breeding season not to lose the proposed new individual and lactation season. Also special care should be paid for minerals and food additive in animal's food stuff for animal welfare and breeder income.

Efficiency of Natural Minerals in Presence of Different Nitrogen Forms and Potassium Dissolving Bacteria on Peanut and Sesame Yields

Gehan H. Youssef, Wafaa M. A. Seddik and Mona A. Osman
Soil, Water and Environ. Research Institute, agricultural Research Center (ARC), Giza, Egypt

ABSTRACT
A field experiment was carried out for two summer seasons at Ismailia Agric. Res. Station to study the effect of some natural minerals combined with potassium dissolving bacteria inoculation in the presence of different nitrogen forms on chemical properties of soil, nutritional status and yield of peanut-sesame. Each experiment was designed in a split-split design with three replications. Three forms of nitrogen fertilizer were included along with two natural minerals, in a presence of potassium dissolving bacteria inoculation, as well as one mineral fertilizer as source potassium fertilizer. Furthermore, data show high significant increases in available N due to the application of ammonium nitrate in combination with feldspar, and calcium nitrate in combination with potassium sulfate in a presence of inoculation for peanut and sesame, respectively. However, application of calcium nitrate combined with potassium sulfate, and ammonium nitrate in combination with feldspar, in a presence of inoculation, led to significant increases in K available in soil for peanut and sesame, respectively. Oppositely, the pH values, different to those of EC, decreased either for inoculation or non-inoculation as compared to control. In spite of that, the values of EC and pH of soil were higher with application of either bentonite or bentonite + feldspar in a presence of all nitrogen fertilizer forms. Generally, the highest EC values in soil, after the two studied seasons were encountered with calcium nitrate fertilizer as well as bentonite mineral. Moreover, applying feldspar mineral and ammonium nitrate treatments had recorded the highest values of yield components as well as nutrient (N and K) uptake by either peanut or sesame crops, particularly in the presence of inoculation as compared to those given by other treatments.

INTRODUCTION

Sandy soils represent the most desert area in Egypt, and they are usually deficient in organic matter and plant nutrients (Abdel Wahab et al, 2003). Potassium is one of the three essential element viz., NPK, for the growth and reproduction of plants; it plays vital roles in its nutrition. The crop production in Egypt relies completely on imports to meet its annual requirement of potash fertilizers; besides the high cost of conventional, water-soluble K fertilizers constrains their use by most of the farmers in the country. In order to reduce the dependence on imported potash, feldspar potash mineral contains 11.25 % K_2O and therefore, it could be a potential K-source for crop production. New approaches are needed to unlock K from the silicate structure of this mineral in order to render K more available for plant nutrition (Badr, 2006). Many researchers showed that microbes can accelerate weathering of minerals and rocks by producing organic acids, phenolic compounds, siderophores and possibly other metabolites, which influence pH and redox conditions. In addition, direct contact between bacteria and minerals may be important in mineral alteration reaction, as microbial surfaces can be complex with metal ions. Some recent reports showed that silicate dissolving bacteria played a promotion role in the release of Si, Fe and K from feldspar (Badr, 2006).

According to Abdel Wahab et al., (2003), the highest values of growth and green yield of pea were obtained in case of organic compost application in combination with chemical or natural sources of P and K. Also, the applied natural sources of P and K gave an almost similar trend to that obtained with the chemical ones combined with the organic compost. The concentrations of phosphorus and potassium in plant tissues increased with increasing compost levels irrespective of their sources. In addition, the combined treatment of organic compost with both sources of P-K achieved the highest values of P and K concentrations in plant tissues.

Significant increases were obtained in height of main stem, branch stem length, number of branches, main stem diameter and leaf area of olive seedlings treated with compost fortified with plant guard and feldspar compared with the control treatment. The same trend was also observed concerning the application of compost and feldspar on micro and macronutrient contents in leaves of the mentioned olive seedlings (Abd El-Motty et al., 2009).

Biofertilizers have been used as sources to improve the status of plant nutrients in sustainable

agriculture. Inoculation with bacterial strain Bacillus edaphicus NBT was found to increase root and shoot growth of cotton and rape. Strain NBT could mobilize potassium efficiently in both plants when illite was added to the soil. In cotton and rape growing on soils treated with insoluble potassium and inoculated with strain NBT, the potassium content was increased by 30 and 26 %, respectively. Bacterial inoculation also resulted in higher N and P contents of aboveground plant components (Sheng, 2005).

Rock P and K applied either singly or in combination did not significantly enhance soil availability of P and K, indicating their unsuitability for direct application. PSB (phosphate solubilizing bacteria) was a more potent P-solubilizer than KSB (potassium solubilizing bacteria), and co-inoculation of PSB and KSB resulted in consistently higher P and K availability than in the control without bacterial inoculum and without rock material fertilizer. Combined together, rock material and both bacterial strains consistently increased further mineral availability, uptake and plant growth of pepper and cucumber plants, suggesting their potential use as fertilizer (Han et al., 2006).

Phosphorus and potassium nutritional status in the soil were markedly improved through inoculation with solubilizing bacteria (Bacillus mucilaginosus); groundnut plant dry matter increased by 125 % and the oil content 35.41 % were increased through bacterium inoculation (Sugumaran and Janarthanam, 2007).

Recently, the treatment of Bacillus circulans + rock phosphate + feldspar was superior in plant height, number of branches, number of nodules per plant and fresh yield (ton/fed.) of snap bean plants when compared with control and the un-inoculated plants. The NPK analysis of shoot dry matter of snap plants showed that as a result of addition of alternatives and the viability of B. circulans, there was marked increases in phosphorus and potassium solubilization (Massoud et al., 2009).

The objective of this study was to determine the efficiency of using different natural mineral as alternative potassium fertilizer in the presence of nitrogen forms and potassium dissolving bacteria inoculation adopted for peanut and sesame plants grown on sandy soil.

MATERIALS AND METHODS

Two summer successive field experiments were carried out on peanut (Arachis hypogaea) – sesame (Sesamum indicum) cropping sequence in a sandy soil under drip irrigation system at Ismailia Agric. Res. Station (A.R.C).

Some physical and chemical characteristics of the studied soil before cultivation are shown in Table (1).

Table (1): Some physical and chemical properties of soil samples representing the studied location.

Soil characteristics	Values
Particle size distribution %	
Coarse sand	50.4
Fine sand	40.4
Silt	3.20

N	166	216
P	2.10	5.76
K	151	400

Peanut and sesame were cultivated in a randomized split-split plot design, each treatment being replicated three times. The main plots were either inoculated or un-inoculated with potassium dissolving bacteria (Bacillus pasteurii) as (Biopotash). The sub main plots were three nitrogen sources, including ammonium sulfate, calcium nitrate and ammonium nitrate, added at the rate of 30 kg N/fed. The sources of nitrogen were added in four equal split doses after sowing. The sub- sub plots

represented the natural minerals (feldspar and bentonite), which were added individually or in combination (50% bentonite and 50% feldspar, as compared to mineral fertilizer (potassium sulfate)) at the rate of 50 kg K_2O/ fed. Phosphorus fertilizer was added at the recommended dose (200 kg/fed.) for both peanut and sesame in the form of superphosphate 15.5 % P_2O_5. Both potassium and phosphorus fertilizers were completely added to soil before cultivation.

Plant and soil were sampled at 150 days and 120 days after sowing for peanut and sesame respectively, which represent the harvesting stage.

Surface soil samples (0-15 cm depth) were taken after harvesting stage to evaluate soil pH, EC and available nutrients (N and K) were determined according to Page et al. (1982).

Peanut and sesame plant samples were taken at harvesting stage to determine the nutrients status and yield components (straw and grain yield). Plant samples were oven dried at 70 ^oC for 48 hrs up to constant dry weight, then ground and wet digested using H_2SO_4:H_2O_2 method described by Page et al. (1982). The digests were then subjected to the measurement of nutrients (N and K) according to procedures described by cottenie et al. (1982).

Obtained results were subjected to statistical analysis using STATISTICA 6.0 (statSoft, Inc, Tusla, USA) according to Hill and Lewicki (2007). Analysis of variance (ANOVA) was employed to examine the independent and interacted effects of inoculation with potassium dissolving bacteria, nitrogen and potassium sources. Also, treatments were compared by using L.S.D. at 0.05 level of probability according to Snedecor and Cochran (1980).

RESULTS AND DISCUSSION

1- Influence of nitrogen fertilizer, natural mineral and inoculation with bacteria on some soil chemical characteristics.

As for the effect of nitrogen forms and natural mineral on nitrogen and potassium availability, at the two studied seasons, results in Fig (1 A, B) reveal that calcium nitrate treatment was superior at available N while ammonium nitrate being superior at available K.

Furthermore, results showed that the highest values of available nitrogen and potassium exist in case of feldspar and potassium sulfate treatments, respectively at the first studied season. Such results are confirmed by Hagin and Shaviv (1990) who reported that the adequate supply of potassium enhances ammonium utilization and thus improves yields. An opposite trend was obtained at second season, which appeared to be highly significant with applied potassium sulfate for available nitrogen with feldspar being highly significant for available potassium. This obtained data could be due to the application of K solubilizing bacteria, which may produce bacterial acids, alkalies or chelates to enhance solubility and release of elements from potassium containing minerals in soil (Lin Qi-mei , et al., 2002 and Seddik, 2006).

To make the picture clearer, it was thought usefully to express the obtained results as interactions between the influences of both natural mineral and nitrogen fertilizer forms; such interactions are shown in Fig (2). For available nutrients (N and K) in soil, at the two studied seasons, values were significantly increased as a consequence of applied natural mineral in the presence of nitrogen fertilizer and inoculation as compared to control. A previous study (Barker, et al., 1997 and Badr, et al., 2006) confirmed that this bacterial strain produces several organic acids such as acetate, butyric, pyruvic, lactic and formic acid during their biological activities. Such acids can increase mineral dissolution rates; carboxylic acid groups, which were shown to promote dissolution of silicate, are also common in extra cellular organic materials. Moreover, some microorganisms in the soil environment contain enzymes that function in ways analogous to chitinase and celluloses. i.e. they specifically break down mineral structures and extract elements required for metabolism or structure purposes (e.g., mineralization).

Also, data in Fig (2) show high significant increases in available N due to the application of ammonium nitrate in combination with feldspar, and calcium nitrate in combination with potassium sulfate in the presence of inoculation for peanut and sesame, respectively. However, application of calcium nitrate combined with potassium sulfate, and ammonium nitrate in combination with feldspar, in the presence of inoculation, led to significant increases in K available in soil for peanut and sesame, respectively.
Concerning EC and pH values, the highest EC values in soil following the two studied seasons were reported for calcium nitrate fertilizer as well as bentonite mineral as a source of potassium fertilizer (Fig 3.A). With respect to pH values, the highest values in soil were reported for calcium nitrate at the first season (peanut) and for ammonium nitrate at the second season (sesame). An opposite trend was generally encountered with natural mineral, particularly for applied feldspar, which led to a decrease in pH values at the two seasons as compared to control (Fig 3.B).

Again, to make the picture clearer, it was thought useful to express the obtained results as interactions between the influences of both natural mineral and nitrogen fertilizer forms; such interactions are shown in Fig (4). Data indicated that,

for both studied seasons, application of different natural mineral significantly increased the EC values but decreased the pH values of the studied soil in the presence of nitrogen fertilizer forms as compared with control, whether inoculation or non-inoculation was performed. Moreover, the indicated values of EC and pH were higher in case of applying either bentonite or bentonite + feldspar ratio in the presence of all nitrogen fertilizer forms. Soil salinity increase could be due to the relatively high content of salts in bentonite (Gouda, 1984).

Fig (6): Response of yield components (Kg fed.$^{-1}$) for both peanut and sesame at two seasons to application of different sources of natural mineral, nitrogen fertilizer and/ or inoculation with potassium dissolving bacteria at harvest stage.

Feldspar treatment had recorded the highest values of yield components for either peanut or sesame, particularly in the presence of inoculation as compared to those given by other treatments. These increases in yield components of peanut crop, recorded 117 % and 46.2 % against 118 % and 39.4 % for sesame straw and grains or seeds as compared to control, respectively. These data agreed with the results reported by Badr (2006) who found that the better performance of feldspar-compost plus silicate dissolving bacteria could be attributed to better maintenance of soil nutrient status in the root zone, which in turn helped the plants to utilize nutrients more efficiently; release of potassium took place frequently, and thus favorably affects growth of the crop. Locascio and Hochmuch (1997) reported that potassium supply by the soil is an extremely important factor in yield production, and the high yield depends on the level of K available to the plants. Recently, Massoud et al. (2009) reported that AM-fungi inoculation combined to B.circulans is highly beneficial to the growth of plants. This combination optimizes the K solubilization from feldspar and increased microbial activity in the rhizosphere of plants. So, the weathering of feldspar by AM- mycrrhizal fungi and B. circulans bacteria enhance the release of K ions that led to encouragement for the growth and consequently, the diverse of rhizospheric microflora.

3- Influence of nitrogen fertilizer, natural mineral and inoculation with bacteria on nutrients uptake at harvesting stage.

A- Nitrogen uptake

With respect to nitrogen uptake of peanut and sesame plants, generally, the highest significant increases for nitrogen uptake of straw and grain or seeds for either peanut or sesame yields were reported for ammonium nitrate fertilizer and feldspar mineral compared to other treatments (Fig 7., A and B). Treatments of nitrogen fertilizer may be generally arranged as follows: ammonium nitrate > calcium nitrate > ammonium sulfate for the two studied seasons. On the other hand, treatments of potassium fertilizer may be arranged as follows: feldspar > potassium sulfate > bentonite + feldspar > bentonite at the first season while arranged as follows: feldspar > bentonite + feldspar > potassium sulfate > bentonite for the second season. Also, behavior of nitrogen uptake followed the same trend of those obtained for yield components at the two studied seasons. In fact, Katai et al. (2010) indicated that the large bentonite doses reduced the nitrate- N content along with available phosphorus and potassium contents of soil, which reflected on nutrients uptake by plants.

To make the picture clearer, it was thought usefully to express the obtained results as interactions between the influences of both natural mineral and nitrogen fertilizer forms; such interactions are shown in Fig (8). Data show that values at the two studied seasons were positively affected by application of natural mineral in the presence of nitrogen forms either of inoculation or non-inoculation compared to control.

Moreover, results showed that the nitrogen uptake was significantly increased with inoculation by potassium dissolving bacteria. These results are in agreement with those of Han et al. (2006) who reported that the soil inoculation with potassium solubilizing bacteria significantly increased nutrients uptake in pepper and cucumber plants, especially when the respective rock potassium were added. Generally, pattern of nitrogen uptake followed the same trend of those obtained with yield components of both crops (peanut and sesame).

Application of feldspar with ammonium nitrate as a source of nitrogen fertilizer generally improved the uptake of nitrogen in plants, especially in the presence of inoculation compared to control. These increases in nitrogen uptake of peanut crop, recorded 214 % and 301 % against 219 % and 176 % for sesame straw and grains or seeds compared to control, respectively.

B. Potassium uptake

However, the highest response for potassium uptake of straw and grains or seeds at the two studied seasons were recorded for ammonium nitrate fertilizer as a source of nitrogen fertilizer with potassium sulfate and feldspar mineral as sources of natural mineral for peanut and sesame yield, respectively. (Fig.9, A and B).

Treatments of nitrogen fertilizer seemed to follow a trend for potassium uptake similar to those obtained for nitrogen uptake. Regarding to treatments of natural minerals, they could be arranged as follows: potassium sulfate > feldspar > bentonite + feldspar > bentonite for the peanut yield while arranged as follows: feldspar > bentonite + feldspar > potassium sulfate > bentonite for the sesame yield. The last behavior of potassium uptake, again, seemed to follow a trend similar to those obtained for nitrogen uptake for the two studied seasons. In the same concern, Badr (2006) found that the total uptake was greater when feldspar- compost plus silicate dissolving bacteria was applied followed by potassium sulfate while the lower was recorded for feldspar. This may indicate that a major portion of K present in feldspar mineral as well as in the organic materials became available for uptake and contributed considerably towards the nutritional requirements of the crop. Further, loses due to drainage, leaching and percolation of potassium from feldspar charged compost are negligible as compared to soluble potassium salts. Hence, use of feldspar in a biological form should be, further, more economical than imported potash fertilizer.

The obtained results as interactions between the influences of both natural mineral and nitrogen fertilizer forms (Fig 10) reveal positive responses for potassium uptake to application of natural mineral treatments in the presence of either nitrogen forms or inoculate as compared to control.

Application of ammonium nitrate with feldspar was generally superior, particularly in the presence of dissolving potassium bacteria. However, an exception being obtained in case of applying calcium nitrate with potassium sulfate for straw at first season compared to control. These increases in potassium uptake of peanut crop, recorded 336 % and 78.3 % against 352 % and180 % for sesame straw and grains or seeds as compared to control, respectively.

From our obtained results, it could be concluded that, the feldspar mineral and ammonium nitrate as a source of potassium and nitrogen recorded the highest values of yield components as well as nutrient (N and K) uptake for either peanut or sesame particularly in the presence of inoculation. Moreover, the effects of both feldspar and feldspar + bentonite was generally similar to that of potassium sulfate, particularly in the presence of inoculation. So, this biofertilizer is highly efficient to achieve the economy of potash fertilizer and reduce the cost of cultivation through the use of cheap and locally potash source.

Acknowledgment

The authoresses wish to express their sincere gratitude and appreciation to the Development of Soil Conditioners Project, Dept. of Chemistry and Physics of Soil, Soils, Water and Environ. Res. Inst., Agric. Res. Center (ARC), Giza, Egypt, for introducing all facilities needed to accomplish this study.

كفاءة المعادن الطبيعية فى وجود صور نيتروجين مختلفة و البكتريا المذيبة للبوتاسيوم على محصولى الفول السودانى و السمسم

جيهان حسنى يوسف – وفاء محمد أحمد صديق – منى عبد العظيم عثمان
معهد بحوث الآراضى و المياه و البيئة – مركز البحوث الزراعية – الجيزة – مصر

الملخص العربى

أجريت تجربة حقلية فى موسمين صيفيين متعاقبين بمحطة البحوث الزراعية بالاسماعيلية لدراسة تاثير فاعلية بعض المعادن الطبيعية فى وجود صور مختلفة من النيتروجين مع التلقيح بالبكتريا المذيبة للبوتاسيوم وتأثير ذلك على الخواص الكيميائية و الحالة الغذائية و الانتاجية لمحصولى الفول السودانى و السمسم.
وقد صممت التجربة فى قطع منشقة فى ثلاث مكررات حيث اضيف ثلاث صور من التسميد النيتروجينى و مصدرين من المعادن الطبيعية هما الفلسبار و البنتونيت كمصدر للتسميد البوتاسى فى وجود البكتريا المذيبة للبوتاسيوم.
أظهرت النتائج ايضا زيادة معنوية فى النيتروجين الميسر نتيجة اضافة نترات الامونيوم مع الفلدسبار وكذلك نترات الكالسيوم مع كبريتات البوتاسيوم فى وجود التلقيح البكتيرى لمحصولى الفول السودانى و السمسم على التوالى. كذلك، تبين وجود زيادة معنوية فى البوتاسيوم الميسر نتيجة اضافة نترات الكالسيوم مع كبريتات البوتاسيوم وكذلك نترات الامونيوم مع الفلدسبار فى وجود التلقيح البكتيرى لمحصولى الفول السودانى و السمسم على التوالى.
أظهرت النتائج انخفاضا قيم الـ pH (مختلفة فى ذلك عن قيم الـ EC) فى وجود أو عدم وجود التلقيح البكتيرى و ذلك خلال الموسمين تحت الدراسة.
و بالرغم من ذلك، أظهرت معاملة البنتونيت و أيضا معاملة البنتونيت مخلوطا مع الفلدسبار فى وجود جميع صور النيتروجين تحت الدراسة أرتفاعا فى قيم الـ EC ، pH بحيث ظهرت أعلى قيمة للتوصيل الكهربى عند المعاملة بالبنتونيت مع نترات الكالسيوم لكلا المحصولين.
أما بالنسبة لنتائج المحصول فأظهرت المعاملة بمعدن الفلسبار مع التلقيح و نترات الامونيوم أعلى قيم للمحصول وكذلك أمتصاص العناصر (النيتروجين و البوتاسيوم) فى كل من محصولى الفول السودانى و السمسم.

Abstract: *Hymenolepis nana* and *H. diminuta* are the most common cestodes in humans, domestic and wild rodents. Since isolates of *H. nana* species are morphologically identical, the way they can be reliably distinguished is comparing the parasite in each host using molecular techniques. In the current study, Mitochondrial Cytochrome *c* oxidase gene especially codons within subunit 1 (*cox1*) of *H. diminuta and H. nana* Egyptian isolates from different developmental stages (adult worms and eggs) and hosts origin (human and rat) were amplified, sequenced and aligned. PCR products were approximately 700 bp, 702 bp and 715 bp of *H. nana* rat isolates, *H. diminuta* rat isolates, and *H. nana* human isolates, respectively. Moreover, despite their host susceptibility differences they all gathered in one cluster with three genbank published isolates of *H. nana*; AB033412.1, AB494472.1 and AY121842.1), forming one clade with 100% similarity, which was non significantly decreased on internal nodes. In addition, clearly far away from *H. diminuta* published sequence AB033412.1 who's assumed to be genetically closely related to Egyptian *H. diminuta* than all other *H. nana* isolates. Both Egyptian murine isolates of Hymenolipidid; *H. diminuta* and *H. nana*, were closer to each other than being to *H. nana* of human origin. The annotated sequences of Egyptian isolates were deposited in GenBank under the following accession numbers; *H. diminuta* (GU433102), *H. nana* rat isolate (GU433103), and *H. nana* human isolate (GU433104). Finally, the development of effective control strategies will only be possible if complete understanding of the epidemiology of infestation is elucidated.

[Omnia M. Kandil, Mona S. Mahmoud, Nesreen A.T. Allam, Amira H. El Namaky. **Mitochoderial cytochrome c oxidase subunit 1 (*cox 1*) gene sequence of the *Hymenolepis* species**. Journal of American Science 2010;6(12):1346-1353]. (ISSN: 1545-1003). http://www.americanscience.org.

Keywords: Hymenolepidid, Phylogeny, Cytochrome *c* oxidase subunit 1 gene (*cox1*), Sequencing.

Introduction

Hymenolepis nana and *H. diminuta* are the most common cestodes in humans, domestic and wild rats, mice and dogs **(Macko and Hanzelova 2008)**. During hymenolepiasis various pathological, immunopathological and physiological alterations are recorded. They similarly stimulate abdominal pain accompanied by diarrhea and anorexia as well as increase in the number of mast cells and eosinophiles in the infected individuals. These uncharacteristic symptoms could not be useful in differential diagnosis clinically or on microscopical examination of fecal samples for eggs **(Raether and Hänel 2003)**. It is believed that infestations with *Hymenolipis* spp., in general, may have been under diagnosed due to sporadic egg shedding **(Thompson et al. 2001)**. Since isolates of *H. nana* infecting humans and rodents are morphologically identical, the only way they can be reliably distinguished is comparing the parasite in each host using molecular techniques **(Macnish et al. 2002a, b)**.

Mitochondrial (mt) genomes are small (usually less than 20000 bp), circular, and maternally inherited **(Boore 1999)**. In addition to high copy-number per cell which has made them attractive and more tractable targets for characterization, population genetic and phylogenetic studies **(Hu et al. 2004; McManus et al. 2004)**. Regions within the mitochondrial DNA (*mt*DNA) have been proven useful in biology, epidemiology and diagnosis of

several parasitic infestations of human and veterinary importance **(Ngarmamonpirat et al. 2005; Ando et al. 2006)**. Methods used to obtain data from flatworm *mt* genomes have included DNA sequencing, restriction fragment length polymorphism (RFLP) analysis and single-strand conformation polymorphism (PCR-SSCP) **(Boore and Brown 1998; Avise, 2000).** Intraspecific sequence variation in coding portions (genes) of the *mt* genomes seems to range from small to moderate, especially when compared with interspecific variation that have demonstrated the deep separations among strains of same species **(Littlewood et al. 2008)**.

Complete or near-complete *mt*DNA sequences are available for 12 species of parasitic flatworms; six cestodes including *Taenia crassiceps* **(Le et al. 2000)**, *Echinococcus multilocularis* **(Nakao et al. 2000)** and *Hymenolepis diminuta* **(von Nickisch-Rosenegk et al. 2001)**. Cytochrome c oxidase (COX) is a 13-subunit protein complex located on the inner mitochondrial membrane that catalyzes electron transfer, proton translocation processes, production of up to 95% of the energy of eukaryotic living cells **(Saraste 1999; Johnston 2006)**, thus directly influence metabolic performance. *mt cox* sub unit 1 is the most highly conserved among 3 genes coding for cytochrome oxidase, therefore has been employed in several phylogenetic studies **(Traversa et al. 2007)**.

DNA sequencing of informative regions within the gene encoding for the COX1 protein have emphasized specific comparative aspects without yet making a detailed genome description but revealed data for basic and applied potential differential studies on *Hymenolopis* spp. determining host specificity and transmission patterns **(Macnish et al. 2003).** Therefore, allow more appropriate approach for control of endemic infestations in Egypt, particular where rodent's population is above control limits and hygienic measures are not strictly applied. Furthermore, for diagnostic purposes since using techniques able to overcome inherent limits of the classical approaches **(Constantine 2003; Thompson et al. 2004)**. Epidemiologically, despite this infection is a hand-to-mouth rote that in general not very pathogenic, however it is extremely difficult to be controlled **(Littlewood et al. 2008)**. Till now education in hygiene is probably the only practical way to reduce the incidence in addition to rodent's eradication **(Behera et al. 2008)**. The genotyping of *Hymenolepis* isolates in different hosts will help in determine host specificity and transmission patterns and thus allow more appropriate approach to control infections in endemic communities. From a public health perspective, a better understanding of the transmission dynamics of a parasite species previously believed to be infective only to rodents will be required to answer questions about the potential for transfer of this parasite to humans and/or animals.

Since control of parasitic disease is dependent on the rapid and accurate detection of causative agents this necessitated traditional techniques being complemented by molecular tools that provide predictive data on genetic variation in and among parasites **(Thompson et al. 2004)**. Thus the present work aims is to characterize, for the first time, partial sequences of *cox1* genes of *H. diminuta* and *H. nana* Egyptian isolates to promote basic knowledge on their *mt*DNA composition, to assess the sequence variation level within local Hymenolepidid from different sources, different developmental stages (adult worms and eggs) and hosts origin (human and rat), and to discuss the potential benefits of such molecular information as record sheets for ecological, epidemiological, transmission and host-parasite interaction and as diagnostic approach of infestation in Egypt.

Materials and Methods

Parasites Samples:

H nana eggs were obtained from infected humans in Endemic Diseases institute. Approximately 2000 *H. nana* eggs were inoculated into 5-week-old male white mice **(Movsesyan et al. 2008)**. Adult worms were dissected from the small intestine approximately 14 days post-inoculation. *H. diminuta* worms were obtained from naturally infected *norvegicus* rat from Abu Rawash, Giza, Egypt. Rats were killed by cervical dislocation and entire small intestine was removed from gut. The worms and eggs washed repeatedly in phosphate buffered saline (PBS) and stored at -80 ^{o}C until used for DNA extraction.

Isolation of DNA from Adult Worms and Eggs

Templates DNA were purified from *H. nana* and *H. diminuta* using QIAmp tissue purification kit **(Qiagen, Hilden, Germany)** according to manufacturer's instructions **(Macnish et al. 2002a)**. DNA was eluted in 200 µl Tris-EDTA (TE) buffer and 1 µl of the extract was added to the polymerase chain reaction mix. Single adult worm and/or eggs for each isolate were used for DNA extraction.

Oligonucleotide Primers Design

Entire *mt* genomes of the following species were aligned *Hymenolepis diminuta* (accession number AB033412.1), *Taenia crassiceps* (accession number NC_002547), *T. solium* (accession number NC_004022), *T. asiatica* (accession number

NC_004826), *Echinococcus granulosus* (accession number NC_008075), and *E. multilocularis* (accession number NC_000928); and annotated sequence of *Hymenolepis nana* (accession number AF314223.1) **(Nakoo et al. 2000, 2002; von Nickisch-Rosenegk et al. 2001).** It was not deemed necessary to include all the available sequences from *Taenia* or *Echinococcus* as conservation of alignable positions between genera and being > 30% GC was more important for PCR primer design. PCR primers pair designed *cox1*-F 5`-ACTTCATTGCTTTTGCTTTTTAGA-3` and *cox1*-R 5`-TGCTGTCATAAATGAACCAACAGT-3` were synthesized by Metabion International AG **(Martinsried/Deutschland)**.

PCR Amplification Protocol

Fragments of the mitochondrial cytochrome *c* oxidase subunit 1 gene were amplified using designed primers and each PCR mix was prepared in 50 µl total volume with 1 µl of template (50 ng), 10 pMoles of each primer, 45 µl of Ready TaqMix Complete **(Mater Mix, AllianceBio, USA)**, and nuclease free water **(Qiagen, Germany)** to complete the total volume of the reactions. PCRs were performed in a PTC-100™ Thermal Cycler **(MJ Research Inc., USA)** using the following cycling protocol: initial denaturation at 95^0C for 3 min and then 40 cycles of 94^0C for 1 min 50 sec, 58^0C for 1 min 30 sec, and 72^0C for 1 min. Final extension was carried out at 72^0C for 7 min. A reagent blank was run as control in every PCR procedure. Positive results by PCR were retested on two further occasions several days later to examine the reproducibility of PCR. Amplified products from the PCRs were electrophorised on 1.5% agarose gels **(Bioshop Canada, Burlington, Ontario, Canada)** stained with ethidium bromide (0.5 µg/ml) **(Bioshop Canada) (Sambrook et al. 1989)**. A 100 bp ladder **(Jena Bioscince, GmbH, Germany)** was loaded in each gel then photographed under UV light with gel documentation system.

Sequencing of *cox1* Gene Products

PCR-product of each isolates were purified with QIAquick-spin PCR purification kit **(Qiagen, Germany)** then directly sequenced from both directions using ABI Prism™ Dye Terminator Cycle Sequencing Ready Reaction Kit **(Applied Biosystem, FosterCity, California)** according to manufacturer's instructions on a 3130XL Genetic Analyzer **(Applied Biosystems)**. At least two independent PCR products were used for sequencing per isolate.

Sequences Analysis

The resulting aligned output was manually adjusted **(Lee et al. 2007)**. Sequences corresponding to the PCR amplification primers were excluded prior to multiple sequence alignment and phylogenetic analysis. The confirmed sequences were then deposited in the EMBL/GenBank Data Libraries of the NCBI. In order to improve the homology statements out group included *Taenia saginata* (AB465239.1), *T. solium* (AY211880.1), *T. multiceps* (GQ228818.1), *Echinococcus granulosus* (AF314223.1), *E. multilocularis* (AF314223.1) and *Spirometra erinaceieuropaei* (AB374543.1), as well as all annotated sequences of *Hymenolepis diminuta* (AB033412.1) and *Hymenolepis nana* (AF314223.1, AY121842.1, AB494471.1, AB494472.1, AB033412.1, AF314223.1) by Basic Local Alignment Search Tool (nBLAST) (www.ncbi.nih.gov/BLAST/) in the NCBI database (National Center for Biotechnology Information, NIH, Bethesda, Maryland, USA) **(Tatusova and Madden 1999).** The alignment gaps were treated as missing data. Phylogeny of Egyptian *Hymenolipis nana* and *H. diminuta* human and rat isolates based on *coxI* gene partial sequences and multiple alignment analysis were performed with CLUSTAL W computer program **(Thompson e al. 1994).**

Phylogeny Construction

The bootstrap consensus tree inferred from 500 replicates is taken to represent the evolutionary history of the taxa analyzed **(Felsenstein 1985)**. Branches corresponding to partitions reproduced in less than 50% bootstrap replicates are collapsed. The percentage of replicate trees and node reliability in which the associated taxa clustered together in the bootstrap test is shown next to the branches **(Felsenstein 1985)**. The tree is drawn to scale, with branch lengths in the same units as those of the evolutionary distances used to infer the phylogenetic tree. The evolutionary distances were computed using the Poisson correction method **(Zuckerkand and Pauling 1965)** and are in the units of the number of amino acid substitutions per site. All positions containing gaps and missing data were eliminated from the dataset (Complete deletion option). There were a total of 99 positions in the final dataset. Phylogenetic analyses were conducted in MEGA4 **(Tamura et al. 2007)**. Neighbor-Joining and UPGMA methods were used to calculate the evolutionary relationship of the Egyptian isolates with genbank references strains **(Saitou and Nei 1987).**

Results

PCR Products of *mt cox1* Gene

PCR products were amplified from *mt* genomes using synthesized primers set. Across the alignment of *mt* genomes few regions were suitably

conserved to allow primer design. The PCR products were approximately 700 bp, 702 bp and 715 bp for *mt cox1* gene of *H. nana* rat isolates, *H. diminuta* rat isolates, and *H. nana* human isolates, respectively, **(Figure 1)**.

Sequences Analysis

Variation occurred in terms of sequence length and nucleotide differences and gaps (nucleotide insertions, deletions, and substitutions)**,** but not G+C percentage where the overall numbers did not differ between amplified fragments; A (23%), C (10%), G (22%) and T (45%). Where Nucleotide alterations were found to be variable and several nucleotide insertions, deletions and substitutions were detected with gaps in the same or different positions **(Figure 2)**.

Phylogeny Construction

Similar topologies were observed in the Egyptian isolates with genbank references strains. Optimal phylogenetic tree with the sum of branch length = 1.91459848 is shown **(Figure 3)**. Egyptian species were genetically distinct from other species used in this study that are phylogenetically relating to Hymenolipidid. In addition, despite their host susceptibility differences they all gathered in one cluster with three genbank published isolates of *H. nana*; AB033412.1 (gi|6045204), AB494472.1 (gi|2262378), and AY121842.1 (gi|2221354), forming one clade with 100% similarity, which was non significantly decreased on internal nodes. Moreover, obviously far away from *H. diminuta* published sequence AB033412.1 (gi|1399136) who's assumed to be quite genetically closely related to Egyptian *H. diminuta* than all other *H. nana* isolates. Both Egyptian murine isolates of Hymenolipidid; *H. diminuta* and *H. nana*, were closer to each other than being to *H. nana* of human origin.

GenBank accession numbers of Egyptian amplicons

The annotated sequences of Egyptian isolates were then deposited in the GenBank of NCBI under the following accession numbers; *H. diminuta* (GU433102), *H. nana* rat isolate (GU433103), and *H. nana* human isolate (GU433104).

Discussion

Mitochonderia play a central role in metabolism, apoptosis, disease, and aging **(Le et al. 2002)**. They are the site of oxidative phosphorylation, essential for the production of ATP, as well as a variety of other biochemical functions. Within these subcellular organelles is a genome, separate from the nuclear chromatin, referred to as mitochondrial DNA (mtDNA), very commonly used in studies of molecular phylogenetics **(Avise 2000)**. Flatworm mitochondrial genomes have a number of distinct features including all genes are coded on the same strand **(von Nickisch-Rosenegk et al. 2001)**, utilize a unique mitochondrial genetic code **(Boore 1999)** and truncated stop codons have also been found among a number of genes **(Nakao et al. 2000, 2003)**.

In the current study the earliest genbank records of *cox1* gene of Egyptian *Hymenolepis* spp. are declared. So far, only a few is known about the relative divergence rates of mitochondrial DNA in *hymenolipis species* especially Egyptian isolates **(Vilas et al. 2005)**, hence only one species belonging to *H. diminuta* is completely sequenced and published in genbank **(Littlewood et al. 2008)**. However, PCR technology and DNA sequencing techniques permit the identification of species, strains, and populations from any stage in their life history to distinguish among morphologically similar parasites **(Boore 1999)**.

Egyptian species were genetically distinct from other species used in this study that are phylogenetically relating to Hymenolipidid. Both Egyptian murine isolates of Hymenolipidid; *H. diminuta* and *H. nana*, were closer to each other than being to *H. nana* of human origin. WHO annual reports maintained the traditional host specificity of hymenolepidid till few years ago **(Lee et al. 2007)**. Unfortunately, the unexpected discovery of a mixed infection with specie which is known to infect rodent as definitive host in surveyed individuals **(Thompson et al. 2001; Macnish et al. 2003)** as well as in dogs living in the same locality as their infected owners declared the public health impact of new infestations, and meditating urgent thorough understanding of the epidemiology of these parasites **(Jenkins and Andrew 1993; Thompson et al. 1993; Macnish et al. 2003)**. Since such deviation in patency of infestation was not previously recorded thus highlights the growing importance of using molecular techniques in both the detection and characterization of parasite species in human and animals' populations especially between morphologically similar species **(Okamoto et al. 1997; Nakao et al. 2000; von Nickisch-Rosenegk et al. 2001; Macnish et al. 2003)**.

In a comparison of genetic makeup, our result suggests that *cox1* gene is generally conserved by each isolate nucleotide sequence analysis. Despite of variation occurred in terms of sequence length and nucleotide differences and gaps (nucleotide insertions, deletions, and substitutions)**,** but not G+C percentage where the overall numbers did not differ

between amplified fragments mostly triggered by a variety of hosts' biological conditions **(Macnish et al. 2002a, b)**. Such data showed consistent patterns with other researcher groups in this regard. They reported that mitochondrial DNA sequences of the Platyhelminthes accumulate nucleotide substitutions at a much higher rate than sequences in comparisons of genetic distances **(Littlewood and Bray 2001; Vilas et al. 2005)**. Base substitutions and additions are characterized by high T content which can, at times, represent poly-T structures. In addition, this may be a consequence of frame-shift mutations or premature stop codons, however, protein-coding genes of the *mt*DNA are error-checked by translating the nucleotide sequences **(Benasson et al. 2001)**. Specific substitution rates include metabolic rates and body mass, generation time, differential fixation of slightly deleterious mutations, DNA repair mechanisms, and nucleotide composition **(Vilas et al. 2005).**

According to the inferred topology of amino acids phylogeny of Egyptian hymenolipidid, hosts effect on the evolutionary relationship between isolates was clear despite their intra species differences which agree with **Johnston (2006)**. This could explain the closer relation of *Hymenolipis* spp. (*H. nana* and *H. diminuta*) collected from rat to be arranged in one cluster despite the disparities in host species and morphology which is in continence with **Littlewood et al. (2008)**. These results agree with previous reports supported variant biological features of *H. diminuta* that are not always identical between isolates is built on genetic background **(Okamoto et al. 1997)**. However, there results are conflicting with both the characteristic cryptic species of *H. nana* **(Macnish et al. 2002a, b)**, and Schmidt classification where *H. nana* should be closer to *H. microstoma* than *H. diminuta* **(Schmidt 1986).** These observations that were revealed from the present study which should not be applied unambiguously to host-parasite associations since it does not take into consideration other factors related to the ecology of the hosts and the dynamics of the host-parasite assemblages **(Johnston 2006)**. However, it should highlight the danger of triggering changes in genetic interspecificity subsequently definitive host susceptibility. Since, *mt cox1* resultant phylogenetic tree did not support the current hypotheses on the basis of morphological evidence for the separation of species **(Littlewood et al. 2008)**.

In conclusion, molecular protocol developed in this study will provide the tools for achieving supplementary comprehensive epidemiological portrait of infestation in Egypt. Consequently, should be applied on much broader scale in screening for *Hymenolipis* spp. infestations. Sufficient clarification of evolutionary relationship of *Hymenolipis* spp. by other ribosomal DNA content, and complete *mt* genome sequencing and its genes arrangement are essentials. These data will ultimately aid investigations on dynamics of morphological and developmental evolution, as well as the biology of parasitism.

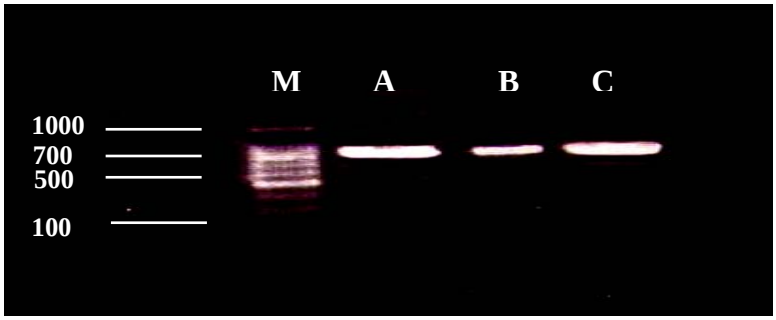

Fig. 1 PCR products of *mt cox1* gene amplified by specified primers pair from Egyptian isolates of (A) *Hymenolipis diminuta* **703 bp fragment, (B) *H. nana* rat isolate 699 bp fragment, (C) *H. nana* human isolate 715 bp fragment, and (M) 100 bp DNA Ladder.**

Abstract: In this paper, 18 species of the subfamilies Exogoninae, Anoplosyllinae, and Eusyllinae (Syllidae, Polychaeta) are reported from the Mediterranean Egyptian coasts, 8 of them are new records for the area: *Odontosyllis fulgurans* (Audouin and Milne Edwards, 1833); *Syllides japonicus* Imajima, 1966; *Salvatoria clavata* (Clapare de, 1863); *Salvatoria euritmica* (Sardá, 1984); *Sphaerosyllis glandulata* Perkins, 1981; *Parapionosyllis labornica* Cognetti, 1965; *Sphaerosyllis* sp.; and *Prosphaerosyllis* sp. Five species were reported previously in the area. Four species are new records for Mediterranean Sea: *Palposyllis prosostoma* Hartmann-Schröder, 1977; *Paraehlersia weissmaniodes* (Augener,1913); *Streptosyllis compoyi* Brito, Núñez and San Martín, 2000; and *Exogone africana* Hartmann-Schröder, 1974); *P. weissmaniodes* and *Exogone africana* are two widely distributed Indo-Pacific species, so they could be considered as Lessepsian migrants. Finally, one new species is described, *Parapionosyllis aegyptia*.

1. Introduction:

Syllidae represent one of the most diverse and systematically challenging families of Polychaeta (Glasby, 2000; Rouse & Pleijel, 2001; San Martín, 2003, 2005; San Martín & Hutchings, 2006; Aguado & San Martín, 2009). It is a widely distributed group, found from the intertidal zone to the abyssal plains all over the world (Glasby, 2000), but less common at depth, with some species symbiotic or parasitic on other marine invertebrates (Martín and Britayev, 1998).

This family is currently divided into 5 subfamilies (Aguado& San Martín 2009): Eusyllinae Malaquin, 1893; Exogoninae Langerhans, 1879; Autolytinae Langerhans, 1879; Syllinae Grube, 1850; and the recently erected Anoplosyllinae Aguado and San Martín , 2009.

To detect newly recorded or new species we will depend on accurate taxonomic identifications and the local biodiversity. The possible existence of complexes of species, whose identity is blurred under one common specific name are present (Aguado and San Martín, 2007).

Knowledge about Polychaetes in the Egyptian waters is still far from complete; as result of less taxonomical studies and less sufficient data about this group. This paper is the second report about Egyptian Syllids, collected from the Northwestern Coast of Egypt through Salsabeel cruise, Autumn 2008 and Spring 2009, also from Gamasa (Spring 2009), under the frame work organized by National Institute of Oceanography and fisheries branch Alexandria, and from Port Said Harbour (Spring 2008), to study the benthic invertebrates. While the first report about syllid and sabellid species in the Northwestern coast of Egypt, were done by Selim (2008a & b respectively), Abd- Elnaby (2009) also studied polychaetes in Gamasa.

Generally, scarce attention has been given to the polychaetes in Egyptian waters. Fauvel (1927) recorded 8 syllid species from the Suez Canal waters of which 6 belonging to genus *Syllis*. On his work on the polychaetes collected from the fishery grounds near Alexandria, Fauvel (1937) gave a checklist of polychaetes were recorded in this area.
Only 16 species of Syllidae were recorded in that paper. More recently, Selim (1978) reported two syllids species in the Eastern Harbour of Alexandria, namely *Syllis (Typosyllis) variegata* and *Trypanosyllis zebra*. Later, the same author (Selim, 1996) added 6 syllid species from Alexandria coast (*Branchiosyllis exilis, Syllis gracilis, S. hyalinae, S. mediterranea, S. prolifera and S. variegate*). Finally, Abd-Elnaby (1999) recorded 7 syllid species, and later (2005) 21 species from Alexandria coast.

The Syllidae of the neighbouring areas were studied by several authors; from Aegean Sea by Çinar & Ergen (2002); Çinar (2003); and Çinar (2005);

from Israel and the Gulf of Elat by Ben-Eliahu (1977a & 1977b), and anteriorly Fauvel (1955, 1957), from Cyprus by Ben-Eliahu (1972), Çinar (2003a& b) and Çinar & Ergen (2003); Lebanon by Aguado & San Martín (2007), and from Turkey by Ergen (1976). A checklist, distribution, and ecological features of Syllidae and other polychaetes from Greece can be reported in Simboura & Nicolaidou (2001), also from Cyprus by many authors, the most recent one Musco et al. (2005), and the biogeographic revision on Syllidae from the Mediterranean Sea (East and West areas) was carried out by Musco & Giangrande (2005).

During the present study 18 species were recorded, 11 of which are new records for the Egyptian waters. Four species are considered as new species for Mediterranean Sea. Three species are considered as new species, although two of them are under process of description, and one species is described here as new for Science. In this paper, detailed description is given also of some interesting species

2. Materials and methods

Two cruises were carried out on the Northwestern Mediterranean coast of Egypt; on two stations (El Hammam, El Alamein), during Autumn 2008 and Spring 2009, and also one collection Spring 2008. The stations are; Port Said Harbour (station 1), in which samples were collected during Spring 2008, and Gamasa (station2, Spring 2009), depth ranging from 0 .25m to 20 m. (Fig. 1). Sediment samples were collected by a Van Veen grab; while, samples from Port Said Harbour were collected by knife and net used for collecting fauna. Sediment samples were washed up and sieved through o.3 µm sieve, then sorted under Stereomicroscope. Specimens of Syllidae were extracted and fixed in 10 % formaldehyde in sea water-solution. Examinations and identification were done by using compound microscope. Drawings were made by a camera lucida. The specimens were Preserved in the Marine Reference Collection Center of National Institute of Oceanography and Fisheries, Alexandria, under Code Number (N. Sp. 2/8/3).

3. Results

In the present study, 18 species belonging to the subfamilies Exogoninae, Anoplosyllinae and Eusyllinae (Syllidae, Polychaeta) were recorded and identified from the Mediterranean Egyptian coasts, 8 of them considered new records for the Egyptian Mediterranean waters: *Odontosyllis fulgurans* (Audouin and Milne Edwards, 1833); *Syllides japonicus* Imajima, 1966; *Salvatoria clavata* (Clapare de, 1863); *Salvatoria euritmica* (Sarda , 1984); *Sphaerosyllis glandulata* Perkins, 1981; *Parapionosyllis labronica* Cognetti, 1965; *Sphaerosyllis* sp.; and *Prosphaerosyllis* sp.; the two later are new species in process of description, although a description of both without any specific name is given by San Martín (2003). Five species were reported previously from different places of Egypt. In addition, four species are considered as a new records for the Mediterranean Sea (*Palposyllis prosostoma* Hartmann-Schröder, 1977; *Paraehlersia weissmaniodes* (Augener,1913); *Streptosyllis compoyi* Brito, Núñez and San Martín, 2000; and *Exogone africana* Hartmann-Schröder, 1974). Finally one species *Parapionosyllis aegyptia* is described as new species. The locations, dates , depth, number of specimens and geographical distribution are presented in Table (1).

Ehlersia ferrugina non Langerhans. Böggemann & Westheide, 2004: 418, fig. 6.
Paraehlersia weissmanioides San Martin & Hutchings, 2006: 312, figs. 43A-C, 47A-I, 48 A-F, 49 D-F.

Material examined. Port Said 0.25 m depth, Spring 2008, one specimen.

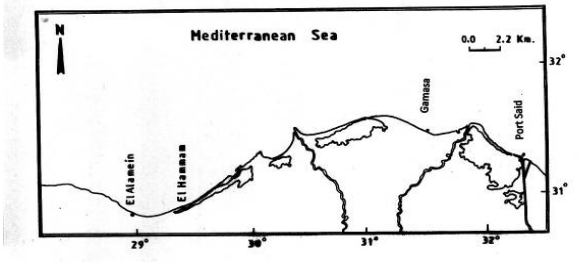

Fig. (1) Map showing the sampling sites, (North western Coast of Egypt, Gamasa and Port Said).

At= Atlantic Ocean, P= Pacific Ocean, Med= Mediterranean, Cos= Cosmopolitan, S-M= Sandy mud, C-S= Coarse Sand, F= Fouling; *= New species, **= New record for Mediterranean Sea, ***= New record for Egyptian waters, ****= Recorded before from Egyptian waters; The most important species will be described in details.

Description. Body broad anteriorly, tapered posteriorly, 11 mm long, 0.2 mm wide, with 41 chaetigers (fig. 2 A). Prostomium oval (75 µm), 4 eyes in trapezoidal arrangement, and 2 anterior eye-spots; lateral antenna 162.5 µm long, midian antenna 150 µm long. Palps broad (87.5 µm), basally fused. Dorsal tentacular cirri 147.5-162.5 µm long, ventral tentacular cirri about one third in length of dorsal tentacular cirri. Antennae, tentacular and anterior dorsal cirri; elongated, indistinctly articulated; articulation variable with short and long articles, up to 22 articles; dorsal cirri becoming progressively smoother posteriorly. Infracirral papillae not seen. Parapodia conical, slightly elongate. Ventral cirri digitiform, slightly longer than parapodial lobes. Parapodia with 12-15 falcigerous compound chaetae; blades strongly bidentate, with fine spines on margin (fig. 2 B), 2-3 distalmost ones longer than remaining (30-42.5 µm) (fig. 2 C). Most dorsal compound chaetae, spiniger-like, blades (75 µm long) on midbody, and about 93 µm on posterior parapodia with fine spines on margin (figs. 2 C, E), absent on most posterior parapodia; indistinctly bidentate. Compound falcigers becoming wider progressively along body, with stronger proximal tooth, slightly hooked (fig. 2G). Dorsal simple chaetae appear from chaetiger 19, truncate, bifid with short spines margin (fig. 2 F, H). Ventral simple chaetae on posterior parapodia, thick, with few long spines on margin, strongly bidentate, proximal tooth large, slightly hooked, and distal one shorter than proximal one (fig. 2 J).

Anterior parapodia with 2-3 slender aciculae, two of them distally rounded with small bending tip and one straight (fig. 2D); from proventricular segments onwards, acicula solitary, with oblique, short tip (fig. 2 I). Pharynx through 6 segments; pharyngeal tooth anteriorly located. Proventricle, rectangular through 4 segments with about 21 muscle cell rows.

Distribution: Australia, Seyhelles. New report for the Mediterranean Sea.

Remarks: The Egyptian specimen is similar to Australian ones; it is likely an Indo-Pacific migrant through Suez Canal.

Exogone verugera africana Hartmann-Schröder,1974a:137, figs. 164-168; 1979; 108, figs.164-168.

Exogone africana San Martín, 2005: 143, fig. 90 a-f.

Material examined. Port Said, 0.25 m depth, on fouling, Spring 2008, 2 specimens.

Description. Body small, slender, relatively broad anteriorly, 3 mm long, 0.23 mm wide, 28 chaetigers. Prostomium oval (fig.3 A); 4 eyes in trapezoidal arrangement. Antennae short, oval, close to each other, inserted between anterior to eyes; median antenna slightly longer and thicker than lateral one. Palps broad, longer than prostomium, totally fused, with a dorsal furrow (fig. 3A). Peristomium shorter than subsequent segments; one pair of small, papilliform tentacular cirri. Dorsal cirri similar to antennae and tentacular cirri, slightly longer than lateral antennae, present on all segments. Compound chaetae of two types on all parapodia: 1-2 spiniger-like, with long blades 31 µm long (fig. 3 B) on anterior parapodia, slightly short on posterior one (25-27.5 µm), distally bifid, with short marginal spines (fig. 3 C), and 4 compound chaetae with short falcigerous blades about 7.5 µm, bidentate, subdistal tooth long and distal tooth short, moderate marginal spines (fig. 3 D); posterior falcigers smaller, three in number, blades about 5µm long (fig. 3 E). Dorsal simple chaetae from anterior segments, with rounded tips (fig. 3 F), subdistally serrated, thicker posteriorly with pointed tip (fig. 3 G). Ventral simple chaetae on posterior parapodia, sigmoid, thick, with some short spines on base of teeth, bidentate, subdistal tooth longer and thicker than distal tooth (fig. 3 H). Acicula solitary, slender, distally rounded (fig. 3 I). Pharynx long, through 4 segments; pharayngeal tooth located on anterior rim. Proventricle occupying 4 segments with 18 muscle cell rows. Pygidium with 2 long anal cirri.

Distribution: Circumtropical. First report to the Mediterranean Sea.

Material examined. El Alamein 20 m depth, Autumn 2008. Holotype and Paratype, coarse sand.

Description. Holotype 3.5 mm, 0.15mm wide 29 chaetigers (fig. 4 A). Prostomium ovate, wider than long; 2 pairs of eyes, anterior pair larger than posterior ones, arranged in trapezoidal arrangement, and 2 small anterior eye-spots. Antennae spindle-shaped to bowling-pin shaped, longer than prostomium; median antenna (77.6 µm) slightly longer than lateral ones (67.5 µm), arising between anterior eyes; lateral antennae arising on anterior margin of prostomium (right one missing on holotype). Palps basally fused, shorter than prostomium. Peristomium with 2 pairs of bowling-pin shaped tentacular cirri, smaller than antennae. Parapodia somewhat elongated (32.5 µm). Dorsal cirri bowling-pin shaped, from 36- 45µm in length anteriorly to 65µm on posterior parapodia. Ventral cirri digitiform, shorter than parapodial lobes.

Anterior parapodia with 7 compound falcigers, unidentate with hooked tips and serrated margin (fig. 4 B); about 10 µm long; shafts becoming posteriorly thick with long curved acute tip, blades with serrated margin on 2 most dorsal ones, and 4-5 unidentate curved, smooth (fig. 4 D). Superior dorsal simple chaetae thin with pointed tip, present in all parapodia, except first one (fig. 4 C), become thicker posteriorly (fig. 4 E). Ventral simple chaetae unidentate, sigmoid (fig. 4 F). Acicula solitary, bent with hollow rounded tip (fig. 4 G). Pharynx extending through 3.5 setigers; mid dorsal tooth on anterior edge. Proventricle extending through 2.5 segments, with 17 rows of muscle cells. Glands small, with granular material, pair on each segment, present from first chaetiger.

Remarks. About 16 species are recognized as *Parapionosyllis*, 6 of them recorded in the Mediterranean Sea. The most similar species is *P. labronica* also found in this collection; both species have posterior compound chaetae with thick shafts, distally curved, and short, unidentate blades, smooth or almost smooth. However, the anterior compound chaetae of *Parapionosyllis aegyptia* are more elongated and provided with somewhat longer spines on margin, and the dorsal simple chaetae are different, being smooth and unidentate in *P. aegyptia* and provided with a sub-distal, thick spine and others shorter, in *P. labronica*. The remaining Mediterranean species are clearly different of these two species, because they have longer compound chaetae (see San Martín, 2003); also, other species of other seas also have more elongated compound chaetae and different dorsal simple chaeta.

Etymology. The species is named after the country in which has been found, Egypt.

4. Discussion

The number of Syllids recorded on Egyptian waters reach about 60 species, a low number when compared with the 190 Syllid species were reported by Musco and Giangrande (2005) from the whole Mediterranean waters, which represents the 31.6 % of the total Mediterranean Syllidae. Also, many other species may possibly remain unreported because of the most coastal area of Egypt are unexplored and many studies are still needed.

Tovar- Hernández *et al*. (2002) referred to the dominance and diversity of syllid members in carbonate sediments, this observation was confirmed by Selim (2008), where El Hammam and El Alamein coasts contain carbonate bottom sediments.

Most of the studied species are well known, common and widely reported for Mediterranean and Atlantic Ocean. The analysis of samples resulted into 18 species,11 of them new record for the Egyptian Mediterranean waters. Four species were reported previously, (*Brevicirrosyllis weismanni* Langerhans, 1879; *Parapionosyllis elegans* (Pierantoni, 1903); *P.brevicirra* Day, 1954 and *Sphaerosyllis taylori* Perkins, 1981, from many Mediterranean coastal areas and one more (*Salvatoria vieitezi* San Martín 1984) from the Suez Canal. Two of the studied syllids are considered apparently cosmopolitan: *Salvatoria clavata,* and *Odontosyllis fulgurans.* In addition, 11 species were known before from Spainish coasts, only 4 species were previously recorded in Greece, 9 from North West Italian, 9 from Turkish Aegean and 6 from Cyprus. Also four species are considered as a new record for Mediterranean Sea: *Palposyllis prosostoma* Hartmann-Schröder, 1977; *Paraehlersia weissmaniodes* (Augener, 1913); *Streptosyllis compoyi* Brito, Núñez and San Martín, 2000; and *Exogone africana* Hartmann-Schröder,1974.

According to geographic distribution through literature there are 9 species belong to Atlantic-Mediterranean category and one species (*Salvatoria vieitezi*) was recorded before from Suez Canal (Selim, 2009), and four species are new for Mediterranean, that means they are Lessepsian migrants; 3species are amphi-Atlantic, *Sphaerosyllis taylori*, *Shphaerosyllis glandulata* and *Salvatoria vieitezi.* Two species are considered cosmopolitan species, *Odontosyllis fulgurans* and *Salvatoria clavata* and five species are considered Atlantic-Pacific categories.

In spite of it, many new recorded species usually discovered by way in new researches, still more not recorded until now, more studies requisite to be done along the Mediterranean and Red Sea coasts of Egypt to cover this point.

The present study showed richness of Eusyllinae, Anoplosyllinae and Exogoninae species inhabiting Egyptian water benthic assemblage.

Association of Depression and Anxiety Disorders with Weight Status among Egyptian School Children: Giza Governorate

Zeinab M Monir , Abla G Khalifa & Manal Mansour
The child health department; National Research Center, *Dokki, Giza*; Egypt,

abla_ncr@yahoo.com.

Abstract: **Background:** The prevalence of childhood obesity is rapidly increasing, and many obese children suffer from emotional and behavioral problems .**The aim** of this study was to explore the relationship between nutritional obesity and psychosocial behavior among school –children in their natural setting. ; and to examine whether social backgrounds play a role in this relationship. Target population was third; fourth and fifth grade primary school children (n=861; mean age10±0.72) attending 3 public elementary schools at Dokki District; in Giza Governorate. **Measurements:** Weight status was assessed through measurements of Body Mass Index percentiles (BAP) for age& sex using World Health Organization Growth Standards. Familial backgrounds**&** academic school achievements of the children were recorded from school files. Data on anxiety and depressive symptoms of children was assessed using standardized methods. **Results:** 23.5% of boys and18.7% of girls showed signs of depression; whereas anxiety was prevalent among 54%of boys and 52% of girls. Calculation of odds ratio (OR) showed that depression and anxiety is higher in low school achievers in girls ($p<0.05$) and boys ($p<0.01$). In a multiple regression model; depression was predicted by anxiety, age and academic achievements ($R^2=0.53$; $P\leq0.001$). Anxiety was predicted by BAP and birth order ($R^2=0.38$; $P\leq0.003$)**. Conclusion:** Obesity affects psychosocial adjustment of children raising the importance of early detection and prevention of obesity in the form of nutritional and health awareness programs and training of school health personnel.

Key words: Obesity - Children - Depression -Anxiety - Academic Performance.

Introduction:

The prevalence of childhood obesity has been rapidly increasing during the past two decades (1). Recent estimates suggest that 6.6% and 14% of Egyptian children are overweight and obese respectively. (2, 3) Some of the most commonly reported and striking consequences of pediatric obesity are psychosocial (4). Today's culture ascribes a negative stereotype to obese people. There is a common belief that the overweight children are unhappy with their weight and experience most psychosocial distresses, particularly depressive symptoms (5). However, existing information on this relationship comes almost exclusively form clinical samples, wherein obese children seeking treatment demonstrate increased psychopathology and social problems compared with their non obese peers. (6) Comparisons of clinical sample of obese children with non clinical samples of non obese children make it difficult to determine the independent effects of obesity regardless of clinical status on psychological factors. One notable exception to this design confound is the research conducted by Braet et al, (7) who found that a clinical group of obese children scored higher on parent-bases reports of psychopathology, including both behavioral and emotional problems, compared with a non-clinical group of obese children. Additional convergent evidence from a clinical sample includes findings that decreases in percentage of overweight during obesity treatment predict improvements in children's psychological functioning (8). Studies involving 9-years-old subject found that the heaviest children expressed the most discontent, having low body

esteem, a desire of thinness, and higher levels of dietary restraint (9).

Increased risk for depression in obese children presenting for treatment had been reported (10) whereas, Erickson et al, (5) had found a modest relation between obesity in primary school children and depression only in girls. The adult's clinical literature has also linked obesity with psychopathology in general and depression in particular (11).

In Egypt, though the school-age years of life are universally accepted to be of profound importance to the emotional and cognitive and social development; yet less psychiatric intervention occurs in this period from the school health system. The current study has attempted to assess anxiety and depression in primary school age children and in relation to family characteristics and school achievement. Relationship to weight status was as well considered.

Assessing psychological status (depression and trait anxiety) as correlates of weight-related distress in a young, , non-treatment-seeking cohort of children across a wide range of weight provides the opportunity to examine the associations between psychological characteristics and weight-related psychological distress (12). Gaining an understanding of the relationship between childhood obesity and psychological distress is important to identify what it is about obesity that may make children unhappy, early identify targets for intervention, and help clinicians identify those children in need of treatment and the types of treatments that may prove successful.

To address these issues, the present study assessed anxiety and depressive symptoms as an index of psychological distress; and their association to weight status; in a sample of elementary school boys and girls in their natural setting. Based on the existing literatures with adolescents and adults samples, the study hypothesized that obesity and psychological distress would be associated and that this would be influenced by the family backgrounds.

Subjects and Methods:

Subjects:

This study was conducted during school year 2008-2009 in three elementary schools in urban Giza Governorate, Egypt. After gaining the approval of local educational authorities; a passive consent procedure was used. Parents were informed of the study in writing. Classrooms surveys and physical measures were completed during regular school hours by trained pediatricians. A total of 436 boys and 435 girls (age ranged 9.5-10.5 years) completed the study protocol.

Methods:

Every child was subjected to a thorough clinical examination (chest, heart, abdominal and neurological examination). Children having congenital anomalies or chronic diseases were excluded from the study as we aim to assess anxiety and depression prevalence in apparently healthy normal primary school children. Age of the children was recorded from birth certificates that were already present in school files.

A-Body Mass Index:

Children's weight was measured in kilograms using a standardized portable scale. Weight was measured twice to the nearest 0.1.Kg without shoes or outer clothing and the mean was used in the analysis: Height was measured in meters by a direct reading using stadiometer. Height was measured twice to the nearest centimeter and the mean of the two measures was used in the analysis. Children Body Mass Index (BMI, calculated as weight in kilograms divided by the square of height in meters) was then calculated from measures of height and weight as a measure of obesity. BMI is the preferred measure of children adiposity for epidemiological and clinical studies (13).

BMI percentile for age (BAP) and BMI for age Z scores (BAZ) were calculated using the Anthro Plus program of the computer. (14, 15)

B- Anxiety and Depression Assessment:

Depressive Symptoms:

The Arabic Children's Depression Inventory (ACDI) derived from kovacs (16) and kazdin, (17) and constructed for Egyptian children by Abdel Khalek, (18) was used. It comprises seven factors that cover the symptoms of juvenile depression; it conations 27 items in which the children have to respond by themselves through three alternatives i.e. rarely, sometimes and often. The ACDI was found to be correlated to the Arabic version; El-Tayeb (19) of the kovac's Children's Depression Inventory (CDI)

and to the Hopelessness scale for children (16) in its Arabic form of Dowidar (20)

2- Personality Assessment Sheet for Assessment of Anxiety:

The anxiety sheet is derived from State-Trait-Anxiety Inventory (STAI) and validated by Abdel khalek (21). It contains 23 items in which the children have to respond by themselves through three alternatives, i.e. rarely; Sometimes; and often.

C-Academic achievement:

School achievement was recorded from the school files of midterm and terms examinations .Sum of Arabic Language and Mathematics Subjects were taken as an indicator of academic achievements.

D-Social Backgrounds:

Social evaluation has been made using father and mother education with scores 1, 2, 3, 4, denoting illiterate, primary school, high school and university education added to the child's birth order and the family number we gave 1st born score 3, 2nd and 3rd born score 2 more than 3rd born was given score 1, also, family number 4 was given score 3, family number-5 given score 2 and more than 5 was given score 1; social score was stratified as low social ≤ 7; middle social 8-9 and high social 10-12 to be used for the multivariate statistics.

E-Statistical Analysis:

Univariate statistics for data description was used. Bivariate statistics using $\chi 2$ test and Pearson`s correlation to assess the strength of relation of BMI and psychological distress (depression and anxiety) was applied. We used the multivariate analyses to examine independent and interactive associations of BMI and social status with each of anxiety and depressive symptoms. BMI and social status were stratified to examine the independent and interactive associations of BMI and social status with depressive symptom. SPSS program of PC (version 13) was used.

Results:

Table 1, a shows parental education of studied children: 68% of the mothers were illiterate or only read and write; 27.5% had preparatory or high school education whereas only 4.2% of the mothers were university graduated, moreover 55.9% of the fathers were illiterate or can read write and 34.8% reached to high school education and only 9% were university graduated. No significant difference between boys and girls was shown using $\chi 2$ test. ***Table 1, b*** shows that 32.1% of the children were first born child; 23.1% were second born; 18.1% were third born and the rest were fourth or more born children. Most of the children came from big families more than or equal four siblings.

Table 2 shows the weight status of boys and girls as measured by percentile BMI/age. 11% & 11.79 of boys and girls were thin; 13.7% & 12.26% of boys and girls were overweight and 7.8% and 8.01% were obese. There was no significant difference among boys and girls as regard weight status distribution.

Table 3 shows that 7.5 % of girls with low school achievement had depression scores < 44, while 2.3% of girls with high school achievement had depression scores < 44 ; and the difference was significant ($\chi 2$ =4.06, p=0.05). The same results w found among boys; where 12% of low achievers in comparison to 31% of good achievers had depression scores < 44; and the difference was significant ($\chi 2$ =6.19, p=0.017).

Table 4 shows that 19% and 11% of *high* achievers boys and girls had anxiety scores < 35 ; while 7% of boys and 8% of girls who are high achievers had anxiety scores > 35. The difference was significant ($\chi 2$ =6.89, p< 0.05 for girls &$\chi 2$ =3.9, p< 0.05 for boys).

Table 5 shows that depression scores of girls was affected by both mother`s and father`s education ($\chi 2$ =4.3, P = 0.03 & $\chi 2$ =8.1,P= 0.01 respectively),and family number ($\chi 2$ =5.8,P = 0.01); while birth order was the only factor that affected depression scores of boys ($\chi 2$ =4.9, P = 0.05).

Table 6 shows that anxiety scores of girls was affected by maternal education

($\chi 2$ =3.18, *P* = 0.05). Social backgrounds of boys have no relation with anxiety scores of boys (P > 0.05 for all parameters).

Factors affecting anxiety and depression Scores were assessed using simple correlation. ***Table 7*** shows that academic achievement was negatively statistically correlated with both anxiety and depression scores (Pearson`s correlation coefficient

r = -0.238; $p \leq 0.000$ for anxiety and r = -0.272; $p \leq 0.000$ for depression). While age; BMI/age; and height /age showed positive correlations with both anxiety and depression. Anxiety scores showed significant positive correlation with depression; (r = 0.741; $p \leq 0.000$).

Three models were applied using multiple regression analysis for prediction of factors affecting depression scores (dependent variable).

Table 8 shows that anxiety was the independent factor affecting depression in the first model with R^2=0.516; $p \leq 0.0001$. This means that 51.6% of depression states are associated with anxiety. In the second model, anxiety and age was the main predictors of depression (R^2 = 0.481; $p \leq 0.0001$). This means that 48% of anxiety states are associated with depression. The third model shows that anxiety, age and academic achievement predicted depression (R^2=0.532; $P \leq 0.0001$) .this means that 53.2% of depression cases could be predicted by anxiety, age and academic achievement; using the equation:

Depression = 0.7 anxiety +1.2 age + 2.2 academic achievement.

Table 9 shows that BMI –Z scores and Birth order was the main predictors for anxiety ($p \leq 0.03$) ;in this model 3.8% of the change in anxiety could be explained by BMI-Z scores and birth order. This means that anxiety is associated with weight status.

Discussion:

Application of ACDI and STAI on elementary school children of Giza Governorate showed that 23.5% of boys and 18.7% of girls had depressive symptoms. While 54, 1% of boys and 52% of girls reported anxiety disorders; with highly significant correlations of depression to anxiety .This finding agrees with Faith et al (22). Despite the common belief that overweight children are less happy than average weight peers, data on the relationship between obesity and depressive symptoms from a population based sample of young Egyptian children were lacking.

In a study on third grade students attending schools in Northern California, Erickson et al (5) found a modest association between depressive symptoms and body mass index for girls ;but not for boys .Girls depressive symptoms were strongly associated with overweight concerns .Other epidemiological studies have not found an association between depressive symptoms and obesity in population based samples of female adolescents and young women (23) , however some studies have found increased social, educational and psychological correlates of weight status in adolescents (24) as well.

Siegel et al (25) contributed poor health over time to overweight and depressed mood in young women. On the contrary, Neumark, (26) pointed to revaluation of psychosocial concerns among overweight adolescents. In addition to these. Ford et al (27)found that among low and increased self reported BMI, significantly impaired physical functioning rather than mental functioning were noticed.

Previous studies have suggested that gender differences in clinical depressive syndromes do not emerge until puberty ;and women are twice as likely to be depressed as men. Our data suggest that gender differences may emerge in childhood. It has been hypothesized that socioeconomic conditions of the family is one of the risk factors that affect depression in girls and boys. As we conclude from our study that parental education, birth order and family size affects depression in girls. While father education and birth order and family size are the factors that affect depression in boys (11& 22)

In this Study .there was significant negative correlations between academic achievements and each of anxiety and depression scores .Rashed et al (28) reported same results among primary school children in Alexandria Governorate. Vey et al (29); proved that school difficulties could be used in children as a substituted criterion of DSM –III criterion for major depression.

Birth order showed significant relation with depression among boys, whereas depression among girls was correlated with all social parameters (father and mother`s education; family number and birth order. This finding reflects the social behavior of the community where most girls stay at home after school; and so her mood is affected by the family circumstances. On the contrary boys are free to stay outdoors. In this study the overall prevalence of anxiety and depression among boys is high; this could be attributed to other factors other than family backgrounds. Nilzon reported significant association of anxiety and depression with social status ;but he found no sex differences (30).

In the multivariate analysis we were able to assess the independent and interactive relationships of BMI and sociodemographic status with levels of depression and anxiety. We found that BMI as well

as social status were associated with depressive symptoms in both girls and boys; after controlling for social status in a time and controlling for BMI in another time, although this study is limited in its cross-sectional design, these results suggest that anxiety and depression is affected by both obesity and social backgrounds.

In Conclusion; Obesity affects psychosocial adjustment of children raising the importance of early detection and prevention of obesity in the form of nutritional and health awareness programs and training of school health personnel for early detection of psychological disorders among children.

Table (1): Sociodemographic Backgrounds of Boys and Girls

a) Parental education.

	Mother education		Father education	
	Girls N (%)	Boys N (%)	Girls N (%)	Boys N (%)
Illiterate/read and write	294 (69)	294 (67.5)	228 (53.5)	256 (58.3)

Abstract: *Back ground and aim:* Metabolic syndrome is a group of interrelated risk factors, accurate clinical diagnosis and treatment is mandatory for detection of population at risk for coronary heart disease and diabetes. Physical exercise protects against the development of cardiovascular disease, partly by lowering plasmatic total cholesterol, LDL and increased HDL .In addition it is now established that increased C - reactive protein (CRP) and plasminogen activator inhibitor-1(PAI-1) play a role in the maintenance of an inflammatory state and in the development of cardiovascular disease. This study aimed to compare plasma levels of LDL, HDL, CRP, and PAI-1 in patients with metabolic syndrome before and 6 months after moderate intensity exercise. **Methods:** Forty five obese non smoker, males with metabolic syndrome living sedentary life were included in the study .Blood samples were collected at the beginning of the study and 6 months later. However only 42 patients completed in our study The plasma lipid profile (Triglycerides, HDL, LDL, total cholesterol), fasting blood glucose, C - reactive protein and PAI-1 levels were determined. Body weight and BMI were also measured before and after the exercise. **Results:** Total cholesterol ,LDL,HDL,triglycerides,CRP,PAI-1 levels were lower after moderate intensity exercise in relation to levels before moderate intensity exercise($p<0.05$).In addition we observed a positive correlation between PAI-1 and LDL after exercise($r=0.301$,$p=0.053$),PAI and triglycerides after exercise($r=0.286$,$p=0.066$), negative correlation between HDL and PAI-1($r=-0.315$,$p=0.042$). These results indicate that moderate intensity exercise induces favourable changes in metabolic syndrome in lowering lipid profile and PAI-1 levels and may reduce risk of cardiovascular diseases.

Keywords: Metabolic syndrome, PAI-1, exercise

1. Introduction

Metabolic syndrome is a cluster of metabolic abnormalities and related clinical syndromes most important of which are coronary artery disease and type 2 diabetes mellitus, insulin resistance, visceral adiposity, dyslipidaemia and chronic subclinical proinflammatory state are the main characteristic features of metabolic syndrome. These inflammatory process include increase in plasma proinflammatory cytokines as tumor necrosis factor alpha (TNF-$\propto$),plasminogen activator inhibitor type-1 (PAI-1), C-reactive protein (CRP) ,Interleukin 6 (IL-6) and reduction of anti-inflammatory cytokines as interleukin 10 (IL-10) and adiponectin [(1, 2)]
Sedentary lifestyle is characterized by alterations in pro-inflammatory markers in the plasma [(3,4)].

The haemostatic abnormality most likely linked to insulin resistance is the elevation of circulating plasminogen activator inhibitor-1(PAI-1).Increased PAI-1 level can be now considered a true component of the syndrome and increases risk of developing cardiovascular disease [(5)].

The aim of this study is to compare plasma levels of LDL, HDL, CRP, and PAI-1 in patients with metabolic syndrome before and 6 months after moderate intensity exercise.

2. Patients and methods:

In a cross sectional study forty five obese, non-smoker men with metabolic syndrome, participated in this study .All subjects were living sedentary life, age (30-49 years),BMI ≥30 ,all patients under went complete history taking, family history of diabetes and personal medical history, history of smoking, physical activity of each subject was defined as either sedentary (<150 min/week) or active (>150min/week) . Patients selection based on International Diabetes Federation(IDF) [(6)] ,metabolic syndrome was defined as central obesity (waist circumference ≥94 cm for men and ≥80cm for women),along with two or more of the following criteria (1) hypertriglyceridemia

(serum triglycerides ≥1.7 mmol/l(150 mg/dl) or current treatment with fibrates (2) an abnormally low HDL cholesterol concentration (<1.03mmol/l for men(<40 mg/dl) and <1.29 mmol/l for women(<50 mg/dl)(3) elevated blood pressure (systolic blood pressure ≥130mmhg and/or diastolic blood pressure≥85mmhg or current use of antihypertensive drugs or (4)elevated fasting glucose ≥5.6 mmol/l (≥100 mg/dl)or previous diagnosis of diabetes. All underwent physical examination including blood pressure recording and anthropometric measurement (BMI, waist circumference). Blood samples of all patients for fasting blood sugar, CRP, total cholesterol, triglycerides, HDL, LDL, PAI-1 were stored at -20^{0}c until analysis. Physical examination and blood samples were collected after 6 months of moderate intensity physical exercise. Only 42 patients completed in the study .The benefits and risks were explained to all patients .They all gave their oral approval to participate in the study.

Blood samples collected after an overnight fast of at least 10 h, stored at -20^{0}c until analysis.
Lipid profiles assay. total cholesterol, triglycerides and HDL were assessed by enzymatic methods using commercially available kits LDL was estimated by Friedewald formula (LDL= total cholesterol-(HDL+triglyceride/5). plasma CRP was measured by kit supplied by (Roche Diagnostics, Indianapolis, IN) and PAI-1was assessed by ELISA kit (Trinity Biotech USA, St. Louis, MO) according to manufacturer instruction .

3. Statistical Methodology:

Data were statistically described in terms of mean ± standard deviation (± SD). Comparison between pre and post data was done using paired *t* test. Correlation between various variables was done using Pearson moment correlation equation for linear relation. A probability value (*p* value) less than 0.05 was considered statistically significant. All statistical calculations were done using computer programs Microsoft Excel 2003 (Microsoft Corporation, NY, and USA) and SPSS (Statistical Package for the Social Science; SPSS Inc., Chicago, IL, USA) version 15 for Microsoft Windows

4. Results:

Results were illustrated in the form of 3 tables. Table 1 shows the mean value of patient anthropometric data(WT, BMI and Waist circumference) and the mean value of the laboratory data(PAI-1, FBS, Total cholesterol, HDL, LDL, CRP and Triglycerides), the table also shows the mean values of systolic and diastolic blood pressure of all patients before exercise.

Table 1: patient anthropometric and lab data before exercise

Parameter	Mean value of the parameters of the 42 patients
Wt(kg)	101.45
BMI(kg/m^2)	31.71
Waist(cm)	105.19
PAI-1(ng/ml)	19.279
FBS(mg/dl)	94.21
Chol(mg/dl)	233.00
HDL(mg/dl)	46.10
LDL(mg/dl)	166.40
TGs(mg/dl)	128.90
SBP(mm hg)	140.12
DBP(mm hg)	87.98
CRP(g/l)	4.12

Table 2: showing comparison in anthropometric and lab data before and after exercise (BMI, lipid profile, CRP, PAI-1) in patients before and after 6 month moderate intensity exercise. In comparison between before and after exercise all parameters show significant difference before and after exercise.

Table 2: Comparison between patient's data before and after exercise.

Parameter	Mean value before exercise	Mean value after Exercise	Correlation	p value
Wt(kg)	101.45	90.45	0.341	0.027*

**p is highly significant p<0.001

5. Discussion:

The metabolic syndrome is associated with an increased risk for the development of cardiovascular disease [7,8], A number of haemostatic abnormalities have recently been associated with the metabolic syndrome ,amongst with elevated concentrations of plasminogen activator inhibitor -1(PAI-1) and tissue plasminogen activator antigen(tPA_{ag}) share the strongest associations and have been studied in the most detail [9]. Consistent associations have also been found with fibrinogen concentrations, vitamin K dependant coagulation factors (factors-vii,ix and x) ,C-reactive protein (CRP) and von willebrand factor (vWF syndrome [10, 11], increase in plasma proinflammatory cytokines as tumor necrosis factor alpha (TNF- ∝) ,Interlukin 6 (IL-6) and reduction of anti-inflammatory cytokines as interleukin 10 (IL-10) and adiponectin [1, 2]. It is now well established that impaired fibrinolysis due to elevated PAI-1 activity ($PAI\text{-}1_{act}$) is an important feature of the metabolic syndrome. [19].

PAI-1, produced by vascular endothelium is an important risk factor for CAD .Increased PAI-1levels may predispose patients to the formation of atherosclerotic plaques prone to rupture with a high lipid –to-vascular smooth muscle ratio as a result of decreased cell migration [12] Circulating levels of PAI-1 are increased in obese subjects with metabolic syndrome, as well as in patients with type2diabetes.The plasma levels of PAI-1 are directly related to the severity of metabolic syndrome [13]. The metabolic syndrome explains a major part of plasma PAI-1 level variability, PAI-1, which otherwise behaves as an acute phase reactant, was demonstrated to be independently associated with metabolic syndrome with this relationship being stronger in men than in women (45%versus 26%). Interventional studies reported that if insulin resistance is improved plasma PAI-1 levels decrease. Race seems to have a definite influence on PAI-1.Both genetic and lifestyle factors may contribute to this difference in plasma levels.[19]

Decreased plasma PAI-1 concentrations were observed after weight reduction by a hypo caloric diet and were associated with decreased body fat. In addition treatment with insulin –sensitizing drugs like metformin or troglitazone decrease plasma PAI-1 levels in subjects with type 2 diabetes and to some extent in normal obese subjects[14, 15,16]. Simvastatin in addition to reducing LDL –c it reduces inflammation in MS subjects Simvastatin also reduces circulating plasminogen activator inhibitor-1 activity in volunteers with metabolic syndrome.

The levels of PAI-1, soluble p-selectin and CD40 ligand play an important role in the

development and progression of atherosclerosis; their levels are increased in metabolic syndrome.

Metabolic syndrome has endothelial dysfunction, decreased circulating adiponectin, and high expression of angiogenic inhibitors such as PAI-1[17]

The mechanism of PAI-1overexpression during obesity is complex and it is conceivable that several inducers are involved at the same time at several sites of synthesis. Interestingly, recent in vitro and in vivo studies showed that beside its role in the atherothrombosis PAI-1 is also implicated in adipose tissue development and in the control of insulin signalling in adipocytes. These suggest that PAI-1 inhibitors serve in the control of atherothrombosis and insulin resistance [18]

The link between PAI-1 and metabolic syndrome with obesity was established many years ago. Increased PAI-1level can be now considered a true component of the syndrome [5]

Like our results in which PAI-1 had positive association between components of metabolic syndrome: BMI (p=0.001),waist circumference (p<0.001) systolic blood pressure (p=-0.015) fasting blood sugar (p<0.001),however no association with triglycerides (p=0.133) or HDL (p=0.855)

In a study done by Greyling et al[19] they observed a lack of association of plasma PAI-1 antigen concentrations with parameters of the metabolic syndrome (general and visceral adiposity, blood pressure and lipids in Africans) ,whereas these associations were prominent in Caucasian women. PAI is directly secreted by adipose tissue, especially by plasma concentrations of PAI in obesity Investigations performed on PAI deficient mice[20] and with pharmacological inhibitors of PAI reinforced the notion that the absence of PAI reduces the differentiation of adipocytes and protects against insulin resistance and diet-induced obesity, suggesting a paracrine effect of PAI on promoting of weight gain . This is also in accordance with several population based prospective studies demonstrating that PAI is the only biomarker that predicts incident metabolic syndrome and diabetes.

Metabolic syndrome subjects have raised levels of PAI-1, associated with an increased risk of MI, correlating with obesity[19,21] PAI-1 which otherwise behaves as an acute phase reactant, was demonstrated to be independently associated with metabolic syndrome, even after adjustment with HOMA-IR and other co-variables ,this finding reinforces the results of previous cross-sectional studies that considered haemostatic and inflammatory markers and observed that outstanding relationship between PAI-1 and metabolic syndrome[22]

The association between PAI_{act} and markers of the metabolic syndrome in Caucasians is well established [9, 11]

The results of the study of Bronat etal[22] indicate that HbA1C and PAI are strongly and independently related to metabolic syndrome .Moreover, the elevation of both markers seems to be a manifestation of the same pathophysiological mechanism that underlies the main characteristics of the syndrome.Therfore, PAI-1 and HbA1C should be considered as true components of metabolic syndrome and may be considered as candidates for inclusion in the list of diagnostic criteria.[22]

PAI-1 is also a valuable biomarker for predicting the metabolic syndrome(MS) in elderly residents in study done by Chou YY et al[23] mean age 79.9+/- 4 years .Elderly resident with MS had higher systolic and diastolic blood pressure (p<0.001) and higher HOMA-IR (p<0.001), CRP (p=0.008),and PAI-1 levels (p<0.001) than those without the MS .On multivariate logistic regression analysis , PAI-1was an independent risk factor for the MS. Elderly with higher waist circumferences and higher levels of plasma fasting glucose and TG and lower level HDL had higher PAI-1 levels than those without the above components[23]. Enhancing endogenous fibrinolysis by targeting PAI-1 inhibitor, the primary inhibitor of circulating plasminogen activators, has been shown to be effective in markedly attenuating the formation of arterial and venous occlusive thrombosis in animal models .In addition ,animal and human studies of PAI-1 deficiency indicate that spontaneous bleeding complications associated with even complete PAI-1 deficiency would be rare .Patients most likely to benefit from PAI-1 inhibition would be those at high risk for vascular events, with elevated PAI-1 levels , such as is in obesity ,diabetes and the metabolic syndrome .Since obesity and metabolic syndrome are now epidemic and will likely have a major adverse impact on vascular thrombotic events. It may be time to test the clinical effectiveness of PAI-1 inhibition in those populations at high risk for vascular thrombosis [24].

Sedentary lifestyle is characterized by alterations in pro-inflammatory markers in the plasma [3,4]. Several studies have consistently shown that low levels of plasma high density lipoprotein (HDL) and high levels of low and very low density lipoprotein (LDL and VLDL respectively) are linked with a sedentary life style and are strong predictor to cardiovascular disease [25, 26, 27]

It remains slightly unknown if long term moderate /high intensity exercise have lowered pro-inflammatory and increased anti-inflammatory markers than sedentary subjects.

In our study total cholesterol, LDL,HDL, triglycerides, CRP,PAI-1 levels were lower after moderate intensity exercise in relation to levels before moderate intensity exercise ($p<0.05$).In addition we observed a positive correlation between PAI-1 and LDL after exercise ($r=0.301$, $p=0.053$), PAI and triglycerides after exercise ($r=0.286$, $p=0.066$), negative correlation between HDL and PAI-1 ($r=-0.315$, $p=0.042$).

Our results were similar to Fabio etal[28], Teramoto etal[29], Coen etal[30] these studies detected the favourable effect of exercise on lipid profile and PAI-1.

In a study done by Fabio et al seven male leading sedentary life and seven highly trained athletes subjects were recruited. Blood samples were collected after an overnight fast, plasma lipid profile, glucose, adiponectin, C-reactive protein and PAI-1 levels were determined. Results of the study showed lower plasmatic lipid profile and PAI-1 levels in highly trained athletes ($p=0.01$) than sedentary subjects. In addition the total plasma cholesterol, LDL-c and TG concentration were positively correlated with PAI-1 levels. These results indicate that life style associated with high intensity and high volume exercise induces favourable changes in the lipid profile and PAI-1 levels and may reduce risk of cardiovascular diseases [28]

The effect of Short-term exercise training does not change PAI-1 levels in normal, asymptomatic men and women. In addition, modest decreases in insulin and triglyceride in individuals with elevated body fatness do not result in changes in PAI-1 after short-term training. It appears likely that decreases in PAI-1 with exercise training require decreases in adiposity and/or marked changes in metabolic variables. This was shown In study done by Bodary PF et al[31] they examined the influence of 10 days of moderate-intensity exercise training on measures of fibrinolysis. Sixteen men and 16 women between the ages of 50 and 70 yr were randomly assigned to exercise (EX) and control groups (CON) that were balanced for gender and hormone replacement therapy. Blood samples were collected on days 1, 2, 11, and 12 for measurement of plasma PAI-1, tPA, insulin, glucose, and triglyceride. Subjects in EX performed 50 min of treadmill walking at an intensity corresponding to 65% of heart rate reserve each day for 10 consecutive days.There were no significant changes in PAI-1, tPA, or associated metabolic variables between exercise and Control group during the intervention period. Within Exercise subjects, those with higher body fatness had a significant decrease in insulin and triglyceride compared with those with lower body fatness. However, no changes in fibrinolytic measures were observed within these subgroups. They concluded that Short-term exercise training does not change PAI-1 levels in normal, asymptomatic men and women. In addition, modest decreases in insulin and triglyceride in individuals with elevated body fatness do not result in changes in PAI-1 after short-term training. It appears likely that decreases in PAI-1 with exercise training [31].

6. Conclusion:

Moderate intensity exercise induces favorable changes in metabolic syndrome in lowering lipid profile and PAI-1 levels and may reduce risk of cardiovascular diseases

Reuse of Industrial Materials in Buildings To activate their application in Egypt

Nermin Mokhtar Mohamed

Researcher in Civil and Architectural Department ,Engineering division, National research centre, Egypt

ABSTRACT: Increasingly stringent rules and regulations on construction and demolition waste, diminishing landfill space and depletion of natural resources are all reasons for the push for industrial byproduct materials recovery. In Egypt, Industrial byproduct materials are generated in large volumes every day that are potentially usable materials, and must be disposed of. The main goal of this paper is to change the way Egyptians' think about waste—to see the value of a used material as a product or commodity, not as a waste, and encourage the use and recycling of these rich, largely untapped resources. Positive economic rewards and environmental results are moving our partners toward more waste reduction and materials management. This paper summarizes the proposed Egyptian industrial materials waste management guidelines to reuse in building ,which cover: (1) Identify the parties involved and the distribution of responsibilities; (2) Complementarily of roles of parties(owner, engineer, designer, and contractor) involved in the process of re-use to remove the causes that hinder the management of such material in Egypt ; and (3) Participation of the Parties to the proposed project to achieve sustainable development fields at the actual application of the project.

KEYWORD: reuse –industrial byproduct materials, waste management, sustainability, Egypt.

INTRODUCTION

The world is becoming increasingly conscious of the environmental implications not only of production processes but also of products discarded after use. The recycling of waste materials as a means of tackling the solid waste problem is attracting growing interest.

This is the problem of solid waste currently producing and increase with increasing Almttrd Census world population of the most serious problems and will remain polluted environment for long periods of up to thousands of years which cause environmental damage and health problems.

In Egypt, the traditional method to get rid of Industrial wastes is send to landfill as waste. Industrial wastes are more damaging to environment, and public health, In addition, Construction and demolition (C&D) materials led to urban pollution image around, as well as the economic burden and the cost of waste transportation.

In pursuit of sustainable development principles, which aims to rely on recycling waste came importance of research on alternatives, Salvaging materials for reuse can be both an economical and environmentally sound alternate to waste stream disposal, and it also saves energy and environmental impacts of producing new products from virgin materials that help communities be sustainable in infrastructure renovation, construction, and maintenance.

With the pursuit of Egypt now to the sustainable development of areas and provide jobs for young graduates, In urgent need for alternative construction materials with rising cost of wood universal waste and demolition and construction that represent a high proportion of solid waste, Find the possibility of reuse industrial materials in building that Re-cycling building materials is an essential part of ecological sustainability.

And therefore need to find research benefit from industrial materials in the possibility of exploitation as an economic environment friendly housing in Egypt organization management process participation and funding for projects on physical development, to activate application construction for environmental development, economic, social and physical in areas

Despite the government attempts to impose penalties or fines or recourse to academic studies and research centers to develop solutions for waste management but it is still a deficiency in complete control of the problem in Egypt.

Research aims to propose a comprehensive and integrated approach to establishing industrial materials and its activation in Egypt by identifying the parties involved and their respective roles for the protection of areas affected by the effects of disposal opening alternatives to creating markets for reuse industrial materials in physical development, and to conserve energy and preserve natural resources.

The main objective of research can be achieved through several sub-objectives, namely: monitor problems resulting from industrial materials pollution in Egypt, current status assessment and

study of causes that hinder the proper management of residues in Egypt, finance and operations planning part of the parties involved to upgrade the project such areas, Identify the areas of development environmental, economic, social, physical and role of parties involved in achieving these areas

1- Sustainable

Sustainable development meets the needs of the present without compromising the ability of future generations to meet their own needs. Basically, it's another term for "green" or "environmentally friendly".

Implementing sustainable projects means achieving an ecologically, socially and economically acceptable future[1].

By taking into consideration all economical aspects and the effects on people, and the environment during the planning and development phases, minimize the use of energy and resources to protect the environment, and increase the efficiency of all projects[2].

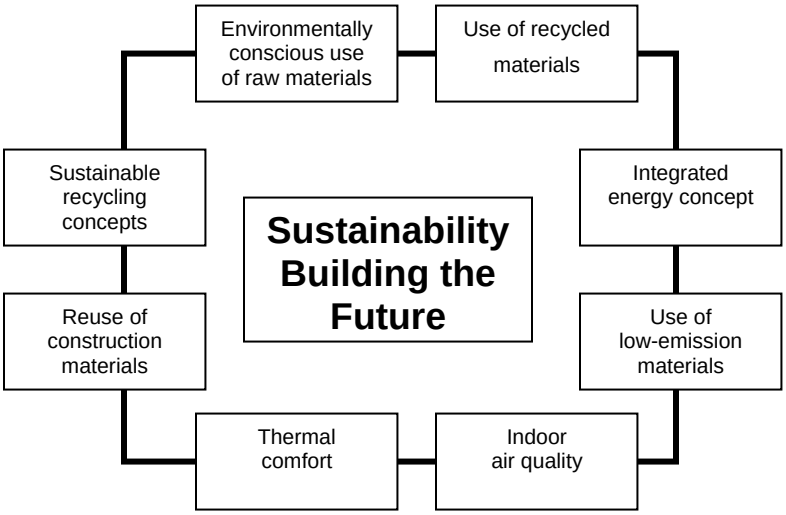

Fig. (1) Aspects of the Sustainability

Fig. (1) Aspects of the Sustainability

1-1 Choosing sustainable materials

It can be difficult to assess exactly how sustainable a product is and which materials are preferable to others[3]. There are some tools that can help you to choose the building materials, table (1).

There are many considerations that should be taken into account when choosing building materials. Since many different definitions exist concerning what constitutes an environmentally friendly or green material, this study use the following set of terms as factors in determining environmentally preferred materials and products[4].

By-product

Unused or waste material from one manufacturing or energy-producing process that can be used in another manufacturing or energy-producing process [5]

- *Agricultural by-product:* Unused or waste material from farming operations, several of which can be used in building products such as strawboard panels, etc.
- *Industrial by-product:* Unused or waste material from power plants or manufacturing operations, several of which can be used in building products, e.g. fly ash concrete, etc.

Table (1): Evaluation tools to choose the building materials

Evaluation tools	**Life-cycle assessment**	This means considering the impact during the extraction of the raw materials, manufacture, transport, handling, installation, the lifetime of its use, recycling and disposal.
	Embodied energy	The total amount of energy that is needed to produce, transport it to site and install it. For building products, it is commonly measured in Mega Joules (MJ) per unit of product.
	Renewable resources	These are resources that will be replenished with time; they include plant and animal products such as timber, paper, cork, wool and leather.
	Sustainable resources	Sustainable resources are the products of cyclic closed systems that do not require outside inputs, and do not generate waste.
	Local resources	Locally sourced products need less energy for transport and they support your local economy.
	Toxicity	Some materials are relatively harmless for humans, but their production might cause habitat destruction or release toxins into the environment. Toxic materials can also be a problem for installers or when they are disposed of at the end of their life cycle.
	Quality	The expected lifetime of the building is short; it makes little sense to use very durable materials.
	Re-use and recycling	Using second-hand or recycled materials is another option for reducing resource use.
	Uncertainty	Materials that have been tested for a long time in your local conditions are a safer choice than new materials or those which have not been proven locally.

2- Industrial materials

Industrial materials recycling, referred to as beneficial use, means reusing or recycling byproduct materials generated from industrial processes. These materials can be used as substitutions for raw materials in the manufacture of consumer products, roads, bridges, buildings, and other construction projects. Thousands of manufacturing and industrial processes and electric utility generators create hundreds of millions of tons of nonhazardous industrial materials that are often wasted[6].

2-1 Examples of practical recycling applications

Nonhazardous industrial materials, such as coal ash, foundry sand, construction and demolition materials are valuable products of industrial processes. Each material may be recycled in a variety of diverse applications, table (2). These materials have many of the same chemical and physical properties as the virgin materials they replace - they can even improve the quality of a product[7].

Table (2): The properties of industrial materials and recycling applications in building

industrial materials	The properties and the problem	recycling applications in building
Cement dust produced during the cement industry	Produced from the burning and grinding of raw materials used in the manufacture of cement, contains a high proportion of the components of the cement but in different proportions, and fails to plant one of the factories of the Egyptian cement per day at least 300 tons in the Mediterranean.	It has been used in many engineering applications, including: Partially replace cement in some industries of construction materials such as bricks, tiles, the cement industry, glass, rubber, sewage treatment, the foundation layer for roads.
Steel slag	It is a byproduct of iron and steel industry and contains a high proportion of the components of the cement, but in different proportions. The amount of (steel slag)	It is used in many engineering applications, including: as heap in concrete works of traditional and light production, types of cement

	from iron and steel sector about a million tons annually, which is a national problem as well as emissions generated from the accumulation of slag	(Ferro-cement - high iron slag - high resistance to sulfate).
Foundry Sands	It is sand that is used to make molds and cores in the metal casting process. Although generally recycled many times internally by the foundries, about 3-4 million tons of foundry sand is discarded each year. The recycling of nonhazardous, spent foundry sand can save energy, reduce the need to mine virgin materials, and may reduce costs for both producers and end users.	the spent foundry sands is used As partial replacement for fine aggregate in asphalt mixtures; in Portland cement concrete; As source material for the manufacture of Portland cement; and As a sand used in masonry mortar mixes, And in the other applications
Coal combustion products	CCPs include the following materials: Fly Ash; Ash; Boiler; Flue Gas Desulphurization Material (FGD); and Other types of material such as fluidized bed combustion ash, and scrubber residues The characteristics and physical properties of CCPs vary. In general, the size, shape, and chemical composition of these materials determines their beneficial reuse as a component of building materials or as a replacement to other virgin materials such as sand, gravel, or gypsum.	Fly ash can be used as a replacement for the Portland cement that binds traditional concrete mixes. The manufacture of Portland cement requires large inputs of energy, and it is estimated that its manufacture constitutes about 8% of all carbon dioxide emissions from human sources. Approximately 75% of the fly ash produced annually is disposed of in landfills, which makes incorporating it into concrete a resource-efficient alternative.
Pulp and paper byproducts	Two significant byproducts from the paper industry are WWTP residuals and boiler ash	There are numerous examples of other uses Building board/fixture, Brick or concrete additive, Glass or lightweight aggregate
Construction and demolition (C&D) materials[8]	It consists of the debris generated during the construction, renovation, and demolition of buildings, roads, and bridges. C&D materials often contain bulky, heavy materials, such as concrete, wood, metals, glass, and salvaged building components[9]. In Egypt, the daily quantity of construction and demolition (C&D) waste has been estimated as 10,000 tones. That is equivalent to one third of the total daily municipal solid wastes generated per day in Egypt[10].	It can make a number of products (solid cement bricks, hollow bricks, paving blocks) using the broken bricks and broken ceramics. As possible, get a light concrete using broken bricks as an alternative partial or total ruins of the great used in industry. You can also use the surplus concrete and rubble after rounding heap for the production of concrete suitable for the various structural elements.

3- Advantages and disadvantages of the process of recycling waste

The process of recycling has some of the advantages and disadvantages[11], Table (3).

4- Building Applications for Industrial Materials

The beneficial use of industrial materials that were previously considered wastes has been expanding with a number of applications gaining market and regulator acceptance. Environmental and economic benefits derived from the recycling and beneficial use of industrial materials are becoming more evident:

- Conserving energy and reducing greenhouse gas emissions by decreasing the demand for products made from energy-intensive manufacturing processes;

- Preserving natural resources by decreasing the demand for virgin materials - recycled materials have many of the same properties as the virgin material they replace, and may improve the quality of the products in which they are used;
- Decreasing the economic and environmental burdens of disposal, as well as reducing the cost of material for end users.

Table (3) Advantages and disadvantages of the process of recycling waste

disadvantages of recycling waste	**Advantages of recycling waste**
- Some materials are generally more difficult to recycle - other materials are dangerous or require more energy inputs to be recycled - The durability of some materials can be extended if they properly protected and maintained while in use - Environmentally preferable materials may be more expensive or difficult to locate - Determining a product's environmental preferability can be a complex process for which no tools exist - Prepare the materials may need more time - Need efficient labors	- Conserves energy and reduces greenhouse gas emissions by decreasing the demand for products made from energy intensive manufacturing processes - reduce the volume of materials which are sent to landfill as waste to achieve the continued development - save the embodied energy content - Preserves our natural resources by decreasing the demand for virgin materials - Saves money by decreasing disposal costs for the generator and decreasing materials costs for end users. - Local employment creation - Reuse of old buildings and use of recycled materials.

This diagram illustrates a variety of common building applications for industrial materials. Note that the availability of specific industrial materials can vary regionally, fig. (2)[12].

Fig. (2) Building Applications for Industrial Materials

Fig. (2) Building Applications for Industrial Materials

Table (4) a variety of common building applications for industrial materials

(a,b) Green Roofs & Landscaping	Green roofs are roofs covered with plants; they reduce storm runoff and provide insulation. Scrap tires can be used to make rubber tile for walkways. Bottom ash can be used as bedding material. Clean wood, recycled gypsum wallboard, and cardboard can be ground and used as soil amendments in both green roofs and landscaping applications.
(c) Landscape Furniture	Benches can be made with plastic lumber containing fly ash or with recycled C&D wood.
(d) Building Facing Material	Manufactured stone, which is concrete mixed with aggregates, is commonly used as building facing materials. fly ash can be used in the production of manufactured stone
(e) Sidewalks	Industrial materials can be used to make concrete sidewalks, and used tires can be recycled to create rubberized sidewalks. Asphalt concrete sidewalks can be made with recycled asphalt pavement and recycled asphalt shingles.
(f) Ceiling Tile	Ceiling tile can contain flue gas desulfurization (FGD) gypsum (a material resulting from burning coal to produce electricity), fly ash, recycled gypsum wallboard, or air-cooled blast furnace slag.
(g) Flooring	Industrial materials can be used in various flooring applications. (h) Carpet backing: Used tires, fly ash, or recycled carpet. (i) Wood flooring: Salvaged lumber or recycled wood. (j) Flooring tile: Fly ash, blast furnace slag. (k) Tile underpayment: Fly ash.
(l) Backfill (Foundation Support)	Backfill surrounds the building foundation, supporting it and providing drainage. Scrap tires provide superior drainage, insulation, and wall pressure relief. Blast furnace slag and recycled concrete also can be used for drainage.
(m) Foundation Structural Fill	Structural fill is an engineered fill that is constructed in layers and compacted to a desired density. Coal fly ash, bottom ash, slag, and spent foundry sand can all be used as structural fill. Concrete can be crushed and used onsite as structural fill.
(n) Poured Concrete Foundation	Concrete, which is composed of cement, aggregate, and water, is used in a wide array of building applications. Industrial materials can be recycled in cement and concrete in many ways. Here are a few examples: • Fly ash and ground granulated blast furnace slag can be used as partial cement replacements. Using these materials can produce stronger, longer-lasting concrete. • Portland cement itself can be made with fly ash, FGD gypsum, foundry sand, recycled gypsum wallboard, blast furnace, and steel slag. • Concrete aggregates can include bottom ash, foundry sand, crushed concrete, and blast furnace slag.
(o) Insulation	Air-cooled blast furnace slag can be used to produce mineral or rock wool insulation (also known as slag wool insulation).
(p)Drywall/Wallboard	FGD gypsum and recycled gypsum wall board can be used to manufacture drywall.
(q) Mortars, Grouts, Stucco	Mortars, grouts, and stucco contain aggregate (sand), binder, and water. Fly ash, foundry sand, silica fume, and slag cement can all be used as partial cement replacements.
(r) Masonry Blocks	Masonry blocks are made from cement and aggregate. Slag cement, fly ash, or silica fume can substitute partially for cement. Bottom ash, blast furnace slag, and recycled concrete aggregate can substitute for newly mined materials.
(s) Base Material	Spent foundry sand can be used in place of natural soil as base material for the building site. Recycled concrete is also commonly used as base material.

5-Case study

Home of the experiences of the World created by using industrial materials reused, table (5)

Case study	Location & Building Specs	Design	Materials Reused or Recycled	Positive Community Impacts
The Lazarus Building[13] is one of the most significant green rehabilitation projects in Columbus.  *Lazarus Before Redevelopment*  *Lazarus After Redevelopment*	Renovation of a 600,000 square foot commercial building in downtown Columbus, Ohio.  	-Reducing, reusing, and recycling materials during renovation and construction -Using recycled-content products and materials in construction -Cost savings and environmental benefits -Environmental awards and recognition -Local community revitalization	Developers retained over 75 percent of the original structure, significantly reducing the amount of materials needed for the project. The renovation employed -Coal fly ash in concrete; -Recycled glass and tile flooring containing up to 100% recycled materials; -Carpets containing recycled nylon; -Restroom partitions containing 100% post-consumer recycled plastic; -Drywall containing at least 96 percent recycled materials, including flue gas desulphurization gypsum; and -Building siding containing 60 percent recycled metal.	-cost savings and avoided local community impacts from trucks hauling debris away. - The project created local jobs, improving the local economy. -a showcase of innovative ways to reduce waste.
EPA's new building[14]  **Architectural Scale Model**  **The exterior environment**  **The interior environment**	200,000 square foot EPA Regional Headquarters office building in downtown Kansas City, Kansas.  	-Many building features contribute to exceptional energy efficiency - The building's operations and maintenance environmentally friendly. -building products and materials are more environmentally sensitive, or "greener"	-Utilizing Fly Ash in concrete design -The aluminum mullions and trim on the windows, sheer wall, sunscreens, cable trays and skylight are all constructed from recycled aluminum. -In restrooms, the floors and walls were constructed with ceramic tile made from over 70% post-industrial recycled waste glass. -The Shaw carpet is made of 25% recycled material - The wood wall base in the atrium is 100% recyclable. - The ceiling tile is made from 93%-recycled slag and the grid system from light gauge steel made from 67% recycled material.	-the reduction of smog was considered when selecting building materials. In order to help reduce the contribution of VOCs into the atmosphere. -a showcase of innovative ways to reduce waste.

6- Waste Management in Egypt

Waste Management is a component of sustainable development, which seeks to reduce the impact of human activities on public health and the environment and development.

The industrial development in Egypt is the main engine of economic growth, where is the advantage of good Waste and exhaust for different industries, one of indicators of progress in the United.

Industrial waste are serious environmental problem and that the lack of local industries based on Exploitation of the waste in other industries, making it a burden and a waste of environmental resources used In production processes, fig. (3). In fact, it can be exploited to become the waste materials with high economic value.

To sustainable improve waste and materials management in Egypt[15] will focus on the active involvement of industrial waste generators in the reduction of waste volumes at source, and will also encourage private sector participation in solid waste management services, particularly collection and recycling.

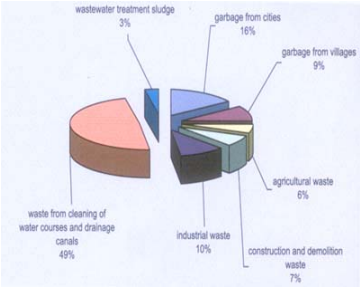

Fig. (3) The proportion of solid waste in Egypt

6-1 About a method to organize and manage the re-use of industrial materials in construction in Egypt:

This part comes to address the negative aspects which appear in the overlapping of roles and responsibilities of the parties involved in the project and overcome the causes that impede the management of re-use of industrial materials in Egypt to achieve urban development[16].

6-1-1 Identify the parties involved and the distribution of responsibilities

Parties to the proposed approach are different bodies responsible for policy development re-use of industrial materials in construction.

They are the government, institutions of technical advisory, executive agencies (investors and a group of capital and local governance), popular participation (beneficiaries), research centers, contractors and specialists (architects). In order to integrate the curriculum leading to activation of the application re-use of industrial materials in construction in Egypt should be considered interested parties and their respective roles to achieve the restructuring of the curriculum by ideal integration of limbs.

(I) the role of government

The success of the reuse industrial materials in building depends heavily on local government engagement and action. Their role is large and vital[17].

- Coordinate and facilitate partnerships to implement the reuse materials action plan.
- Lead by example in government
- Provide incentives that encourage green design, construction, and deconstruction and begin removing disincentives
- Expand capacity and markets for reusing and recycling construction and demolition materials.
- Increase awareness, knowledge, and access to reuse industrial materials
- Encourage innovative product design
- to encourage beneficiaries to participate in these projects beneficial to the environment
- amend laws and existing environmental legislation

(Ii) The role of NGOs non-governmental organizations:

- Implementation of development projects in the environment and recycling waste.
- Training of local technical staff
- Coordination between the professional societies and funding for the implementation of various development programs.

- Galvanize the efforts of various parties (government, individuals, and investors) with the coordination between them.
- Support salvaged materials collection centers.
- Subsidize warehouse space to support the collection and distribution of salvaged materials.
- Create incentives for deconstruction, recycling, and the use of salvaged or recycled materials into construction procurement contracts.

(III) The role of professional engineers[18]

Specialists are planners, architects, economists, social, the most significant roles played by professionals in the following:

- Create new buildings that save energy and water, use fewer material resources, and create less waste.
- The design appropriate to the building to suit the Egyptian environment, according to the needs of the population and location
- Created propose a method suitable for the Egyptian environment and the work of drawings.
- Technical guidance and training courses for users and individuals to create technical staff can participate in all phases of the project.
- building designers have a responsibility to specify preferred materials and methods of construction which are suited to recycling

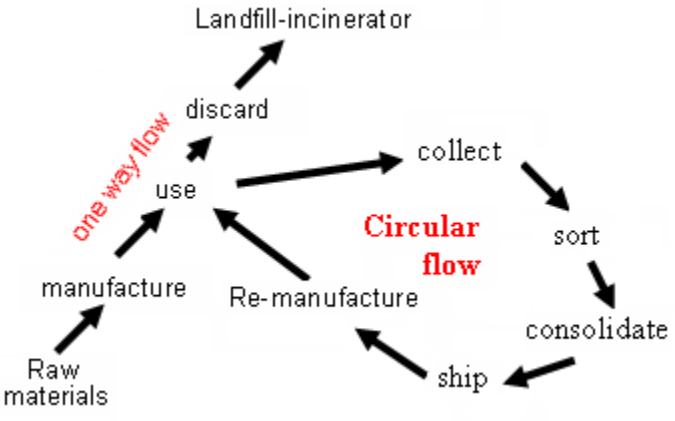

Fig.(4): Circular and linear flows of materials

(IV) Contractor` Role

- Design and plan to Prevent Waste, and develop a Construction Waste Management Plan
- Survey the Site Before Demolition or Deconstruction, Plan for Recyclable Materials
- Identify Reusable or Salvageable Items, all materials should be examined using a precautionary approach to eliminate possible toxicity or future regulatory constraints to their use and disposition.
- Select Salvage Removal Alternatives
- Estimate the Costs and Savings
- Prevent Contamination
- Separating the components will facilitate adaptation and reduce the complexity of deconstruction
- Building contractors need to exercise care during demolition, and should be prepared to re-use suitable materials on projects.

Fig. (5) Reuse –recycle can occur onsite and offsite [19]

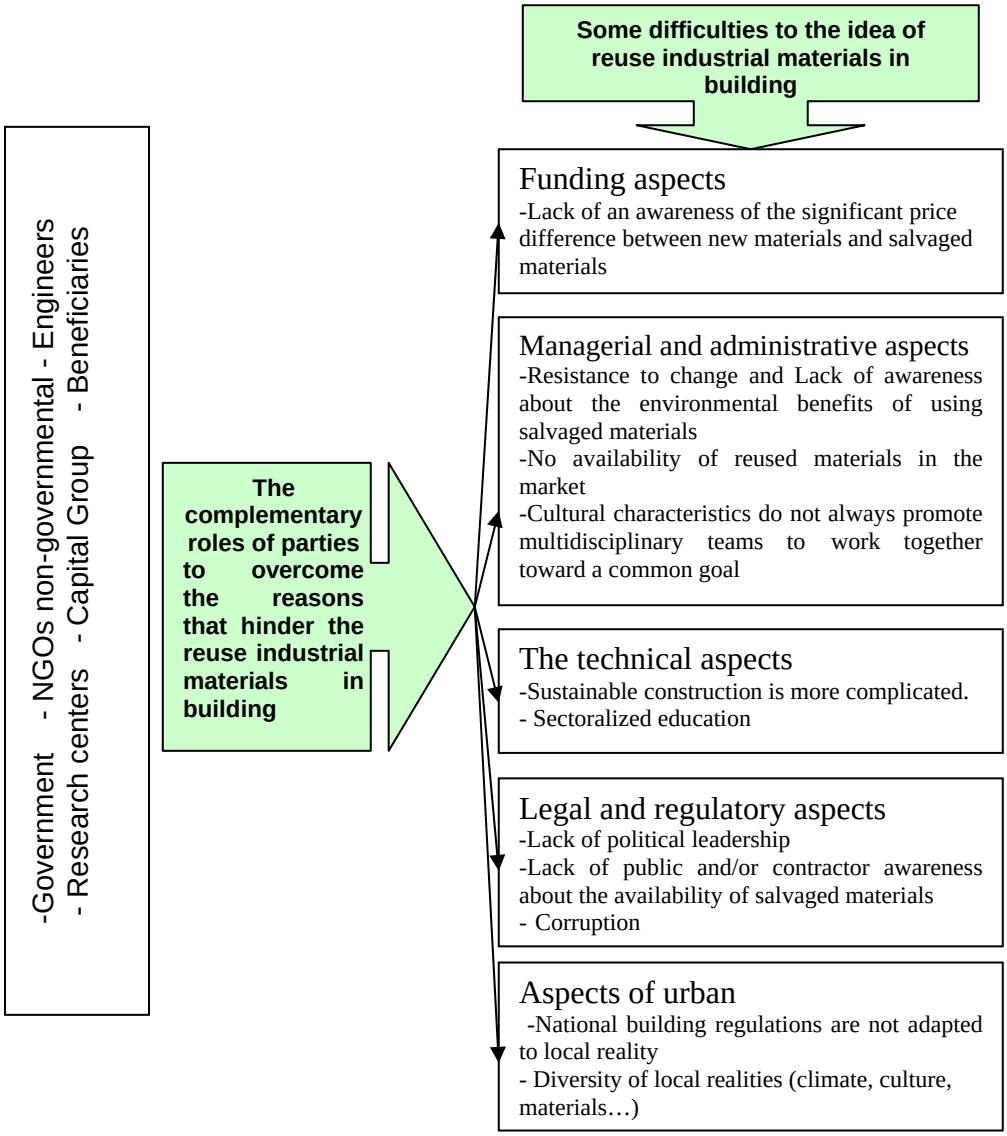

Fig (6) overcome the reasons that hinder the reuse industrial materials in building in Egypt

(V) The role of research centers

- Examine the adequacy of recycled materials used with the Egyptian environment.
- Insurance system building against fire, moisture and insects, and the work of all the tests required, and improve the implementation of this new technology.
- Study ways to improve the properties of the construction of the building using this new technology.
- Employment training to create this type of installations.
- the use of certain programs to achieve energy efficiency within enterprises, and may remove energy consumption to the minimum (Zero Energy)
- Monitoring of constraints and variables that occur in the region and draw conclusions to contribute to approve the project with the environment and the needs of the user, the study of the potential physical and technical implementation, and improve the economic viability of the project.

(Vi) The role of Group Capital (investors and businessmen, banks, real estate specialist)

- Develop and/or fund training programs. Subsidize training costs for participants.

- receipt of the site, and provide the necessary potential for re-use of building materials to be used
- coordination between manufacturers and specialists to bring in industrial materials and re-use in construction
- Follow-up after implementation of changes in operations and maintenance

(Vii) The role of beneficiaries / individuals

the user is the basis of urban development which is capable of maintaining the physical output, and can be user participation in several areas.

- participate in the implementation of self-help
- participate in the maintenance and improve the local environment
- Participating home improvement loans to upgrade facilities and infrastructure and public services.
- Owners should insist on the use of recycled materials… in the interest of ecologically sustainable development.

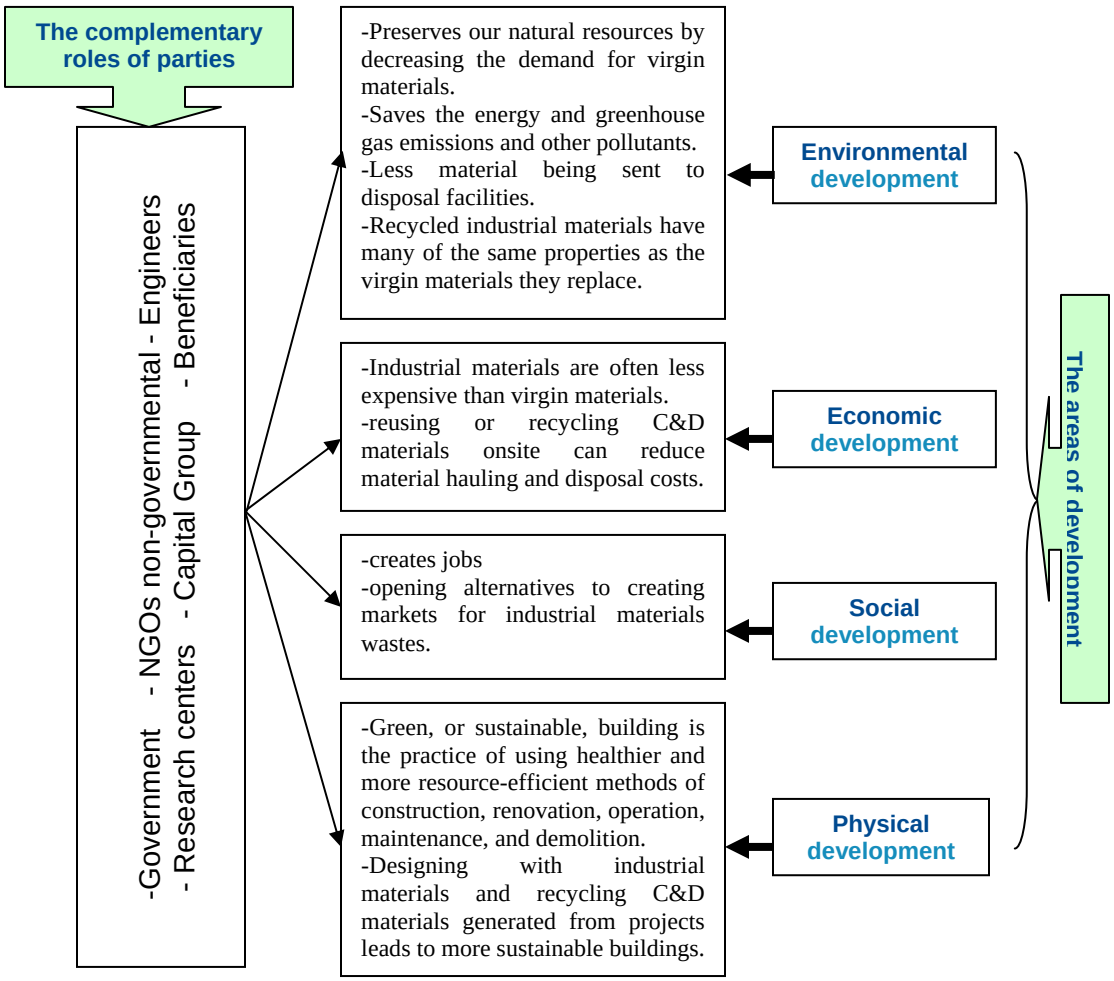

Fig (7) increase the effectiveness of the parties involved in the process of reuse industrial materials in building in various facets of development (environmental, economic, social and physical) for sustainable development

6-1-2 Complementarily of roles of parties involved in the process of re-use to remove the causes that hinder the management of such material in Egypt, figure (6).

(a) between industry and regulators to increase the understanding of the beneficial use of industrial materials and regulatory programs; (b) among state regulators to share information and experiences on beneficial use regulations

and determination processes; (c) among industries to share experiences on successful reuse and recycling, and to assess the potential to utilize each others' materials, and (d) among researchers, nonprofit representatives, industry, and regulators to share information and concerns regarding risk assessment, beneficial use determinations, environmental safety, and new research.

6-1-3 Participation of the Parties to the proposed project to achieve sustainable development fields at the actual application of the project.

Integration of the roles of the participants in the process of re-use of industrial materials in construction is conducive to the development of environmental, economic, physical and social**,** figure(7).

7- CONCLUSIONS

Based on the data collected from the literature survey, it is revealed that the production of industrial materials waste is escalating both on the international and national scales. Furthermore, environmental, safety, visual and technical related problems generated from these wastes has severely added to the long-term negative impacts of these wastes on the surrounding environment.

The essence of the recommended guidelines in this paper is to offer systematic procedures that could help in minimizing the magnitude of the industrial materials waste problem in Egypt. Therefore the disposal option can be avoided by the implementation of reuse them in building.

Waste reduction opportunities begin with the earliest choices made in the building process, including architectural design and material selection. Effectively balancing resource-efficient design concepts requires the attention of skilled and environmentally conscious building professionals. These concepts include waste prevention, durability, and recyclables.

And has been monitoring some of the negatives facing the potential to activate the application of construction materials industry and are summarized as follows:

1. Limited NGO non-governmental organizations concerned with the field of urban development in general and re-use of industrial materials in particular.
2. Does not represent low-income housing a sufficient degree of urbanization, culture and enable them to participate in such environmental projects in an effective manner.
3. Difficulty of maintaining such environmental projects for low-income.
4. Building design re-use of industrial materials zero energy consumption in Egypt still needs some time.
5. Non-participation of specialists sometimes leads to delays in implementation and increase the cost and other obstacles that may face the project when actual implementation.

8- RECOMMENDATIONS

(1) Increased awareness, acceptance and proactive government policies are critical in order to continue the upward trend of recycling and reusing materials whenever possible

(2) More political support is required to enforce the implementation of waste management scheme in the construction/building field, collect industrial material wastes under the direct supervision of authorities. Imposing a special tax levied on wastes when exceeding a certain level determined by the government.

(3) It is also recommended to extend research on the area of recycling and reusing techniques of industrial materials in building to induct feasibility studies, including cost/benefit and payback period analysis for each technique. The research should survey the Egyptian market and seek the potential possibility of using waste as raw materials in factories. This research should integrate both the construction industry and the manufacturing industry to bridge the gap between the two disciplines.

(4) Overcoming these challenges may require advocacy work to strengthen policies and incentives to reduce construction and demolition waste, intensive education and marketing to expand the demand for reused building materials, as well as smart partnerships and inventory management to keep the right mix of reused materials in stock to meet local demand.

Molecular Biological And Biochemical Studies On Avian Influenza Virus Receptors In Different Avian Species

Hussein I. El-Belbasi; Mohamed F. Dowidar and Safaa I. Khater

Department of Biochemistry, Faculty of Veterinary Medicine, Zagazig University,Egypt
H_elbelbasi2003@yahoo.com

Abstract: Avian influenza viruses are considered to be the key contributors to the emergence of human influenza pandemics. A major determinant of infection is the presence of virus receptors on susceptible cells to which the viral haemagglutinin is able to bind. Avian viruses preferentially bind to sialic acid α 2,3-galactose (SA α 2,3-Gal) linked receptors, whereas human strains bind to sialic acid α 2,6-galactose (SA α 2,6-Gal) linked receptors. Although ducks are the major reservoir for influenza viruses, they are typically resistant to the effects of viral infection, in contrast to the frequently severe disease observed in chickens In order to understand whether differences in receptors might contribute to this observation, we studied the expression of influenza receptors in upper and lower respiratory organs of ducks and chickens (expression of ST3Gal-III sialyltransferase and ST6Gal-I sialyltransferase genes) using semi quantitative RT-PCR. There was a marked difference in the expression of primary receptor type in the trachea of chickens and ducks. In chicken trachea, SA α 2,6-Gal was the dominant receptor type whereas in ducks SA α 2,3-Gal receptors were most abundant. This suggests that chickens could be more important as an intermediate host for the generation of influenza viruses with increased ability to bind to SA α 2,6-Gal receptors and thus greater potential for infection of humans. Chicken tracheal and intestinal epithelial cells also expressed a broader range of SA α 2,3-Gal receptors in contrast to ducks, which suggests that they may be able to support infection with a broader range of avian influenza viruses.

Keywords: Host receptors, influenza, , chicken, duck, ST3Gal-III sialyltransferase, ST6Gal-I sialyltransferase, gene expression.

Introduction

The influenza viruses are medium-sized, comprising enveloped and negative sense RNA viruses with a segmented genome. Taxonomically, they belong to the virus family Orthomyxoviridae. There are three genetically and antigenically distinct types of influenza viruses called A, B, and C. Type A viruses are further divided into subtypes according to the combination of two main envelope glycoproteins the hemagglutinin (HA)and neuraminidase (NA). To date, 16 HA subtypes (H1–H16) and 9 NA subtypes (N1–N9) have been found (**Ghaleb, 2009**). Influenza A virus infects several hosts, including humans, birds, swine, and horses, but individual viruses are usually adapted to sustained infection in only one species. Viruses isolated from these different species bind sialic acid through their surface glycoprotein, hemagglutinin, and require this interaction for productive infection. (**Gambaryan et al., 2005).** The first step in the virus infection process is the recognition of cellular structures that act as specific receptors. This determines the virus tissue tropism and is performed by viral adhesion proteins (**Tardieu et al., 1982**) .The viral attachment to the host cell is critical for tissue and species specificity of virus infections. (**Debby et al., 2007**). Influenza virus initiates infection by binding of the viral hemagglutinin (HA) to sialic acid on the cell surface. (**Stray and Air, 2001**). The receptors for influenza viruses are sialic acids (SAs), which are usually formed 2,3 or 2,6 configuration linked to the cell-surface glycoproteins and glycolipids **(Harduin-Lepers et al.,2005).** Sialic acid is an essential component of cell surface receptors for a variety of microorganisms and microbial toxins (**Mouricout,** 1997). Sialic acid is added to the terminal sugar of glycoproteins and glycolipids by enzymes called sialyl transferases (**Harduin-lepers et al., 2005).**

Sialyl transferases (SiaTs) are required to synthesize all known sialyloligosaccharides. (**Shuichi, 1995**). The ST3Gal III, preferentially transfers sialic acid in α 2,3 linkage to the Galß1-3GlcNAc disaccharidic sequence (**Catherine et al.,1999).** While ST6Gal-I generates an α 2-6 linkage of sialic acid to underlying N-acetyllactosamine (**Weinstein et al.,1982**). The differential expression of sialic acids in the mammalian respiratory tract may help to explain the low infectivity but high pathogenicity of some avian strains. (**Gambotto et al., 2008**).

Influenza infection is initiated by virus attachment to sialic acid-containing cell-surface

molecules traditionally called viral receptors. The spectrum of sialylglycoconjugates varies substantially between viral host species as well as target tissues and cell types of the same species leading to variations in the receptor-binding specificity of viruses circulating in these hosts. It is believed that a poor fit of avian viruses to receptors in humans limits the emergence of new pandemic strains(**Matrosovich et al.,2008).** Influenza A viruses attach to host cells by binding of the hemagglutinin (HA) protein to sialosaccharides on the host cell surface. The HAs of influenza A viruses from different host species differ in their specificity of binding. For example, HAs of human influenza A viruses preferentially recognize sialic acid (SA) α 2,6-Gal-terminated saccharides(α 2,6-SA) ,whereas HAs of avian influenza viruses preferentially recognize SA α 2,3-Gal-terminated saccharides (α 2,3-SA) **(Connor et al.,1994**). These differences generally correspond with the variation in the type of SAs expressed at important sites for influenza A virus replication in the respective host species. For example, human tracheal epithelium expresses mainly α2,6-SA, whereas duck intestinal epithelium expresses mainly α 2,3-SA. Therefore, the type and distribution of SA is considered to be an important factor in the susceptibility of different host species to influenza A viruses (**Suzuki et al., 2000**). The SA recognized by influenza A virus is not only important in the host species range but also in its transmissibility(**Tumpey et al., 2007**).The HA protein mediates virus binding to sialic acid (SA)-containing host cell surface molecules and promotes the release of viral ribonucleoprotein complexes through membrane fusion.

Influenza virus infectivity is influenced by **2** entities:-
1- SA species (N-acetylneuraminic acid [NeuAc] and N- glycolylneuramic acid [NeuG].
2- the type of linkage to galactose (sialyloligosaccharides terminated by SA linked to galactose by an (alpha 2,6 linkage [Ac alpha 2,6Gal] or an alpha 2,3 linkage [Ac alpha 2,3Gal]) on the host cell surface (**Rogers et al., 1985).**

The host range selection of the receptor binding specificity of the influenza virus hemagglutinin occurs during maintenance of the virus in different host cells that express different receptor sialo-sugar chains (**Yasuo, 2005).** Ducks and chickens are important hosts of avian influenza virus (AIV) with distinctive responses to infection. Frequently, AIV infections in ducks are asymptomatic and long-lasting in contrast to the clinically apparent and transient infections observed in chickens. These differences may be due to the host response to AIV infection.(**Sean et al., 2009).**

Material and methods

Bird selection and grouping:

Four groups of healthy, four weeks aged birds are classified as fellow :

1. group 1 : 5 chicken (Baladi).
2. group 2 : 5 chicken(Hubber).
3. group 3 : 5 duck(Baladi).
4. group 4 : 5 duck(Pekeni).

Tissue preparation :

- Birds were sacrified using highly sterilized scissors (180°Cfor 6 hours) to avoid RNA degradation by RNases and latex gloves weared to minimize RNase contamination.
- After excision of trachea and lung of tested birds , they were wrapped in aluminium foil and put immediately in liquid nitrogen container to make snap-freezing of tissue and minimize action of endogenous RNase.
- Samples were taken to detect the level of gene expression of ST3Gal-III(Galβ1-3(4)GlcNAcα2,3-sialyltransferase) and ST6Gal-I (Galβ1-4GlcNAcα2,6-sialyltransferase) in that organs.

Reverse transcriptase polymerase chain reaction (RT–PCR): Using a semi-quantitative RT–PCR according to **(Mallet et al., 1995).**

A-Protocol of RNA extraction from tissue: total RNA was extracted with RNeasy Mini Kit (QIAGEN).

B-Protocol of reverse transcription polymerase chain reaction: (one step RT-PCR) by using Robus T 1 RT-PCR kit(FINNZYMES)

The protocol was as fellow:

All components, reaction mixes and samples were kept on ice. And the following reaction component were added to a nuclease free tube placed on ice.

Reaction set up:

RT-PCR mix component	**volume**
10x Robus T reaction buffer	5 µl
50 mM MgCl2	1.5 µl
dNTP mix(10mM each)	1 µl
Template RNA	5 µl
Down stream primer	10 pmol
Up stream primer	10pmol
AMV RT 5 U/ µl	1 µl
DyNAzyme EXT DNA polymerase 1U/ µl	2 µl
RNase free water	Add to 50 µl

Gently mix the components, cycling conditions have to be optimized for each amplicon. and was transferred to the thermal cycler.(2720 thermal cycler Applied Biosystems).

Cycling instructions:

1-**For ST3Gal lll gene**:- the primer for ST3Gal lll was synthesized to amplify PCR products that cross introns to avoid confusion between mRNA transcript and genomic DNA.

The primers used to amplify this gene are:

Forward: 5- CGGATGGCTTCTGGAAATCTGT- 3

Reverse: 3- AGTTTCTCAGGACCTGCGTGTT-5

The product size was 300 bp.

Cycle step	Temp	time	Number of cycle
cDNA synthesis	48 °C	30 min	1
Inactivation of AMV reverse transcriptase and denaturation of the cDNA-RNA hybrid	94 °C	2 min	1
PCR amplification Denaturation Annealing extention	 94 °C 63 °C 72 °C	 30 sec 1 min 1.5 min	 36 cycles
Final extention	72 °C	7 min	

2-**For ST6 Gal I gene:** :- the primer for ST6 Gal I were synthesized to amplify PCR products that cross introns to avoid confusion between mRNA transcript and genomic DNA.

The primers used to amplify this gene are:-

Forward: 5- TGGGCCTTGGCAGGTGTGCTGTTG-3

Reverse: 3-AGGCGAATGGTAGTTTTTGAGCCCACATC-5

The product size was 150 bp.

Cycle step	Temp	time	Number of cycle
cDNA synthesis	48 °C	30 min	1
Inactivation of AMV reverse transcriptase and denaturation of the cDNA-RNA hybrid	94 °C	2 min	1
PCR amplification Denaturation Annealing	 94 °C 50 °C 72 °C	 45sec 1 min 1 min	 35 cycles
extention			
Final extention	72 °C	7 min	

Glyceraldehyde 3 phosphate dehydrogenase (GAPDH) were amplified parallely as internal control (481bp) and its sequence:

Forward: 5--ACTTGTGATCAATGGGCACGCCATC - 3

Reverse: 3--CTTCCCATTCAGCACAGGGATGAC-5

For the Glyceraldehyde 3 phosphate dehydrogenase (GAPDH) amplified by 35 cycle using (2720 thermal cycler Applied Biosystems). Each cycle consist of :

Denaturation 94°C for 45 second

Annealing 62 °C for 30 second

Extention 72°C for 45 second

The PCR products were separated by agarose gel electrophoresis.

C-Agarose gel electrophoresis (Sambrook and Maniatis.,1989)

1- **Run parameters** :
   - Use 1-5 volts/ cm of the tank lenth.
   - Allow bromophenol blue to run 2/3 of the gel lenth before terminating the run.

2- stop the run and transfere the gel to a transilluminator, observe and photograph. Photographing using polarized camera and parameters are preferably 302 nm wave lenghth, 2500 uW / cm2 , or more, and using 22 A filter.

10- Using 100 bp- DNA ladder for electrophoresis of PCR product of GAPDH,ST3Gal-III and ST6Gal-I (100,200,300 ,400,500,600,700,800,900and 1000bp) from Quiagen.

11-Analysis of PCR product using GEL pro-software to detect quantitation of bands for GAPDH, ST3Gal-III and ST6Gal-I genes.

Results and discussion:

The host receptor distribution pattern in the chicken and duck upper and lower respiratory tract may be functionally significant for the evolution of viruses with a human like receptor specificity and thus for the transmission of influenza from birds and mammals. In this work, We conducted an extensive examination on the level of expression of influenza virus Receptors in trachea and lung of two different breeds of each chickens and ducks. Their was no difference in the reported results

observed due to the breed of animals, and the receptor expression was consistent between individual animals within each species. Using RT-PCR in the gene expression of ST3GAL III and ST6GALI which add sialic acids to the terminal sugar of glycoproteins and glycolipids, we found that the trachea of ducks (Baladi, Pekeni) show high expression level of ST3GAL III) while trachea of chickens(Baladi, Hubber) show law expression level. (Figure:1) but Chickens trachea (Baladi,Hubber) show very high expression level of ST6GAL I in comparson to that of ducks trachea(Baladi, Pekeni) that show lawer expression level of ST6GAL I. (Figure:3). These results were in agreement with **(Suresh et al.,2009**) who reported that The major species difference that they observed between chickens and ducks in the relative distribution of SA α 2-3 Gal and SA α 2-6 Gal receptors was along the tracheal epithelium. In chicken tracheal epithelium, SA α 2-6 Gal was the dominant receptor type, whereas in ducks the SA α 2-3Gal receptor was more abundant in the ciliated cells of the tracheal epithelium, it was found that the ratio of SA α 2-6 Gal to SA α 2-3 Gal in chickens trachea was approximately 10:1 whereas in duck the ratio was 1:20. The tracheal mucous glands of both chickens and ducks predominantly expressed SA α 2-6 Gal receptor type. The observed difference in dominant receptor type between chickens and ducks was confined to the upper airway (trachea). While the dominant SA α 2-6 Gal receptor expression pattern in chickens trachea was in contrast to a previous study **(Wan and Perez, 2006)** which, using lectin binding, found that 85% of the epithelial cells in chicken trachea were positive for SA α 2-3 Gal receptors, while only 10% were positive for SA α 2-6 Gal receptors.

Also we found that the lung of ducks (Baladi, Pekeni) showed high expression level of ST3GAL III .while lung of chickens(Baladi, Hubber) showed low expression level. but the difference between expression level of ducks trachea and lung tissues is high in case of trachea more than the lung tissue, but the expression level of chicken trachea is lower than that of lung tissue. (Figure:2). And Chickens lung (Baladi,Hubber) showed very high expression level of ST6GAL I in comparson to that of duck lung (Baladi, Pekeni) that show lower expression level of ST6GAL .

But the difference between expression level of ducks trachea and lung tissues is high in case of lung more than the trachea tissue, while the expression level of chickens lung is lower than that of trachea tissue. (Figure:4). The present results were also in agreement with the findings of **Gambaryan et al (2002),** who reported that human influenza viruses with SA α 2,6-Gal specificity bound to cell membranes isolated from chickens (but not ducks) tracheal cell membranes. Chicken alveolar cells expressed both receptor types. The difference in the predominant receptor across the tracheal epithelial lining in chickens and ducks could be an important contributing factor to influenza virus entry via the upper respiratory tract. In particular, such differences could impact on the susceptibility of each species to avian H5N1 influenza with its preferential tropism for infection of the respiratory tract rather than the intestines.

The differences in receptor expression reported in the present study suggest that they may be responsible, at least in part, for some of the differences between ducks and chickens in the pattern of disease following influenza infection. While the presence of a virus receptor is clearly not sufficient to confirm that cells or tissue support efficient virus replication or transmission, the widespread replication of influenza virus in multiple organs has been reported in both chickens **(Swayne, 1997).**
and ducks **(Londt et al., 2008)** following infection with highly pathogenic viruses.

This study suggests that some chickens and ducks tissues may facilitate entry of both human and avian viruses, with the ensuing danger of virus reassortment. However, further work is required to confirm that the tissues expressing both receptor types are able to support virus replication. The dominant presence of SA α 2-6 Gal receptor along the
chicken tracheal epithelium shows some similarities to the prevalence of the receptor in mammals such as human and pig. This suggests that chickens may be important intermediate hosts for the transmission of influenza to humans, in particular for influenza viruses such as H5N1,
which show a respiratory tropism in birds. Whilst much attention has been placed on the role of pigs as "mixing vessels", the potential importance of chickens for the evolution of humanised influenza viruses should not be overlooked and, as such, wants further studies.

Previous studies on the role of sialic acid linkage (SA α 2,3 or SA α 2,6) during influenza virus infection have shown the importance of expression of these glycans in restricting infection by viruses in different hosts.

In this work, we found the presence of both S.A α 2-3 Gal receptor and SA α 2-6 Gal receptor in chikens trachea and lung due to the expression of the two genes suggest that they may be susceptible to infection with wider range of avian influenza viruses with broader receptor specificity.

الملخص العربى

لوحظ أن إصابة الأنواع المختلفه من الطيور بفيروس إنفلونزا الطيور يختلف إختلافا كبيرا حسب نوع الطائر حيث وجد أن إصابة الدجاج بفيروس إنفلونزا الطيور تظهر أعراضه بصوره شديده وواضحه وتصل نسبة الوفيات إلى 100% بينما فى حالة إصابة البط قد لا يظهر عليه أى عرض ولا ينتج عنه وفيات ويقوم البط كحامل للفيروس . وقد يعزى هذا إلى الإختلاف فى نوع وعدد مستقبلات فيروس إنفلونزا الطيورفى كل من الدجاج والبط .
لذا أستهدف من هذه الدراسه بحث الفرق بين مستقبلات فيروس إنفلونزا الطيور
(حامض السياليك) فى كل من الدجاج والبط من خلال دراسة التعبير الجينى لإنزيمى السياليل ترانسفيراز 6 و السياليل ترانسفيراز 3 فى الدجاج والبط.
ولقد أستخدم فى هذا البحث 5 دجاجات بلدى و 5 دجاجات أبيض و5 بطات بلدى
و 5 بطات بكينى وقد تم شراء هذه الطيور من مزارع خاصه بمحافظة الشرقيه وعمرها أربعة أسابيع وقد أخذت كافة برامج التحصينات المتبعه وكانت الطيور بحاله صحيه جيده
تم ذبح هذه الطيور وأخذت مباشرة عينات من القصبه الهوائيه والرئتين وتم وضعها فى ورق ألومنيوم ووضعت العينات فى وعاء به نيتروجين سائل.

وقد طحنت هذه العينات تحت ظروف عاليه من التعقيم لإستخلاص الحمض النووى الريبوزى الخاص بهذه العينات ثم تم حفظ هذا الحمض النووى الريبوزى فى نيتروجين سائل لإجراء تفاعل البلمره المتسلسل العكسى ثم الفصل الكهربى لهذه العينات بإستخدام الأجاروز وجهاز الفصل الكهربى. وتم تصوير النتائج بإستخدام كاميرا ديجيتال.

وقد لوحظ الأتى :
لقد أظهرت النتائج زيادة معدل الحمض النووى الريبوزى لإنزيم السياليل ترانسفيراز 6 فى القصبه الهوائيه للدجاج ولكن فى حالة البط لوحظ أن معدل الحمض النووى الريبوزى لهذا الإنزيم منخفض جدا بالمقارنه بالدجاج بينما فى حالة الرئتين لوحظ أيضا زيادة معدل الحمض النووى الريبوزى لهذا الإنزيم فى الدجاج عنه فى البط ولكن الإختلاف فى معدل الحمض النووى الريبوزى فى الرئتين ليس كبير مثلما فى حالة القصبه الهوائيه .
و لقد أظهرت النتائج أيضا زيادة معدل الحمض النووى الريبوزى لإنزيم السياليل ترانسفيراز 3 فى القصبه الهوائيه للبط وإنخفاض معدل الحمض النووى الريبوزى فى حالة القصبه الهوائيه فى الدجاج وأيضا زيادة معدل الحمض النووى الريبوزى فى رئتين البط عنها فى الدجاج.
ولوحظ أنه لايوجد إختلافا ملحوظا فى معدل الحمض النووى الريبوزى للإنزيمين نيجة إختلاف سلالة البط أوسلالة الدجاج.

Abstract: In the present study formulated synbiotic tarhana (Turkish fermented cereal food) was produced as a functional food from the fermentation of wheat flour, some spices [salt, pepper, dill and sweet marjoram (Organum majorana)], some vegetables [tomato (Lycoprsicum esculentum), pepper (Capsicum annum) and onion (Allium cepa)], and synbiotic yoghurt which prepared with prebiotic (Inulin and lactose each 3%) and different concentrations of the probiotic culture (0.5, 1.5, 3, 4.5% DVS-ABT2 containing Streptococcus thermophilus, Lactobacillus acidophilus and Bifidobacterium bifidum). After fermentation (3 days), tarhana dough was dried in the sun. The effect of the fermentation (0, 1, 2 and 3 days) and the probiotic culture concentration on the chemical composition and the probiotic population of the wet tarhana were evaluated. The effect of the probiotic culture concentration on the chemical composition, the probiotic population and the sensory attribute of dried tarhana were evaluated. Also the effect of dried tarhana (prepared from yoghurt which was fermented by 4.5% probiotic culture) on the plasma lipid profile of human subjects was studied. The results showed that the pH value decreased while the acidity increased, acetaldehyde and diacetyl values increased during the fermentation period and by increasing the probiotic culture concentration of the wet and the dried tarhana. Neither the fermentation nor the concentration of the probiotic culture of wet and dried tarhana affected the crude protein, ether extract, crude fibre, and ash values. The numbers of probiotic bacteria increased until the second day of fermentation. However, in the following day, with an increase of the acid content their number decreased. Generally the increasing of the probiotic culture concentration increased the numbers of probiotic bacteria of the wet and dried tarhana. Also the concentration of the probiotic culture didn't affect the sensory attributes of dried tarhana. Subjects supplemented with dried tarhana showed significant reduction in total serum cholesterol, low density lipoproteins (LDL-C) and triglycerides, while high density lipoprotein (HDL-C) increased.

1. Introduction

Fermentation as an old and economical method of producing and preserving food, it is carried out to enhance flavor, aroma, shelf-life, texture, nutritional value and other pleasant and appealing properties of foods (Steinkraus, 2002). It is possible to obtain probiotic foods from several matrices, including both fermented and non-fermented products (Rivera-Espinoza and Gallardo-Navarro 2010). Tarhana is a traditional fermented milk-cereal mixture containing lactic acid bacteria with probiotic properties. Tarhana has been considered as one of the oldest probiotic foods (Ozdemir *et al*. 2007).

Tarhana is a popular traditional Turkish fermented wheat food produced both commercially and in homes. It is mainly used in the form of a thick and creamy soup consumed at lunch or dinner and is easily digested (Bilgicli and Elgun 2005). Tarhana is prepared by mixing wheat flour, yoghurt, yeast and a variety of cooked vegetables and spices (tomatoes, onions, salt, mint, paprika) followed by fermentation for one to seven days (Daglioglu 2000). Lactic acid bacteria and the yeast are responsible for the acid formation during fermentation and the leavening effect. The dough at fermentation is called as wet tarhana. Afterwards, the dough is dried in the sun or by dryer as a lamp, nugget or thin layers to obtain dry tarhana. Also the tarhana is locally consumed as snack after being dried as thin layer or nugget, not to be ground. Since there is no standard production method, nutritional properties of tarhana strictly depend on ingredients and their ratios in the recipe (Erbas *et al*. 2006).

Tarhana is a good source of minerals, organic acids and free amino acids which make it healthy for children, the elderly and medical patients. In addition, it is a good source of vitamins such as thiamine, riboflavin and vitamin B12 (Ibanoglu *et al*. 1995). Ascorbic acid, niacin, pantothenic and folic

acid are also present (Ekinci, 2005, Ekinci and Kadakal 2005). Lacticacid bacteria (LAB) from yoghurt also aid in absorption of nutrients, which would otherwise, be indigestible or poorly digestible. (Farnworth, 2003).

Fermentation of tarhana dough is generally carried out using yoghurt bacteria, such as Lactobacillus bulgaricus, Streptococcus thermophilus and Baker's yeast (Saccharomyces cerevisiae) (Bilgicli and Ibanoglu 2007). This is similar to other natural systems (e.g. Kefir grains) in which associations of LAB and yeasts are used in food fermentation (Gobbetti 1998). The fermentations occur simultaneously during this aspect of production (Bilgicli et al. 2006). Yeast fermentation proceeds through the Embden-Meyerhof pathway (EMP), in which glucose is transformed into ethanol (via piruvate and acetaldehyde), carbon dioxide, and traces of other acids and carbonyl compounds (Gobbetti 1998, Gelinas and McKinnon 2000). According to Mugula et al. (2003) a combined culture of yeasts and lactobacilli cause a more significant decrease in pH (increase in acidity), than with the use of single cultures in the fermented millet.

The present study was initiated to produce synbiotic tarhana and evaluate it as a functional food. The effect of fermentation time (0, 1, 2 and 3 days) and starter concentrations (0.5, 1.5, 3 and 4.5%) on the chemical composition and the probiotic bacterial counts of wet tarhana were evaluated. Also the effect of starter concentrations (0.5, 1.5, 3 and 4.5%) on the sensory attributes, chemical composition and the probiotic bacterial counts of dried tarhana were evaluated. The hypocholesterolemic effect of dried tarhana on human subjects was studied.

2. Material and Methods

Tarhana ingredients: Vegetables [Tomato (Lycopersicum Esculentum), Green Pepper (Capsicum Annum), Chicory (Cicohorium Intybus) and Onion (Allium Cepa)], Cereals [Wheat (Triticum oestivum)], Spices [salt, pepper, dill and sweet marjoram (Origanum majorana)], Yeast (Saccharomyces cervisiae, press form) were purchased from the local market, Cairo, Egypt. Lactulose syrup (52.40% lactulose, 4.3% lactulose and 2.5 galactose) was obtained from the Egyptian International Industries Company (EIPICO), Cairo, Egypt and Spray dried skim milk (low heat) was obtained from Dina for Agriculture Investments, Egypt.

Probiotic Culture: DVS-ABT2 (containing Streptococcus thermophilus, Lactobacillus acidophilus and Bifidobacterium bifidum) were obtained from Chr. Hansen's Lab., Copenhagen Denmark. M17 agar, MRS-Salccin agar, violet red bile agar (VRBA), potato dextrose agar, and MRS agar. All media were purchased from Oxoid LTD, London.

Preparation of Chicory Water-Soluble Extract

Chicory Water-Soluble Extract was prepared according to the methods described by Kim and Shin (1998) as follows: 10g dried chicory plant was dissolved into 200 ml distillated water, soaked for 24 hours under refrigeration, heated at 70 ^{o}C for 15 min. then filtered. Chicory extract was then added to the synbiotic yoghurt.

Preparation of synbiotic yoghurt

Milk samples were standardized by adding skim milk powder to achieve 16% total solids content, pasteurized (15 min. at 85 ^{o}C) and cooled to 40 ^{o}C. Chicory extract and lactulose syrup (3% each) were individually added to milk samples, then inoculated with different concentrations (0.5, 1.5, 3, 4.5%) of the DVS-ABT2 culture, then milk was dispensed into pasteurized plastic cups (100 ml), capped, incubated (5 hours at 44 ^{o}C) cooled and stored in the refrigerator at 5 ^{o}C to prepare synbiotic tarhana.

Preparation of synbiotic tarhana

The ingredients of tarhana are presented in Table (1). Production method of tarhana is presented in fig. (1). All ingredients were prepared (cleaned, peeled and cut), then mixed, blended, pasteurized (30 min. at 65^{o}C) and cooled at 25^{o}C, whole flour, salt, synbiotic yoghurt (with different concentrations of the probiotic culture) and Baker's yeast were added to the mixture, then kneaded to form tarhana dough. The dough was fermented (3 days at 25^{o}C) in an incubator. The samples were withdrawn at time intervals (0, 1, 2 and 3 days) for chemical analysis and microbial analysis. Also tarhana samples (fermented for 3 days) were dried in the sun, filled in small packages and stored. The dried tarhana were subject to chemical, microbial and sensory evaluation and it was also used in human studies to evaluate its hypolipidemic effect.

Chemical analysis

pH value, total acidity, crude proteins, ether extract, crude fiber and ash were determined according to AOAC (2000). Acetaldehyde was estimated as described by Lees and Jaco (1969). Diacetyl was determined according to Lees and Jaco (1970).

Microbial analysis

Bifidobacterium bifidum was enumerated according to Dave and Shah (1969) using the modified MRS agar supplemented with 0.05% L. cysteine-HCl. The plates were anaerobically incubated at 37°C for 48 hours using anaerogen sheets.

Lactobacillus acidophilus count was estimated according to Dave and Shah (1969) on MRS-salccin agar. Incubation was carried out at 37°C for 48 hours.

Streptococcus thermophilus count was estimated according to Terzaghi and Sandine, (1975) using M17 agar. Incubation was carried out at 25 °C for 48 hours.

Moulds were enumerated according to standard methods for examination of dairy products (APHA, 1994). Incubation was carried out at 25 °C for 4 – 5 days.

Coliform group bacteria were enumerated according to standard methods for examination of dairy products (APHA, 1994) using violet red bile agar (VRBA). Incubation was carried out at 37 °C for 48 hours.

Sensory evaluations

Synbiotic tarhana samples were organoleptically evaluated by 10 panelists from the staff members of food science and nutrition department of the National Research Center, Dokki, Cairo, Egypt. The panelists evaluated the samples using a five point Hedonic scale (5 = Liked Extremely to 1 = Unacceptable) adopted from (Iwe, 2000). All samples were evaluated for appearance, taste and general acceptability. The samples were filled in small white porcelain bowl (150 ml) and they were coded with numbers and served to the panelists at random.

Human experiment

Fifteen hyperlipidemic volunteers aged between 40 and 55 years old were studied, all were in good general health, with no history of cardiovascular or gallbladder disease, non of the volunteers were taking any medications. They were given their regular diet which was daily supplemented with 200g of synbiotic tarhana (prepared from yoghurt which was inoculated by 4.5% probiotic culture) for 45 days.

Blood sampling

Blood samples were collected from each volunteer, before supplementation and at the end of the experimental period, after overnight fasting and withdrawn through heparinized tubes for serum. The blood was allowed to clot at room temperature for one hour, and then the serum was separated by centrifugation at 3000 rpm for 15 minutes, clear serum was divided into aliquots and stored at 20°C until analyzed.

Biochemical analysis

Blood lipids were estimated according to the following methods, total cholesterol (Allain et al., 1974), total triglycerides (Fossati and Prencipe 1982), high density lipoproteins (Lopes-Virella et al., 1977), and low density lipoproteins (Friedewald et al., 1977).

3. Results

Evaluation of tarhana dough

Changes in some of the chemical components of tarhana dough samples [prepared with yoghurt and inoculated by different concentrations (0.5, 1.5, 3 and 4.5%) of the probiotic culture (DVS-ABT2)] were studied in relation to different fermentation time. Table 2 shows that for all tested tarhana dough samples, fermentation time had no effect on crude fiber, ether extract and ash. However, fermentation time had an effect on pH value and acidity of tarhana dough. The acidity content of all studied tarhana dough samples increased by increasing the fermentation time and consequently the pH values decreased until the end of fermentation course. Also increasing of probiotic culture concentrations from 0.5 to 4.5% decreased the pH values and increased the acidity content of the resultant tarhana dough samples. The pH value decreased from 5.47, 4.89, 4.62 and 4.57 to 4.89, 4.09, 4.08 and 3.92 while the acidity increased from 3.9, 5.0, 6.8 and 7.7 to 7.4, 9.7, 10.2 and 13.6 respectively during the fermentation time when a probiotic culture inoculation of 0.5, 1.5, 3 and 4.5% respectively was added.

Acetaldehyde and diacetyl contents of tarhana dough samples increased during fermentation. Also they increased with increasing of the probiotic culture concentrations in tarhana dough as shown in Figure 2 and 3.The effect on fermentation time on microbial counts of tarhana dough samples are presented in Table 3. Results indicate that the microbial counts numbers increased by increasing the fermentation time reaching the highest level at the second day of fermentation, then these decreases by increasing that period to record the lowest level at the end of fermentation (3 days). It was found that increasing the probiotic culture concentrations 0.5, 1.5, 3 and 4.5% (samples A, B, C and D) increased the numbers of probiotic bacteria as shown in Table 3. The highest population of probiotic bacteria from tarhana dough samples that contained 0.5, 1.5, 3 and 4.5% probiotic culture was recorded at the second day of fermentation being 8.5 x 10^7, 5.9 x

10^9. 9.7 x 10^{10} and 9.9 x 10^{10} (cfu/g) for *L. acidophilus*, 7.2 x 10^7, 6.4 x 10^9, 6.1 x 10^{10} and 7.6 x 10^9 (cfu/g) for *S. thermophilus* and 6.4 x 10^7, 8.6 x 10^8, 8.2 x 10^9 and 9.0 x 10^9 (cfu/g) for *B. bifidum*. Also, the results indicate that all tarhana dough samples were free from coliform and mold during the fermentation period, indicating no contamination occurred from the environment or the row materials.

Sensory characteristics (flavor, body and texture and appearance) of dried tarhana samples (A, B, C and D) prepared with different concentrations of probiotic culture (0.5, 1.5, 3 and 4.5%) were evaluated as shown in Table 4. The obtained results show that the sensory evaluation properties of dried tarhana had good scores and were acceptable for all the samples which contained different concentrations of probiotic culture.

Chemical composition of dried tarhana samples prepared by yoghurt inoculated with different concentrations of probiotic culture (0.5, 1.5, 3 and 4.5%) is presented in Table 5. Results indicate that all dried samples (A, B, C and D) had a protein content that ranged between (19.87-19.88%). All dried samples (A, B, C and D) had a fiber and ash content that ranged between (3.80-3.82%) and (9.93-9.95%) respectively. All dried samples (A, B, C and D) had an ether extract that ranged between (2.90-2.92%). Concerning pH value and acidity content of dried tarhana sample results Table 5 disclose that the acidity increased and pH value decreased by increasing the concentration of the probiotic culture. The highest acidity (13.4) and the lowest pH value (3.9) were recorded for dried tarhana sample D (containing 4.5% probiotic culture). Acetaldehyde and diacetyl contents of the dried tarhana are shown in figure 4. Acetaldehyde and diacetyl contents of the dried tarhana samples increased by increasing probiotic culture concentration. The highest content of Acetaldehyde (0.65 µmol/ml) and diacetyl (0.55 µmol/ml) were obtained for tarhana samples contained 4.5% probiotic culture, while the lowest contents were obtained for sample having 0.5% probiotic culture being 0.46 and 0.31 µmol/ml consecutively.

Effect of sun drying on microbial population of tarhana samples (A, B, C, and D) is shown in Table 6, data presented disclose that all dried tarhana samples recorded a sharp decrease in probiotic bacterial counts after drying compared to the corresponding values at the end of fermentation (day three) as shown in Table 3.

Hypolipidemic effect

Table 7 shows the changes in total cholesterol, total triglycerides, low and high density lipoprotein of the subjects that consumed dried synbiotic tarhana for 45 days (prepared from yoghurt which was inoculated by 4.5% probiotic culture). Results show a significant hypocholesterolemic effect where the mean of the serum cholesterol concentration was (222.0 ± 5.2) at the start of experiment then decreased to (202.6 ± 8.5) at the end of the experiment, triglyceride level showed a highly significant reduction from (179.8 ± 5.4) at the start of experiment to (169.0 ± 5.5) at the end of the experiment, high-density lipoprotein cholesterol was significantly raised from (50.1 ± 1.0) to (57.8 ± 0.9) at the end of the experiment. As for the low-density lipoprotein cholesterol there was no significant change with a value of (92.7 ± 0.7) at the start of experiment to (81.9 ± 0.5) at the end of the experiment.

Table 1: Synbiotic Tarhana Ingredients (% w/w)

Ingredients	% w/w
Whole wheat flour	35
Synbiotic Yoghurt	25
Fresh onions	12
Fresh tomato	10
Fresh red pepper	6
Green pepper	4
Baker's yeast	4
Salt	2

4. Discussion:

In the present study, changes in some of the chemical components of tarhana dough samples were studied in relation to different fermentation time. Results show that for all tested tarhana dough samples, fermentation time had no effect on crude fiber, ether extract and ash. This is in the agreement with the results obtained by Erbas *et al*. (2005), who found out that fermentation had no significant effect on dry matter, crude protein, ether extract and ash.

Data obtained revealed that the acidity content of all studied tarhana dough samples increased by increasing the fermentation time and consequently the pH values decreased until the end of fermentation course. The increase in the acidity followed by a decrease in pH value may be due to the formation of organic acids from fermentation of sugars mostly by probiotic bacteria. Such findings coincide with those reported by Ibanoglu *et al*. (1995) and Erbas *et al*. (2005), who demonstrated that the acidity of tarhana dough increased and the pH decreased during fermentation.

Acetaldehyde and diacetyl are two important aromatic compound. Acetaldehyde and diacetyl contents of the tarhana dough samples increased with increasing of the probiotic culture concentrations in tarhana dough. Acetaldehyde content is attributed to probiotic bacteria (Erbas *et al*. 2005).

Results indicate that the microbial counts numbers increased by increasing the fermentation time reaching the highest level at the second day of fermentation, then it decreases by increasing that period to record the lowest level at the end of fermentation (3 days). These results are in accordance with those obtained by Daglioglu *et al*. (2002) using Turkish tarhana. The results of bacterial counts are close to those reported by Capela *et al*. (2006), who, reported that the viability of probiotic organisms in yoghurt that had been inoculated with 4% was more than in yoghurt that had been inoculated with 2% before and after fermentation. Ibanoglu *et al*. (1999) found that the increasing of yoghurt amount from 500g to 1000g in tarhana

during the fermentation increased the population of probiotic bacteria of tarhana.

Sun drying is a slower but a more common and economical approach for traditional tarhana production. As for the drying process the critical moisture value is 13 – 15% for the inhibition of undesirable microbial growth in dry recipes produced from wheat flour (Bozkurt and gurbuz, 2008). The moisture content of tarhana is low, that it can be stored for 2 or 3 years without deterioration (Ibanoglu et al. 1999, Tarakc et al. 2004).

The results of the sensory analysis show that the use of yeast in the tarhana formula had a positive effect on the sensory properties. This shows that yoghurt bacteria and yeast together produce lactic acid, ethyl alcohol, carbon dioxide, and other fermentation products, which give tarhana its characteristic taste and flavour (Koca et al. 2002).

The protein content of the dried samples was higher than that obtained by Daglioglu (2000), Kose and Cagndi (2002) who reported that the crude protein content of dried tarhana were between 14.5 – 16 %. The latter author added that dried tarhana is a good source of protein. This can be explained by the differences in the tarhana formulas produced in different regions of Turkey.

The fiber and ash content in the present study were higher than that obtained by Daglioglu (2000), Erbas *et al.* (2006) who reported that the crude fiber and ash content of dried tarhana were 1% and 6.2%. The ether extract content was less than that obtained by Daglioglu (2000), Erbas *et al*. (2006) who reported that the ether extract content of dried tarhana was 5.4%. This can be explained by the differences in the tarhana formulas produced in different regions of Turkey.

Drying treatments can slightly affect the increase in the pH and the decrease in acidity contents of the tarhana samples. The acetaldehyde and diacetyl contents of the dried tarhana may be due to the formation of aromatic components which is attributed to the presence of probiotic bacteria as reported by Erbas et al. (2005).

The sharp decrease in probiotic bacterial counts after drying coincide with the results reported by Daglioglu et al. (2002) who observed a sharp drop in L.A.B. population of tarhana samples after conventional drying. Also Erbas *et al.* (2005) attributed the decrease of L.A.B. population to the low water content of dried tarhana samples.

In the present study it was found that increasing the probiotic culture concentrations increased the number of probiotic bacteria of dried tarhana. These results are in agreement with those reported by Capela *et al.* (2006) who, disclosed that the viability of probiotic organisms in freeze-dried yoghurt was increased by increasing the inoculums volume from 2 to 4 %.

Hypolipidemic effect

The relationship between atherosclerotic cardiovascular disease and nutrition is very important. Many functional foods have been found to be potentially beneficial in the prevention and treatment of cardiovascular disease. (Anderson 2003).

The hypocholesterolemic effect of dried tarhana may be due to its content of probiotic bacteria and prebiotic inulin because it is soluble in water and not hydrolyzed by human digestive enzymes, it is expected to behave like a soluble fiber and to have a hypolipidemic effect (Kim and Shin 1998), wheat flour which as explained by Illman et al. 1993 lowers plasma cholesterol and increases cecal steroids relative to whole wheat flour, wheat bran and wheat pollard in rats. Also wheat is among cereals containing high concentrations of ß-glucan which is known to have a cholesterol lowering effect (Newman et al. 1989, Mc Intoch et al. 1991). Vegetables such as onion have hypocholesterolemic effect by inhibiting hepatic cholesterol biosynthesis (Gupta and Porter 2001, Singh and Porter, 2006) , Lycopene from tomatoe led to reduction of serum total cholesterol (Agarwal and Rao 1998) and green pepper which prevents arteriosclerosis and lower cholesterol (Mezzetti et al. 1995).

5. Conclusion

Fermentation process is an important stage for the development of sensory profile of tarhana. Fermentation and increasing probiotic culture concentrations decreased the pH values and increased acidity, acetaldehyde and diacetyl values while neither the fermentation nor the concentrations of the probiotic culture affected crude protein, ether extract, crude fibre and ash values of wet and dried tarhana.

The increasing of the probiotic culture concentration from 0.5 to 3% ensured probiotic bacteria population of wet and dried tarhana at satisfactory level while increasing the probiotic culture concentration from 3 to 4.5% slightly increased probiotic bacteria population. Generally drying process decreased the viability of probiotic bacteria as drying decreased the water activity. So it has a poor medium for pathogens and spoilage organisms.

Since tarhana is a good source of B vitamins, minerals, organic acids, and free amino acids, and since it is a product of L.A.B. and yeast fermentation, it may be considered a functional and probiotic food with hypolipidemic effect.

Abstract: Background and aims: Since adiponectin plays an important role in the pathogenesis of both obesity and anorexia nervosa, its level might be altered in protein energy malnutrition (PEM) patients which would highlight the pathogenesis of the morbidities that those patients suffer from. This work was thus designed to assess the adiponectin level in PEM and its relation to the severity of the condition.
Methods: The present study was conducted on 20 PEM infants in comparison to ten clinically healthy infants. Dietetic history and anthropometric measurements were taken. Routine laboratory investigations were done as well as serum adiponectin level by ELISA. Patients were re-evaluated after nutritional rehabilitation.
Results: Initial serum adiponectin levels were significantly higher in PEM patients in comparison to the controls and decreased after nutritional rehabilitation. Distinct negative correlation was found between initial adiponectin levels and both the z score and serum albumin in all studied patients.
Conclusions: Adiponectin level is increased in PEM patients and decreases upon nutritional rehabilitation which further proves the inverse relationship between adiponectin level and both weight and body fat. This up regulated adiponectin level in PEM may have an anti-inflammatory role which awaits further studies.

Key words: Adiponectin; Protein energy malnutrition; Nutritional rehabilitation..

1. Introduction:

Adiponectin, the most abundant adipose-specific protein, is suggested to possess anti-hyperglycemic, anti-atherogenic and anti-inflammatory properties [1]. Low levels have been associated with obesity, insulin resistance, Type II diabetes and cardiovascular disease [2]. In anorexia nervosa an inverse linear relationship was reported between adiponectin level and fat mass [3].

Protein energy malnutrition (PEM) is by far the most lethal form of malnutrition. Children are its most visible victims. Malnutrition "the silent emergency" is an accomplice in at least half of the 10.9 million child deaths each year [4]. PEM is manifested primarily by inadequate dietary intake of protein and energy. However, PEM is almost always accompanied by deficiencies of other nutrients. For this reason, the term severe childhood undernutrition (SCU), which more accurately describes the condition, is preferred [5]. The pathogenesis of the affection of various body systems in PEM is still the center of attention of many researchers. There is definite change in body weight and fat content as well as many inflammatory changes.

We hypothesize that since adiponectin plays an important role in the pathogenesis of both obesity and anorexia nervosa, its level might be altered in PEM patients which would highlight the pathogenesis of the morbidities that those patients suffer from. This work was thus designed to assess the adiponectin level in PEM and its relation to the severity of the condition. The effect of nutritional rehabilitation on these levels was studied as well.

2. Patients and methods:

The present study was conducted on 20 infants having protein energy malnutrition (PEM) based on the criteria of [6]. Their ages ranged between 6-24 months, with mean age of 11.15 ± 4.85 months. They were 8 males and 12 females.

The PEM patients were recruited from the Outpatient Clinic, Nutrition Clinic and Inpatient Department, Children's Hospital, Faculty of Medicine, Ain-Shams University in the period from June 2005 till April 2006. They were free from any chronic renal or liver diseases, any neurological deficits, chromosomal or congenital malformations and were born full term.

They were classified on the basis of Z score of weight for length and presence or absence edema according to *Gernaat and Voorhoeve classification* [7] into two groups. The non-edematous PEM group which included 12 infants, their Z score of weight for length was < -2 SD with no edema. The second group is the edematous PEM group: Which included 8 infants, their Z score of weight for length was < -2 SD with edema.

Ten clinically healthy, age and sex matched infants having their anthropometric measurements within the normal range for age and sex according to *Ogden et al.,* [8] were included as the control group. They were 5 males and 5 females with mean age of 13.65 ± 5.57 months.

After the approval of the ethical committee of the Children Hospital, Faculty of Medicine, Ain Shams University, an informed verbal consent was obtained from parents or legal guardians. Enrolled cases were then subjected to complete history taking with special emphasis on dietetic history including 24 hours recall of feeding. Thorough clinical examination was done laying stress on the anthropometric measurements, signs of PEM and associated vitamin deficiencies as well as systemic examination.

Weight was measured using regularly calibrated scale with minimal clothing. Length was measured using a special calibrated board. Skull circumference (SC) was measured by passing a tape over the most prominent part of the occiput and just above the supraorbital ridges. Readings was approximately to the nearest millimeter. Mid arm circumference (MAC) was measured midway between the tip of acromial process and the epicondyle of the humerus. The measuring was the mean of two reading taken the nearest millimeter. Skinfold thickness (SFT) was measured using Harpenden skinfold callipers over the triceps, supra-iliac and under the scapula, applying a constant pressure of 10 g/mm2 at a contact surface of 20–40 mm. The measurements were read 2 s after full pressure was exerted by the jaws of the caliber. Weight, height and skull circumference were plotted against the percentiles to obtain the percent from the median for age according to *Ogden et al.,* [8].

Venous blood was collected under complete aseptic condition. The sample was divided into two tubes one containing EDTA and designed for the complete blood count using coulter GEN-S (Coulter Corporation USA) and the other was plain to allow blood to clot for 30 minutes before being centrifuged at 3000g for 15 minutes at room temperature. Plasma were rapidly separated and part was used to estimate the liver and kidney functions by Hitachi 917 automated analyzer and the rest of the sample was stored at -40 degree centigrade until used later to determine serum adiponectin level by ELISA using the kit purchased from A&D Company.

Patients entered a nutritional rehabilitation program according to the *WHO,* [9] for a period of 2 – 4 months then they were re-evaluated using the previously mentioned clinical and laboratory parameters.

Regarding the statistical methods, the standard computer program SPSS for Windows, release 10.0 (SPSS Inc, USA) was used for data entry and analysis. All numeric variables were expressed as mean ± standard deviation (SD). Comparison of different variables in various groups was done using student t test and Mann Whitney test for normal and nonparametric variables respectively. Paired t or Wilcoxon signed ranks tests were used to compare variables before and after therapy. Multiple regression analysis was also performed to determine effect of various factors on a dependent variable. Pearson's and Spearman's correlation test were used for correlating normal and non-parametric variables respectively. For all tests a probability (p) less than 0.05 was considered significant. Graphic presentation of the results was also done [10].

3. Results

The results of the present study reveal lower anthropometric measurements in non-edematous as well as edematous PEM patients compared to those of the controls (table 1). These measurements show significant improvement after nutritional rehabilitation (yet not reaching the control values in most of them) (table 2).

Tables (1) and (2) also show that both serum albumin and hemoglobin (Hb) levels are significantly lower in both groups of PEM compared to the controls and their values show significant improvement after nutritional rehabilitation yet not reaching the control values.

Figures (1) and (2) demonstrate that initial serum adiponectin levels are significantly higher in non-edematous and edematous PEM patients in comparison to the controls. After nutritional rehabilitation these levels decrease yet they are still significantly higher than the controls. Additionally, no significant difference is detected between the adiponectin level of non-edematous and edematous PEM patients whether before or after nutritional rehabilitation [t = 0.32 (p>0.05) and t = -0.61 (p>0.05) respectively].

The correlation studies reveal distinct negative correlation between initial adiponectin levels and both the z score and serum albumin in all

studied patients yet these correlations don't reach statistical significance (Figures 3 and 4).

4. Discussion:

The results of the current study revealed statistically initial lower values of the studied anthropometric measurements in both studied groups of PEM in comparison to the controls with significant improvement after nutritional rehabilitation. The decreased initial values of weight and length agree with Wellcome's classification of PEM [6] and are fulfilling one of the constant features of malnutrition, namely growth retardation in weight and height [11]. The lower skull circumference measurement agrees with *Needlman* [12] who stated that severe under nutrition depresses head growth and this is considered as ominous predictor of later cognitive disability. As regards the low measures of mid arm circumference, it is reinforced by *Castiglia,* [13] who stated that mid arm circumference reflects the state of muscle and subcutaneous fat so it is affected in PEM especially the non-edematous. Additionally, similar to our results *Curran and Barness,* [14] reported decreased skin fold thickness in PEM patients.

As regards the hematological parameters we found that the initial hemoglobin and albumin levels were significantly lower in both groups of patients in comparison to the control group with significant

p<0.01 is highly significant and p<0.001 is very highly significant.

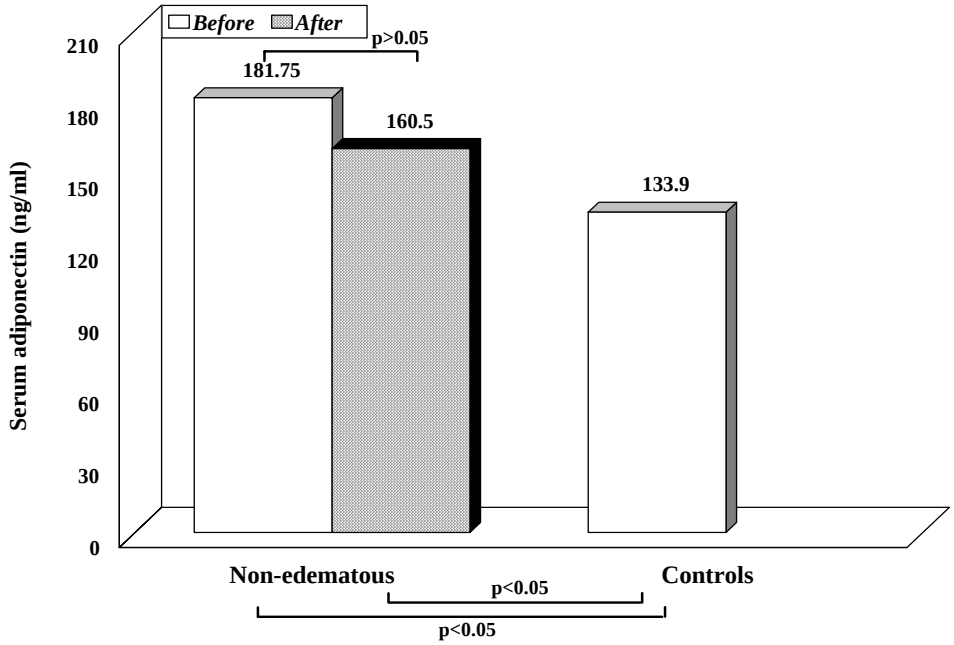

Figure (1): Serum adiponectin levels of non-edematous PEM patients before and after nutritional rehabilitation and that of the control group.

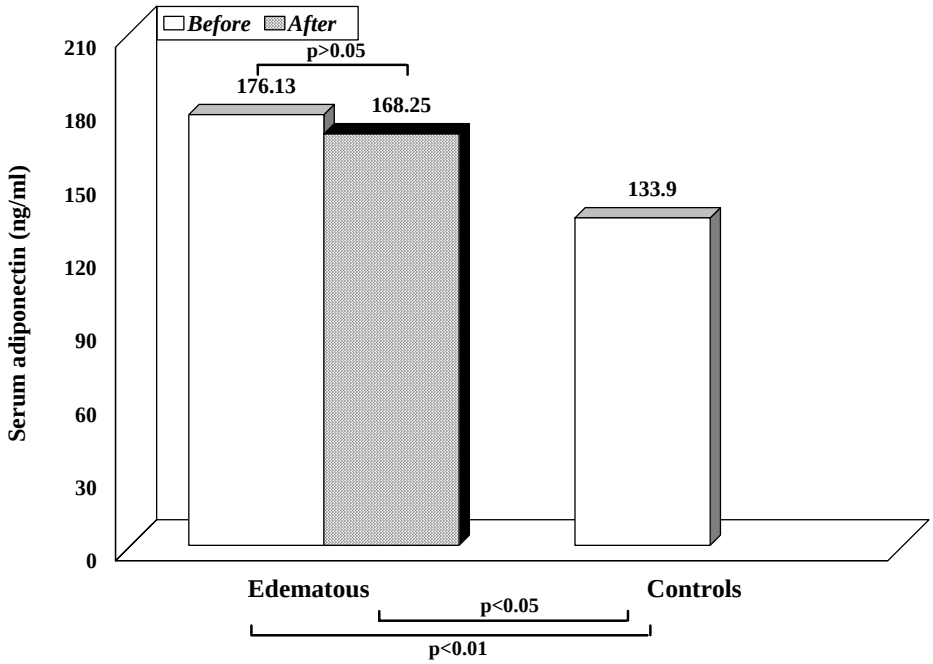

Figure (2): Serum adiponectin levels of edematous PEM patients before and after nutritional rehabilitation and that of the control group.

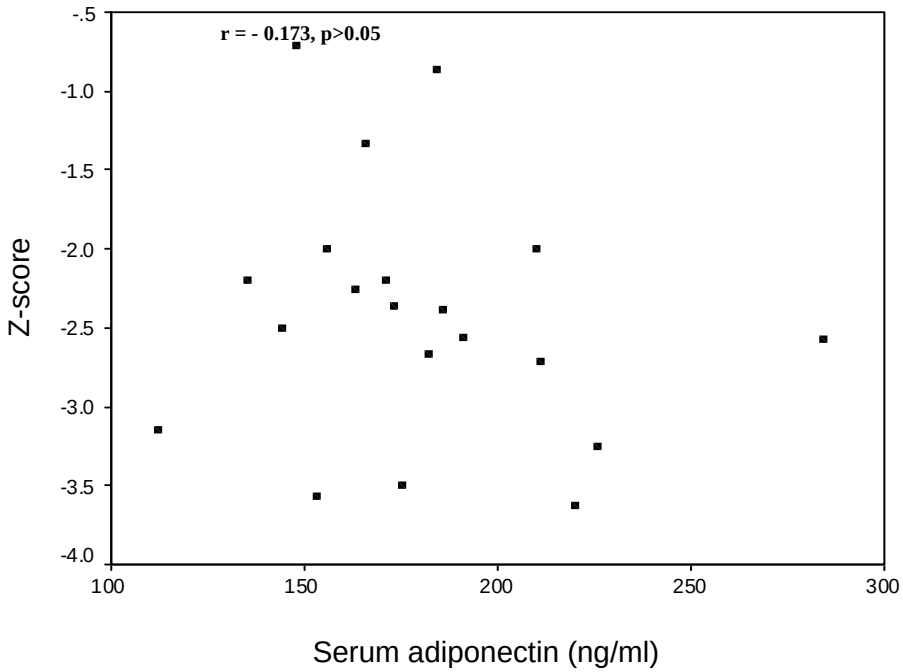

Figure (3): Correlation between serum adiponectin levels and Z score in PEM patients.

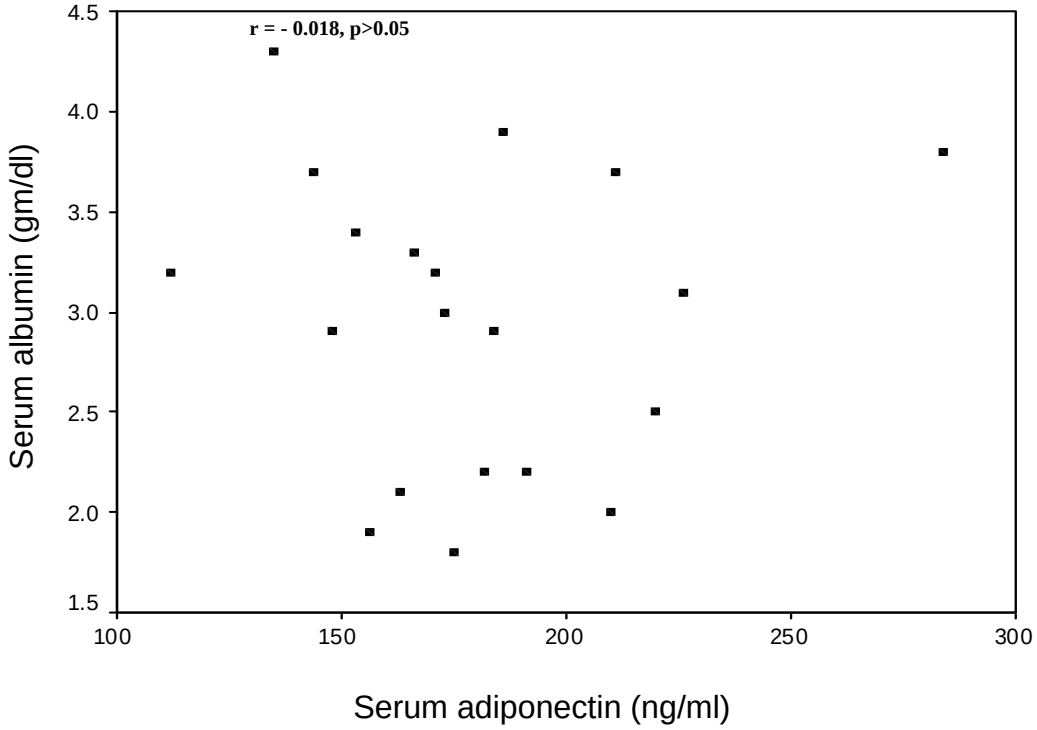

Figure (4): Correlation between serum adiponectin levels and serum albumin in PEM patients.

improvement after nutritional rehabilitation which further proves the success of its implementation. The anemia initially detected in our patients comes in agreement with *Sive et al.,* [15] *and Ashour et al.,* [16]. Regarding the hypoalbuminemia it agrees with the results of *Morlese et al.,* [17], who detected hypoalbuminemia in both edematous and non-edematous groups of PEM cases. They explained its deficiency by increased rate of catabolism rather than impairment of synthesis and attributed this mainly to infection. Additionally, *Karp,* [18], suggested that hypoalbuminemia here comes from the decrease in its synthesis.

Serum adiponectin level was measured in both groups of PEM patients and both showed significantly higher values before nutritional rehabilitation as compared to the control group. After nutritional rehabilitation the serum adiponectin level showed non-significant decrease in both groups, but it was still higher than control group values.

The current study shows increase in adiponectin level in PEM patients and decrease in this level upon nutritional rehabilitation which entails an increase in body weight. Our results denote an inverse relation between circulating adiponectin level and weight. Comparatively, circulating adiponectin level was reported to be down regulated in obesity [19], and increased upon weight reduction [20].

Considering the relation between body fat and adiponectin level *Hotta et al.,* [21] reported significant decrease in adiponectin levels in cases of obesity who suffer from excess fat accumulation. Conversely, PEM is characterized by loss of body fat [22] and this explains the increased adiponectin level in our series of patients. These findings, regarding PEM patients, further prove the inverse relation between body fat and adiponectin serum level that is found in obese subjects.

Additionally, *Pannacciulli et al.,* [23] found that anorexia nervosa is associated with increased adiponectin serum levels. This agrees with our research, when taking into consideration that anorexia nervosa is characterized by decreased caloric intake, low weight and reduced body fat [24]. Thus the findings of the former authors further support our conclusion about the relation between body fat and adiponectin levels in PEM patients.

On the other hand *Tagami et al.,* [25], found that adiponectin levels were significantly low in the patients with AN and bulimia nervosa, compared with normal weight control subjects, and hypoadiponectinemia was reversed by weight recovery in the patients with AN. The authors suggested that this might be normal physiological response to starvation or abnormal feeding behavior.

The distinct negative yet non significant correlation between serum adiponectin level in PEM patients and serum albumin and Z score revealed in the current study proves that the increase in adiponectin level in PEM patients is judged by the severity of the condition.

From another perspective *Engeli et al.,* [26], found an inverse relation between inflammatory mediators and adiponectin levels in obese women which was explained by *Ajuwon and Spurlock* [27] by the fact that adiponectin directly targets the adipocytes to suppress IL-6 and TNF mRNA expression. It has been reported earlier that chronic undernutrition and micronutrient deficiency compromise cytokines response and affect immune cell trafficking [28]. We thus hypothesis that the increased adiponectin level in our series of patients may be in part responsible for their altered inflammatory mediators response. In a way this increased level can be considered as a protective mechanism that the body utilizes to overcome hard times.

In conclusion, adiponectin level is increased in PEM patients disregards its type

and decreases upon nutritional rehabilitation which further proves the inverse relationship between adiponectin level and both weight and body fat. This up regulated adiponectin level in PEM may have an anti-inflammatory role. Large multi-centric study are thus recommended to highlight the level of adiponectin as well as other growth factors in PEM patients in a trail to detect the interrelation between them and the feedback mechanism controlling their levels in such disease. Further studies should also concentrate on exploring the anti-inflammatory and the possible anti-atherogenic role of the upgraded adiponectin level in PEM patients.

Acknowledgements

We acknowledge the help provided by Professor Dr Ehab El-Hakeem to analyze the data and perform the required statistical tests.

Funding

We, the authors, declare that we did not receive any form of funding throughout the whole steps of the study. Ain Shams University gave us the privilege of using the laboratory instruments and the kits used for the hormonal assay was purchased by the authors themselves.

Atypical Bacteria in Ventilator Associated Pneumonia; an Egyptian University Hospital Experience

Egypt

dr_mona_zaki@yahoo.co.uk

Background Ventilator-associated pneumonia (VAP) is the most common hospital acquired infection seen in ICU in patients on mechanical ventilation. A diversity of microbes can cause VAP, causative agent differ according to patient populations and types of ICUs. Atypical bacteria not cultured by routinely used methods , have been implicated as causes of VAP, still no sufficient studies to assess size of their role as causative agent in VAP. In this study we aim at estimation of the potential role of atypical bacteria as Mycoplasma pneumoniae, Chlamydia pneumoniae and Legionella pneumophila in ventilator-associated pneumonia in the intensive care units of Alexandria Main University Hospital. **Materials and methods:** 60 endotracheal aspirates were collected from VAP ICU patients. Samples were subjected to routine culture as well as PCR amplification using specific primers for detection of the following atypical bacteria : Mycoplasma pneumoniae, Chlamydia pneumoniae and Legionella pneumophila. **Results:** Out of the 60 endotracheal aspirate, routine culture revealed growth of: enterobacteriaecae in 14 (23.3%) aspirate, pseudomonas in 13(21.7%), candida in14(23.3%) , and MRSA in 10 (16.7%) . In 19 (31.7%) endotracheal aspirates, no growth was encountered on routine culture. PCR reaction was positive for Atypical bacteria in 9 (15%) out of 60 samples, five were positive for mycoplasma, three for Legionella, and only one was positive for Chlamydia. Atypical bacteria positive results were encountered in 4 (21%) out of 19 aspirates with no growth culture results. **Conclusion:** Our results point that atypical bacteria are not an uncommon cause for VAP. This finding has to be taken into consideration while tailoring the empiric antimicrobial coverage of patients diagnosed with VAP.

[Egypt. **Atypical Bacteria in Ventilator Associated Pneumonia; an Egyptian University Hospital Experience**. Journal of American Science 2010;6(12):1423-1428]. (ISSN: 1545-1003). http://www.americanscience.org.

Keywords: Atypical Bacteria; Ventilator; Pneumonia

Introduction

Ventilator-associated pneumonia (VAP) is considered as the most frequent ICU-acquired infection among patients receiving mechanical ventilation (MV). This kind of respiratory tract infection prolong the duration of Mechanical ventilation and delay the release from ICU. Most antibacterial chemotherapy prescribed in an ICU are administered for respiratory tract infections. [1]

VAP can be caused by a large variety of microorganisms . the causative agent may differ according to the population of patients in the ICU, the durations of hospitalization and stay in the ICU. "Atypical" pneumonia differ from typical one in not to be associated with shaking chills [2] and caused by atypical bacteria which cannot be grown by routinely used microbiologic culture media and techniques as *Mycoplasma pneumoniae, Chlamydia pneumoniae and Legionella pneumophila* [3-5].

Mycoplasma pneumoniae was first atypical pathogens to be identified as a cause of respiratory tract infection in 1944.[6,7] Characterized by absence of a rigid cell wall, poor staining by Gram method, and high nutritional requirements for its culture as it needs a high concentration (10-20%) of serum or supplements . This makes diagnosis of mycoplasma by conventional microbiologic examination difficult. [7] *Chlamydia pneumonia* laboratory diagnosis depended on non- specific and technically demanding techniques till 1990 but now it has been replaced by detection of chlamydial antigens or detection of DNA by PCR. [7] *Legionella pneumophila* are nutritionally fastidious, intracellular bacilli, gram negative organisms. [8] Infection with *legionella is* associated with exposure to artificial water systems ,condensers and respiratory therapy equipments .[9] Use of PCR as a rapid and specific diagnostic method for legionella infection overcame the long culture time needed for its growth (3-5 days) and the need of media supplemented with iron and cysteine as well as difficult colonial identification in mixed cultures. [7]

Accurate diagnosis of VAP remains a difficult target to achieve, that relies mainly on clinical, microbiological and radiological diagnosis.[10,11] Main clinical criteria for VAP diagnosis have been reported to be new lung infiltrate on chest X-ray with fever , leukocytosis or leukopenia, and purulent secretions. [12-14] Inadequate antibiotic treatment have been always reported by researchers to be related to poor prognosis of VAP. [15,16] Microbiological culture and sensitivity results remains a gold standard for planning treatment for the VAP patient before empirical antibiotic administration [17] . This have been emphasized by

the Guidelines from the Infectious Disease Society of America (IDSA).[18]

It is well established that Beta-lactams are not effective against such organisms because *Chlamydia pneumoniae* and Legionella species are intracellular organisms and *Mycoplasma pneumoniae* lacks a cell wall. In those cases Erythromycin and tetracycline can be useful . Other antibiotics effective against atypical bacteria, includes Macrolides, Doxycycline and Flouroquinolones.[6] Our study aims at assessment of the potential role of atypical bacteria as Mycoplasma pneumoniae, Chlamydiae pneumoniae and Legionella pneumophila in ventilator-associated pneumonia in the intensive care units of Alexandria Main University Hospital.

Materials

The study was conducted on 60 patients on Mechanical ventilators for more than 48 hours and acquired VAP during their stay in the ICU of Critical Care Department in the Alexandria Main University Hospital in the period between April 2009 and April 2010.Cases included in this study have been informed and consented. Inclusion criteria were fever, leukocytosis, development of persistent radiographical pulmonary infiltrate during stay in the ICU and with no history of a previous pulmonary disease or pulmonary symptoms at the time of admission. Thirty ICU patients on ventilators for more than 48 hours without developing VAP, within the same period of time, were included as a control group.

Methods

Endotracheal aspirates as well as clinical data have been collected from patients and controls. Samples were subjected to routine culture as well as DNA extraction with subsequent PCR amplification for detection of specific DNA sequences of the following atypical Bacteria genus : Mycoplasma pneumoniae, Chlamydia pneumonae and Legionella pneumophila.

The endotracheal tube was previously inserted guided by a laryngoscope. A sterile suction catheter was introduced blindly into the endotracheal tube after disconnecting ventilator. 2 ml of endottracheal aspirates were obtained by suction. The part of the catheters containing the aspirates were cut and placed in sterile test tubes and sent to the laboratory.

The endotracheal aspirates, within catheters in test tubes, were homogenized and liquefied by adding 2 ml sterile 1% N-acetyl L-cysteine (equal volume of the specimen). All tubes were centrifuged for 15 minutes at 4×10^3 rpm and then vortexed and left at room temperature for another 15 minutes.[19,20] Each homogenized specimen was then divided into 2 equal portions in 2 sterile Eppendorfs. The first part was used for conventional microbiological studies while the other was kept at -20^{o}C for PCR assay. Each aspirate was streaked on Blood agar, MacConkey's agar and Sabouraud's Dextrose agar plates. All plates were incubated aerobically at 37 ^{o} C for 24 hours. Any growth was identified according to the conventional bacteriological and mycological techniques.[19,20]

PCR assay: Extraction of DNA was performed using QIAamp DNA blood mini kit (Qiagen). Separate PCR reactions were performed for amplification of each DNA sequence of each organism using Techne Progene thermal cycler. Reaction mixture consisted of 5µl DNA extract, 25 picomoles of each of the forward and reverse oligonucleotide primers specific for Mycoplasma pneumonia [21] , Legionella pneumophila [21] and Chlamydia pneumonia [22] , 12.5 µl Taq PCR master mix (MBI Fermantas), and 4.5 µl nuclease free water. For detection of the amplified products: [21] 10 µl of the amplification products were electrophorised into 2% agarose in Tris-borate EDTA containing 0.5 µg/ml ethidium bromide at 80 volts for 45 minutes. Revealed DNA bands were visualized on an ultraviolet transilluminator.

Results

The mean age of the VAP study group was 43.1 ± 24.68 (18-85) year, while that of the control group was 49.7 ± 20.5 (12-70). There was no statistically significant difference between them as regards age and gender: male to female ratio was 33:27(55:45%) in patient group while in the control group, the male to female ratio was 19:11 (63:36.6%). As regards causes of hospital admission for the 60 VAP patients and the control group It has been found that cardiac problems were the most commonly encountered among both patients (38%) and controls (28%), rest of causes for admission included accidents, poisoning, Renal and hepatic problems. In the endotracheal aspirates obtained from the 60 VAP patients included in this study, 41 specimens were positive by conventional microbiological cultures and 19 were culture negative. In the control group, 11were positive and 19 specimens were culture negative. See table 1.

The conventional microbiological culture revealed that among cultures of the patients group, *Candida* spp was the commonest organism isolated accounting for 23.3%. Only 16% were of significant count ($\geq 10^5$ CFU/ml). This was followed by *Pseudomonas aeruginosa* (21.6%) and 15% were of significant count, then the polymicrobial growth 20% and 16% with significant count, *Staphylococcus*

aureus 16% and 10% with significant count, *Acinetobacter* spp 8.3% and 6.6% with significant count, *Proteus* spp 6.6% and 5% with significant count, *Klebsiella* spp 6.6% and 5% with significant count, *E-coli* 5% and 1.6% with significant count, *Coagulase-negative staphylococci* 1.6% which were of significant count and *Diphtheroids* 1.6% which were also of significant count. It is also to be noted that 31.6% of the total endotracheal aspirates of the 60 VAP cases were negative by conventional microbiological culture.

Table 1: The results of conventional microbiological culture of the endotracheal aspirates from the 60 VAP patients and the control group

	Conventional microbiologic Culture results*	
	Positive	**Negative**
Cases n=60	41 (68.3%)	19 (31.7%)
Controls n=30	11 (36.6%)	19 (63.3%)
Total n=90	52 (57.7%)	38 (42.2%)

*P value = 0.004

While in the control group, bacteria revealed from cultures were *Pseudomonas aeruginosa* accounted for 20%, *Klebsiella* spp 10%, *Candida spp* 10% also, then *Staphylococcus aureus* 3.3%, *Coagulase-negative staphylococci* 3.3% and *Proteus* spp 3.3%. In addition, 10% were culture negative and 13.3% were polymicrobial. The growth counts of the endotracheal aspirates of the control group were insignificant ($\leq 10^5$ CFU/ml). Atypical bacteria DNA detection by PCR was positive in 9 (15%) out of 60 samples, the majority of them (5) were mycoplasma, 3 were positive with Legionella, and only one sample was positive with Chlamydia. The Atypical bacteria positive results was encountered in 4 (21%) out of 19 aspirates with no growth culture results. See figure 1.

It was found that 5 specimens were positive for *Mycoplasma pneumoniae*, three were positive for *Legionella pneumophila* and only 1 was positive for *Chlamydia pneumoniae.* Among the 5 positive specimens for *Mycoplasma pneumoniae*, 3 were positive by conventional microbiological cultures and grew other associating microorganisms, while 2 were culture negative. The 3 specimens that were positive for *Legionella pneumophila*, only 1 grew other microorganism by conventional cultures and the other 2 were culture negative. The only positive specimen for *Chlamydia pneumoniae* did not grow any microorganisms by conventional microbiological cultures. As for the control group included in this study, none of their DNA extracts were positive in the PCR assay for atypical bacteria.

Table 2: PCR and culture results of cases and control

	Culture**		PCR*	
	Culture positive	**Culture negative**	**PCR positive**	**PCR negative**
Cases	41 (68.3%)	19 (31.7%)	9 (15%)	51 (85%)
Controls	11 (36.6%)	19 (63.3%)	0 (0%)	30 (100%)

* PCR was done using primers for Mycoplasma pneumonia, Legionella pneumophila, Chlamydia pneumonia.
**All specimens were cultured on Blood agar, MacConkey's and SDA.

Table 3: Results of PCR assay in relation to conventional microbiological culture resutls inVAP patients.

PCR assay	Conventional microbiological culture		Total
	Positive(n= 41)	**Negative (n= 19)**	
Mycoplasma pneumoniae	3(7%)	2 (10%)	5 (8.3%)
Legionella pneumophila	1 (2.4%)	2 (10%)	3 (5%)
Chlamydia pneumoniae	0	1 (5%)	1 (1.6%)
Total	4(9%)	5(26%)	9 (15%)

DISCUSSION

VAP complicates the course of 9 – 20% of mechanically ventilated patients and mortality varies greatly from 8 to 76%,. Once pneumonia is suspected, bacteriologic confirmation should be obtained and empiric therapy must be instituted as soon as possible, as a delay in therapy or inappropriate therapy greatly increases mortality.[23] Awareness of the potential microbial causes of VAP and confirmation of the specific cause in an individual patient are essential to guide optimal antibiotic therapy.[24]

Endotracheal aspirates, chosen in this study as the respiratory specimen, are used more frequently as a diagnostic method in intubated patients with suspicion of pulmonary infection, because of its

simplicity and minimal training required, but the fact that the culture also contains other non-pathogenic organisms from the upper respiratory tract flora, results in a low positive predictive value of this test. However, this can be avoided by the use of the semiquantitative method of culture of the obtained specimen, with a designated threshold value above which diagnosis of VAP can be established.[25,26] Cultures revealed that *Candida* was the commonest organism isolated accounting for 23.3%, while 16% only were of significant count ($\geq 10^5$ CFU/ml). This was followed by *Pseudomonas aeruginosa* 21.6% and 15% were of significant count, then the polymicrobial growth 20% and 16% with significant count, *Staphylococcus aureus* 16% and 10% with significant count.

The results of our study agree with the results of several previous studies.[27 -31] where *Pseudomonas aeruginosa* was the predominant organism isolated by endotracheal aspiration and bronchoalveolar lavage, followed by *Staphylococcus aureas* and *Klebsiella pneumonia*.[32] The significantly high rate of Gram negative bacilli in our study and many other studies probably indicates the high incidence of prolonged hospital stay and the prolonged duration of mechanical ventilation that predisposes the patients to acquire infections from the multidrug-resistant pathogens . In contrast , Other authors reported other bacterial strains as *Acinetobacter baumanii and Streptococcus* .[33-34]

.

The results of PCR assay for atypical bacteria of the DNA extract of the endotracheal aspirates of the 60 VAP patients revealed a total of 9 positive cases (15%) for the tested microorganisms, 5 cases were positive for *Mycoplasma pneumonia* (8.3%), 3 cases were positive for *Legionella pneumophila* (5%) and only 1 case was positive for *Chlamydia pneumonia* (1.6%).

Many were studies conducted for detection of atypical bacteria by PCR. Hassan et al reported detection of legionella and Chlamydia pneumonia in VAP cases while no cases were positive for *Mycoplasma pneumonia*e.[28] Moreover, Bachinskaya et al reported that 9% of their patients were positive for *Mycoplasma pneumonia*e and 9% were also positive for *Chlamydia pneumoniae.*[35] In another study by Apfalter et al, where real time PCR was used as a fast diagnostic tool for non-conventionally cultured microorganisms, they reported that 3% of their cases were positive for *Mycoplasma pneumonia*e and 2% of cases were positive for *Chlamydia pneumoniae.* They concluded that *Mycoplasma pneumonia*e and *Chlamydia pneumoniae* should be considered as causative agents in critically ill patients who develop early-onset nosocomial ventilator-associated pneumonia. Thus, empirical antimicrobial regimens should cover *Chlamydia,* and *Mycoplasma*.[36] Furthermore, El-Ebiary et al also diagnosed six cases of *Legionella* pneumonia among patients with definite VAP. Using specific culture for *Legionella* and serology for *Legionella pneumophila, Mycoplasma pneumoniae Coxiella burnetti, and Chlamydia pneumoniae,* only *Legionella* was diagnosed in 2 patients by serology and in 4 patients by culture.[37] Our results draw attention towards the possibility of these rarely diagnosed agents as being not infrequent causative agents for VAP. The prevalence of such atypical pathogens is to be taken into consideration while tailoring the empiric antimicrobial coverage of patients diagnosed with VAP.

E-mail address:dr.rosa@hotmail.com

Abstract : This investigation aims to study the effect of radiofrequency (RF) radiation on DNA damage in brain cells of male Wistar rats using the comet assay and to investigate the role of HSP70 as a protective molecular chaperone that increases stress tolerance of brain cells. Male Wistar rats (118±20g) were divided into three groups. The 1st (exposed) group was subdivided into three subgroups and exposed for 15 min to activated cell phone emitting a frequency radiation of 900 MHz, at non-thermal specific absorption rate (SAR) of 2.9×10^{-3} W/Kg. The 2nd (exposed) group was also subdivided into three subgroups but was exposed for 30 min to the cell phone. The third group was the sham-exposed (control). Animals in each group were sacrificed after 1, 3 and 7 days recovery period. The comet assay parameters showed significantly increased DNA damage in brain cells after 1 and 7 days in the first group and after 7 days in the second group. The HSP70 showed significantly increased levels after 7 days in both exposure groups. Meanwhile, HSP70 showed significantly decreased levels after 1 day in the second group. The results of the present study demonstrate a damaging effect of RF radiation on DNA of the brain cells. This damaging effect initially inhibits the synthesis of HSP70; But after a 7 day recovery period, the levels of HSP70 increase significantly possibly due to powerful capacity of the cells for recovery.

Keywords: comet assay, DNA damage, brain cells, heat shock protein 70, radiofrequency radiation

Introduction

The cellular response to stress is represented at the molecular level by the induced synthesis of a set of highly conserved proteins, heat shock proteins (HSPs) (Park et al., 2000) which protect cells and organisms against oxidative stress and often prevent cell death. While prolonged exposure to conditions of extreme stress is harmful, and can lead to cell and tissue death, induction of HSP synthesis can result in stress tolerance and cytoprotection. The cytoprotective effect of HSPs has been attributed to one of the major HSPs, HSP70 (Lee et al., 2001) that is particularly relevant as it is the major protein induced transcriptionally by various forms of stress including lethal heat shock, anoxia, heavy metals, ionizing and non-ionizing electromagnetic radiation (Santoro, 2000, Calini et al., 2003).

In recent years, there has been growing concerns about the potential effects of radiofrequency electromagnetic fields (RF-EMFs; 10MHz—300GHz) on human health, especially the influence on DNA damage (Panagopoulos et al., 2007, 2010; Yan et al., 2007; DeIuliis et al., 2009), because of the wide use of mobile phones. The proximal distance of mobile phone to the head has raised anxieties about the biologic effects of microwave radiation (300MHz – 300 GHz) on the brain (Lai and Singh, 2005; Paulraj and Behari, 2006; Luukkonen et al., 2009). It has been demonstrated that mobile phones affect neural function in human. These effects range from changes in the permeability of the blood brain barrier (Grigor'ev, 2005; Nittby et al., 2009) to changes in electroencephalogram (EEG) pattern (Croft et al., 2002) suggesting that exposure to an active cell phone affects the resting EEG in humans. Functions such as sleep (Hamblin and Wood, 2002), attention (Lee et al., 2001) or learning and memory (Koivisto et al., 2000) have been also shown to be ″mobile phone sensitive″. Cell phone exposure may also lead to brain cancer and that link is via the heat shock response (French et al., 2000).

Although many studies have reported that RF-EMF does not induce genotoxic effects (Maes et al., 2001; McNamee et al., 2003; Scarfi et al., 2006; Zeni et al., 2008), several independent studies (Sykes et al., 2001; Baohong et al., 2005; Lixia et al., 2006; Yao et al., 2008; Luukkonen et al., 2009), have provided evidence for DNA damaging alterations. Since RF-microwave EMF is non-ionizing, it is not considered to induce direct alterations in DNA, the mechanism is unclear. Previous studies have shown that RF-EMF increased the formation of reactive oxygen species (ROS) which have been shown to induce DNA damage (Moustafa et al., 2001; Stopczyk et al., 2005; Yao et al., 2008). Oxygen free radicals may play a role in mechanism of biological effects induced by RF-EMF. In aerobic cells, ROS

are generated as a by-product of normal mitochondrial activity. If not properly controlled, ROS can cause severe damage to cellular macromolecules, especially DNA (Barzilai and Yamamoto, 2004). There may be some association between the overproduction of ROS and DNA damage induced by RF-EMF.

The comet assay is considered a sensitive assay for detecting DNA single strand breaks, double strand breaks, alkali labile sites, incomplete excision and repair sites (Fairbairn et al., 1995). So, the present study aims to investigate whether RF-EMF induces DNA damage in male Wistar rat brain. The comet assay was used to measure DNA damage after two different exposures to GSM radiation (15 and 30 min) and the animals were sacrificed after a recovery period of 1, 3 and 7 days. The stress response to RF-EMF was also determined by measuring the levels of HSP70 in male Wistar rat brain.

Materials and Methods

Animals

Male Wistar rats weighing about 118±20g were obtained from Helwan Farm for Vaccine and Biological Preparations. The animals were housed in cages 5 animals in each cage in the laboratory for one week before the beginning of the experiment. The animals were maintained on 12h dark/light cycle and were given food and water *ad libitum*.

Experimental design

After the acclimation period, animals were randomly divided into two exposed groups and one sham-exposed (control) group:

Group 1: exposed 15 min (n=15).
Group 2: exposed 30 min. (n=15).
Group 3: sham-exposed (control) (n=15).

Animals in groups 1 and 2 were kept for a recovery period of 1, 3 and 7 days (with 5 animals in each) after which they were sacrificed.

Method of exposure

During irradiation, each animal was placed in its own restrainer rocket Plexiglas (15 cm length, 6 cm diameter) and a cone (3 cm length) in which the rat inserted its head. A cell phone in the ″on″ mode (spiking mode) was placed against the cone directly above the rat́s head. The end of the cone was opened and holes were made in the rocket to facilitate breathing and minimize body temperature elevation. A Plexiglas disk was placed at the back to prevent the rat from backing out of the rocket. The cell phone was manufactured by Nokia (model 6300 type RM-217, GSM 900MHz, SAR 1.6 W/Kg) in the “on” mode (spiking mode) was placed with its antenna above the head of the rat . Control animals were treated identically as the exposed ones; but the cell phone is ´switched off˝ during of the sham-exposed.

Preparation of brain samples

Rats from each group were anesthetized by anesthetic ether and then decapitated and their brains were dissected out. Whole brain was washed three times with phosphate buffer solution (PBS: NaCl, 8.0g, KCl, 0.2g, $Na_2HPO_4.12\ H_2O$ 2.8g, $KH_2PO_4$0.2g, pH 7.4), cut into pieces with stainless steel scissors, homogenized with the appropriate amount of PBS at 4ºC and pH 7.4 in a glass homogenizer at 0-4ºC, and then sifted through a 300-µm sieve. The slides were previously stained by trypan blue (3,3'-{[3,3'-Dimethyl(1,1'-biphenyl)-4,4'-diyl]bis(azo)}bis(5-amino-4-hydroxy)-2,7-naphthalenedisulfonic acid, tetra-sodium salt), and under a microscope up to 90% of the brain cells were found to be alive. The cells were resuspended at approximately 10^6 cells per ml in PBS and then used immediately for comet assay.

The comet assay

To measure the potential DNA damaging effect of microwave radiation in Wistar rat brain, the comet assay was carried out as described by Ge *et al.* (2005) with some modifications. At least 100 cells per slide subjected were analyzed (original magnification ^{x}200) under a fluorescent microscope (BX51, Olympus) equipped with a green light excitation and at 590-nm barrier filter. Comets form as the broken ends of a negatively charged DNA molecule becomes free to migrate in the electric field toward the anode. For each cell, the length of DNA migration (comet tail length) was measured in micrometers from the center of nucleus to the end of the tail. The percentage of damaged DNA concentration in the comet tail was determined by measuring the total intensity of ethidium bromide fluroscence in the cells, which was taken as 100% and determining what percentage of this total intensity correspond to the intensity measured only in the tail.

Determination of HSP70 levels

The levels of HSP70 (pg/ml) in the brain samples were determined according to the method described by Oc et al. (2008) using ELISA Kit (DUOSEt®IC, US).

Statistical Analysis

Data were expressed as a mean ± standard error (SE). Differences between the control and treated groups were tested using Student's t-test with the help of statistical software origin 7.5. Differences between control and exposed animals were considered statistically significant when $P< 0.05$.

Results

Table (1) shows the mean tail length and the mean % of damaged DNA (comet assay parameters) performed on rat brain cells after exposure to 900 MHz of RF radiation for 15 min and sacrificed after 1, 3 and 7 days recovery period. Mean tail length and mean % of damaged DNA showed significantly (P<0.05) increased levels after 1 and 7 days of the recovery period as compared to the control animals. No significant differences in the comet assay parameters were observed after 3 days of the recovery period.

After 7 days of the recovery period, the mean levels of HSP70 showed significantly (P<0.05) increased levels (Table.1). Meanwhile, HSP70 levels showed non significant decreased levels after 1 and 3 days recovery period as compared to the control group.

The data of the comet assay parameters (mean tail length and mean % of DNA damage) performed on rat brain cells after exposure to 900 MHz microwaves for 30 min and sacrificed after 1, 3 and 7 days recovery period are summarized in table (2). As shown in the table, there were non significant increased levels of the comet assay parameters after 1 and 3 days of exposure, while after 7 days recovery period, the comet assay parameters showed significantly (P<0.05) increased values as compared to the control ones.

Mean levels of HSP70 of rat brain exposed to 900 MHz microwaves for 30 min showed significantly (P<0.05) decreased levels after 1 day recovery period, non significantly decreased levels after 3 days and significantly increased levels after 7 days recovery period as compared to the control group (Table 2).

Table 1. Comet assay parameters (mean tail length and mean % of damaged DNA) and mean HSP70 levels performed on rat brain after exposure for 15 min to 900MHz RF radiation and sacrificed after 1, 3 and 7 days recovery period as compared to the control group.

Parameter	control	1 day	3 days	7 days

* statistically significant difference between control and exposed group at (P<0.05).
Number of cells (100 cells per each animal).

Discussion

The need for research regarding biological effects of electromagnetic fields is justified by the dramatic increase of RF-EMF sources and therefore, the population exposed during recent years (Zotti-Martelli et al., 2005). Mobile phones emit RF radiation into the heads of their users and the brain is one of the energy absorbing structures in the body. This resulted into a variety of neurological effects such as headaches, change in sleep patterns, modification in the electroencephalogram (EEG) and increase in blood pressure (Ilhan et al., 2004). Because DNA damage is closely related to every aspect of physiological and pathological activity of cells, one of the most active areas of RF radiation investigation is the assessment of direct and indirect effects on DNA (Brusick et al., 1998).

The comet assay is a sensitive method for detecting DNA damage in eukaryotic cells. It has become one of the standard methods for assessing genome damage in genotoxicity tests as well as in fundamental research of DNA damage and repair (Garaj-Vrhovac et al., 2009).

The present study, provides evidence that RF radiation from GSM cell phone exposure results in damaging effect on DNA of the brain cells, with remaining observable effects 7 days after the exposure. The study also shows that 15 min exposure to GSM has no effect on comet assay parameters after 3 days recovery period and after 1 and 3 days recovery period of the exposure time 30 min. These observations suggest that exposure to RF radiation can induce damaging effect on DNA in rat brain. DNA damage is closely related to human risk particularly DNA damage in brain cells could affect neurological functions and possibly lead to neurodegenerative diseases (Lai and Singh, 1996). The exact mechanism by which RF radiation induced DNA damage is still unclear. As is well known reactive oxygen species (ROS) are reactive and readily damage biological molecules, including DNA (Barzilai and Yamamato, 2004). Stopczyk et al. (2005) found that oxidative stress after exposure to microwave may be the reason for many adverse changes in cells. The study of Moustafa et al. (2001), indicated that acute exposure to the RF-EMF of commercially available cellular phones may modulate the oxidative stress of free radicals by enhancing lipid per oxidation and reducing the activation of superoxide dismutase and glutathione peroxidase. A number of studies have indicated that exposure to RF-EMF could lead to DNA damage through free radicals and interaction with transitional metals (e.g: iron) (Zmyslony et al., 2000; Jajte et al., 2001; Lai and Singh 2004; Phillips et al., 2009). Iron have also implicated to play a role in the genotoxic effects of RF-EMF exposure.

Several reports have indicted that EMF enhances free radical activity in cells (Lai and Singh, 2005; Oral et al.; 2006, Simkó, 2007; Phillipis et al., 2009) particularly via the Fenton reaction (Lai and Singh, 2004). The Fenton reaction is a process catalyzed by iron in which hydrogen peroxide, a product of oxidative respiration in the mitochondria, is converted into hydroxyl free radicals which are very potent and cytotoxic molecules. This supports the view that RF-EMF affects DNA via indirect secondary process, since the energy level associated with EMF exposure is not sufficient to cause direct breakage of chemical bonds within molecules, the effects are probably indirect and secondary to other induced biochemical changes in cells.

Since the brain is exposed to rather high levels of EMF during cell phone use, the consequences of EMF induced genetic damage in brain cells are of particular importance. Brain cells have high levels of iron. Special molecular pumps are present on nerve cell nuclear membranes to pump iron into the nucleus. Iron atoms have been found to intercalate within DNA molecules. In addition, nerve cells have a low capacity for DNA repair and DNA breaks could easily accumulate. Another concern is the presence of iron particles in body tissues, particularly in the brain. These particles could enhance free radical activity in cells and thus increase the cellular-damaging effects of EMF. These factors make nerve cells more vulnerable to EMF. Thus, the effect of EMF on DNA could conceivably be more significant on nerve cells than other cell types of the body (Phillips et al., 2009). Since nerve cells do not divide and are not likely to become cancerous, the more likely consequences of DNA damage in nerve cells include changes in cellular functions and in cell death, which could either lead to or accelerate the development of neurodegenerative diseases. Double-strand breaks, If not properly repaired are known to lead to cell death. Cumulative DNA damage in nerve cells of the brain has been associated with neurodegenerative diseases, such as Alzheimer's and Parkinson's diseases. However, another type of brain cell, the glial cell, can become cancerous as a result of DNA damage. Mausset-Bonnefont et al. (2004) showed an increase in the glial reactivity after 3 days recovery period of acute exposure to 900 MHz EMF. The authors concluded this increase in glial reactivity was due to an astrocyte hypertrophy as a result of the effect of microwaves. These observations are in agreement with the results of the present study, since the increased DNA damage was observed after 1 and 7 days of exposure to EMF.

It has been shown that exposure to mobile phone signals can influence cellular processes such as proliferation (French et al., 1997, Velizarov et al.,1999), cell morphology (Donnellan et al.,1997) and the level of heat shock protein expression (Kwee et al.,2001; Leszczynski et al.,2002). The results demonstrated here showed that HSP70 levels decreased 1 and 3 days after 15 and 30 min exposure to mobile phone radiation and then increased significantly after 7 days. This could be due to the possibility that after 1 and 3 days of recovery period, the basal content of HSP70 which protects brain cells from microwave exposure is consumed. Another thing is that some neurons do not appear to express HSP70 during stress.

There are two characteristics that determine a cell's response to a stress factor: (i) its original pre-stress level of HSP70 and (ii) its ability to rapidly accumulate the protein. Nollen et al. (1999) reported that there are basal levels of HSP70 which can protect a cell against harmful conditions without the need for additional synthesis of the protein. Although the protective system based on HSP70 exists in all tissues and organs, some cell types do not appear to express the protein. Among these are certain types of neurons (Sprang and Brown, 1987).

The results of the present study demonstrates three interesting findings: one is the finding of detectable DNA damage after 1 and 7 days from the 15 min exposure and after 7 days from the 30 min exposure. The second is significant decreased levels of HSP70 after 1 day from the 30 min exposure. The third is the significant increased levels of HSP70 after 7 days from both exposure durations. This means that exposure to GSM 900 MHz RF radiation at SAR 2.9×10^{-3} w/Kg induces a transient DNA damage in rat brain. The significant decrease in HSP70 levels after 1 day recovery from the 30 min exposure means that the disrupting action of RF radiation on DNA delayed the induction of this protein. The significant increase in the levels of HSP70 after both exposure durations means that brain cells induced the synthesis of the protein for protecting themselves from DNA damage and thus have a powerful capacity for recovery from damage induced by RF radiation.

In conclusion, this study confirms the existence of genotoxic effect of RF radiation on brain cells, this effect is not statistically significant but it becomes significant 7 days after the exposure. The data presented here show that HSP70 can be induced with exposure of brain cells to a GSM signal of 900MHz at SAR 2.9×10^{-3} W/Kg. But the cells have a powerful capacity for recovery from damage induced by RF radiation. The study also prove the potential for HSP70 to be used directly as cytoprotective agents in wide variety of clinical situations involving neurodegenerative diseases.

Perception Of Student Nurses Towards The Use Of Portfolio In A Faculty Of Nursing

*Salwa S. Kaml and **Nagwa R. Attia

***Assistant Professor Medical Surgical Nursing, Faculty of Nursing, Ain Shams University**
****Lecturer Medical Surgical Nursing, Faculty of Nursing Tanta University**

Sal232@hotmail.com

Abstract: The use of portfolio for learning and assessment within nursing education has recently increased. The main purposes of developing a portfolio is to link understanding about clinical experiences and theoretical knowledge, promotion of student-centered learning and reflective learning. It is important that students developing a portfolio understand the process. Unless portfolio is perceived by students to be relevant and useful, they will not be committed to using portfolios to their full potential. This paper aimed to identify perception of student nurses towards the use of portfolio and to compare the perception of first and second year student nurses towards the use of portfolio. The sample of the study composed of 376 first and second year students studying medical surgical nursing, in a faculty of nursing. Students were asked to respond voluntary to portfolio perception questionnaire, which was developed by researchers. The results of the present showed that students stated that portfolio encourage their independent learning, understanding and utilization of basic concepts. The results showed also some discrepancies between first and second year students in their perceptions toward portfolio. Students expressed how the portfolio process could be improved and they recommended the continued use of portfolio in subsequent study years.

Keywords: Portfolio, Perception, Nursing education.

1. Introduction:

Professionals, such as architects, engineers, and graphic artists, have long used portfolios as authentic evidence of their professional accomplishments (Kear and Bear, 2007)[1]. In recent years, the use of portfolios as learning and assessment tools has become more widespread across the range of health professions (Buckley et al, 2009)[2].

There is evidence within the literature of an increasing use of portfolios in nursing education in North America (Tracy et al, 2000, and Robertson et al, 2004)[3,4], Australia (Emden et al, 2003)[5] and United Kingdom (Buckley et al, 2009)[2], in pharmacy education (Plaza et al., 2007)[6], and in engineering education (Saker and Hu, 2006)[7].

McMullan et al (2003)[8] stated that, a portfolio is a collection of evidence of both the products and process of learning that attests to achievement and personal and professional development. Portfolio-based learning is an interactive process. Each student identifies learning experiences, integrates new knowledge into practice, identifies areas for improvement or personal growth, and envisions a plan for meeting further learning needs. Thus the portfolio is a qualitative and interpretive record of learning that is amenable to continuous assessment (Bell, 2001)[9].

A comprehensive literature review into the use of portfolios as a tool for assessing competence in nursing has been carried out by McMullan et al (2003)[8]. They identified that portfolios are being used for a variety of theoretical and clinical reasons. These include using them to assess clinical competence; to reduce the theory practice gap; monitor student learning over a period of time; and for personal and professional development.

Morgan (1999)[10] identified different types of portfolio based on the National Education Association definition that "a portfolio is a record of learning that focuses on student's work and his/her reflection on that work". These included 'assessment portfolios' documenting student learning on specific curriculum outcomes and 'skills area portfolios' demonstrating acquired skills in specific areas such as problem solving Gannon et al (2001)[11] point out that in preregistration nursing the portfolio of evidence must enable the student to demonstrate that they are fit to practice as registered nurses.

Items typically included in a comprehensive portfolio are reflective writings, samples of work and written evaluations. Both cognitive and affective

learning are demonstrated as the student briefly describes the experience, applies the pertinent concepts, and then offers personal thoughts on the transaction (Kear and Bear, 2007)[1].

For the portfolio process to be successful, it is vital that students own their work (Challis, 1999)[12]. For this to happen, students need to invest time and effort into the portfolio process and to assume responsibility for the content and direction of their work (Harris et al, 2001)[13]. In this way, they learn to decide for themselves, which aspects to include in their portfolio. This is consistent with Knowles (1975)[14] concept of adult learning and with life long and self directed learning (Brown, 2002)[15].

The educational value of portfolios is accepted with regard to the promotion of student-centered learning deep learning and reflective learning (Davis et al, 2009)[16]. The potential of portfolios to drive student learning in an educationally desirable direction and the importance of identifying individual strengths and weaknesses with regard to limits of competence as part of professional clinical practice may be some of the reasons for the current wave of enthusiasm for portfolios in the health care professions (Challis, 2001)[17].

According to Saker and Hu (2006)[7] portfolios emphasize the process of learning and the learners' comments on their success in meeting the learning outcomes. Thus students' confidence and motivation are enhanced as they reflect upon their improvements. By enabling students to assess themselves, they begin to take responsibility for their own learning. Portfolio learning has the potential advantage of encouraging students to draw on a wide range of sources of evidence to demonstrate their competence; that is demonstrating their academic and clinical learning outcomes.

There are several studies in both higher education (Zeichmer and Wray, 2001)[18] and nursing education (Dolan et al, 2004)[19] that have identified that, unless portfolio is perceived by students to be relevant and useful, they will not be committed to using portfolios to their full potential.

Significance of the study:

In today's challenging health care environment, nurses must be able to clearly articulate what they do. The development of clearly defined outcomes and identification to measure nurse's competencies is critical to the nursing education. So, it is an important challenge to prepare nursing students to meet and document competencies desirable for nurses practicing in the 21st century.

The use of portfolios in nursing education could help students to promote lifelong learning and professional goal achievement (Bell, 2001)[9].

Internationally, portfolios are used in nurse education, there has been researches into how portfolios are perceived, understood and used by student nurses (McMullan, 2008; Williams et al, 2009)[20,21]. Students should perceive portfolio to be relevant and useful to be able to use in their professional development, therefore the aims of this study is to identify and compare the perception of first and second year nursing students. In Egypt, the researchers did not find any published researches concerning portfolios in nursing education during the period of 2000-2007. This study is an attempt to start researching in this important issue.

Aim of the study:

The aims of this study were to identify and compare the perception of first and second year student nurses towards the use of portfolio.

Research questions:

1. What is the perception of student nurses toward the use of portfolio?
2. Are there any differences in the perception of first and second year student nurses towards the use of portfolios?

2. Subjects and Methods:

Study design:

A descriptive comparative research design was utilized in this study.

Setting:

This study was conducted in the Faculty of Nursing Tanta University in Egypt.

Sampling:

The eligible sample for this study was 709 first and second year student nurses. The time table when students were in classroom settings provided the researchers with a potential sample of 400 students in two classroom settings in the period of data collection. In total 376 students completed the questionnaire, which gave us a response rate of 94% and representation of 53% of the total pre-registration student population. We compared the demographic statistics with the portfolios of the 709 eligible students and found that the present research sample of students is representative across gender and age. Slightly more than half (52%) of the students (195) were in their first year and (48%) in the second year (181).

Tools:

A students portfolio perception questionnaire was specifically developed for this study constructed by the researchers dependent on the review of the literature. The questionnaire composed of three parts:

Part I: Used to gather students perception toward building of portfolio. Composed of six statements related to the students' perception of receiving clear complete portfolio guidelines, its importance, frequent teachers feedback, searching necessary information, participation by students to build portfolio and monitoring of student progress.

Part II: Included data about students perception toward portfolio as a learning activity. Composed of three statements, that portfolio helped them to improve their understanding and utilization of basic concepts as problem solving and communication skills, statement two concerned with portfolio encouraged students to be responsible for their independent learning, theory-practice link, decision making, using information technology and self-assessment. Statement three related to portfolio reflects the students' knowledge activities and skills.

Part III: Concerned with data about students' perception toward usefulness of portfolio compared with other teaching/learning methods as clinical placement, academic assignments, classroom based teaching/learning and usefulness of portfolio for personal life and professional career development.

Students were asked to rate the statements in part I, II and III using a 3-point Likert scale where 1=disagree, 2= neither and 3=agree.

In addition, students were asked to add hand written open comments toward portfolio.

Tool development:

The students portfolio perception questionnaire was tested for content and face validity by seven assistant professors and lecturers in the fields of Medical Surgical Nursing, education and psychology at the Faculty of Nursing and Faculty of Arts. All experts were affiliated to Ain Shams University, Cairo, Egypt. Modifications were done accordingly to ascertain relevance and completeness.

Ethical consideration:

Ethical approval was given by the Dean of Nursing Faculty, Tanta University. Students were verbally informed about the purpose and procedure of the study. The voluntary nature of their participation and that anonymity and confidentiality would be maintained when the questionnaires were distributed. This was reinforced in the front page of the questionnaire. No individuals were identified in the study.

Pilot study:

The pilot study was conducted on 10% of the sample to evaluate the developed tool for clarity; applicability and then necessary modifications were carried out. The data obtained from the pilot study were not included in the actual study.

Procedure:

The questionnaires were handed to the students studying Medical Surgical Nursing during classroom session identified previously at the end of the semester. The questionnaire took nearly fifteen to twenty minutes to be completed. Students were asked to complete the questionnaire at the beginning of the session data collected during April-May 2008.

Statistical analysis:

Results were collected and tabulated. Statistical analysis was done using statistical package for social science (SPSS version 13). Chi-square test (X^2) was used for comparison between two groups regarding qualitative data. Results were considered significant at $p \leq 0.05$.

The context of the study:

The study reported here was developed specifically to identify student's perception towards the use of portfolio within a Faculty of Nursing, Tanta University. Portfolio was introduced into the pre-registration-nursing curriculum in this faculty of nursing two years ago when the nursing curriculum was reviewed.

It was anticipated that as portfolio was introduced into the curriculum that over time students demonstrate an increasing ability to effectively link between theory and practice during the course of the study, to be self independent learner, and to achieve clinical learning outcomes. The evidence for these achievements is recorded in their practice record which is assessed at the end of each clinical placement by the registered nurse acting as their

clinical instructor during their placement. The clinical instructor is responsible for assessing the student's level of clinical competence and enabling the students to achieve their clinical learning outcomes. An academic lecturer in a Faculty of nursing also has responsibilities in terms of portfolio building and development. The academic lecturer assures that a clinical instructor has evaluated the student's achievement of clinical learning outcomes and reviews the content and structure of the student's portfolio to ensure that it reflects ongoing professional development.

The components of the portfolio include patient assessment sheet, planning and practice recording, student evaluation sheet, assignments, case study, activities and projects. Portfolio component is summative assessed by the clinical instructor and verified by the lecturer to ensure student achievement of expected learning outcomes.

Guidelines for building of portfolio:

The guidelines were discussed and handed to students at the beginning of the semester to help students build their portfolios. Two main features of the guidelines were selection of content and reflection on learning, as the following:

- Selection of contents, the following points was suggested for consideration of items to be included in portfolio.
  - Re-reading the course syllabus focusing on the learning outcomes.
  - Select the written works that demonstrate best work.
- Reflection.
  - The purpose of portfolio.
  - What are the activities performed to achieve learning outcomes?
  - What skills were developed to meet requirements of the course?
  - How the knowledge and skills acquired during the course could be applied in their personal life and professional career development?

3. Results:

Table (1) showed nursing students' perception regarding the building of portfolio. The majority of the students in group I agreed that they receive clear and complete portfolio guidelines (purpose, learning outcomes) and important to them to receive it 98%, 95%, 90, 87% respectively, while for the second year nursing students (group II) the percentage of agreement were decreased for the same items as 81%, 70%, 71%, 35% respectively (X^2 = 30. 83 , X^2 =42.40* , X^2 =24.80* , X^2 =117.45* at P level 0.0001) respectively.

The same table illustrated that nearly all first year students (92%) and less than half of the second year students (48%) stated that frequent teacher's feedback is important during the semester. The majority of students in group I (80.5%) and less than half of the students in group two (43%) stated that portfolio encourages them to search necessary information by themselves. Students in first and second group verbated that they participated in the building of portfolio (85%, 57%) respectively. Also, students in first and second group stated that portfolio helped them to monitor their progress (88%, 58%) respectively (X^2 = 88.88*, X^2 =68.16*, X^2 =38.56*, X^2 =45.99* at P level 0.0001) respectively.

Table (2) regarding to the role of portfolios as a learning activity. The students in group I and II stated that portfolio helps them to improve understanding and utilization of problem solving and communication skills. 93%, 94%, 56%, 59% respectively at significance (X^2 = 67.89*, X^2=69.60*, at P level 0.0001) respectively. The same table showed that students in group I and II stated that portfolio encourages them to be responsible for independent learning, theory practice link, decision making, using information technology and self assessment. 89%, 91%, 92%, 70%, 91%, 62%, 58%, 48%, 48% and 59% respectively at significance (X^2 =41.50*, X^2 = 55.45*, X^2 =88.51*, X^2 =22.78*, X^2 =55.50* at P level 0.0001) respectively. The majority of students in group I and less than half of students in group II reported that portfolio help them in their personal life and professional career 79%, 44% respectively (X^2 =48.42 at P level 0.0001).

Table (3) illustrated that the nursing students in group I agreed that building a portfolio is the most useful learning activity followed by classroom based teaching/learning, academic assignments and clinical placements representing 89%, 87%, 72% and 69% respectively X^2= 39.88*, X^2 =54.20*, X^2 =18.67* and X^2 = 8.04*. While the students in group II agreed that the portfolio building is the most useful learning activity followed by clinical placements, classroom based teaching/learning: 62%, 55%, 53%, and 51% respectively. The same table showed that portfolios are useful for career development as stated by nursing students in group I and group II: 94%, 79% respectively (X^2 =19.44* at p level 0.0001).

Table (4) showed the mean scores of nursing students' perceptions toward portfolio. It was apparent that students in both groups perceive portfolio as a learning activity followed by building portfolio and then its usefulness (t=15.43; 12.01; 7.89, respectively at p level 0.0001).

Table (5) showed the students comments toward portfolio. Students in group I and II stated some negative comments as too much paperwork and time consuming, little emphasis and interfere with clinical practice, little guidance and difficult in writing and not certain what to include: 69%, 15%, 3%; 30%, 56%, 27% respectively. Some students (18%) in group I required teachers to provide weekly portfolio ungraded feedback during the semester. Some positive comments were given only by students in group I as portfolios help them to be confident to learn independently, reflects their abilities, knowledge, skills and improves students' communication and with the faculty staff: 21%, 18%, 8% respectively. The same table indicated that nearly more than half (51%) of the students in group I recommended to continue use of portfolio in subsequent years.

4. Discussion:

Portfolio-based learning is an active learning strategy that is individualized, learner centered, outcome oriented, and promotes contextual learning and valuing learning. Portfolios provide a mechanism for documenting the application of knowledge in practice (Kear and Bear, 2007)[1].

It was essential to consider the guidelines provided to build a portfolio as important, particularly if the portfolio is being assessed. It can be seen that nearly all first year students and majority of second year nursing students receive complete and clear portfolio guidelines. However, there, was some confusion among the second year students, although this was not their first experience building a portfolio. This was reinforced by responses to the open-ended questions, "little guidelines on how to make the portfolio; not certain what to include".

This is in accordance with the study done by Saker and Hu (2006)[7] in that students stated in one of the responses to the open-ended questions, "give more on how to make the portfolio". Students need to be given clear guidelines about the purpose, content and structure of portfolio to balance the open-ended nature of its content and structure (Gannon et al, 2001; McMullan et al, 2003)[11, 8].

In contrast the findings of the present study Dolan et al (2004)[19] found that the majority of preregistration nursing students surveyed at their university rarely discussed the contents of their portfolio with their academic tutors. They speculate that this may have occurred because the portfolio was not summatively assessed.

As stated by Nairn et al (2006)[22] in their study to examine the knowledge, skills and attitudes of student nurses about the value and purpose of portfolio, they concluded that nursing students believed that academic tutors did not make the purpose of a portfolio clear and more than half of students did not consider that the content of portfolio was sufficiently explained. McMullan (2006)[23] concluded that portfolios can be very effective as an assessment and learning tool, but it is essential that both students and mentors receive clear guidelines on and comprehensive support with their use.

The present study showed that feedback was considered as important factor in building and using a portfolio, it was provided by clinical instructor once, in the middle of the semester. It was suggested by students in open-ended questions that portfolio be assessed weekly to encourage students to use it more seriously and efficiently. However, weekly assessment might not be practical in many cases because it would significantly increase the workload of the instructors, especially in a large class. The frequency of the feedback on portfolio needs to be based on factors such as number of students, weight of portfolio in the overall assessment and instructor's workload.

The present study results showed that the majority of first year students and more than half of second year students agreed that portfolio building helped them better understand and apply concepts as communication and problem solving. In contrast to this result, Nairn et al (2006)[22] found that students did not generally consider portfolios useful for developing their communication skills. Despite the portfolio being one way to communicate learning from academic and clinical activities.

The present study results showed that portfolio encouraged students to be responsible for their own learning, theory practice link, using information technology, self assessment and reflecting on their learning activities. In general, the students' responses support the use of a portfolio for better understanding of the concepts keeping track of learning progress through reflection. This supports the findings of Tillema and Smith (2000)[24], that portfolio assist reflection of the learning process by focusing students' attention on the unit outcomes.

Portfolios are commonly used in nursing education, both as a tool for reflective learning and as an innovative way of documenting student learning and evaluating clinical competence (McMullan et al, 2003)[8].

The present study results were supported by McMullan (2008)[20] who conducted a study to obtain nursing students' perception on using portfolio for their clinical practice learning and assessments. Students stated that portfolios helped them in their development of self-awareness and independent learning.

On the same line, Bukley et al (2009)[2] concluded that, studies reported direct measurement of changes in student skills or attitudes, the main benefits of portfolio use identified as improvement in student knowledge and understanding, greater self-awareness encouragement to reflection and the ability to learn independently. While, on the contrary to the results of the present study, the same author indicated that students found portfolios do not sufficiently address the assessment of their clinical skills and the integration of theory and practice.

The present study comprehensively documented that the process of building a portfolio increases students' reflective abilities. This is in agreement with Syndre et al (1998)[25] and Klenowski (2002)[26] as they indicated that reflection is made during the portfolio process because there is a requirement that students document knowledge and clinical practice as they co-evolve. To do this students require specific teaching and support to develop the cognitive processes of critical reflection, self-learning and assessment, which will help them to develop this work of portfolio. The teacher's role as a facilitator is vital here to provide support and regular feedback. This develops the student's confidence, independence and ownership of the process (McMullan et al, 2003)[8] and has positive effects on students' perceptions toward portfolio learning (Klenowski, 2002)[26].

In a study done by Davis et al (2009)[16] to identify students perception to the portfolio assessment, they concluded that students perceived that portfolio construction increased their understanding of the learning outcomes and enabled reflection on their work. Student reactions to the portfolio process were initially negative, although they become familiar with their work over time.

It was possible that student perceptions towards portfolios could influence the degree with which they embrace or reject the portfolio as a method for effective learning. To see the level of positive or negative perceptions towards portfolio some items evaluated the perceptions that students held towards portfolios as an important approach to teaching and learning compared to other methods and as being useful for career development.

The present study results indicated that portfolios were seen as more useful activity than other teaching and learning activities for both first and second year nursing students. Also the majority of first year nursing students and nearly half of second year nursing students found that classroom based teaching and learning were useful to them. Clinical placements were seen as a least useful activity by the first year nursing students, whereas, academic assignments were seen as a least useful activity by the second year nursing students.

On the contrary, Nairn et al (2006)[22] reported that nursing students did not see portfolios as more useful than other teaching and learning activities. Moreover (91%) nursing students found teaching and learning within clinical placements useful compared to (81%) of students having a positive attitude towards classroom based teaching and learning.

As related to the perception of nursing students towards portfolios as being useful for career development. Nearly all first year students and the majority of second year students agreed that portfolios were useful for personal life and professional career development. It could be concluded that the perceptions about portfolios as facilitating career development are maintained throughout the first and second years. McMullan (2006)[23] stated that portfolios encourages both personal and professional career development through the process of reflective practice and critical analysis.

The students in the present study found that portfolio building interfered with clinical learning. The students' mentioned that there was too much paperwork in the portfolio process and it was time consuming. In the same line McMullan (2006)[23] the students reported that portfolios were very time consuming, causing them a great deal of anxiety, and were not very effective in developing and assessing their learning.

On the contrary, Dolan et al (2004)[19] in their study to investigate the students and staff usage and perceptions of portfolio, concluded that the majority of students felt that too little time was spent on the portfolio than any other aspect of the course, although many students and staff appreciate the potential value of using the portfolio, it is not a requirement of the course and so tends not to be treated as a high priority. Davis et al (2009)[16] stated

that reduction in portfolio content may be responsible for improvements in student perceptions to portfolio process.

In responses to the open-ended questions, some students stated that they need more guidance on the portfolio, have difficulties in writing and not certain what to include. These responses were reported mainly by second year nursing students. They did not give any positive response in open ended questions and they have the lower proportion of agreement on the perception statements compared to first year nursing students.

Second year nursing students who participated in this study were the first group-within the faculty of nursing where the study was undertake who have required to maintain a portfolio building to demonstrate academic progression and achievement of clinical learning outcomes and competencies. This could be due to that lecturers and clinical instructors, might be failing to fulfill the need for support and guidance on portfolio building and use which they where the students were in their first year.

Nairn et al (2006)[22] reported that students in their third year were less optimistic about the use of portfolio than students in the first year.

Contrary to the present study findings Robinson (2000)[27] found positive attitudinal change towards portfolio assessment and the initial feeling of student uncertainty and resentment is a finding common to several portfolio assessment studies. Robinson (2000)[27] added that although some frustration was exhibited by several students at the beginning, this tapered off quickly as students become familiar with portfolio development process.

In a study done by Williams et al (2009)[21] to measure lecturers and students perceptions toward portfolio, they found that third and fourth-years students were the least positive compared to lecturers, added that the value of portfolios becomes less salient to student nurse towards the end of their training course.

The study results indicated that portfolio improved communication and relationship between first year students and faculty staff. In the same line Harris et al (2001)[13]; McMullan et al (2003)[23] stated that student-faculty link is an important component in the reflective portfolio process. Challis (1999)[12] suggested that the student-faculty link could take many forms ranging from regularly scheduled formal meetings with a mentor to telephone or e-mail communication as needed. This student-faculty link could potentially reduce negativity and confusion associated with the use of portfolio, as well as provides valuable formative assessment information to both students and faculty a like.

Findings of this study revealed that first year nursing students in their open ended responses stated that portfolio helped them to be confident and efficient in their independent learning and that portfolio could be continued through the years of the study.

Saker and Hu (2006)[7] concluded that in engineering education students reported that creating a learning portfolio generally helped their learning since they took responsibility for their own learning.

5. Conclusion and Recommendations:

Student nurses in the present study stated that portfolio process helped their learning since they took more responsibility for their own learning. Also, portfolio helped them to understand the basic concepts, improve the students-teacher relationship and portfolios are useful for their professional career development.

There were same discrepancies between first and second year nursing students in their perceptions towards portfolio. The value of portfolio becomes less salient to second year nursing students.

Some aspects considered important by students in building a portfolio including: provision of clear guidelines, regular frequent feedback, decrease the paperwork required and increase the marks allocated for portfolio appropriate to the workload involved.

Portfolios were seen by student nurses as more useful learning activity than other teaching and learning methods. The positive feedback from students also supported the continued use of a portfolio in subsequent study years.

Based on the findings of the present study, it could be recommended that:

- Portfolio can be very effective learning method but it is essential that students receive clear guidelines on and comprehensive support with their use.
- Portfolios should be designed in such a way that they are clear, relevant, objective and not time-consuming with refined content and should be linked with learning outcomes.
- Lecturers and instructors need to look at students' perceptions and why some students' perceptions deteriorate. There could be regular discussion with students to see how and why the students begin to see portfolios less useful for

their education and continual professional development.

- Provision of portfolio template could help students to make decisions about the type, quality and content of documents to include in their portfolios.
- The small class size in this study limits the generalization of the findings. Further studies based on a larger sample size are recommended to strengthen the evidence for portfolios use, particularly studies which observe changes in students' perceptions, knowledge and abilities.

Utilization of Alfalfa and Atriplex for Feeding Sheep under Saline Conditions of South Sinai, Egypt

Afaf M. Fayed*, Abeer, M. El- Essawy, E.Y. Eid, H. G. Helal, Ahlam, R. Abdou & H. M. El Shaer

Department of Animal & Poultry Nutrition, Desert Research Center, Mataria, Cairo, Egypt
a_fayed2007@yahoo.com*

Abstract: The objective of this study was to assess the influence of replacing percent of alfalfa by percent of Atriplex as roughage fed to animals. Twenty four adult Barki lambs weighed an average 49± 77 kg and age 3 years were used in six digestibility trials (4 animals each). Experimental diets were made of alfalfa and *Atriplex nummularia* in different ratios to each other as follow:R1: 75 % alf + 25% At, R2: 50 % alf + 50 % At, R3: 25 % alf + 75 % At, R4: 100 % At, T5: 100 % alf furthermore R6: berseem hay (BH) . All animals were fed barley at 25 % of energy requirements in R1, R2, R3, R4 and R5 while R6 fed concentrate feed mixture (CFM) .

Results obtained indicated that: all experimental diets had comparable values of dry matter (DM). Mixing of plants affecting chemical composition of feed ingredients where highest crud protein (CP) was recorded in R5 and least one was in R4. Crude fiber (CF) values were decreased as follow in R6, R5, R1, R2, R3 and R4, respectively. R6 and R4 had comparable values of condensed tannins while highest saponin levels were recorded in R4. Animals fed on R5 showed highest DM and total digestible nutrients (TDN) intake g/kg BW followed by those fed R1 and R2. Nitrogen intake showed higher values in R5 followed by R1, R2, R3, R6 then R4. Nitrogen retention also was maximum in R5 and minimum in R6. Animals fed At alone showed highest water intake with significant ($P< 0.05$) differences when compared with other treatments. There is a sampling time effect (zero and 6 hrs post feeding) on serum metabolites, liver enzymes and some minerals. Indeed the prefeeding rumen parameters ($NH_3 - N$) and TVFA,s were increased significantly to reach the peak value at 8 hr post feeding. Some minerals Na, K, Ca and P were analyzed.Na and P intake increased with increasing Atriplex level while Ca and K intake increased with increasing alfalfa level. Finally R2 is nutritious despite the generally low nutritive value and energy content.

[Afaf M. Fayed, Abeer, M. El- Essawy, E.Y. Eid, H. G. Helal, Ahlam, R. Abdou & H. M. El Shaer. **Utilization of Alfalfa and Atriplex for Feeding Sheep under Saline Conditions of South Sinai, Egypt**. Journal of American Science 2010;6(12):1447-1461]. (ISSN: 1545-1003). http://www.americanscience.org.

Key words: Salt tolerant fodders, digestibility, antinutritional factors, voulantry intake, rumen and blood metabolites, sheep

1. Introduction:

South Sinai is hyper arid region with salt affected natural resources (water, soil, plants, etc). Therefore, feed resources in the region are that represent one of the main obstacles for animal production development in the region. Salt tolerant forage species could play an important role in the region. *Atriplex nummularia* has great potentialities since it is known to be tolerant to salinity and drought (El Shaer., 2010). In addition to high content of crude protein, fiber and mineral contents.. However, it is deficient in energy and around 65% of nitrogen is non- protein nitrogen (Ben Salem *et al*, 2005 b). The high salt level in Atriplex limits its intake and digestion by ruminants (Hassan, 2009). Also *Atriplex* species contain some secondary metabolites as condensed tannins which may restrict feed intake and lead to a negative impact on animal performance (Ben salem., 2005). Alfalfa is the main cultivated legume crops in saline lands due to its high productivity,its high nutritional value and palatability (Anon , 2009). Mixing alfalfa with Atriplex as green fodders to sheep may increase the palatability and consequently intake and utilization of Atriplex which lead to improvement of the performance of animal . The objective of the study was to compare the nutritional evaluation of mixtures of alfalfa and Atriplex with different proportions fed to sheep in South Sinai.

2. Materials and methods

The study was carried out at South Sinai Research Station, Ras Sudr, South Sinai Governorate where the experimental forages diets *Atriplex nummularia* (At) and Alfalfa (*Medicago sativa*) (alf) were cultivated in saline soils and irrigated with saline water (total salinity 8500 ppm in ground water)

Animals and feeding management

Twenty four adult Barki lambs, weighing 49 ±1.62 kg and 3 years old, were used in the study where the sheep were equally divided into six

treatments (4 animals / treatment) and allocated to one of six dietary treatments. Animals received the experimental diets for 30 days as a preliminary feeding period followed by a 15- day digestibility trial where animals were kept in individual metabolic cages. The first ten days of the digestibility trial were devoted as an adjustment period. The weighed tested forages were offered twice daily, at 8.00 am and 3.00 pm. Measured amounts of drinking fresh water were left free choice for all animals. Barley grains were offered once daily at 12.00 pm as an energy source to all animals in R1, R2, R3, R4 and R5 and CFM to aimals in R6. Feed and refusals were collected, weighed and recorded during the preliminary period. In the following five days (collection period) measurements of 24 hours urine and fecal samples were collected for chemical analysis. At the end of the collection period, blood samples were taken before the morning feeding, then 6 hours post feeding. Rumen liquor were collected by stomach tube before feeding, 4 and 6 hrs post feeding. Live body weight and forage intake were recorded. Alf and (At) grown at the experimental farm were daily harvested, collected separately and chopped into small pieces (2-3 inches) then mixed in different ratios in the following basal rations (R) as follows:
R1: 75% alf + 25% At; R2: 50% alf + 50% AT; R3: 25% alf + 75% At; R4: 100% At; R5: 100% alf and R6: Berseem (*Trifolium alexandrinum*, 4th cut) hay (BH) as a control group. All animals were given feed supplements to cover 25% of TDN maintenance requirements according to Kearl (1982). Barley grains were given to animals in R1, R2, R3, R4, and R5 where animals in the control treatment (R6) were fed concentrate feed mixture (CFM). The CFM consisted of 25% cotton seed cake, 30% yellow corn, 35% wheat bran, 3% rice bran, 3% molasses, 1% urea, 2% limestone and 1% common salt.

Analytical methods

Proximate chemical analysis for all feed ingredients, refusals, fecal samples and urine were determine according to(A.O.A.C., 1997). Neutral detergent fiber (NDF), acid detergent fiber (ADF) and acid detergent lignin (ADL) (Goering and Van Soest, 1970). In addition, Sodium (Na) and potassium (K) were measured using flame model (Jenway PFP7) photometer and calcium (Ca) and phosphorus (P) were determined using Atomic absorption Spectrophotometer model (Unicam 929) in all dietary, fecal and urinary samples.

Anti-nutritional factors (ANF) analysis

Qualitative and quantitative estimation of condensed tannins (CT) and saponins (Sap) as the main ANF in all feed ingredients was carried out by Porter *et al.* (1986) and Balbaa *et al.* (1981), respectively.

Rumen and blood analysis:

Rumen liquor was withdrawn by stomach tube just after the end of the collection period before feeding, 4 hr and 8 hrs post feeding. Blood samples were collected before morning feeding and 6 hrs post feeding. The pH of rumen liquor was immediately recorded using Gallen Kamp pH Stick pH K-120 – B. Rumen liquor samples were analysed to determine total volatile fatty acids (TVFA 's) according to Warner, (1964) and ammonia – nitrogen (NH_3) (A. O. A. C. 1997). All serum samples were analyzed for Sodium (Na) and potassium (K) using flame photometer model (Jenway PFP7), calcium (Gitelman, 1967), inorganic phosphorus (Goodwin, 1970), triglycerides (Trinder, 1969), cholesterol (Roeschlau *et al.*, 1974), total protein (Reinhold, 1953), albumin (Rodkey, 1965), urea –N (Berthelot, 1959), creatinine (Seelig and Wust, 1969), alanine amino transferase (ALT) and aspartate amino transferase (AST) (Wilkison *et al.*, 1972). All kits used from Human Co. (Germany) using Jenway spectrophotometers (UK).

Statistical analysis:

Analysis of variance (ANOVA) was used to test the obtained data using the general linear modeling procedure (SAS, 2000). The used design was one way analysis. Duncan 's multiple tests (1955) were applied for comparison of means .

3. Results and Discussion:

Chemical composition:

Considerable variations were observed among the chemical composition of the studied forage crops (Table 1). Berseem hay (BH) fed to animals in R6 and *Atriplex nummularia* (At) had similar CP concentrations (averaged 12.25%) while alfalfa (alf) contained higher CP concentration (19.25%). Similar figures were recorded by El-Shaer *et al.* (2001) and Ben Salem *et al.*,(2005). However, the CP of *At* may lower than those reported by other workers Aganga *et al.* (2003) that could be attributed to different climatic, environmental, stage of growth factors. At, as a halophyticshrurb, contained lower concentrations of energy (324.087 GE, Mcal / kgDM) and organic matter (81.93%) compared to the other feed materials. Therefore, CP, OM and energy values in the mixture forage treatments were decreased as alfalfa ratio decreased and the increased portions of Atriplex in the forages diets. Such results are in agreement with those found by El –Shaer *et al.* (1991) and Ben Salem *et al.* (2005)

The OM was highest in BH followed by alf diet, while it was the lowest in At. On the other hand, NDF, ADF and ADL concentrations were higher in At compared to alf and BH. At attained the highest lignin content followed by R3, R2, R6, R1 then R5 (alf). Fiber fractions in the forage mixtures diets (R1, R2, R3) were increased by increasing the inclusion of At (R4) portion in the diets.

Data in Table (1) showed that Na, K, Ca and P levels were higher than probable dietary requirements (0.09 – 0.18, 0.50 – 0.80, 0.36 – 0.42 and 0.29 – 0.31%, for Na, K, Ca and P, respectively, as described by (NRC, 1985) but still below maximum tolerable levels (4.0, 2.0, 1.5 and 0.6 %, respectively as reported by (NRC, 1980) . The higher levels of minerals Na, K, Ca and P in saltbush offered to sheep could be due to the high content of these minerals in saltbush leaves. Saltbush leaves are more palatable than other plant parts (Gihad and El – Shaer, 1992). P value in alf was similar to those reported by Karabulut *et al*. (2006) while values of Na, K and Ca were different. These differences may possibly be due to maturity differences in alfalfa used in this experiment.

Phytochemical screening of the experimental feed materials revealed that they contained saponins (sap) and condensed tannins (CT) except the BH. which was free from sap.. Also, barley grains as energy source and concentrate feed mixture (CFM) were free from both (sap) and (CT). Therefore, quantitative determination for such materials was necessary before using such feed materials for feeding sheep.

The levels of ANF's are varied from plant to plant and from season to season (El-Shaer *et al*., 2005). At. (R4) and BH. (R6) showed the highest levels of CT followed by R3, R2, R1 then R5, respectively. Thus, the concentrations of CT declined as the proportions of At. decreased in the dietary mixture. The present levels of CT ranged from 1.48 to 2.30 mg/ 100g DM. So, it is safe for animals according to the previous studies.

At. (R4) showed the greatest level of sap. followed by R3, R5. R2 then R1

Table (1): Chemical composition and secondary metabolites levels of the feed ingredients(roughages,barley and CFM) on DM% bases.

Feed intake, digestion coefficients and nutritive values:

Results in Table (2) indicated that the highest DMI (P≤ 0.05) was observed for animals fed alf (R5) followed by those in R1, R2, R3, R4 while the lowest value was recorded for animals fed R6 (the control group). These findings may be due to the fact that fresh alf. and At. were more palatable compared to berseem hay (BH) in R6. These results were in-agreement with those reported by Shawket and Ahmed (2009).

The present data clearly indicated a significant (P≤ 0.05) effect of the roughage type on DMI. Daily DMI was negatively affected by saltbush. This is attributed to higher salt content and higher levels of fiber especially ADL and NDF in At. Similar results were reported by Ben Salem *et al*. (2005), Masters *et al*. (2006), and Hassan (2009). Moreover, due to high ash content, at forage is relatively low in energy. As shown in table (2); the apparent digestibility of OM, CF, NFE, ADF and ADL were higher with fresh alf than other groups containing At with no significant difference. However the control group R6 has the lowest (p≤0.05) CP digestibility. Similar trend was observed by Abdel – Malik *et al*. (2001) who found that CP digestibility of berseem was lower than that of alf. Introducing of At. instead of alf in other treatments slightly decreased the digestibility coefficients of CP, CF, NFE, cellulose with no significant differences. Similarly, Al Owaimer *et al*. (2008) concluded the same result. These results may be due to higher salt content of Atriplex which is the major negative component in Atriplex species (Wilson, 1992) thus leading to increment of animal water intake and shortening the rumen turnover time with consequential influences on rumen physiology and metabolism (Warner and Casson, 1992 and Konig, 1993).

Such results might be also attributed to the secondary metabolites in At which include oxalates, tannins and saponins which might decrease the production of volatile fatty acids in the rumen. The same results were reported by Shawket and Ahmed (2009) and Abu – Zanat and Tabbaa (2005). Inclusion of Atriplex in diet up to 50% insignificantly increased OM, CP, CF, NFE, NDF and cellulose than At alone. Getachew *et al*. (2008) found that digestibility of NDF and nitrogen was reduced by all levels of tannic acid compared with control.

Furthermore, Positive digestibilities of the CT were reported in the present study and the variations among groups were significant (P≤ 0.05). The highest digestibility of CT was in R4 followed by those fed R2, R3, R1, R6 then R5 (alf), respectively.

It is clear that R4 contained the highest concentration of CT as mentioned before in table (1). This finding could be explained by DM intake. In general, as DM intake increased, apparent digestibility decreased in sheep which could be due to higher rumen turnover rates observed in both sheep and cattle (Mulligan et al., 2001). Also, the same finding was reported in case of saponins.

R4 fed animals showed the highest saponin digestibility followed by R5, R3 and R2 showed a comparable value of digestibility then R1 was the lowest one. Saponin was absent from R6 (BH) so, it is not evaluated in BH fed animals.

When the nutritive values expressed as TDN and DCP a significant difference (P≤ 0.05) was observed for TDN g/kg BW values with alfalfa diets and the lowest in R4. Moreover, TDN% of intake was significantly (P≤ 0.05) increased in R1 followed by R5, R6, R2, R3 and R4, respectively. The elevation of TDN in alf. may be due to the highest digestibility of OM, CP, CF and NFE than those of At. Al- Owaimer *et al*. (2008) consistent with our results where they noticed that lambs fed alf hay had higher TDN than those fed At Ahmed *et al*. (2001) showed that the value of TDN for ration containing At was lower by 7.15% than that containing BH. Shawket, (1999) reported that the nutritive value expressed as TDN was 55.7 and 67.8%, respectively for diets containing At alone and with energy supplement.

Digestible crude protein (DCP) g/kg BW value increased (P≤ 0.05) significantly on (R5) followed by R1, R2, R3, R4 then R6. Similar observations were reported by Abdel – Malik *et al*. (2001). Results obtained may be attributed to higher CP content of alf and its rapid fermentation followed by At and BH. The percentage of DCP of intake had the same trend.

ME, Mcal / Kg DM varied significantly (P≤ 0.05) among treatments. Results indicated that the values of ME Mcal / Kg DM were decreased (P≤ 0.05) with 100% and 75% At. than other treatments. However 50% At + 50% alf expressed comparable values with those of 75% alf +25% At.

This finding may be due to lower energy content of At than alf and BH. Shawket, (1999) concluded similar results, she found that the utilization of At was enhanced with the energy supplementation. Ben Salem *et al*. (2005) found that animal performance was improved by feeding At supplemented with barley than those fed At alone.

Nitrogen balance:

As shown in Table (3); Total nitrogen intake (NI) expressed as gm / head / day for animals fed R5 was the highest (p≤0.05) followed by R1 and the lowest one was R4. These differences may be due to the type of forage and its content of nitrogen and also these findings were matched with the CP intake in the experiment. These results are in agreement with those of Shawket *et al.,* (2005) and Al – Owaimer *et al*., (2008). Results showed that the main pathway of N excretion was through urine for all tested roughages except BH group.

Table (3): Nitrogen balance (gm / head / day) of animals fed the experimental diets

Item	Rations						
	R1	R2	R3	R4	R5	R6	±SE
Nitrogen intake gm/head/day	43.63 ^{b}	38.18^{cb}	32.24^{c}	28.74^{c}	64.68^{a}	29.53^{c}	5.06
Excreted nitrogen: (g/h/d) :Fecal nitrogen	11.85^{ab}	10.69^{b}	9.17^{dc}	7.78^{d}	14.92^{a}	14.32^{ab}	2.026
Urinary nitrogen	19.23 ^{b}	19.32 ^{b}	17.49^{cb}	14.81 ^{cb}	33.84^{a}	12.97^{c}	2.52

R3: 25 % Alfalfa + 75 % Atriplex+ barley , R4: 100 % Atriplex+ barley. R5: 100 % Alfalfa+ barley ,
R6: Berseem hay + CFM.
F N: fecal nitrogen , U N : urinary nitrogen , N R : nitrogen retention
a, b, c and d : values with different letters in the same row means statistically significant at P<0.05

These findings may be attributed to the rapid hydrolysis of alf and At CP in the rumen which led to accumulation of ammonia (Weston *et al*., 1970) which is inefficiently increase urinary nitrogen excretion. Values of total nitrogen excretion clearly indicated that animals fed on 100% alf lost higher ($p \leq 0.05$) values of nitrogen followed by R1 and R2 and the lowest one was R4.

Nitrogen retention (NR) was higher in animals fed R5 and the lowest value was in R6. However R3 and R4 had comparable values of NR which have higher percent of At. This may be due to higher CP content and its higher digestibility in alf than At and BH. Data of NR% of intake showed that R1 indicated the highest ($p \leq 0.05$) nitrogen utilization while R6 was the lowest one.

Water balance:

As shown in Table (4); the highest water intake was observed in animals of R4 and R3 and this attributed to At. with high salt content. The lowest amount of water intake was recorded in sheep fed control diet with significant ($p \leq 0.05$) differences among the experimental groups.These results are inharmony with those reported by Bhatti *et al*. (2009), Hassan (2009), Shawket &Ahmed (2009) and Shawket *et al*. (2005) who reported that the salt content of At. can influence the animal water requirements because additional water is required to excrete their high salt content.

As expected urinary water was higher in R4 followed by R3 ($P \leq 0.05$), respectively and R6 was the lowest one. These findings are in agreement with El Aich (1987), Eid (2003) and Allam *et al*. (2006) who indicated that the high content of ash in halophytes lead to push animals to increase excretion of urine as natural channel to excrete minerals.

Water balance ml/h/day values for sheep fed R2 and R3 are significantly higher ($p \leq 0.05$) than those of animals fed R1 and R5. While the lowest was R6.

Table (4): Water balance (ml / head / day) of animals fed the experimental diets.

a, b, c and d : values with different letters in the same row means statistically significant at $P<0.05$.

Rumen parameters:

Data revealed that the ammonia–N (NH_3–N) concentration mg/100ml rumen liquor (RL) was significantly ($p \leq 0.05$) higher in R5 which is rich diet with CP than those of R1, R6, R2,R3 and R4, respectively (Figure 1).

The prefeeding ammonia–N values increased significantly to reach to the peak value at 8 hr post feeding (Fig 1). Mehrez *et al*. (2001) found that 20.61mg/100 ml RL NH3–N would satisfy microbial needs for N and hence maximize the rate of fermentation of the experimental diet in the rumen. Hassan (2009) also reported that ruminal microbial protein synthesis requires an adequate supply of nitrogen to achieve maximal efficiency. Also, because of lower nitrogen content uncoupled fermentation could occur (McMeniman, 1976).

The average values of ruminal total volatile fatty acids (TVFA's) (Fig. 2) showed that the highest ($p \leq 0.05$) value was recorded in R5 and the lowest in R4 . This result may be due to higher salt and lower energy contents of Atriplex which shortening the rumen turnover time with consequential influences on rumen physiology and metabolism (Warner and Casson; 1992 and Konig, 1993) and decrease the production of VFA 's in the rumen (Shawket and Ahmed, 2009).

The prefeeding TVFA's values (Fig.2) significantly ($p \leq 0.05$) increased to reach the peak value at 8 hr post feeding.

Blood metabolites:

Blood metabolites (Table 5) were used to monitor nutrient status. In the current study, there

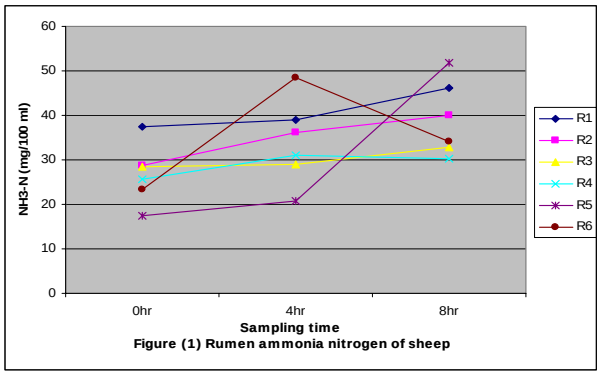

Figure (1) Rumen ammonia nitrogen of sheep

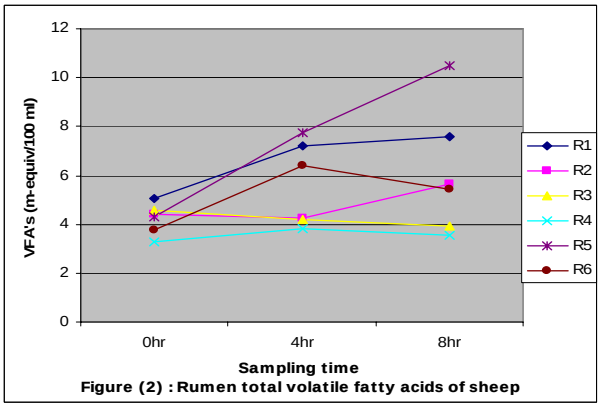

Figure (2) : Rumen total volatile fatty acids of sheep

was a sampling time effect after feeding for all the studied parameters. Serum biochemistry was within the range that was reported by other authors (Rankins *et al*. 1991 and Getachew *et al*. 2008) and there were different variations among the studied groups before and after feeding.

Serum total protein (TP) showed a significant ($p \leq 0.05$) elevation post feeding (Table 5). The lowest value was recorded in control group and the highest one in R5. These findings agree with the fact of dietary CP which was highest in R5 (alfalfa) and lowest in BH and R4 (At). Moreover, dietary CT was highest in BH and R4 and lowest in R5. Although Getachew *et al*. (2008) found that alfalfa protein is poorly utilized by ruminants due to its rapid degradation in rumen. Indeed, the alfalfa digestibility was reduced in the diet containing barley grains (Jahani-Azizabadi et al.,2009). CT may share in these variations as CP forms a complex with tannins under aerobic conditions causing a lowering in the available protein intake (Wina et al, 1999). Also, the ability of tannins to precipitate different proteins varies considerably (Bennick, 2002).

BH was free from saponins as previously reported and At (R4) was the highest ration in saponins. Saponins reduce protein digestibility by the formation of less digestible saponin – protein complexes affecting the nutritive value of the diet (Potter et al,1993). *In addition* the complementarity's of tannin – rich shrubs and a saponin-rich shrub positively influenced biomass intake (Rogosic et al,2006) . Alao, CT and saponin alleviate the adverse effect of each other (Makkar, 2003).Neglecting the sampling time, there was no significant variations among experimental rations. Albumin showed the same pattern among groups where the highest levels were recorded in R5 and the lowest ones in R6 . Significant ($p \leq 0.05$) differences were reported when neglecting sampling time. Globulin showed significant ($p \leq 0.05$) diet effect among the studied groups.

Urea –N was decreased ($P \leq 0.01$) in post feeding and when neglecting time (Table 5) reflecting low protein intake by sheep fed the experimental diets. Present results were in agreement with those reported by Rankins et al,(1991) who mentioned that low protein intake although serum total protein, albumin and globulin were elevated but protein intake was not low enough to compromise protein synthesis by liver. Samanta *et al*. (2003) showed that plasma urea – N reflects the dietary CP intake. Getachew *et al*. (2008) found that only blood urea – N was affected by both the level of tannin and sampling time after feeding although other metabolites were affected by sampling time. They proved the blood urea –N was elevated at 2h after feeding and started to decline to the pre – feeding level. Romero *et al.* (2000) also showed that sheep fed with tanniferous diet had reduced blood urea-N level than sheep fed lower dietary tannin.

Creatinine levels were elevated significantly ($p \leq 0.05$) before and after feeding and indicating impairment of renal functions (Brenner *et al*., 1987).

As can be observed, considerable decrease in cholesterol levels in all studied groups except R5 and R6 was recorded before and after feeding even when neglecting time. This result is consistent with those reported by Potter *et al*. (1993) and Matsuura (2001) who found that saponins from different sources causing lower serum cholesterol levels in a variety of animals as several dietary saponins have a hypocholesterolaemic action (Francis et al, 2002). Also, if causes a delaying of the intestinal absorption of dietary fat by inhibiting pancreatic lipase activity (Han *et al*., 2000). On the other hand, tannins play a considerable role in lipids digestibility by complexing with fatty acids(Romero *et al*., 2000) causing a decrease in cholesterol absorption and increase in fat excretion (Bravo *et al*., 1993).

Cocerning serum enzymes, AST was significantly ($p \leq 0.05$) increased post feeding and on neglecting the time factor. This elevation could be attributed to tannin content of the diet. Reed (1995) and Silanikove *et al*. (1996) reported hepatotoxicity and elevated AST in goats and cattle fed on

tanniferous forages, while Romero *et al*. (2000) did not find such elevation. Fitcher (1993) explained the elevated AST to be due to muscle destrophy. ALT showed nonsignificant variations except post feeding values. Makkar *et al*. (1988) assumed that the inhibitory or stimulatory effect of tannins on enzyme activity may result from a change in the conformation of the enzyme in the presence of tannins leading to a variable variability of substrate at the catalytic site of the enzyme.

As show in Table (5), indicated that Sodium and potassium levels in blood serum of the studied animals were not differed significantly among the studied groups neither at 0 hr nor at 6 hr post feeding. Na and K were within the normal concentrations which are in agreement with the findings of El – Shaer *et al*. (2001). On the other hand sheep fed R2 had higher (P≤ 0.05) Ca level than sheep fed saltbush alone, alfalfa or the traditional ration (BH) at 0 hr. There were also considerable variations in P level in the blood serum of the studied sheep where the highest P levels were recorded in those fed R6. This elevated P level in this group could be due to that P content in At and BH was slightly higher than maximum tolerable levels (NRC, 1980) (0.702 and 0.666 % vs. 0.6%. Generally, these hypocalcemia in R6 could be attributed to the presence of high levels of CT in BH because tannins can disturb the absorption of minerals by chelation of them within the gastrointestinal tract of the animal (Cowieson *et al*., 2004) and / or increase the endogenous losses of the minerals such as Ca (Mansoori and Acamovic, 1997). Also, BH may contain oxalic acid which binds with Ca to form a non soluble, non digestible Ca oxalate (Cheeke, 1995). Moreover, the imbalanced Ca: P ratio in this group might be responsible for decreasing Ca availability of sheep in the same group (McDowell, 1992) while the rest of animal groups were within normal levels of both minerals (9 -12, and 4.5-6mg/dl) respectively for Ca and P as described by Kincaid (1993).

Minerals retention:

As shown in Table (6), Na intake was increased as the ratio of Atriplex increased. This results was matched with the fact of that Atriplex contain the highest concentration of Na (table 1). Sodium intake increased in the following order from R1, R5, R2, R6, R3 and R4, respectively. Wilson (1996) consistent with our results in that high amount of Na and K salts found in Atriplex species. Differences in Na intake among studied groups were significant (P≤0.05) while fecal Na excreted without significant differences . Urine is generally accepted as main pathway for the excretion of Na (McDowell and Arthington, 2005). Significant (p≤0.05) urinary sodium loss was noticed among tested animals . The highest urinary sodium was reported in R3 and R4 (the highest Na intake groups and highest percent of Atriplex). Sodium balance also follows the same pattern where Na balance increased as a result of increasing Atriplex (from R1, R2, R3 and R4). R5 (100% alf) revealed the least sodium balance with significant (p≤0.05) differences.

It is clear that animals fed alfalfa alone had the highest K intake followed by control animals R6 then R1, R4, R2 then R3. Differences among groups were significant (P≤0.05). Potassium content of alf and Atriplex were comparable but K intake in R5 could be attributed to highest DM intake in R5 (Table 2) however, the lowest K intake in R3 was attributed to lowest DM intake in the same group. Fecal and urinary K output varied significantly (p≤0.05) among treatments but most of the excreted K was via urine and this consistent with the fact that urine is the major pathway for the excretion of potassium (McDowell and Arthington, 2005). Potassium balance was slightly different among groups.

The highest (p≤0.05) Ca intake was recorded in R5 while R1, R2 and R3 revealed comparable values of Ca intake. R4 and R6 were also comparable. Fecal Ca revealed significant (p≤0.05) differences among groups . It is well known that feces is the main route of Ca excretion (McDowell and Arthington, 2005). The present study revealed that fecal Ca was affected by saltbush percentage in the diet which contains high levels of secondary metabolites mainly oxalic acid which binds with Ca to form calcium oxalate, non – soluble, non – digestible compound (Alazzeh and Abu Zanat, 2004 :Cheeke, 1995). Generally, urinary Ca loss tended to remain low and constant. There are no differences among groups in urinary Ca . Calcium balance was positive for all different groups with significant (p≤0.05) differences.

The higher levels of P intake in diets as a result of increasing saltbush to reach its peak in R4 could be due to the high content of P in saltbush as reported in Table (1). Al azzeh and Abu – Zanat (2004) reported similar conclusion where saltbush leaves are rich in minerals and more palatable than other parts of the plant. Feces is the main pathway for P excretion in ruminants (McDowell and Arthington, 2005). There were no differences among studied animals in fecal phosphorus. The highest fecal P was recorded in R4 and this finding consistent with the experimental findings which recorded that saltbush had the highest level of P and animals of this group showed highest P intake. However, the least level was in R6 where animals fed traditional ration.

Urinary P was different significantly (P≤0.05) among groups. The highest urinary P was recorded in

R3 and R4. R1 and R2 showed comparable values. The lowest levels were noticed in R5 and R6, respectively. Phosphorus balance was positive in the present study with significant ($p \leq 0.05$) variations .

Feeding saltbush to sheep affecting minerals status in animal body leading to a decrease in Ca and P levels in blood as noticed in Table (5) whether saltbush was introduced as a complementary feed or alone. Also, all studied minerals were in positive balance because alf can alleviate constrains of saltbush in diets. Therefore, special attention should be taken when feeding saltbush to sheep for long periods.

Table (6): Mineral balance (gm/ dl) of sheep fed the experimental roughage

Mineral	Item	R1	R2	R3	R4	R5	R6	± SE

4. Conclusion and recommendation:

From the aforementioned results we could conclude that*:* *Atriplex nummularia* had a pronounced nutritive value as a fodder component when mixed with other plant species for livestock as previously detected in (R1, R2 and R3) rather than its intake alone (R4). The main disadvantages of using *A. nummularia* alone as animal feed are: high in ash and minerals contents and has insufficient energy density for sheep. This fact affecting negatively on its DMI, DCP and TDN as appeared in R4. Finally R2 is nutritious despite the generally low the nutritive value and energy content.

Oxidative stress in brains of rats intoxicated with aluminum and the neuromodulating effect of different forms of sage

EL-Kholy, W.M.; EL-Habibi, E.M. and Mousa, A.T.
Zoology Dept., Faculty of Science, Mansoura University, Mansoura, Egypt

ABSTRACT: The present study was designed to investigate the role of oxidative stress and the status of antioxidant system in the management of aluminum chloride (AlCl3) induced brain toxicity in rats and further to elucidate the potential role of three forms of *Salvia officinalis* (sage) in alleviating such negative effects. The results revealed that the levels of thiobarbituric acid reactive substances (TBARS) and protein carbonyl (PC) were significantly increased, while the activities of superoxide dismutase (SOD) and catalase (CAT) as well as the reduced glutathione (GSH) content were significantly decreased in the cerebral cortex (Co) and hippocampus (Hip) of rats intoxicated with $AlCl_3$. Regarding the lipid profile, total lipids (TL), total cholesterol (TC) and triglycerides (TG) were significantly increased in serum and the mentioned brain regions, while phospholipids (PL), total protein (TP) and serum HDL-C were significantly decreased in $AlCl_3$ group. Additionally, serum and brain regions acetylcholinesterase (AChE) as well as alkaline phosphatase (ALP) and acid phosphatase (ACP) activities were significantly increased. On the other hand, the results exhibited that, sage when given in any form along with $AlCl_3$ was able to regulate the mentioned parameters and the values returned close to the normal ones. It can be concluded that Al-induced neuronal oxidative stress and inhibition of the antioxidant system, and the consequent disturbed lipid profile, total protein and enzyme activities could be the mechanisms of $AlCl_3$ neurotoxicity. Moreover, the results suggested that the different sage forms, by their antioxidant constituents, could be able to antagonize Al neurotoxicity perhaps by reducing the oxidative stress and improving the antioxidant status and particularly by inhibiting the acetylcholinesterase activity, thus may improve memory and other brain cognitive activities.

Key words: Aluminum neurotoxicity- Alzheimer's disease- *Salvia officinalis* - Lipid peroxidation - ntioxidants-acetylcholinesterase

INTRODUCTION

Aluminum has been implicated in many human neurodegenerative diseases; various investigations have suggested that Alzheimer's disease (AD) is more common in areas where Al content in water supplies is the highest **(Lynch *et al*., 2000)**. Alzheimer's disease is a complex, multifactor, heterogeneous mental illness, which is characterized by an age-dependent loss of memory and an impairment of multiple cognitive functions **(Mattson, 2004)** and has been shown to be associated with both plaques and tangles in the brain. Indeed, the brain is a target of Al toxicity which can alter blood-brain barrier (BBB) mediating Al transport to the brain **(Zatta *et al*., 2002a)** and gets deposited in the cortex **(Platt *et al*., 2001)** and hippocampus **(Struys-Ponsar *et al*., 1997)**. This can be occurring by altering the physiological ligands present at these barriers in states **(Yokel, 2001)**.

Possible mechanisms of Al induced neurotoxicity have been related to cell damage via free radical production and oxidative stress **(Kumar *et al*., 2009a, b)**. High aluminum levels exposure leads to increased central nervous system (CNS) Al concentrations that altered CNS concentrations of the essential trace elements; iron and manganese and increased the susceptibility of CNS to lipid peroxidation (LPx) **(Oteiza *et al*., 1993)**.

Oxidative stress, caused by reactive oxygen species (ROS), is known to cause the oxidation of biomolecules leading to cellular damage. Increased lipid peroxidation (LPx) is the major consequence associated with oxidative stress. It is also speculated to be pathologically important in various neurodegenerative processes including cognitive deficits that occur during normal cerebral aging, Alzheimer's (AD), and Parkinson's diseases **(Gray *et al*., 2003)**. Alternatively, the most remarkable biochemical change in AD patients is a reduction of acetylcholine (ACh) levels in the hippocampus and

cortex of the brain **(Jaen *et al*., 1996)**. Therefore, inhibition of acetylcholinesterase (AChE), the enzyme responsible for hydrolysis of ACh at the cholinergic synapse, is currently the most established approach to treating AD **(Akhondzadeh *et al*., 2003)**.

On the other hand, *Salvia officinalis* (sage) specially the oil had apparent dual cholinergic activity, as it was active on both, AChE and butyrylcholinesterase (BuChE) **(Savelev *et al.*, 2004).** Besides the cholinergic activity, there has already been a wider range of activities reported for the genus *Salvia*, which may be relevant for CNS disorders. These include antioxidant **(Celik and Isik, 2008 and Carla *et al*., 2009),** nicotinic activity **(Wake *et al*., 2000),** anti-inflammatory properties **(Moretti *et al*., 1997), and** glutamergic activities **(Kuang and Xiang, 1994)**. The essential oils of the plant, also, tested for its memory-enhancing effect **(Akhondzadeh *et al*., 2003)**. Therefore, the main goal of the present study was to examine the possible mechanisms by which Al exposure could induce Alzheimer-like condition related alterations in brain of male rats, and extend to investigate the beneficial effects of sage in preventing or modulating these risks.

Material and methods

Chemicals:

Aluminum Chloride ($AlCl_3$) was obtained from agents of Sigma Chemicals (St. Louis, MO, USA). *Salvia officinalis* (sage) oil was obtained from (NATURE'S ALCHEMY) distributed by LOTUS BRANDS, USA. Dried leaves of sage, for preparations of sage tea (water extract and ethanolic extract), were purchased from a local herb market. The taxonomic identity of the plant was confirmed by the botanist of the Department of Botany, Faculty of Science, Mansoura University, Mansoura, Egypt. All other chemicals were purchased locally and were of analytical reagent grade.

Sage extracts preparation:

1- Sage water extract (sage tea): was routinely prepared by pouring 150 ml boiling water onto 2 g of dried grounded leaves and allowing it to steep for 5 min. **(Lima *et al*., 2005)**.

2- Sage ethanolic extract: was prepared according to the method described by **Eidi *et al*. (2006)**. Dried grounded leaves of *Salvia officinalis* (60 g) were subjected to extraction with 300 ml of ethanol (80%) in a glass container for 72 h. The extract was decanted and filtered through Whatman No 1 filter paper into a clean flask. This same procedure was repeated a further two times. The solvent was evaporated using a rotary evaporator, and then the flask was weighed to determine dried weight of extract. The supernatant was reconstituted using 53% ethanol and assayed using serial dilutions and the dose was calculated according to **(Ghosh, 1971)**

3- Sage oil: diluted 1:2 in sunflower oil according to **Perry *et al.* (2002)**.

Experimental animals:

This study was carried out on 48 adult male albino rats weighing 130 ±10 g b.w., supplied by The Urology & Nephrology Center; Mansoura University. The rats were maintained under controlled humidity; temperature (25 ± 2˚C) and light (12h light/ 12h dark). They were fed standard commercial rodent pellet diet and water *ad libitum* (free access to water and food).

Experimental Protocol:

After one week of acclimatization, the rats were divided into 8 groups consisting of 6 animals each. All treatments were continued for 90 days as follows:

1- Normal control
2- Sage water extract (given instead of drinking water) according to **Lima *et al*. (2005)**.
3- Sage ethanolic extract (given orally by stomach tube as 0.1 ml/kg b.w.) **(Akhondzadeh *et al*., 2003)**.
4- Sage oil group (given orally by stomach tube as 100 µl/ kg b.w.) every other day **(Perry *et al*., 2002)**.
5- Aluminum (Al) treated group (mixed with diet as 100mg $AlCl_3$/ kg b.w.) **(Bilkei, 1993)**.
6- Al + sage water extract group (given as in groups 5&2 respectively).
7- Al + sage ethanolic extract group (given as in groups 5&3 respectively).
8- Al + sage oil group (given as in groups 5&4 respectively).

Sample preparation:

At the end of the experimental period, overnight-fasted animals were decapitated, blood samples were collected and sera were separated and stored at -20°C until biochemical assay. The brain was then gently removed; the cerebral cortex and hippocampus were separated on an ice-chilled glass

plate as described elsewhere **(Nayak and Chatterjee, 2001)**. The tissue samples were quickly frozen on dry ice, weighed, and stored at -80°C until biochemical assay. Cortex and hippocampus were chosen for the present study because; aluminum affects more severely the cortex and hippocampus regions than any other area of the central nervous system **(Urano *et al*., 1997)**. Also, these brain regions are known to be particularly susceptible in Alzheimer's disease, and have an important role in learning and memory functions **(Bihaqi *et al*., 2009)**.

Biochemical analysis:

Determination of lipid peroxidation product thiobarbituric acid reactive substances (TBARS) was carried out according to the method of **(Ohkawa *et al*., 1982)**. Meanwhile, protein carbonyl was measured spectrophotometrically according to the method of **(Smith *et al*., 1991)**. On the other hand, superoxide dismutase (SOD) and catalase (CAT) activities were determined following the methods of **(Nishikimi *et al*., 1972)** and **(Bock *et al*., 1980)**, respectively. Additionally, reduced glutathione (GSH) content was determined spectrophotometrically according to the method of **(Prins and Loose, 1969)** as well as Acetylcholinesterase (AChE) activity was measured according to the method of **(Ellman *et al*., 1961)**. On the other hand, alkaline phosphatase (ALP), acid phosphatase (ACP), total protein (TP), total lipids (TL), phospholipids (PL), triglycerides (TG), total cholesterol (TC) in (serum, cortex and hippocampus) and serum HDL cholesterol were determined by using commercial kits from (Biodiagnostic, 29 Tahreer St., Dokki, Giza, Egypt).

Statistical analysis:

Data were presented as means ± standard error (SE). The statistical analysis was performed with one-way analysis of variance (ANOVA) using SPSS (version 17) software package for Windows followed by *Dunken test*. A p-value of less than o.o5 was considered statistically significant.

RESULTS

Cortex and Hippocampus Lipid Peroxidation (LPx), Protein Carbonyl (PC) and Antioxidants:

As observed in table (1), the statistical analysis showed that the level of cortex and hippocampus TBARS and PC were significantly increased by Al intoxication in comparison with the control value.

Concerning sage only, there were significant decreases and increases in hippocampus TBARS level and catalase activity respectively in the groups administered (ethanolic extract and oil) comparing to the normal control group. Regarding the antioxidants, the data indicated that, Al group exhibited significant reduction in cortex and hippocampus SOD, CAT activities as well as GSH content compared to normal control group.

Sage administration to rats intoxicated with Al caused a significant reduction in the elevated cortex and hippocampus TBARS and PC concentrations compared to Al intoxicated group. The reduction in hippocampus TBARS reached levels below the normal ones and was significant, only, in (Al + sage ethanolic extract) group. On the other hand, daily administration of sage preparations to Al intoxicated animals revised the decreases in the cortex and hippocampus SOD and CAT activities as well as GSH contents to marked increases compared to Al intoxicated group.

Indeed, the modulating effects of sage preparations on both the oxidative stress markers (LPx and PC) and the antioxidant system (SOD, CAT and GSH) arrived them to values within the normal ranges where non significant alterations were seen in comparison with the normal group except a significant reduction in Hip LPx of (Al + sage ethanolic extract) and a significant increase in Hip CAT of (Al + sage water extract) and (Al + sage oil) groups as well as in Hip GSH of (Al + sage oil) group.

Serum, Cortex and Hippocampus Total Lipids (TL), Total Cholesterol (TC), Triglycerides (TG) and Phospholipids (PL) Concentrations:

The data presented in table (2), exhibited that, serum, cortex and hippocampus total lipids (TL), total cholesterol (TC), and triglyceride (TG) contents showed significant increases, but phospholipids (PL) exhibited significant reductions in Al intoxicated animals in comparison with normal control.

Concerning sage only, cortex phospholipids content was significantly increased in the groups administered (sage water extract and oil) and in hippocampus of (sage ethanolic extract and oil) groups comparing to the normal control group. But, significant decreases were observed in TC of cortex in (sage water extract and ethanolic extract) as well as Hip TC and TG in the groups administered (sage oil). Such results referred to the benefits of sage preparations, specially the oil for reducing TC and increasing brain PL.

On the other hand, concomitant administration of sage (different preparations) with Al reduced the elevation of serum, cortex and hippocampus TL, TC and TG contents and enhanced serum, cortex and hippocampus PL approaching most of them to the normal values except in case of cortex PL only of (Al + sage water extract) which showed a non-significant increase compared to Al intoxicated animals indicating no protection.

However, the reduction in serum, cortex and Hip TL levels reached to values within normal levels, except Hip TL in (Al + sage ethanolic extract) which, still, exhibited a significant reduction compared to normal control group. Regarding TC, the reduction was, still, significant in both, cortex of (Al + sage ethanolic extract) and hippocampus of (Al + sage oil) groups comparing to control one. Concerning TG, the reduction arrived to values significantly lower than normal in serum TG of (Al + sage ethanolic extract) and Hip TG of (Al + all sage preparations) groups comparing to control one.

On the other hand, the enhancement in serum and cortex PL by sage was non-significantly changed in (Al + all sage preparations) compared to normal control. But in the Hip, PL reached to values that still significantly lower than normal in all (Al + sage different preparations) groups.

Serum HDL-C, Serum, Cortex and Hippocampus Total Protein (TP) Content:

As seen in table (3) serum, cortex and hippocampus total protein content and serum HDL-C showed highly significant decreases in Al intoxicated animals compared to the normal control group. Concerning sage only, total protein exhibited a significant increase in hippocampus of the groups administered all sage preparations compared to the normal control group.

Administration of different preparations of sage to Al intoxicated animals reversed the decrement in serum, cortex and hippocampus total protein contents and serum HDL-C to significant increases compared to Al group. But, there were non-significant elevations in serum HDL-C conc. of (Al + all sage preparations) except (Al + sage water extract) group, exhibited a non-significant reduction compared to normal control group. Interestingly, the elevation in TP arrived to the normal levels except hippocampus total protein in (Al + sage water extract) and (Al + sage ethanolic extract) which showed significant increases compared to the normal control group. These results indicated pronounced ameliorating effects of sage oil, followed by sage ethanolic extract, the water extract showed the lowest protective effect

Serum, Cortex and Hippocampus Acetylcholinesterase (AChE), Alkaline phosphatase (ALP) and Acid Phosphatase (ACP) Activities:

As shown in table (4), in Al intoxicated rats, there were significant elevations in serum, cortex and hippocampus AChE, ALP and ACP activities compared to normal control ones. Concerning sage only, ALP and ACP activities were significantly decreased in hippocampus of (sage oil) group only compared to normal control one.

On the other hand, significant reductions were seen in all (Al + sage treated) groups serum, cortex and hippocampus AChE, ALP and ACP activities comparing to Al intoxicated group, arriving the values within the normal levels, with the exception of AChE activity, which was still significantly higher than normal control in cortex of (Al + sage ethanolic extract) group and hippocampus in (Al + sage oil) group in comparison with normal control.

Regarding ALP activity, it was still significantly higher than the control activities in all (Al + sage preparations) groups except serum (Al + sage water extract) and cortex (Al + sage ethanolic extract) groups which showed non-significant elevations (within normal ranges) when compared to control.

Concerning serum, cortex and Hip ACP activities, marked ameliorations were seen, where non-significant decreases and increases were shown respectively compared to normal control animals except hippocampus ACP activity of (Al + sage ethanolic extract) and (Al + sage oil) groups which were still, significantly declined comparing to the normal control.

DISCUSSION

Aluminium has an association with the etiology of Alzheimer's disease and some other neurodegenerative diseases. It exerts its toxic effect on nervous system especially at high concentration, causing loss of memory, speech disturbances, dysparaxia, tremors, jerking movement's impaired muscular coordination and paralysis **(Drago *et al.*, 2008)**. *Salvia officinalis* (common sage) is a medicinal plant that has strong antioxidant properties **(Baricevic and Bartol, 2000)**. For that reason, the present study aimed to look into

the antioxidant potential of various sage preparations against Al neurotoxicity.

In the present study, there were significant increases in the oxidative stress markers lipid peroxidation (LPx) and protein carbonyl (PC) contents following Al exposure for 90 days in both cerebral cortex and hippocampus regions of rats. Such results are in harmony with those obtained by **Deloncle *et al.* (1999)** and **Johnson *et al.* (2005**) who reported that the neurotoxicity of Al may be a result of LPx.. Furthermore, **Nehru and Anand (2005)** reported a significant increase in brain thiobarbituric acid reactive substances in rats after stimulation by Al salts which was known to be bound by the Fe^{3+} carrying protein transferrin, thus reducing the binding of Fe^{2+} and increasing free intracellular Fe^{2+} that causes the peroxidation of membrane lipids and consequently membrane damage. Aluminum, being an inert metal, has been suggested to induce oxidative damage indirectly by potentiating the peroxidative effect of Fe^{2+}. It promotes reactive oxygen species (ROS) formation**.** ROS subsequently attack almost all cell components including membrane lipids thus producing lipid peroxidation **(Christen, 2000)**.

The findings of the present study, also, showed that the rise in LPx in Al treated rats was accompanied by concomitant decrease in the activity of some antioxidant enzymes involved in the detoxification of ROS, namely SOD, CAT as well as the level of GSH in the cortex and hippocampus tissues comparing with the control declaring the prooxidant effect of Al. These findings agreed with the antecedent studies of **Savory *et al.* (2003) and Johnson *et al.* (2005)** whom showed that Al exposure enhanced the neuronal lipid peroxidative damage with concomitant alterations in the enzymatic antioxidant defense status, thus having serious bearing on the functional and structural development of the central nervous system **(Dua and Gill, 2001)**. Similar data recorded a decrease in the antioxidants such as GSH **(Wu and Cederbaum, 2003)** and SOD activity **(Yousef, 2004)** in the brain of Al exposed rats **(Chainy *et al.*, 1996)** and human **(Dua and Gill, 2001)**.

Moreover, such results are consistent with the studies indicated that Al intake produced an oxidative stress-related change, contributed to its neurotoxicity **(Flora *et al.*, 2003)**. However, in rats, a significant relationship between Al exposure and the presence of oxidative stress was established also by **Gómez *et al.* (2005)**. This could be caused by inflicting damage to membrane lipids, proteins and antioxidative enzyme defense system **(Jyoti *et al.*, 2007)**.

The elevation of LPx in the cortex and hippocampus in the present study and other ones **(Dua and Gill, 2001)** suggested participation of free-radical-induced oxidative cell injury in mediating neurotoxicity of Al. Lipid peroxidation of biological membranes results in the loss of membrane fluidity, changes in membrane potential, an increase in membrane permeability and alterations in receptor functions **(Nehru and Anand, 2005 and Albendea *et al.*, 2007)**.

However, the increased Al concentration could deleteriously affect the neurons, leading to depletion of antioxidants and metal ions **(Kumar *et al.*, 2008)** through the induction of free radicals, that exhausting SOD and CAT which function as blockers of free radical processes. These results are in accordance with (**Nehru and Anand, 2005)** who recorded a significant decrease in the activities of SOD and CAT in brain of rats after Al treatment. Alternatively, the decreased enzyme activities could be related to a reduced synthesis of the enzyme proteins as a result of higher intracellular concentrations of Al **(Albendea *et al.*, 2007)**.

The data obtained by the present study illustrated, further, that administration of water, ethanolic extracts of *S. officinalis* as well as sage essential oil to Al treated rats caused a significant decrease in the level of TBARS and protein carbonyl in the cerebral cortex and hippocampus and elevated the SOD and CAT enzymes activities and GSH contents when compared with Al intoxicated rats. Moreover, the plant extracts and oil significantly, improved or restored the normal activities of the antioxidant enzymes (SOD and CAT) and GSH in both of the cortex and hippocampus regions as compared to normal control.

Generally, the antioxidant effects of sage extracts have often been attributed to phenolic and monoterpenic compounds **(Ren *et al.*, 2003)**. Flavonoids are a diverse group of polyphenols **(Havsteen, 2002)** rosmarinic acid being the most representative that possess several modulatory effects, either inducing or decreasing the expression of SOD and CAT enzymes depending on structure, concentration, and assay conditions. Rosmarinic acid is the predominant phenolic compound in sage **(Lima *et al.*, 2005)** and its effects was attributed to the compound's antioxidant properties acting as scavenger of reactive oxygen species **(Zheng *et al.*, 2004)**.

In point of fact, all of the tested forms of sage have previously shown to potently suppress hydroxyl

radical formation **(Kosar *et al*., 2005)**. Additionally, the protection of cell viability conferred by sage extracts seemed to be due, mainly, to their ability to prevent GSH depletion by their main phenolic compounds, rosmarinic acid and luteolin-7-glucoside. Nevertheless, unknown compounds other than phenolics also seem to contribute to the antioxidant effects of sage on basal GSH levels **(Lima *et al*., 2007)**. However, the later authors **(Lima *et al*., 2007)** besides other ones **Brandstetter *et al*. (2009)** showed the ability of sage (mainly the methanolic extract) to increase basal GSH levels, probably by the induction of glutathione synthesis. However, sage ethanolic extract strongly decreased the level of lipid peroxidation compared to Al intoxicated rats, such effect which may be due to its free radical scavenging potential induced by ethanol where various species of Salvia has inhibitory and quenching impact on lipid peroxidation along with enhancement of antioxidant defense system in brain tissue of rats treated with Aluminum **(Zupkó *et al*., 2001)**.

In fact, the glutathione peroxidase system consists of several components, including GSH that effectively remove (hydrogen peroxide) and serves as a cofactor for glutathione transferase, which helps remove certain drugs and chemicals and other reactive molecules from the cells. Moreover, GSH can interact directly with certain ROS (hydroxyl radical) to detoxify them, as well as performing other critical activities in the cell. So, GSH is probably the most important antioxidant present in cells. *Salvia officinalis* had a potent increasing effect on GSH content in brain compared to Al treated rats. Also, the enzymatic antioxidant defense system including SOD and CAT which can decompose superoxide and hydrogen peroxide in the cells are the main defense against oxidative injuries. The decreased level of these biomolecules may lead to increased severity of Al toxicities in the brain **(Tripathi *et al.*, 2009)**. Most likely, the sage tea effects observed, herein, was a result of interactions and synergisms among the different compounds and metabolites present, which makes it difficult to attribute them to any particular compound or family of compounds **(Lima *et al*., 2005).**

2- Lipid profiles

The present data indicated that serum, cortex and hippocampus total lipids (TL), total cholesterol, (TC) and triglycerides, (TG) were significantly increased by aluminum ingestion, while phospholipids (PL) and serum HDL-C levels were decreased; such results are in accordance with the results reported by **Yousef (2004)**. Similarly, **Wilhelm *et al*. (1996)** suggested that long-term exposure to Al specifically altered the brain lipid/phospholipid metabolism and/or their transfer to various membrane systems and resulted in significant changes in phospholipid classes and in cholesterol contents of the rat brain. Alternatively, studies in monkeys revealed the chronic effects of Al exposure on brain physiology, including alteration of the lipid composition and the activities of various membrane-bound enzymes; Al was found to decrease significantly the total lipid, glycolipid, and phospholipid concentrations in the primate brain **(Sarin *et al*., 1997)**. In addition, cholesterol and cholesterol/phospholipid ratios were shown to be remarkably increased, indicating a relevant loss of membrane integrity, and consequently a strong effect of Al on the activity/functionality of various membrane-bound enzymes, including AChE **(Atack *et al*., 1983)**. Similarly, the long-term exposure to $AlCl_3$ was shown to result in a 60 % decrease in the total phospholipids content while total cholesterol content increased by 55 %. It is possible that this altered lipid /phospholipid content and composition could affect the insulation properties of the myelin. The finding may thus have some bearing on loss of short-term memory in Alzheimer's disease .

The increase in serum cholesterol and total lipids due to Al administration indicated, also, a loss of membrane integrity **(Sarin *et al*., 1997)**. This was further confirmed when Al was found to have a significant effect on the various membrane-bound enzymes **(Newairy *et al*., 2009).** One possible way to explain the relatively more intense lipid peroxidation due to Al is that the susceptibility to catalyze oxidative cascades which is much easier for lipids than it is for proteins. Moreover, Al exhibited high affinity for phosphate groups and binds to the phospholipid head groups through electrostatic forces, which may disturb the order as well as the other dynamic parameters of the lipid bilayer **(Martin, 1986)**. From the foregoing results it is clear that Al resulted in significant reduction in the phospholipid content accompanied by major compositional changes, which is consistent with membrane hypothesis of AD. According to this hypothesis, in order to make up for the choline deficiency, the neurons try to extract choline from choline containing phospholipids. These results leads to the disruption of cell membranes and ultimately to neuronal cell death **(Roth *et al*., 1995)**. Such elevations in TL, TC together with the reduction of HDL-C following Al intoxication shown herein, represent risk factors for atherosclerosis and decreased blood flow to the brain (ischemia) which may be added to the mechanisms involved in Al-induced neurotoxicity.

On the other hand, the present study showed that treatment of rats with $AlCl_3$ plus different preparations of sage decreased serum and brain total lipids, total cholesterol and triglycerides and enhanced phospholipids and serum HDL-C levels compared to $AlCl_3$ intoxicated group. These results are in agreement with **Ninomiya *et al.* (2004)** and **Carla *et al.* (2009)** who found that oral administration of sage significantly lowered total cholesterol, triglycerides in serum of rats; and increased serum levels of HDL-C. Also, **Akram and Maryam (2009**) showed that oral administration of sage water extract significantly decreased serum cholesterol and triglycerides. These results suggested that *S. officinalis* tea consumption is accountable for the improvement of the lipid profile inducing an increase in the HDL-C particles, contributing, therefore, positively to the control of the dyslipidaemia observed in Type 2 diabetes but also related to other diseases **(Nesto, 2005)**. However, sage modulating results may attributed to several sage natural components have been shown to act on cholesterol metabolism by reducing its absorption or its synthesis, such as catechins **(Plana *et al*., 2008)**. This is in addition to the polyphenols, especially, phenolic rosmarinic acid in sage which has potent antioxidant effects protecting membrane lipids of fatty acids and phospholipids from oxidative stress (**Lima *et al*., 2005)**.

3-Total protein content

The data of the present work showed that Al intoxication caused a significant decrease in the protein contents of serum, cortex and hippocampus protein. These results are in good accordance with those obtained by **Nayak *et al.* (2006) and Newairy *et al.* (2009)**.

Thus, the observed alterations could be attributed to direct or indirect effects of aluminum on protein synthesis and breakdown and interaction with neurotransmitter synthesis and degradation, through a series of reactions that depends on many enzymatic pathways and regulatory mechanisms **(Goncalves and Silva, 2007)**.

The decline in the levels of protein in Al-treated rats is in close agreement with **Chinoy and Memon (2001)** and might be due to changes in protein synthesis and/or metabolism and could be, also, attributed on one hand to an under nutrition and on the other hand to a reduction of the protein synthesis in the liver resulted from Al intoxication as well as to reduced enzymes of protein synthesis as a result of higher intracellular concentration of Al **(Tripathi *et al*., 2009)**.

Alternatively, since GSH has been reported to be involved in protein and DNA biosynthesis so, the reduction in its content and in the antioxidant enzymes (SOD and CAT) resulted from Al intoxication may partly explain the decline in the total protein content. Additionally, Al induced reactive oxygen species (ROS) formation and promoted oxidative stress **(Exley, 2004 and Kumar *et al*., 2009 a,b)** enhancing peroxidative damage to lipids and proteins of the cellular membranes **(Julka and Jill, 1996)** is another suggestion for protein decline. Such an explanation, which was confirmed by **Jyoti *et al.* (2007),** indicated that Al exposure caused oxidative stress inflicting damage to membrane lipids, proteins and antioxdative enzyme defense system. Exposure of proteins to free radicals leads to gross structural and functional modifications including protein fragmentation, formation of cross-links and aggregates, protein peroxides generation, and enzymatic oxidation and degradation or clearance **(Albendea *et al*., 2007)**.

On the other side, the results, herein, indicated that all sage preparations enhanced the protein contents in serum and cerebral cortex and hippocampus of Al intoxicated rats reached them within or near the normal levels comparing to the control group. Regarding the protective mechanisms of sage, it has been speculated that antioxidative properties of sage components may be primarily involved, since changes related to the oxidative stress, where lipid peroxidation and oxidative DNA damage, were shown to be eliminated by sage tea consumption; possibly due, in part, to scavenging the nitrogen oxide or their radical derivatives **(Lima *et al*., 2005)**. Since the antioxidants play an important role in the regulation and maintenance of metabolism in the body against oxidative stress. So, sage constituents with their antioxidant properties overcame the lower in the total protein content perhaps by preventing oxidative stress and protein breakdown and enhancing protein synthesis and antioxidant system. Not only phenolic **(Durling and Catchpole, 2007)** or other flavonoids **(Wang *et al*., 2001)**, but all other sage components known to be participating in the series of reactions, hence the observed improvement in the present results may be due to all those components.

4- Acetylcholine system:

Cholinesterases are a large family of enzymatic proteins widely distributed throughout both neuronal and non-neuronal tissues. In Alzheimer's disease (AD), analytical as well as epidemiological studies suggested an implication of an abnormal focal accumulation of Al in the brain **(Zatta *et al*., 2002b)**.

In this devastating disease, Al may interfere with various biochemical processes including acetylcholine metabolism, and can thus act as a possible etiopathogenic cofactor. Aluminum is known to interfere with cholinergic **(Amador *et al*., 2001)**, glutamatergic and gamma-aminobutyric acid neurotransmission. A disturbance in the enzyme activities involved in the acetylcholine metabolism has, also, been reported following Al exposure **(Cordeiro *et al*., 2003)**.

In the present work, the data obtained showed that Al intoxication caused significant activation of AChE in the serum, cortex and hippocampus. Prior studies have reported the influence of Al on the metabolism of acetylcholine **(Jankowska *et al*., 2000)**. They exhibited that, specifically, there was a selective loss of acetylcholine releasing neurons in the basal forebrain, hippocampus and cortex. However, impaired cholinergic function in AD has been correlated with loss of memory.

Generally, there have been some hypotheses to explain pathogenesis of the disease such as "cholinergic hypothesis" and "amyloid formation hypothesis". Nowadays, the most accepted treatment strategy in AD has been accepted as "cholinesterase inhibitors" that can inhibit acetylcholinesterase (AChE) enzyme in order to increase acetylcholine level in the brain **(Akhondzadeh *et al*., 2003)**. In fact, the most remarkable biochemical change in AD patients is a reduction of acetylcholine (ACh) levels in the hippocampus and cortex of the brain. Therefore, the inhibition of AChE (the enzyme responsible for hydrolysis of AChE at the cholinergic synapse), is currently the most established approach to treating AD **(Tariot *et al*., 2000)**. Al interacts with the cholinergic system, acting as a cholinotoxin According to **(Kaizer *et al*., 2005)** the alterations in the lipid membrane could be a decisive factor in changing the conformational state of the AChE molecule. However, another explanation for increased AChE activity following Al exposure could be the allosteric interaction between the cation and the peripheric anionic site of the enzyme **(Gulya *et al*., 1990)**.

On the other hand, the results of the present study showed that sage administration alone or to Al-intoxicated rats led to AChE inhibition. However, it has been reported that *Salvia officinalis* has CNS cholinergic receptor binding activities that may be relevant to enhance or restore mental functions including memory **(Wake *et al*., 2000)**. Similar effects are also observed *in vivo* **(Howes *et al*., 2003),** at least for AChE, suggesting that relevant components of *Salvia* can cross the blood– brain barrier and increase cholinergic transmission via cholinesterase inhibition **(Perry *et al*., 2002)**.Similarly, up to date, a number of studies on AChE inhibitory activity of several *Salvia* species have been reported. Among these, the essential oil and ethanolic extract of S. officinalis have been shown to possess anti-cholinesterase activity **(Perry *et al*., 1996)**. This finding is consistent with recent reports established sage benefits to memory following administration of the essential oil in healthy young adults **(Andrew *et al*., 2008)**. Moreover, the essential oil as well as its major components, α-pinene, 1, 8-cineole, and camphor were determined to have uncompetitive and reversible acetylcholinesterase inhibitory activity **(Perry *et al*., 2000)**. Additionally, the constituents contained within *Salvia* oil may combine non-linearly to produce cholinesterase inhibition. A combination of the major monoterpenoid constituents (camphor, 1,8-cineole, borneol, α-pinene and β-pinene) reconstituted in a naturally occurring ratio was significantly less potent than that of the whole oil **(Perry *et al*., 2003 and Savelev *et al*., 2004)**. The monoterpenoids may therefore act synergistically to inhibit AChE.

The activity of the essential oils was concluded mainly to be due to its monoterpenoids. The data indicated that the terpenoids, monoterpenes in particular, may have anticholinesterase activity **(Orhan *et al*., 2007)**. Alternatively, the ethanolic extract of *Salvia officinalis* potentiated memory retention and it has also, an interaction with muscarinic and nicotinic cholinergic systems involved in the memory retention process **(Eidi *et al*., 2006)** but to less extent than oil.

5- Alkaline and acid phosphatases

The present study illustrated that Al ingestion led to significant elevation in alkaline phosphatase (ALP) and acid phosphatase (ACP) activities in sera, cerebral cortex and hippocampus. Alkaline phosphatase is a membrane-associated enzyme, which predominantly concentrated in the vascular endothelium in the brain. There is a more or less continuous sheath of ALP covering all internal and external surfaces of the central nervous system including the spinal cord and thus it may functionally be part in the blood-brain barrier mechanism. On the other hand, intracellular ACP is largely confined to lysosomes, which primarily respond to cellular injury. Within the brain, the ACP is found to be concentrated in the gray matter, although it shows the activity in the white matter, also, to some extent**.** However, significant contribution by Al was observed to induce changes in ACP activity **(Dasgupta and Ghosh, 1993)**.

The increased activity of ALP and ACP enzymes in serum & brain of animals treated with $AlCl_3$ are in accordance with the findings of **Ochmanski and Barabasz (2000)**. Also, **El – Demerdash (2004)** found that the activities of these enzymes were increased in serum of mice fed on wheat containing Al residue of 0.2 g /kg b.w. The present results are further, in consistent with the recent findings of **Esmaeili *et al.* (2009)** who showed that chronic Al consumption caused significant increases in the activities of ALP and ACP enzymes which could be due to severe damage to tissue membranes.

In addition, the increase in the activity of ALP or ACP in blood might be due to the necrosis of liver, kidney and lung **(Sallam *et al.*, 2005)**. Our own interpretation for increased levels of ALP and ACP is the disruption of the blood brain barrier and oxidative damage of tissue membranes, releasing membrane bound enzymes following Al intoxication which is also confirmed previously by **Exley (2004)** and recently by **Esmaeili *et al.* (2009)**.

Moreover, regarding Al enhanced serum, cortex and hippocampus ACP activities of rats, herein, it was in agreement with the earlier observations recorded altered activities of specific lysosomal hydrolytic enzymes in neuronal tissues **(Suzuki *et al.*, 1988)** due to Al administration. From these observations it can be suggested that Al induced an increase in ACP activity of the brain may be an indication of lysosomal proliferation and increasing catabolic rate. The increased ACP activity may result in phosphate accumulation within the lysosomes, and this in turn may lead to decreased plasma inorganic phosphate concentration **(Hussain *et al.*, 1990)**.

In the present work, administration of sage tea, ethanolic extract and oil caused marked reduction in the elevated activities of ALP and ACP in Al treated rats. Such decrease could be due to the antioxidant properties of sage constituents as polyphenols (carnosol, carnosic acid, and rosmarinic acid) and flavonoids (apigenin) that protect cellular membranes integrity from Al-induced oxidative damage and repair the antioxidant system (**Carla *et al.*, 2009**) ,consequently, improve brain structure and function against Al toxicity.

CONCLOSION

From the data presented here, there is ample evidence supports the fact that aluminum plays a pivotal role in the neuropathology of many neurodegenerative diseases including AD and validate the fact that chronic exposure to aluminum causes oxidative damage to the membranes and neural cells leading to memory loss and other cognitive dysfunction and exhaust the antioxidant system. Further, it clearly demonstrated that sage (all forms) has a neuroprotective effect against aluminum induced neuronal structural dysfunction.

The overall beneficial effects of sage different preparations against aluminum disturbances may be attributed, mainly, to their high ability to scavenge ROS and augment the repair of the antioxidant system as well as its anti-ChE activity, thus it has been suggested that sage has shown promise in the treatment of many neurodegenerative diseases including Alzheimer's disease. No fixed pattern of protection was seen specific for the different preparations of sage, but, we can arrange them in the following order: sage oil> ethanolic extract> water extract Future study may be designed and further warrants the need for molecular studies to elucidate the mechanisms underlying the protective effects of sage and its active components.

Study on immune response of quail for avian influenza vaccines

M.A.saad ,A.I.Abd-Elhady, A.EL-nagar

Central laboratory for evaluation of veterinary biologics Quail influenza

Abstract: This study was a trial to evaluate: The immune responses of quails vaccinated with common AI commercial vaccines in Egypt The results revealed that: There were high to moderate levels of maternal immunity against AIV (H5N1and H5N2) on the 1st, 5th day of age and low levels on the 7th day of age. There was no significant difference concerning the immune response of H5N1 and H5N2 AI vaccines ($P < 0.05$) in vaccinated quails. Vaccination at 8-days of age with 0.5ml of vaccine, gave satisfactory titers, on the 3rd week post vaccination. By the 4th week post vaccination quails exhibited highest titers and continued to the 5th week post vaccination(age of slaughter or marketing of quail) against AIV.

Keywords: immune response; quail; avian influenza; vaccines

Introduction

Avian Influenza (AI) is a disease of poultry that has occurred worldwide over the past 100 years (Easterday et al., 1997). Two clinical forms are seen in the field: a mild disease affecting the respiratory, reproductive and or urinary tracts, and a severe systemic disease, causing high morbidity and mortality. AI viruses are classified as highly pathogenic (HP), mildly pathogenic (MP) and a non-pathogenic (NP) based on the mortality rates (Senne et al., 1986; US Animal Health Association (USAHA, 1994). Over the past decade, the emergent HPAI viruses have shifted to increased virulence for chickens. HPAI viruses typically produce a similar severe, systemic disease with high mortality in chickens and other gallinaceous birds (Swayne, 2007). 26 epizootics of HPAI have occurred in the world since 1995. The largest of these outbreaks has been the H5N1 HPAI which has caused problems in poultry and some wild birds in over 60 countries of Asia, Europe and Africa since beginning in 1996 (Maines *et al.*, 2005). In Africa, H5N1 HPAI cases approved in February 2006 in several countries. It began in Nigeria then other African countries including Egypt. (Swayne, 2008). On 17 February 2006, the Egyptian government confirmed that bird flu had broken out in the nation's poultry.

Quails are migratory game birds belonging to the same family as the domestic fowl (Weatherbee and Jacobs, 1961).

Highly pathogenic avian influenza (HPAI) virus subtype H5N1 has caused significant losses in Thailand's poultry industry since its initial detection in January 2004 (Tiensin *et al.*, 2005). Chickens and quail are highly susceptible to HPAI H5N1 infection; however ducks, considered more resistant, are probable "Trojan horses" or carriers (Hulse-Post et al., 2005; Tiensin et al., 2005).

AI virus was detected in quail and chickens muscles and organs by indirect immunofluorescent assay (Antarasena, C. et al. (2006).

The HI test against AI showing positive results in quail sera collected random samples from Egypt. (Elmahdy et al. 2009).

A formalin-inactivated oil-emulsion vaccine was prepared from a high-growth H5N1/PR8 virus (Chen *et al.* 2005). Vaccine candidates of influenza A viruses of H5N1 subtype have been generated in several laboratories (Lu *et al.*, 2007). In the face of disease outbreaks in quail industry and the potential pandemic threat to humans caused by the highly pathogenic avian influenza viruses (HPAIVs) of H5N1 subtype, improvement in biosecurity and the use of inactivated vaccines are two main options for the control of this disease, for that we designed our present study to measure the immune response of quail to AI vaccines H5N1 and H5N2.

Materials and Methods

1-Quails: two hundred and fifty, one day old quail were used in this experiment.

2-AI Vaccine: commercial AI H5N1 and H5N2 vaccines, used for vaccination of quail.

3-Serum samples: quail blood samples were collected and sera were separated to apply HI test.

4- AI antigen: local inactivated HPAI virus was obtained from CLEVB and used as AI antigen with a titer of 2^6 HA units/ml. and was used at a final concentration of 4 HA in HI test for the tested serum samples.

5- HA haemagglutination test: HA test were carried out according to (Anon 1971) to estimate the HA titer of used antigens.

6- HI haemagglutination inhibition test: Was carried out according to (Takatsy 1956) the test was applied

to quantify AIV antibodies in sera according to OIE (2008)

Experimental design

Experiment 1

Maternal immunity: fifty quails were selected for determination of maternal immunity that acquired from vaccinated parents by HI test.

Experiment 2

Immune response of the vaccinated quail: 200

Quails were used for:

Determination of the immune response of quails by vaccinated S/C with either inactivated oil-emulsion H5N1 or H5N2 vaccines. Commercially available oil emulsion vaccines were used: H5N1 (subtype, Re-1 strain - A/chicken / China, Puerto - Rico) and H5N2 (subtype chicken / England, Mexico) of = 10^4 EID50 haemagglutination antigen content. The dosage was 0.3ml at age 4-days and 0.5ml at age 8-days Blood samples were collected 1, 2, 3, 4 and 5 weeks post vaccination. The flocks were arranged as follows:

A- Vaccination at 4 days old with 0.3ml of vaccine.

B- Vaccination at 8 days old with 0.5ml of vaccine.

Results and Discussion

Table 1: Maternal immune wading in quails § acquired from vaccinated parents by AIV inactivated oil-emulsion vaccines H5N1 and H5N2.

Age of Quail	H5N1	H5N2
	HI	HI
1 day	5.3	4.8
5 days	4.4	4.3
7 days	4.0	3.6
10 days	2.9	2.8
14 days	2.0	2.0

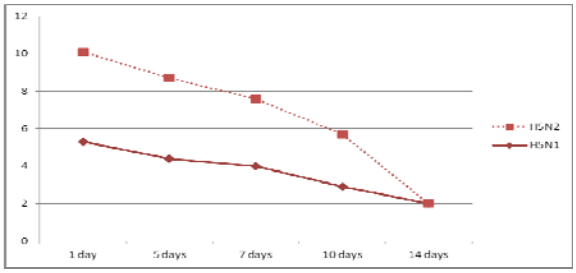

Figure 1: Maternal immune wading in quails § acquired from vaccinated parents by AIV inactivated oil-emulsion vaccines H5N1 and H5N2 .

Table 2: The immune response of quails vaccinated by AIV inactivated oil-emulsion vaccines H5N1 and H5N2 .

Group No.	Type of vaccine	Age of vaccine	Dose	HI titer post vaccination				
				1^{ST} W	2^{nd}W	3^{rd} W	4^{th} W	5^{th} W
1	H5N1	4 days	0.3 ml	2.1	3.0	5.7	5.9	5.0
2	H5N1	8 days	0.3 ml	1.8	2.6	5.5	6.2	5.3
3	H5N1	4 days	0.5 ml	2.3	3.2	6.1	6.4	5.4
4	H5N1	8 days	0.5 ml	2.0	2.8	6.5	6.8	6.0
5	H5N2	4 days	0.3 ml	2.0	2.8	5.2	5.7	4.7
6	H5N2	8 days	0.3 ml	1.7	2.4	5.4	5.9	5.0
7	H5N2	4 days	0.5 ml	2.2	3.1	5.7	6.1	5.2
8	H5N2	8 days	0.5 ml	1.9	2.6	5.9	6.3	5.7

Now quails are raised commercially for meat and egg production and kept as pet birds and experimental birds in most parts of the world. (Lima et al., 2004). Quail are resistant to many diseases but they are susceptible to most naturally occurring viral diseases of chickens, especially when reared under poor management conditions. However the reports of the naturally occurring diseases are few when compared to those of chickens and this may be due to the fact that there are few quail farms (Ratnanohan, 1993). we have recently shown that quail are highly susceptible to infection with highly pathogenic H5N1 viruses isolated from geese. These viruses cause disease in quail; however, infected quail have a longer disease period than do chickens and thus are more likely to transmit the virus (Webster et al., 2003).

Table 1 and Fig.1 illustrated The results of maternal immunity,they show that:

1: There were high to moderate levels of maternal antibodies against AI (H5N1) and (H5N2) on the 1st and 5th day of age and low levels on the 7th day of age [HI mean values were 5.3, 4.4, 4.0, 2.9 and 2.0 (log-2) respectively]for H5N1 . On the other hand, quails vaccinated by H5N2 at ages of one-day, 5-days and 7-days, were 4.8, 4.3, 3.6, 2.8 and 2.0 respectively (HI titer values).

2: After the age of 7 days the level of maternal immunity was greatly reduced and it was fade at the age of 14 days.

3: There was no significant difference concerning the immune response of H5N1 and H5N2 AI vaccines (P <0.05).

Determination of immune response in quails vaccinated with inactivated oil-emulsion H5N1 and

H5N2 vaccines Vaccination at 4-days old: In one hand, Table 2 Showed that: H5N1 and H5N2 vaccination at 4-days of age (0.3ml of vaccine) resulted in positive antibody response on the 1st week post vaccination (HI titers were, 2.1 and 2.0 (log-2) respectively). The antibody response was gradually increased up to the 4th

week post vaccination (HI titers were, 5.9 and 5.7, log-2

respectively).while at 4-days of age (0.5ml of vaccine) resulted in positive antibody response on the 1st week post vaccination(HI titers were, 2.0 and 1.9 (log-2) respectively) The antibody response was gradually increased up to the 4^{th} week post vaccination (HI titers were, 6.4 and 6.1, log-2

respectively)

Vaccination at 8-days old: On the other hand,

Vaccination at 8 - days of age with 0.3ml of vaccine,

Gave satisfactory titers, 3 weeks post vaccination (HI

Titers were, 5.5 and 5.4 (log2) respectively), but highest

Titers were exhibited on the 4th week post vaccination (HI

Titers were, 5.9 and 5.7 (log2) respectively) and then

Continued to the 5th week post vaccination. While 0.5ml of vaccine gave satisfactory titers, 3 weeks post vaccination (HI

Titers were, 6.5 and 5.9 (log2) respectively), but highest

Titers were exhibited on the 4th week post vaccination (HI

Titers were, 6.8 and 6.3 (log2) respectively) and then

Continued to the 5th week post vaccination.

Our results pointed out that, vaccines do not sufficiently

Reduce the probability of infection up to 3 weeks post vaccination and this is indicated by the low HI titers. Although H5N1 or H5N2 vaccination at the age of 8-

Days, gave protection 3 weeks post vaccination where,

The titer ranged from 4.2 to 5.7 (log2), but maximum

Levels of HI titers occurred 4 weeks post vaccination (4.6 to

6.1, log2) and continue with protective titer to five weeks of quail age (age of slaughter or marketing of quail) .Our results agreed with Swayne, D.E. 1999. Study The influence of vaccine strain and antigen mass on the ability of inactivated avian influenza (AI) viruses to protect chicks from a lethal, highly pathogenic (HP) AI virus challenge were they affect the immune response to AV vaccine.

Further studied needed by application of challenge test to estimate the vaccine efficacy in quails but these test need critical high registrations to use the virulent AV virus to apply these test.

Our results suggested in regard to The immune response of vaccinated quails Against AIV.that The ideal age for quails Vaccination by AI vaccine is between 4 and 8-days of age, otherwise quails maternal immunity should be considered if they vaccinated at one-day of age. Quails one-day old of age which have low or no maternal immunity should be vaccinated at one-day old (with a dose of 0.3ml, H5N2), followed by a second dose (0.5ml) at 15-21-days of age.

The effectiveness of the available commercial vaccines in protection against the disease required . Two main categories for the control of this disease:

1: The use of efficient inactivated vaccines (targeted Control strategies).

2: Improved, strict and satisfactory biosecurity measures.

First Record Of Microsporidium *Neonosemoides* Sp. And Some Ciliates Infecting *Chrysichthus Auratus* (Bagridae) From The Damietta Branch Of River Nile, Egypt

Enayat Salem Ahmed Reda
Department of Zoology, Faculty of Science, Mansoura University, Mansoura, Egypt

Abstract: The present study was carried out as a general survey for the possible ectoparasites that can infect the Nile fish *Chrysichthus auratus*. A total of 52 fish specimens were collected from Damietta branch of River Nile. Examination of the investigated fish revealed that, fish were infected with four ectoparasitic species belonging to three genera. These species were: *Neonosemoides* sp., *Scyphidia* sp. 1, *Scyphidia* sp. 2 and *Ichthyophthirius multifillis*. The first three species were recorded for the first time in Egypt. The recovered parasites have pathological effects on the host fish with subsequent economic losses were discussed.

[Enayat Salem Ahmed Reda. **First Record Of Microsporidium *Neonosemoides* Sp. And Some Ciliates Infecting *Chrysichthus Auratus* (Bagridae) From The Damietta Branch Of River Nile, Egypt.** Journal of American Science 2010;6(12):1479-1482]. (ISSN: 1545-1003). http://www.americanscience.org.

Key words: *Neonosemoides* sp., Ciliates, *Chrysichthus auratus*, River Nile. Egypt.

Introduction

Microsporidia are obligate intracellular parasites. Infected cells usually enlarge to accommodate the proliferating parasite. In 1968 Wiessenberg coined the term "xenoma" on the host cell with completely changed structure and the parasite proliferating inside it. According to Klaus Rohde (2005) microsporidia infect most invertrbrate phyla and all classes of vertebrate. There are 17 genera are known to infect fishes; 13 genera infect marine fishes and 4 genera infect freshwater fishes: *Heterosporis* (Schubert, 1969), *Nosemoides* (Vinckier, 1975), *Neonosemoides* (Faye, Toguebaye and Bouix, 1996) and *Pseudoloma* Matthew, Brown, Larison, Bishop-Stewart, Rogers and Kent, 2001 (Klaus Rohde 2005).

Genus *Neonosemoides* is one of microsporidian genera parasitizing freshwater fishes and at the same time produce xenoma which play an important agent of diseases in commercial fishes.

Although there is considerable information on the species of microsporidia (Lom and Dykova, 1992; Sprague *et al*., 1992; Lom, 2002; Lom and Nilsen, 2003), little is known about those from Africa. Sakiti and Bouix, 1987 recorded *Neonosemoides tilapia* from *Tilapia zillii* from Benin and Faye and Toguedaye, 2005 recorded 4 unidentified species from carangid fishes from Senegalse.

External protozoa are cited as major problem in freshwater fishes; sessilines ciliates like genus *Scyphidia* utilize gills and skin as a substrate for attachment.

On the other hand mobilina ciliates like genus *Ichthyophthirius* which is an obligate parasite of gills, skin and fins has a worldwide distribution (Paperna, 1980) also has been found to cause the white spot disease which is accompanied by severe morbidity and eventually end with fish mortality (Hoffman, 1970). Abu-El Wafa, (1988) and Koura *et al*., (1997), described *I. multifiliis* from some freshwater fishes. This study aims to contribute to the ciliates fauna infecting *Chrysichthys auratus* with special emphasis on genus *Neonosemoides* as a first record in Africa and to establish a background for further studies.

\

Materials and Methods

A total of 52 fish of *Chrysichthys auratus* were collected from Damietta branch of River Nile near El-Mansoura. The collected fishes were transported to the laboratory in tank with good aeration. Fishes were kept a live until required in aerated glass aquaria. Fishes were identified according to Bashai and Khalil (1997).

Fish skin, fins and gills were firstly examined by the naked eye for detection of any macroscopically visible lesions. Samples of mucus were scraped gently from the skin, fins and gills, then spread on a clean slide and freshly examined under phase-contrast microscope for the presence of ectoparasitic protozoans. Some of the positive slids were air-dried and stained according to Klein;s dry silver impregnation method. Other positive slides were also air-dried, fixed with absolute methanol and stained with 10% Giemsa stain.

Detected protozoa were examined freshly, stained and identified according to Shulman (1984) and Lom and Dykova (1992 & 2005). All measurements were taken in micrometers (µm) mean

± SD (range). Figures were drawn with aid of camera lucida.

Results

The detected protozoan parasites were classified into two main phyla; Microsporidia and Ciliophora as following:

Phylum: Microsporidia
Genus: *Neonosemoides*
***Neonosemoides* sp.**

Xenomas are white spherical, inhabiting gills range in size from 50-70 µm (mean 60 µm) in diameter. Xenoma consists of a simple lamellar wall measures 2.2 µm, contains only 16 mature macrospores in direct contact with the cytoplasm of the host cells and the three lobes hypertrophic nucleus of host cell. All spores in generally are surrounded by a light zone. Fully formed xenoma appears as "a bag of spores". (Figs. 1A & 3A).

Spore description

Spores are egg-shaped with bluntly rounded poles (Fig. 1B). It measures 3.2±0.2 (3.0-3.4) µm in length X 1.6±0.3 (1.3-1.8) µm in width. The spore has a thin outer finly corrugated layer (exospore), thin inner layer (endospore) and an inner most simple cell membrane. The spore consists of three parts which determine the anterior-posterior polarity of the spore (Fig. 1C).

The anchoring disc (polar cap) is mushroom cap like-shaped and stained as a red granule by Giemsa stain (Lom & Dykova,1992) , which is highly characteristic of the group (Fig. 3A). It is eccentric (subapically) located.

The polar tube; is the first part and is inserted into the base of the polar cap. The manubrium part of the polar tube extends from the cap opliquely backwards. There is an outer sheath around the polar tube, acting as a sleeve, through which the tube slides while extruding.

The isofilar polar filament forms 4 regular and helically arranged coils around the surface of the posterior vacuole in the posterior half of the spore. The second part is the polaroplast; lamellar organelle consisting of an anterior region of closely packed membranes and posterior region of more loosely packed membranes that surrounding the basal part of the polar tube. The third part, is the posterior vacuole, that lies inside the coils of the polar tube and occupies more than one-third of the spore cavity.

The remaining space within the spore and between the polaroplast and the posterior vacuole is occupied by the infective germ itself, the sporoplasm. The nucleus is single, spherical and centrally located between the polaroplast and the posterior vacuole.

Phylum: Ciliophora
I-Genus: *Ichthyophthirius*
I. multifiliis

This parasite appears as a rounded-shaped ciliated organism (Figs. 2A, 3B & 4A). In heavily infested fish, this parasite could be easily detected by the naked eye inhabiting the gills, skin and fins. It is white in colour, tiny dots, exhibits a sluggish movement and measures 44.2-90.6 µm in diameter (mean 67.4). The body is uniformly covered by dense rows of cilia. The number of meridional kineties are ranged from 77-98 (mean 88), converging anteriorly and apically raised into a pointed elevation. The cytoplasm appears to be grossly granulated containing many small food vacuoles, the horse-shoe macronucleus measures (32.3-44.6) µm in length (mean 38.5) and lies in middle of the body. A rounded micronucleus is almost adhering to the macronucleus. There are many contractile vacuoles.

II-Genus: *Scyphidia*
***Scyphidia* sp. 1**

This ciliate is solitary large parasite, inhabiting gills with cup-shaped body measures 57.6±3.6 (54-61.2) µm in length X 49.9±3.1 (46.8-53) µm in width. Epistomial disc is vaulted and slightly elevated above the peristomial disc. The peristomial disc is narrow and encircles the epistomial disc. The macronucleus is ribbon shaped, sinuous and measures 48.4±4.4 (44-52.8) µm in length. Micronucleus is very small. There are some scattered contractile vacuoles. Transverse striations of pellicle conspicuous and ranged from 80-110 (mean 95). There is non ciliated groove near the narrow scopula (Figs. 2B, 3C& 4B).

***Scyphidia* sp. 2**

This peritrich is solitary parasite, inhabiting gills with cup-shaped body and measures 35.2±2(33.1-73.2) µm in length X 36.3 ±2(34.4-38.1) µm in width. Peristomial disc is narrow. Both epistomial disc and peristomial lips are at the same level. The macronucleus is ribbon-shaped, sinuous, occupies almost all the body cavity and measures 33.6±5(28.6-38.5)µm in length X 5.5±0.8(4.6-6.2). The giant micronucleus situated in close contact with the macronucleus and measures 11.3±1.4(9.9-12.6) µm in length X 2.2±0.4(1.9-2.7) µm in width. Scopula attacted to the host skin directly by a secretory layer of sticky material. Infundibulum small and extends between the two nuclui by cytopharynx. There is a non ciliated groove situated anteriorly (Figs. 2C & 3D).

Discussion

1-Genus *Neonosemoides*

Neonosemoides sp.

The more conspicuous characteristics of the spore, the shape, wall, polaroplast, polar filament and posterior vacuole are used to distinguish microsporidia from other taxonomic group (Sprague *et al*., 1992). According to the site of infection the present xenomas were found on the gills of freshwater fish *Chrysichthys auratus*, so it belong to genus *Nosemoides* (Lom and Dykova, 1992). Recently (Lom and Dykova, 2005) reported that genera of microsporidia that comprise xenoma-forming species can be grouped in several categories according to xenoma wall, hypertrophic nucleus and type of spores inside xenoma. Accordingly the present investigated xenomas belong to genus *Neonosemoides*. Type and only species recorded in this genus is *Neonosemoides tilapiae* from *Tilapia zillii* (Sakiti and Bouix, 1987 and Faye *et al*., 1996) from Benin (West Africa). Comparing the present species with *N. tilapiae*, it was found many differences as listed in Table (1). So the present species assigned to the same genus but further ultrastructure and molecular study need to reveal the exact taxonomic assignment of this species.

The pathogenic effects induced by Microsporidia in host include physical disruption of cells due to occupation of intracellur space, host cell hypertrophy, change to host cell metabolism and reorganization of host cell components. The direct effects include increased mortality (Klaus Rohde, 2005). In the present work parasites are generally surrounded by a light zone the existence of which, is to be explained by the action of their proteolytic enzymes, which dissolve the host protoplasm around parasites and render it suitable for assimilation.

2- Genus: *Ichthyophthirius*

I. multifiliis

The parasite is identified by its characteristic horse-shoe shaped macronucleus in addition to the coarsely granular and vacuolated cytoplasm. Abu El-Wafa (1988) described *I. multifiliis* from different species of fishes but with smaller measurements (28 µm in diameter). He also found the same species in the grass carp *ctenopharyngodon idella* with the measurements much larger (about 710 µm in diameter). The present study (67.4 µm) is similar to Koura *et al.* (1997) described the parasite from *Oreochromis niloticus* (57.5 µm).

The first symptom of heavy infection, white spots appear over the entire body "white spots disease". Fins begin to fray, skin starts being eroded, gills are pale (anemia). Scales may detach, eyes sunken, fish hardly move followed by death (Lom and Dykova, 1992).

3- Genus: ***Scyphidia***

***Scyphidia* sp. 1**

The present investigated parasite is resemble in shape and measerments to *Scyphidia doliaris* Chernova, 1977 (cited in Schulman 1984), but the latter has one contrctile vacuole, epistomial disc is below the peristomial disc level and there is no non ciliated groove. This species is first record in Egypt.

***Scyphidia* sp. 2**

Scyphidia sp. investigated during this study was characterized by the cup-shaped body, ribbon-shaped irregularly twisted macronucleus, occupies almost all the cell cavity. The most characterized feature was the detection of the giant micronucleus. The present *Scyphidia* sp. 2 is similar in shape and macronucleus to *Scyphidia* sp. described by Ahmed *et al*. (2000), but the present parasite have-smaller size and has giant micronucleus. The present parasite is closely resemble *S. globularis* described by Solomatova, 1977 (cited in Shulman, 1984), but the latter has a smaller macronucleus besides the micronucleus not detected. This species is first record in Egypt.

The pathogenicity of genus *Scyphidia* is attributed to disturbance in the respiratory process of the infected fishes, leading to asphyxia. (Paperna, 1980).

Explanation of figures

Fig. (1). Diagram of zenoma of *Neonosemoide* sp. (A) showing 16 macrospores, three lobes of hypertrophic nucleus and light zones. Mature spore (B) with characteristic egg-shaped and posterior vacuole. Mature spore (C) in details.

Fig. (2). Diagram of *Ichthyophthirius multifiils* (A). with characteristic round-shaped, horse-shoe macronucleus and meridional kineties. *Scyphidia* sp. 1(B) with transverse striation of pellicle. *Scyphidia* sp. 2(C) with cup-shaped body. Note the ribbon-shaped and sinuous macronucleus and giant micronucleus.

Fig. (3). Giemsa stain zenoma (A). Note the presence of anchoring disc as a red granule (arrowhead), silver impregnation Ichthyophthirius *multifillis* (B) and *Schyphidia* sp. 1(C) and Giemsa stain *Schyphidia* sp. 2(D). Not the sinuous ribbon-shaped macronucleus.

Fig. (4). Phase contrast microscope photograph of living specimens of *I. multifillis* (A) and *Schyphidia* sp. 1(B). Note the non ciliated groove.

Abbreviations for all figures

A Novel Self-adaptive Behavior Quantum Evolutionary Algorithm

Hassan K. Khalafi

School of Mathematics and Computer Science, Damghan University,
Damghan, Semnan, P.O. Box 36715-364 Iran
h_kadkhodaei@du.ac.ir

Abstract: In accordance with tradition quantum evolutionary algorithms can obtain excellent results in the optimization of Multi-peak functions. In any case, they are easy to be trapped to hurriedness. In this article, A Novel Self-adaptive Behavior Quantum Evolutionary Algorithm is recommending on the basis of the concepts and tenet of quantum evolutionary algorithms in order to enhance the efficiency. Firstly, Self-adaptive Behavior triploid chromosome is constructed to keep the population variety; Secondly, double mutation is used to make sure the variety of the swarm, then individual chromosome cross will be imported into this new algorithm in order to achieve the information communication between the chromosomes and enlarge the search scope in the available space. Experiments on test functions of varied intricacies are implemented and compared with other EAs. The result indicates that the new algorithm in this article can search and get the global most efficient solution in a shorter time.

Keywords: Self-adaptive Behavior; Evolutionary Algorithm; QEA; Double Mutation; Discrete Cross

1. Introduction

Evolutionary algorithms (EAs) such as Genetic Algorithm [1] , Evolutionary Programming [2] , Evolutionary Strategies [3] , which can find out the best solution when they are used to deal with the complexity problems Cso they have widely applied into parameters estimate, mode recognition, machine learning, neural network, industry control and so on. However, when they are used to deal with the optimization of non-linear system, both of them often exist in the problem of prematurity and slow convergence speed.

The quantum evolutionary algorithm [4] is proposed in order to solve above problems. QEA is a new probability optimization method based on quantum computing theory. In recent years, much attention is paid to QEA because it has the characteristics of strong parallelism, rapid convergence, good search capability, short computing time, and small population size. Some QEAs and its improvement have been proposed for some combinatorial optimization problems. Although the QEA show better performance in solving combinatorial optimization problems than the traditional evolutionary algorithm, it is not suitable for solving complex optimization problems. So this paper presents a real-coded quantum evolutionary algorithm (RCQEA). RCQEA uses the variable component of the solving complex functions and qubit to construct a real-coded triploid chromosome in order to increase the diversity of the swarm, then all of the individuals (chromosomes) will evolve based on the double mutation and random discrete cross in order to achieve a balance between the local search and the global search. Standard simulation on the testified function shows that RCQEA which is used for solving complex optimization function has a very good performance.

2. Overview of QEA

As a new research field, QEA combines the quantum computing with genetic evolutionary algorithm. QC deals with investigations on quantum mechanical computers and quantum mechanics like qubits representation and superposition of states. QC can process huge numbers of quantum states simultaneously in parallel.

In QEA, the smallest unit of information stored in two-state quantum computer is called qubit, which maybe in the “1” state, or in the “0” state, or in any superposition of the two. The state of a qubit can be described as

$$|\psi\rangle = \alpha|0\rangle + \beta|1\rangle$$

Where α, β are complex numbers that specify the probability amplitudes of the corresponding states. $|\alpha|^2$ gives the probability that the qubit will be found in the 0 state and $|\beta|^2$ gives the probability that the qubit will be found in the 1 state. Normalization of the state to unity guarantees

$$|\alpha|^2 + |\beta|^2 = 1$$

The state of a qubit can be changed by the operation with a quantum gate. Inspired by the concept of quantum computing, QEA is designed with a novel Q-bit representation, a Q-gate as a variation operator, and an observation process.

A Q-bit individual as a string of n Q-bits is defined as

$$q_j^t = \begin{bmatrix} \alpha_{j1}^t & \alpha_{j2}^t & \cdots & \alpha_{jm}^t \\ \beta_{j1}^t & \beta_{j2}^t & \cdots & \beta_{jm}^t \end{bmatrix} \quad (3)$$

Where m is the number of qubit, i.e., the string length of the qubit individual, and $j = 1, 2, \cdots, n$ The following rotation gate is used as a Q-gate in QEA, such

$$U(\theta) = \begin{bmatrix} \cos(\theta) & -\sin(\theta) \\ \sin(\theta) & \cos(\theta) \end{bmatrix} \quad (4)$$

Where θ is a rotation angle of each Q-bit toward either 0 or 1 state depending on its sign.

The structure of QEA implies that most operations of QEA are based on the probabilistic, and QEA can not use any prior knowledge in the whole computing process.

The basic structure of QEA is described in the following [5] :

Procedure QEA
Begin
$t \leftarrow 0$
Initialize $Q(t)$
Make $P(t)$ by observing the states of $Q(t)$
Evaluate $P(t)$
Store the best solutions among $P(t)$ into $B(t)$
While (not termination condition) do
Begin
$t \leftarrow t+1$
Make $P(t)$ by observing the states of $Q(t-1)$
Evaluate $P(t)$
Update $Q(t)$ using Q-gates
Store the best solutions among $B(t-1)$ and $P(t)$ into $B(t)$
Store the best solution b among $B(t)$
If (global migration condition)
Then migrate b to $B(t)$ globally
Else if (local migration condition)
Then migrate b to $B(t)$ locally
End
End

Where $Q(t)$ is a population of qubit chromosomes at generation t , and $P(t)$ is a set of binary solutions ate generation f .

3. A New Real-Coded Quantum Evolutionary Algorithm

In this paper, the basic idea of RCQEA is as follows: Firstly, to reject the traditional encoding method in order to form a structure of real-coded triploid chromosome; then the chromosomes will be evolved based on the specific design of the real-coded triploid chromosome; Thirdly, double mutation is used to make sure the diversity of the swarm, then discrete chromosome cross will be imported into this new algorithm in order to achieve the information communication between the chromosomes and enlarge the search scope in the available space. At last, the new algorithm create the new chromosome through improved quantum gate.

3.1. Real-coded structure

As the multi-peak function optimization problem, it generally consists of two parts: The objective function:

$$Min(f(X)) = f(x_1, x_2, \cdots, x_n)$$

Subject to: $L \le X \le U$

$$X = \{(x_1, x_2, \ldots, x_i, \ldots, x_n) \mid l_i \le x_i \le u_i\} \} \in R^n$$

$$i = 1, 2, \ldots, n$$

Where $L = (l_1, l_2, \ldots, l_n)$, $U = (u_1, u_2, \ldots, u_n)$, L and U are the solution space, as for the since the variables x_i , its lower bound is l_i , and its upper bound is u_i . Real-coded triploid chromosome is composed of a variable component of the function and qubit. That is to say, the new chromosome is described as follows:

$$\begin{bmatrix} \alpha_1 & \cdots & \alpha_i & \cdots & \alpha_n \\ \beta_1 & \cdots & \beta_i & \cdots & \beta_n \\ x_1 & \cdots & x_i & \cdots & x_n \end{bmatrix}$$

Where $|\alpha|^2 + |\beta|^2 = 1$

3.2. Double mutation and random discretecross

In this paper, every new chromosome in the swarm will be mutated in one gene bit, that is, only one gene bit in the chromosome will be mutated every time, and other gene bits in this chromosome will keep invariability in order to build a new chromosome. The experiment has show that single gene mutation has higher search efficiency than the entire gene mutation [6].

Suppose the swarm in the t generation is:

$$P(t) = \{p_1^t, p_2^t, \ldots, p_j^t, \ldots, p_N^t\}$$

As a chromosome p_j^t , the new algorithm will select one gene bit random:

$$[\alpha_{ji}^t, \beta_{ji}^t, x_{ji}^t]^T \ , i = 1,2,\ldots,n$$

variable x_{ji}^t can be mutated as follows:

$$x_{ji}^{t+1} = x_{ji}^t + \sigma_{ji}^t N(0,1)$$

$$\sigma_{ji}^t = (u_j - l_j)\exp(\frac{-\mu k + \sqrt{\mu k}}{2})$$

Where $0 \le \mu \le 0.3$, μ is a step, which will be changed in a smaller range. The value of μ is related to the expectations precision of the objective function, k is the number of generation. In order to control the variation does not exceed the value of the domain, the parameters is adjusted as follows:

If $x_{ji}^{t+1} + 1 > u_j$

Then $x_{ji}^{t+1} = 2 \times u_j - x_{ji}^{t+1}$

If $x_{ji}^{t+1} < l$

Then $x_{ji}^{t+1} = 2 \times l_j - x_{ji}^{t+1}$

Repeat this process until x_{ji}^{t+1} can meet the conditions of a viable solution. If the new chromosome after mutation is better than the original chromosome, then this process is considered as a beneficial mutation for the evolution; otherwise as a invalid mutation for the evolution. As to the α_{ji}^t , β_{ji}^t in the original chromosome, the new algorithm will make mutation in its low bit (multi-point mutation), which can represent a larger search space, increase the diversity of the swarm. In this paper, when the solving function is very complex and the variables have strong correlation, so the algorithm will carry out random separated-cross in order to avoid the algorithm trapped into the local optimization, the process is as follows: Select an appointed chromosome p_u^t , and select another chromosome p_v^t random from the swarm, $(u \ne v)$. Then both of them will carry out random separated-cross as follows:

$$i = fin(random \times N)$$

Where i is the cross location in the chromosome, $fin(x)$ is a function, its result will be the maximum integer which is less small than x . $random$ will create a new random number between $[0,1]$; N is the length of chromosome.

The new two chromosomes after the random separated-cross are through the gene bit exchange in the location of i .

3.3 The procedure of RCQEA

Begin

Step 1. $t = 0$ initialize $Q(t) = \{q_1^t, q_2^t, \ldots, q_n^t\}$ according to the formula 6, define a empty memory storeroom;

Step 2. Make $R(t)$ by observing the states of $Q(t)$;

Step 3. Evaluate the whole swarm, and select the best chromosome;

Step 4. While the termination is true, the output of RCQEA is p_{best}^t , and the algorithm ends, otherwise, go to the next step;

Step 5. The chromosomes are evolved according to the 3.2 ;

Step 6. $t = t + 1$ go to step 4. End

4. Experimental results

$0/1$ knapsack problem [7] is referred to n articles with various value and weight, as well as partial articles are selected. To each article, there are two ways: select or not. The total weight of selected articles can't overrun that of knapsack appointed boundary and should reach the maximum of total value. If the total weight of all articles is less than that of the knapsack, then the problem will be extremely simple. And the benefit is equal to the total value of the whole articles. But actually, the knapsack's weight is always less than the total weight of the articles.

$0/1$ knapsack problem is an effective criterion to verify the performance of all kinds of algorithms. $0/1$ knapsack problem is a typical combinatorial optimization problem, it belongs to a NP-complete, we can describe it as follows:

Suppose something related to travel, its number is n , the quality and value of each one is $w_i(w_i > 0), c_i(c_i > 0), (i = 1, 2, \ldots, n)$. The capacity of this knapsack is $V(V > 0)$, then to solve an answer $x = (x_1, x_2, \ldots, x_n)$ to make sure the total value of this knapsack which is loaded with a lot of things is the most largest. We can describe this question as follows:

$$\max \quad f(x_1, x_2, \ldots, x_n) = \sum_{i=1}^{n} c_i x_i$$

Subject to

$\sum_{i=1}^{n} w_i x_i \le V$, $x \in \{0,1\}$, $(i = 1,2,...,n)$, x_i is a decision variable, if $x_i = 1$, which means res i has loaded in this knapsack; if $x_i = 0$, which means res i has not loaded in this knapsack.

In order to get a result, all the test data in this experiment have the strong correlation between weight and value.

$$w_i = random([1,10]) \ (Equably)$$

$$c_i = w_i + 5$$

And the average capacity of the knapsack:

$$V = 0.5\sum_{i=1}^{m} w_i$$

Before we solve knapsack problem, we have some prior knowledge, which are:

• When people begin to install a knapsack, they will choose bigger value of "profit/weight" firstly;

• When people begin to eliminate the capacity of knapsack, they will choose smaller value of "profit/weigh" to discard firstly.

So this is character information, and we will use them in our new RCQEA. In order to compare the new RCQEA with others in this paper, we adopt traditional GA, QEA, and RCQEA to validate the knapsack problem. The matlab 7.0 software was adopted for the implementation of the approach described previously. The number in knapsack problem is 250, and 500 respectively, and the size of population is 100 in GA and QEA. The size of population is 50 in RCQEA. The three evolutionary algorithms run 50 times and get their statistical results, respectively. The statistical results are in Table 1. We can find that the RCQEA's performance improve obviously compared with GA and QEA.

Table 1. statistical results

Number	Value	GA	QAE	RCQEA
300	Best	1653.4	1681.3	1732.1
	Average	1507.6	1595	1671.2
	Worst	1302.7	1421.4	1620.4
50	Best	2722.3	2907.2	3301.5
	Average	2599.4	2767.1	3113.4
	Worst	2278.2	2635.9	2997.1

5. Conclusions

This paper proposed a new algorithm RCQEA, inspired by the concept of Real-Coded. Compared with the traditional quantum evolutionary algorithm, its encoding method is convenient, running time is short, the speed of convergence is fast, and its global search ability is strong. So it is suitable for optimizing the complex functions such as 0/1 knapsack problems.

The Factors For Free Flow Speed On Urban Arterials – Empirical Evidences From Nigeria

Ibrahim Tunde Yusuf
Department of Civil Engineering,
University of Ilorin, P.M.B. 1515,
Ilorin, Kwara State of Nigeria (zip code: 234).
Email: ityusuf@yahoo.com; tunde_aroes@hotmail.com

ABSTRACT: Many generic factors of the weather, environment, vehicles (machines), fixed facilities (roadway) characteristics, humane (driver) and traffic streams either singly or in combination influence the free flow speed. The quantitative measures of these factors are desirable for reliable system design, analysis and evaluation for effectiveness, especially as reflect the typical humane-machine-environment system prevailing in Nigeria. This paper therefore presents the outcome of the quantitative evaluation of the influence of some factors on the free flow speed on an arterial in a medium sized urban settlement in Nigeria with a view to determining the probable analytical values for towns of similar hierarchy in Nigeria. Instantaneous speeds of forty test vehicles were observed in-vehicle at lull periods on the 7.1km Offa Garage-Emir's Market urban Road, Ilorin with simultaneous collection of data on age of driver, age of vehicle, passenger occupancy, roadside packed vehicles and businesses. The geometric properties of the arterial ware earlier established and segmented to four uniform sections. The data were computed using the category and statistical analysis approach. The results of the study indicated that the three factors of the environment (weather), humane and roadway geometry have negative influences on the free flow speed on an urban arterial. Estimates of the reduction of the various factors were detailed in the paper which was recommended for adoption for design and analysis of traffic stream in Nigeria and other medium sized towns in Nigeria.

Keywords: Free flow, instantaneous speed, lull period, roadway geometry, environment, in-vehicle data**,** time speed and traffic stream.

INTRODUCTION

Free flow speed can be defined as the drivers' desired average space mean speed in a low volume traffic stream when the density and flow theoretically tend to zero as mathematically represented by the fundamental traffic equation; $q = U_sD$, where q is flow (veh/hr), D is density (veh/km) and U_s is space mean speed (km/hr) (Agent et al (1998) and Dixson et al (199)). It occurs when no obstructions to flow either in terms of operational delays (congestion) or other adverse conditions prevail. Three principal factors of (a) roadway geometry and condition (b) drivers attributes and (c) environment have been reported to influence the values in the American urban traffic streams and highways (Kyte et. al. (2000) and Lamm et. al. (1990)). These authors showed from different studies that the percentage reduction due to the environment in the free flow speed are 8, 14, 15 and 17 – 18 respectively for wet pavement, high wind (greater than 24 km/ hr), low visibility (less than 0.28km) and rains; with a combined effect of all in the range of 30-38%. Lamm et al (1990) additionally observed that drivers also adjust speeds by as much as 10km/hr less during heavy rains when visibility becomes substantially obstructed, while Dowling et al (1997) equally identified drivers attributes and vehicle characteristics as the major factors in the free flow speed in the urban traffic. Younger drivers (in age), level of passenger occupancy, age of vehicles and trip purpose have impacted higher values on the speed while horizontal / vertical alignments and parked vehicles along the road impacted negatively on free flow speeds; (Blake, 1989).

The free flow speed is very important in traffic stream analysis for incidents and bottlenecks and hence the factors influencing its value should attract equal, if not higher attention because it is the source and not the effect. Besides it shall be helpful in sensitivity analysis. No wonder the Highway Capacity Manual (HCM 2000) underscores the importance of the various factors as pertaining to lane width/lateral clearance, the number of lanes and the driver's lateral wander etc. Indeed, Liang et al (1998) presented a chapter of detailed analysis of the effect of human factors (drivers') on the free flow speeds in the premise of person-machine control system. The phenomenon of perception-reaction time, control movement time responses to movement of other vehicles, handling of hazards in the roadway and the peculiarities of the different segments of driving population were examined, while the evolving formulation were tested with the American traffic situations and various models. Two of such models

are the (a) Hick-Heyman's law for perception-response time and (b) Fit's law of braking inputs.

Of particular interest for Nigerian situation are the age of drivers, age and condition of vehicles, the roadway geometry and pavement condition. It is an open secret that majority of vehicles on Nigerian roads are old and second hand that have already operated on the streets of country of manufacture before being imported to this country. Obviously, the enumerated models can not completely address the Nigerian situation because Nigerian drivers must have, at least characteristic vehicle handling practices, which must reflect on the traffic stream operation.

Traffic stream analysis and design in Nigeria presently apply either the American or British values which are empirical evidences of the operation in the developed countries. Hence the assessment of the influence of some of these factors to reflect the traffic operation in Nigeria shall be a worthwhile exercise, in that the closeness of the prevailing values to those usually borrowed from other countries' traffic situation, environment and humane (driver) attributes, shall offer the desired confidence and reliability when used for Nigeria traffics. It will appropriately reflect on Nigeria's peculiarities, her drivers' characteristic behaviors behind the wheels, the vehicle conditions/age, passengers' perceptions of trip purpose and other latent issues or combined effects.

The aim of this study is therefore to establish both quantitative and qualitative measures of the influence of the roadway factors (geometry), pavement condition, human (drivers) and the environment; on the free flow speeds on a typical Nigeria urban arterial. The specific objectives include (1) determination of traffic volume trend on different sections of a typical urban arterial in Nigeria, the Offa Garage – Emirs road, (2) determination of the inventory and geometric characteristics of each section of the arterial, (3) determination of the respective free flow speed at different weather conditions, (4) comparison of the free flow speed at each section, at different weather conditions and level of various factors, (5) to catalogue the various factors responsible for the prevailing free flow speed at each section and hence (6) postulate how the different factors influence the free flow speed on the Murtala Muhammad road in Ilorin, a medium sized urban centre in Nigeria or other Nigerian towns with the same political, historical and transportation hierarchy. Actually one would need to examine more than fifty geometric parameters for an attempt at comprehensive summation evaluation of the effects of factors on any parameter for traffic such as the free flow speed. This study is however limited to a few roadway environment (wet/dry condition), roadway geometry and vehicles (carriageway, roadway shoulder and width, lane width, number and obstruction, vehicle age and passenger occupancy); and driver' age.

MATERIALS AND METHODS

Studied Arterial

The studied arterial is 7.1km in length with the last 5km dualised. It originates from the Offa Garage and terminates at the Emir's palace, Ilorin, the Kwara State capital in the central western part of Nigeria. The road traverses four distinct sections; in terms of different levels of the road way characteristic, land use (road side development and business) and traffic volume. The respective partitions are designated as sections A, B, C and D.

Section A: Offa garage to Gaa Akanbi Junction, which is the section without median, Section B: Gaa Akanbi Junction to "A" Division which is a section with isolated and dedicated educational or public buildings which is not densely populated and thereby having a low level of activities, Section C: "A" Division to Post Office, which is a central business district of the town and Section D: Post Office to Oja-Oba, the predominantly market and indigenous area of the town which is densely populated and thereby highly characterized by a high level of activities. Figure 1 presents the diagrammatic sketch of the studied arterial.

Study Methods and Test Data

1. Road and Traffic Characteristics.

The influence of the three factors of roadway characteristics, drivers (human) and environment were studied using the manual observatory approach for the road inventory, traffic volume and drivers characteristics at different weather conditions. The lull period was established in order to determine the timings for the speed measurement. Table 1 presents the geometric properties of the studied arterial while Table 2 presents the probable measurement timings of free flow speed for the various days of the week.

2. Free Flow Speed Data and Factors

The free flow speed measurement data was carried out simultaneously with drivers' attributes data collection using the in–vehicle method at pre-determined lull periods with two observers. Forty (40) test vehicles were selected ensuring that the two predominant passenger commuting vehicles (taxis) and small buses ("turo–turo") on the township roads were sampled. Observer (1) noted the instantaneous speeds (the speedometer reading) at three spots, approximately third portion along the length of each section of the arterial, while simultaneously observer (2) recorded the numbers of parked vehicles along the roadsides and passenger occupancy of the test car. Thereafter both observers interviewed the drivers to obtain the relevant information about respective attributes of age, sex, vehicle age and condition and pavement condition. A category analysis of the mean speed with the various parameters or factors was carried out. A summary of the free flow speed with respect to various factors for section A is presented in the Appendix.

RESULTS

1 Free Flow Factors Relationship

Table 3 presents the matrix of the relationship between the average free flow speed and the driver's age for the four sections and subjected to further analysis. For instance, the average free flow speed for cars driving along section A and driven by drivers within the age range of 60 – 69 years is (61.7 + 66.7 + 60.0)/3 which equals 62.8km/h. The average free flow speeds for the other three sections under consideration were similarly found for each age range and summarized in Table 4. These average values were then plotted against their corresponding ages as shown in Figure 2 whose slope was computed to be 0.46 km/hr/yr.

Table 5: Average Free Flow Speed – Number of Passengers in Cars Relationship

No of Passengers	Section A	Section B	Section C	Section D	Average free flow speed
2	76.5	71.8	66.8	52.6	66.9
3	74.1	71.3	71.7	56.5	68.4
4	67.9	75.5	71.5	60.2	68.8
5	62.2	82.5	71.7	61.0	69.4
6	71.3	80.8	81.6	66.0	75.0

This procedure was repeated for the other factors of j number of passengers in the car, car age and number of parked cars along roadsides with corresponding results as represented in Tables 5, 6 and 7. The results were correspondingly displayed in Figures 3, 4 and 5. From the graph of average flow speed against number of passengers in car as shown in Fig. 3, the slope value in km/hr/passenger is -0.548. From the graph of average free flow speed against car age shown in Figure 4, the slope in km/hr/yr of age of car is -1.59. The graph of average free flow speed against number of parked cars is shown in Figure 5. The relationship is of quadratic form with peak at about 25 parked cars.

2. Free Flow Speed – Environmental Factor Relationship

The mean free flow speed was calculated respectively for dry and wet pavement conditions for the four different sections. Table 8 presents the summary of statistic data (mean and standard deviation) for section A while Table 9 is the corresponding summarized true speed at 95% upper confidence level (mean + 1.96 x standard error). There was a reduction of 0.5km/hr to 14.0km/hr on the road due to the wet condition which approximates to percentage reduction of 0.9% to 21.0%. The corresponding values based on time means at 95% confidence levels were 1.7km/hr to 9.98km/hr.

3 Free Flow Speed and Road Geometry/Condition

Table 10 shows the summary of average free flow speed and geometric condition at each section of the road. The graph of average free flow speed against each of the road geometry i.e. road width, number of lanes, shoulder width, number of intersections, travel way width and number of traffic control units are shown in Figures 6-11. These outcomes can form the basis of adjustment factors for the free flow speed of traffic stream on an urban arterial. For instance, a road width of 8metres or more will not attract any reduction in operating value but lower widths will attract at a unit rate of 17km/hr or less. The corresponding values for the different factors are summarized in Table 11.

Table 8: Mean Free Flow Speed Statistics (mean + standard deviation) (km/hr)

Section	A	B	C	D
Wet condition	73.8±11.10	66.8±14.99	71.1±10.72	57.5 ±6.10
Dry condition	72.0±12.00	80.8±7.18	74.2±5.00	58.0 ±7.76
Reduction (km/hr)	1.8	14.0	3.1	0.5
% Reduction	2.2	21.0	4.2	0.87

DISCUSSIONS

As can be observed from Tables 4-11 and the corresponding Figures 2-11, the results of this study established that the drivers' desired speed on an urban arterial are influenced quantitatively by the various factors. For instance, the pavement condition when wet could impact as much as 10-14km/hr or 12-21% reduction in free flow speed; which are relatively higher than the reported 10km/hr for rains and 8% for wet pavement for other countries. This observation could be explained by many reasons, among which include the general state of pavement condition (various degrees of failures - potholes, edge breaks etc.), driver's age and state of mind, roadside

land-use and density, businesses and parking. The variation in free flow speed values (66.8, 71.1 and 57.5km/hr (wet) and 80.8, 74.2 and 58.0km/hr (dry)) for the different sections, especially B (with exception of section A) even attested to this deduction. Their corresponding coefficient of variation (CV = 100xSD/mean) of 22.4%, 15.1% and 10.6% for wet and 8.9%, 6.7% and 13.9% for dry show a reasonable consistency of the vehicles movement and by implication the behaviour of the drivers on the arterial. The better performances of the drivers during dry weather clearly show the influence. However, the results for section A showed otherwise which is absolutely a negation of the common logic.

However, it could still be explained by the fact that this section, being the only undivided portion allows the drivers more latitude to demonstrate their personal attribute and desire at overtaking and perform other movement manouvres. The simple principle for car following theory with which traffic stream flow operations are analyzed can easily breakdown. An organized movement is more probable on the divided arterial because the interactions with on-coming vehicles have been completely eliminated. It is at the intersections that it may manifest and will involve only for the left turning vehicles. Even, the highest values obtained for this section during the wet period is still more suspect. Another reason is that it is a sub-urban and hence the operating free flow speed should be close to that of the freeway. This is even more probable because the coefficient of variation for the two pavement conditions is 15% and 16.7% implying a good consistency of the data and person-machine control-road response system. The instantaneous speed is the most discerning indication of the overall duration for the performance of all the necessary activities for safe driving on a road.

Table 4 clearly shows the influence of drivers' age on free flow speeds. Their quantitative measures are averagely in the range of 0.36 and 0.68km/hr. As expected, the younger drivers operate on higher speeds than the older ones and it is consistent for all the sections. However, an interesting observation is noted for the drivers of age 40-49years. The drivers in the group operate on a speed same with or atimes higher than those in the 20-29 age brackets. This can be explained by their probable better understanding of the roads due to long time of driving coupled with their energy. As drivers grow older, such energy decreases in obedience to the law of nature – older bones get weaker and hence fewer propensities for higher work rate. Driving age in Nigeria commences from 18years while there is no official terminal age. It depends on how the body can cope. An equally relevant and related factor is the age of the vehicles. It is definite that age of the vehicle impact negatively on the performance of the road. The quantitative measurements are 1.30, 2.86 and 1.3625km/hr/year age of vehicle; with an average of 2.07km/hr/yr unit reduction factor. The reasons for this are obvious. The performance of vehicles decreases as they age and it is at old age they are converted to transportation operations. Both vehicles and drivers have their respective lifespans.

Another factor is the level of passenger occupancy of the vehicles. The speeds are averagely higher as the passenger capacity for each vehicle is being met. The measure of this effect was estimated for sections B, C and D to be in the range of 2.46-2.73km/hr/passenger. Table 5 and Figure 3 show that for section A (undivided), there is a reduction in speed because the occupants of a vehicle fast arriving from a non-urban journey shall be alighting at their destinations. This implies that the only activity predominating in the mind of the driver is how to reach the destination and return for more passengers. The usual stops to either drop or pick a passenger no longer exist. The various effect of the road geometry is succinctly summarized in Table 11. The critical values and the unit values reasonably agree with applicable modifications to various operational parameters for traffic stream analysis. The carriageway width of 8.0m, number of lanes of 2 and shoulder width of 1.4m are reasonable as they compare with standards. The same applies to other factors.

CONCLUSIONS

The following conclusions were reached from the study.

1. The traffic volume distribution on an urban arterial in Ilorin is trimodal with morning, noon and evening peaks and lulls in between.
2. The changes in the road geometry on each section of the arterial in terms of shoulder width, number of lanes, road/carriageway width and distance of nearest obstruction to the edge of the road do affect the instantaneous speeds. The corresponding numerical values of these factors on the Offa Garage-Emir's Road are about 0.5, 15, 27 and17km/hr for sections A, B and C respectively.
3. Different free flow speeds operate on distinct sections of the arterial. Respectively, the values are 72.0, 80.8, 74.2 and 58.0km/hr for section A, B, C and D when the pavement is dry, but correspondingly for wet conditions they are 73.9, 66.8, 71.1 and 57.5km/hr. Section B (Gaa Akanbi junction to "A" Division) has the highest average free flow speed while Section D (Post Office to Oja-Oba) has the lowest average free flow speed. The density

or level of usage reflects the deteriorating values along the routes.

4. A linear relationship exists between free flow speed of commuter vehicles and drivers' age, number of passengers in the car and car age with following respective rates of (a) decrease of 0.46km/hr/yr of driver's age, (b) an increase of 0.53km/hr per passenger in the car, (c) a decrease of 1.48 km/hr/yr of age of car.

5. A linear relationship does not exist between free flow speed and road side parking situation due to other prevailing factors.

6. The average free flow speed of commercial saloon cars is lower on wet pavement than on dry pavement, the percentage reduction being about 12%.

7. There are variations in free flow speed with changes in road geometry and characteristics.

RECOMMENDATIONS

The estimates of the various factor modification parameters obtained from this study can be used in urban road highway planning and analysis on Offa Garrage-Emir's road and other Nigerian roads with similar characteristics with the Ilorin transportation system evolution. The free flow speed modifications can be applied in the analysis and design of Ilorin urban arterial. This study should be conducted on arterials in other towns in Nigeria so that a national operational data base value could be established.

AKNOWLEDGEMENTS

This paper cannot be put together without the tremendous background information made available by various research workers, authors of excellent books and articles which have been referred to and listed in my references. I thank them.

Abstract: Genetic polymorphism was investigated in six conifers representing four Pinus species, i.e (*P.halepensis, P.canariensis, P.pinea, and P.roxburghii)* which belong to family *Pinaceae* and two members of family *Taxodiaceae, i.e. (Sequoia sempervirens and Taxodium distichum).* In this respect, genetic biochemical (proteins and isozymes), as well as molecular (RAPDs and ISSRs) analysis were investigated. Proteins and peroxidase banding patterns resulted in extensive polymorphism among conifers under investigation, however, Adh isozyme banding patterns were not satisfactory in this concern. RAPD analysis exhibited a total of 66 bands, out of them 25 bands were polymorphic (37.88%). Five ISSR primers generated reproducible and informative amplified products. those were used to distinguish between the six conifers, since 38 bands were polymorphic out of total 81 bands with 47.95% of polymorphism which can be considered as useful markers for identifying conifers. Based on combined data obtained by proteins, peroxidase, RAPD and ISSR analysis, it was possible to discriminate between the six conifer trees under investigation. The present study indicates that the application of biochemical and molecular fingerprinting of the six conifers provided a solid ground that will allow an easier and faster genetic identification of other woody trees species.

Keywords: Conifers, *Pinus*, *Sequoia*, *Taxodium*, fingerprint, RAPD, ISSR, SDS-PAGE, Peroxidase, alcoholdehydrogenase.

1. Introduction:

In forestry, genomic discovery will support genetic improvement of tree varieties for solid wood, pulp and paper, biofuels, and biomaterials through integration into traditional breeding approaches in domesticated tree population (Neale, 2007).

Characterization of the genetic diversity and examination of the genetic relationship among conifers are important for the sustainable conservation and increase use of plant genetic resources. Traditionally, comparative vegetative anatomy and plant systematic were two common strategies to assess the relationships among conifers (Wang, *et al.*, 2009).

Tree breeding generally involves recurrent selection and population improvement in each cycle of breeding and each cycle can take many years (White, *et al.*, 2007). In trees, breeding populations are often large and genetically diverse in their composition, as opposed to line breeding in many agricultural crops where the number of genotype is often limited. Tree breeders could then use genomic selection directly for population improvement or, more likely, combine genomic selection approach to maximize genetic gain per unit time (Neale, *et al.*, 2007).

The genus *Pinus* is among the most widely distributed and prominent genera of trees in the world, including many of the most economically valuable species of forest trees. The taxonomy of *Pinus* is based mainly on morphological and partially on molecular data that are incomplete for many taxa (Strauss and Doerksen, 1990).

Taxodium disticum is a deciduous conifer in the family *Taxodiaceae*, which has numerous attributes that qualify it as a supreme urban landscape tree and as a species to mediate harsh coastal wetland and flood plains of major rivers in the south (Zhou, 2007). *Sequoia sempervirens* has a very decay and fire resistant wood, as well, resistant to weather, insects and fungus attacks. The bark is used as hog fuel, insulation, or garden mulch. This species lives up to 1500 years, and reaches 116 m height (as the tallest stands record). The economic value of the tree is so high, however, little attention has yet been paid to it (Clark and Scheffer, 1983). There is only one *Sequoia sempervirens* tree in Egypt which had been threatened, never produces seeds, neither vegetatively propagated, however, it was possible to propagate through tissue culture techniques (Gad, *et al.*, 2006).In Egypt, no attention has been paid to evaluate the genetic relationships between such conifers which were introduced and grew well under the local environmental conditions. This study was designed to assess the pattern of genetic variation between different genetic resources of conifers genera and species. This was achieved through the use of electrophoretic (protein and isozymes) and molecular (RAPD and ISSR) techniques which have been increasingly applied to the study of tree species in

recent years, to provide information in support of conservation planning and management. Therefore, the objective of this study is to identify and characterize species-specific biochemical and molecular markers among the conifers of the two families (*Pinaceae* and *Taxodiacea*e) in order to establish genetic relationships among them. Moreover, the resulted genetic relationships can be directed towards tree genetic resources sustainable conservation as well as to exploit these investigations in breeding programs to maximize genetic gain per unit time in order to support genetic improvement of tees under investigation.

2.Materials and Methods:

2.1.Materials:

2.1.1.Plant materials

This investigation was achieved during the period from 2006 to 2010 at Biotechnology Research Laboratory, Horticulture Research Institute (HRI), Agricultural Research Center (ARC), Ministry of Agriculture, Egypt.

Genetic resources of six mother trees, morphologically identified conifers located at Orman Botanic Garden, Giza, were used as germplasm sources for this research work, namely *Pinus halepensis*, *Pinus canariensis*, *Pinus pinea*, *Pinus roxburghii*,(belong to family *Pinaceae*), *Sequoia sempervirens* and *Taxodium distichum*,(belong to family *Taxodiacea*)

2.2.Methods:

2.2.1.Biochemical genetic identification.

2.2.1.1. Protein electrophoresis:

Young fresh leaves were collected from conifers under investigation and were ground into a fine powder by using liquid nitrogen (-196 °C) and a mortar and pestle. A sample of 0.5 g was homogenized with 0.9 ml extraction buffer (10 ml 0.5 M Tris pH 6.8, 16 ml 10% SDS, 30 ml D.W.). The extracts were transferred into Eppendorf tubes and centrifuged for 10 min. at 1000 rpm under cooling (4 ºC). Supernatants (containing protein extract) were transferred into clean tubes and used for SDS-PAGE analysis. Isozymes were extracted, as described by Jonathan and Weeden (1990). A volume of 120 µl of protein extract was loaded into sodium dodecyle sulphate polyacrylamide gel (SDS-PAGE), 12% W/V vertical slab using BIORAD Techware 1.5 mm according to the method of Laemmli (1970) and modified by Studier (1973). The molecular weights of proteins were estimated relative to a standard protein marker with a wide range of molecular weight (Fermentas .com).

2.2.1.2. Isozymes electrophoresis

Native – polyacrylamide gel electrophoresis (Native - PAGE) was conducted to identify isozyme variations among the six studied conifers using two isozyme systems using 12% (W/V) slab gel according to Stegmann *et al.* (1985). Isozymes were extracted from 0.2 g of fresh and young leaves samples in a 1 ml of 0.125 M Tris – borate buffer, pH 8.9. A volume of 50 µl extract of each sample was mixed with 12.5 µl of glycerol, and 60 µl from this mixture was applied to each gel well.

2.2.1.2.1. Peroxidase Detection:

Peroxidase was detected by incubating the gel in a darkness for one hour at 37°C in a mixture of 15 ml of 10% benzidine (in 95% ethanol); 50ml of 1mM potassium acetate and 1 ml of 1% H_2O_2 (pH 4.7). After the incubation period the gel was rinsed in a distilled water and fixed in a 50% glycerol for one hour. The gel was placed into this solution and 5 drops of hydrogen peroxide solution were added. The gel was incubated at room temperature until bands appeared, (Brown, 1978).

2.2.1.2.2 Alcohol dehydrogenase (*Adh*):

Gel was placed in a solution composed of 100 ml of 0.1M Tris-pH (7.5), NAD 30 mg, MTT 20 mg, phenazine methosulfate (PMS) 5 mg and ethanol 6 ml, and incubated at 30 ºC for 30 min. until bands appeared.

2.2.1.2.3 Gel documentation

Gels were digitally photographed and analyzed using Gel Doc Viller Lourmat system to capture the image and to calculate band intensities.

2.2.2.Molecular genetic identification

DNA extraction:

Total genomic DNA was extracted and purified from 0.1 g of freeze – dried powered samples as described by Dellaporta *et al.* (1983). DNA present in the supernatant was precipitated according to the

described protocol, re-dissolved in a sterile, distilled water (D.W.) and quantified.

2.2.2.1. Randomly amplified polymorphic DNA (RAPD).

Amplification of genomic DNA using polymerase Chain Reaction (PCR)

Different preliminary experiments were carried out in order to optimize the factors leading to clear reproducible amplification products. A total of ten random DNA oligonucleotide primers were independently used according to Williams *et al.* (1990) in each PCR reaction.

Only five primers (Operon biotechnologies, Inc. Germany) were succeeded to generate reproducible polymorphic DNA products. Table (1) displays the base sequence of these DNA primers those produced informative polymorphic bands.

PCR was performed in a 30µl reaction volume containing the following : 3.0µl of dNTPs (2.5 mM), 3.0µl Mg-Cl_2 (25mM), 3.0 µl of 10 x buffer, 2.0 µl of primer (10 ρmol), 0.20 µl of Taq DNA polymerase (5u/ µl), 2.0 µl of template DNA (50.0 ng/ µl), 16.80 µl H_2o (sterile D.W.). The DNA amplifications were performed in an automated thermal cycle (Techn.TC-512 PCR system). The reaction was subjected to one cycle at 94ºC for 4 min. followed by 45 cycles of 1 min. at 94 ºC, 1 min. at 36 ºC, and 2 min. at 72 ºC. The reaction was finally stored at 72 ºC for 10 min.

The amplification products were separated in 1% (w/v) agarose gel in 1 x TBE buffer and visualized by staining with ethidum bromide. Reproducibility of DNA profiles was determined by replicating all RAPD reactions at least three times.

After electrophoresis, the RAPD patterns were visualized with UV transilluminator and photographed by gel documentation system (Gel Doc Bio Rad 2000). RAPD markers were scored from the gel as DNA fragments present or absent in all lanes. Each experiment was repeated twice and only stable products were scored.

2.2.2.2. Intersimple sequence repeats (ISSR)

ISSR- PCR reactions were conducted using five primers. PCR was performed according to Wang, *et al.* (2002) in 30 µl reaction volume containing 2.5 µl dNTPs (2.5 mM), 2.5 µl Mg Cl_2 (25 mM), 2.5 µl buffer (10 X), 3.0 µl primer, 2.5 µl Taq DNA polymerase (1 U/1 µl), 2.0 µl Template DNA (25 ng) and 11 µl H_2O (sterile D.W.).

The PCRs were programmed for one cycle at 94 ºC, for 4 min. followed by 45 cycles for 1 min. at 94 ºC, 1 min. at 57 ºC and 2 min. at 72 ºC then 12 min. at 72 ºC for one cycle and the reaction was finally hold at 4 ºC. The PCR products were separated on 1.5 % agarose gels and fragments sizes were estimated with the 100 bp ladder marker. Table (2) illustrates the base sequence of the DNA primers, those produced informative polymorphic bands.

2.2.3.Data analysis:

The similarity matrices were done using Gel works ID advanced software UVP- England Program.

The relationships among genotypes and species as revealed by dendrograms were done by using SPSS windows (Version 10) program. Dice computer package was used to calculate the pairwise difference matrix and plot the phenogram among conifers genotype under investigation. The resultant similarity matrix was employed to construct a dendrogram using Sequential Agglomerative Hierarchical Nesting (SAHN) based Unweighted Pair-Group Method with Arithmetic Means (UPGMA) to infer genetic relationships and phylogeny(Sensi, et al., 2003)

3.Results:

3.1.Biochemical genetic identifications

3.1.1. SDS- PAGE protein banding patterns of conifers leaves.

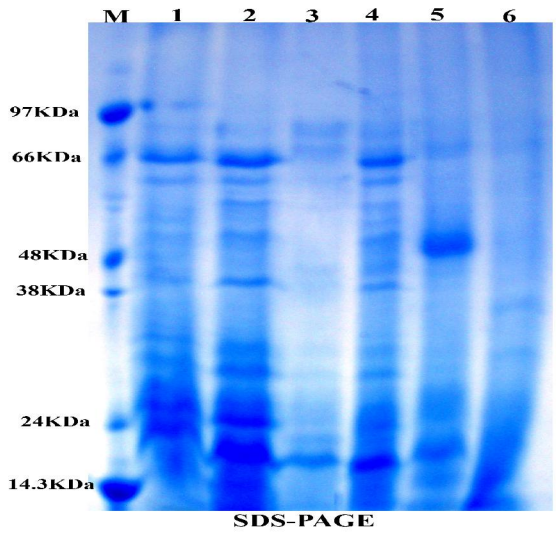
The needle leaves protein banding profile which was separated using SDS-PAGE of the six genera and species of conifers are illustrated in Fig. (1). The total number of bands was 23 with molecular weights ranged from 15.798 KDa to 100.751 KDa (Table 3). The highest number of bands was 16, detected in *Pinus roxburghii* while the lowest number of bands was 8, identified in *Taxodium distichum.*

Demonstrative analysis of the presence and absence of bands were assessed with (1) and (0), respectively, are illustrated in Table (3). It is observed that two bands were monomorphic (29.677 and 21.287 KDa), while 18 bands were polymorphic, giving 91.304% polymorphism and 3 unique bands (100.751, 92.825 and 24.963 KDa) among the examined conifers.

The matrix of similarity index for the six conifers germplasm is presented in Table (4). The highest coefficient was 86.7 recorded between *Pinus canariens*is and *P.roxburghii*, followed by 80.0 recognized between *Sequoia sempervirens* and *Taxodium distichum*, followed by 75.9 between *P.roxburghii* and *P.halepensis* and finally 74.1 between each of (*P.halepensis* and *P.canariensis*) and (*P.roxburghii* and *P.pinea*). On the other hand, the lowest coefficient value was 28.6 observed between *P.halepensis* and *Taxodium distichum.*

3.1.2. Isozymes banding patterns.

The isozymes banding pattern of peroxidase and alcoholdehydrogenase (*Adh*) isozymes of the six conifers genotypes is presented in Fig. 3 (a and b), while data are scored in Table (5).



Fig(1): SDS-PAGE protein banding patterns of leaves of the six conifers

[M :standard protein (KDa) ,
1-Pinus halepensis,
2- P.canariensis,
3- P.pinea,
4-P.roxburghii,
5-Sequoia sempervirens,
6-Taxodium distichum].

The peroxidase patterns exhibited a total number of 20 bands, 13 of them are polymorphic, with (100%) polymorphism while 7 bands are unique, though, no monomorphic bands were scored. Polymorphism exhibited by this pattern completely discriminated between the studied conifers.

Table (4) A Proximity matrix of protein banding patterns

Case	Matrix file input					
	1	2	3	4	5	6
1		0.741	0.583	0.759	0.400	0.286
2	0.741		0.720	0.867	0.538	0.455
3	0.583	0.720		0.741	0.522	0.316
4	0.759	0.867	0.471		0.500	0.333
5	0.400	0.538	0.522	0.500		0.800
6	0.286	0.455	0.316	0.333	0.800	

Pinus roxburghii was discriminated by the presence of the unique bands with Rf values (0.105 and 0.361). Besides, *Sequoia sempervirens* was distinguished by the absence of the unique negative bands with Rf values (0.279, 0.336 and 0.387) and the presence of unique bands with Rf values (0.731, 0.790, 0.836 and 0.900). As well, *Taxodium distichum* was identified by the presence of (0.055) and the absence of (0.597) unique bands, in addition, to other polymorphic bands recognized in each conifer.

Table (3): Data matrix illustrating the presence or absence of bands in the leaves protein electrophoresis banding patterns for the six conifers.

Band number	MW (KDa)	P.halepensis	P canariensis	P.pinea	P.roxburghii	S.sempervirens	T.distichum

23	15.798	0	1	0	0	1	1
Total		13	14	10	16	12	8
Polymorphism %	91.304						

In Fig (3-b) and Table (5) there is a quite evidentence that only four polymorphic bands were identified out of five total scorable bands with 80% polymorphism, while one monomorphic band (Rf 0.863) was recognized as well as 1 unique band was scored in the illustrated *Adh* profile. Only *Taxodium distichum* was discriminated with the presence of the unique band with (0.205) and the absence of (0.268) Rf values, while the other taxa shared the presence and absence of several bands. Each of *P. halepensis* and *P. canariensis* shared the presence of the bands with RF values (0.268, 0.363 and 0.863) and the absence of (0.205 and 0.739) bands. Besides, each of *P. pinea*, *P.roxburghii* and *S. sempervirens* shared the presence of bands with Rf values (0.268, 0.739 and 0.863) and the absence of the bands (0.205 and 0.363) Rf values. Therefore, *Adh* isozyme patterns were not satisfactory to detect

phylogenetic relationships among conifers genotypes used in this study.

Consequently, isozyme profile permitted the identification of three conifers under investigation, *i.e. Pinus roxburghii*, *Sequoia sempervirens* and *Taxodium distichum* by the presence of two unique markers found in peroxidase isozyme with *P. roxburghii*, four with *Sequoia sempervirens* and absence of three bands and the presence of one with *Taxodium distichum* with absence of one unique band.

6-*Taxodium distichum*

3.2.Molecular markers:

3.2.1. Randomly Amplified Polymorphic DNA (RAPDs) analysis

Out of ten decamer (RAPD) primers tested, five revealed distinct polymorphism among the six conifers under investigation. A total of 66 DNA bands were detected; 25 of them showed polymorphism. Out of these polymorphic bands, 10 unique bands were scored (Table 6). However, polymorphism ranged between 18.182% (primers OP-F01, OP-F05 and OP-C11) and 58.824% (primer OP-Z01). The range of DNA bands size was between 97.071 and 882.55 bp (Fig 4).

From Table (6) and Fig (4) it could be noticed that a maximum of two polymorphic (18.182% polymorphism) and nine monomorphic DNA bands were recorded in the RAPD profiles generated by the primer OP-C11, while no polymorphic-unique bands were scored. The first polymorphic band (about 350 bp) was observed in all conifers genera and species, except in *P.halepensis*, while the second polymorphic band (313.4 bp) was identified in all conifers, except in *S.sempervirens*. The absence of the forementioned polymorphic bands could be considered as negative unique bands for both genera.

It could be observed that the primer OP-F01 generated a total of two polymorphic bands, inducing 18.182% polymorphism and nine monomorphic DNA bands in the studied species and genotypes, while one unique band (positive) was identified out of the total polymorphic bands. This unique band (molecular size 587.065 bp) was detected in *Sequoia sempervirens*, while the absence of the (negative) band (molecular size 473.151 bp) was observed in *Pinus canariensis*. These unique bands (positive and negative) clearly discriminate both of *Sequoia sempervirens* and *P.canariensis* from the pool of conifers investigated.

Table (6) and Fig (4) illustrate the RAPD profile generated by the primer OP-F05, which produced nine monomorphic and two polymorphic DNA bands with 18.182% polymorphism. One polymorphic band was identified as a unique band (with fragment size 337.427 bp) in *Taxodium distichum*. The other polymorphic, non-unique band, was detected at about 592.501 bp distinguishing the four *Pinus* species by its presence, while it was absent in each of *S.sempervirens* and *T.distichum*. This primer could discriminate each of *S.sempervirens* and *T.distichum* from the group of *Pinus* species, since *S.sempervirens* exhibited no polymorphic bands while *T.distichum* was distinguished by the presence of 337.427 bp unique band.

A total of nine polymorphic bands out of 16 total observed bands with 56.25% polymorphism were generated by the primer OP-F08, three bands were scored as unique, out of the polymorphic bands. All the three unique bands (with 562.785, 366.313 and 341.174 bp) discriminated *S.sempervirens* from the other genera. On the other hand, seven monomorphic bands were scored at about 386.7, 328.8, 290.1, 271.8, 212.2, 180.4 and 158.8 bp. Each of the six conifers is characterized by polymorphic non unique bands, *i.e. P.halepensis* recorded 521.2, 441.9 and 97.07 bp polymorphic bands, *.canariensis* scored only 97.07 bp as polymorphic band while *P.pinea* and *P.roxburghii* involved 235.06 and 97.07 bp. On the other hand, each of 443.2, 343.1 and 235 bp bands were observed in both of *S.sempervirens* and *T.distichum*, in addition to 521, 441.9, 212.2, 180.4 and 158.8 bp bands in *S.sempervirens*.

The primer OP-Z01 generated a total of ten polymorphic (58.824% polymorphism) and seven monomorphic DNA bands in the studied conifers genotypes and species. Five unique bands were scored out of the total identified polymorphic bands in the conifers under investigation. *S.sempervirens* was characterized by the presence of the unique bands with fragment size 838.8, 483.3 and 98.9 bp while *T.distichum* was distinguished by the unique bands (235.5 and 219.5 bp). Moreover, *P.pinea* scored the polymorphic band (364.7 bp) as well as *P.roxburghii*,

S.sempervirens and *T.distichum*. In addition, the polymorphic band (453 bp) was recorded in each of *P.roxburghii*, *S.sempervirens* and *T.distichum*. Besides, *S.sempervirens* and *T.distichum* were both discriminated by the polymorphic bands (546.6 and 269.66 bp), while each of *P.roxburghii* and *T.distichum* were characterized by the presence of (270.4 bp) polymorphic band. However, non of *P.halepensis* and *P.canariensis* scored polymorphic bands. The forementioned polymorphic and unique bands generated by the primer OP-Z01 represent the most distinct ones, therefore, these bands provide additional potentiality for discrimination among the studied genotypes and conifers species.

Table (5): Isomers of peroxidase and Adh enzymes (0/1) and their Rf value.

3.2.2. **Genotype identification by RAPD markers**

The RAPD assay permitted the identification of the six conifers under investigation by unique positive and / or negative markers, as well as the polymorphic markers, as recorded in Table (6) and Fig. (4). *Pinus halepensis* was characterized by the presence of the polymorphic markers with molecular size (521.2, 441.9 and 97.07 bp) obtained from the primer OP-F08 and the polymorphic marker (313.4 bp) obtained from the primer OP-C11. *Pinus canariensis* was distinguished by the absence of the negative unique marker (473.1 bp) revealed with primer OP-F01 and the presence of the polymorphic marker (97.07 bp) obtained with the primer OP-F08. However, *P.pinea* was poorly recognized by the presence of the polymorphic marker (364.7 bp) only as revealed by the primer OP-Z01. *Pinus roxburghii* was characterized by the presence of the polymorphic markers (453, 364.7 and 270.4 bp) all together revealed by the primer OP-Z01. On the other hand, each of *S.sempervirens* and *T.distichum* were highly discriminated from other conifers, as *S.sempervirens* was distinguished by the presence of the unique marker (587.1 bp) by the primer OP-F01, the unique markers (562.8, 366.3 and 341.2 bp) by the primer OP-F08 and the unique markers (838.8, 483.3 and 98.9 bp) out of the primer OP-Z01. Besides, eight polymorphic markers obtained by the primer OP-F08 (521.2, 443.2, 441.9, 343.1, 235, 212.2, 180.4 and 158.8 bp) provided additional potentiality for the discrimination of *S.sempervirens* from the other conifers. *Taxodium distichum*, as well, was highly differentiated by the presence of the unique marker (337.4 bp) out of the primer OP-F05, and the unique markers (235.5 and 219.5 bp) by the primer OP-C11. Moreover, the presence of the polymorphic markers (443.2, 343.1 and 235 bp) from the primer OP-F08 and the polymorphic markers (546.6, 453, 364.7, 270.4 and 269.6 bp) obtained from the primer OP-Z01 and the polymorphic markers (350 and 313.4 bp) recorded by the primer OP-C11 played a considerable role in discriminating *T.distichum*.

3.2.3 Inter Simple Sequence Repeats (ISSRs)

Five ISSR primers successfully amplified DNA fragments of the six conifers under investigation with total number of 81 fragments producing 38 polymorphic bands (7 unique + 31 non-unique) with 47.95% of mean polymorphism, as demonstrated in Table (8). Besides polymorphism range was recorded between 42.11% (primer A98) and 55.56% (primer HB12) and the range of DNA band size was between (120 – 1460) bp.

Table (8) and Fig. (5) illustrate that primer A98 produced 8 polymorphic bands (42.11% polymorphism) and 11 monomorphic DNA bands in the studied conifers, while 1 unique band was observed out of the polymorphic bands. Four unique bands (491, 436, 305 and 276 bp) were recorded in *P.halepensis*, other four unique bands (389, 303, 278 and 215 bp) were observed in *P.canariensis*, two unique bands (214 and 135 bp) were seen in *P.pinea* and one unique band (478 bp) in *P.roxburghii*. However, *S.sempervirens* and *T.distichum* did not record any unique band concerning for the primer A98. Moreover, *P.halepensis* did not show any non-unique polymorphic band with the primer A98.

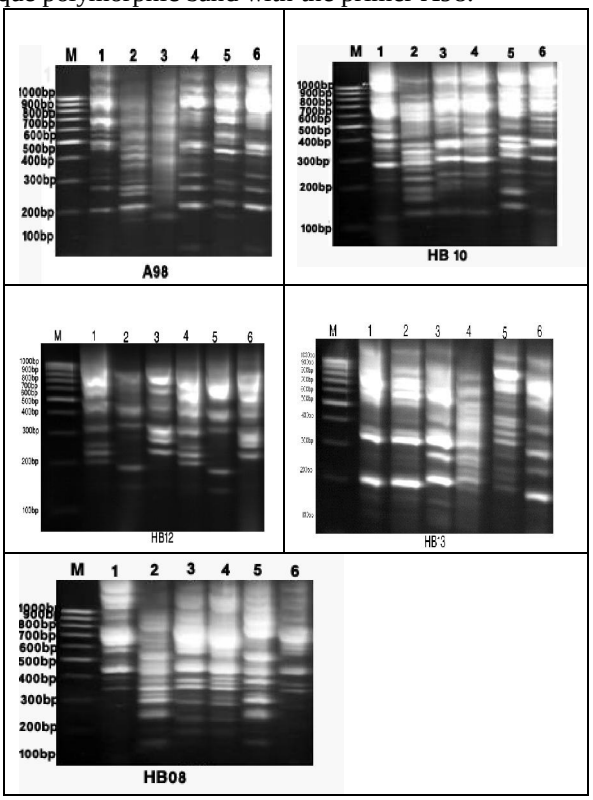

Fig. (5): ISSR profiles for the six conifers as detected with primers:OP-A98,OP-HB10,OP-HB12,OP-HB13, OP-HB08

Primer HB08 resulted in the amplification of twenty DNA fragments with molecular size range from 139 to 1460 bp, with nine polymorphic bands (45% polymorphism), two of them were unique (384 and 598 bp) in *P.roxburghii* and *T.distichum*, respectively. The primer HB 10 produced total of seventeen DNA fragments with molecular size range from 131 to 1288 bp, eight of them were polymorphic (47.06% polymorphism) with two unique DNA bands (256 and 1288 bp) considered as plant specific markers to *P.canariensis* and *T.distichum*, respectively.

Table (8): Type and number of amplified DNA bands generated by five DNA-ISSR primers used for the identification of the six conifers.

Primer code / Band type	A98	HB08	HB10	HB12	HB13	Total
Monomorphic	11	11	9	4	8	43
Unique	1	2	2	0	2	7
Polymorphic (non unique)	7	7	6	5	6	31
Total bands	19	20	17	9	16	81
Polymorphism (%)	42.11	45.00	47.06	55.56	50.00	Mean: 47.95
Fragment size range (bp)	134-1446	139-1460	131-1288	126-763	120-1018	

On the other hand, the primer HB12 resulted in nine DNA fragments with molecular size range from 126 to 763 bp, but did not produce any unique bands, only recorded five polymorphic bands (55.56% polymorphism). Besides, the ISSR profile generated by the primer HB13 (Fig. 5 and Table 8) produced eight polymorphic bands (50% polymorphism) out of them two bands were identified as unique (187 and 147 bp) both were noticed in *P.roxburghii*. The molecular size range generated by the primer HB13 was between 120 and 1018 bp

Each conifer subjected to this study could be discriminated from the others by ISSR-PCR specific markers, except *P.pinea* and *S.sempervirens*. *Pinus halepensis* was characterized by the presence of the unique band 491 bp (primer A98), *P.canariensis* was distinguished by the presence of the unique band 256 bp by the primer HB10. While *P.roxburghii* was discriminated by the unique band 384 bp (primer HB08) and (187 and 147 bp) generated by HB13 primer. Besides, *T.distichum* was distinguished by 598 bp unique band from HB08 primer and 1288 bp generated by the primer HB10

It is evident from Table (9) that the highest similarity coefficient values are (93.4%) between *P.canariensis* and *P.halepensis*, (91.2%) between *P.roxburghii* and*P.halepensis* and 91% between *P.roxburghii* and *P.pinea*. On the other hand, the lowest values are observed between *T.distichum* and *P.pinea* (78.7%) followed by *T.distichum* and *P.halepensis* (79%) and between *T.distichum* and *P.roxburghii* (79.7%).

Table (9): Similarity coefficient among the six conifers as estimated by ISSR analysis

species	*P.halepenses*	*P.canariensis*	*P.pinea*	*P.roxburghii*	*S.sempervirens*	*T.distichum*
P.halepenses	1.00					
P.canariensis	0.934	1.00				
P.pinea	.0.88	0.904	1.00			
P.roxburghii	0.912	0.885	0.910	1.0		
S.sempervirens	0.868	0.855	0.85	0.829	1.0	
T.distichum	0.790	0.840	00.878	0.797	0.865	1.0

3.3. The overall polymorphism detected by the biochemical and molecular markers:

The relationship among the six conifers based on the overall polymorphism detected by the biochemical assays (leaves protein and isozyme polymorphism) and the molecular markers (RAPDs and ISSRs) are presented in Table (10). The total produced bands were 190 out of all markers, 104 (77 non-unique polymorphic and 27 unique bands) were polymorphic bands with 54.74% polymorphism and 86 monomprphic bands. Peroxidase marker gave the highest proportion of polymorphism (100%) followed by protein marker (91.3%), while ISSR and RAPD marker resulted in lower propotion of polymorphism (46.91% and 37.9%), respectively and overall mean (54.74%) of polymorphism % out of the whole assays

Table (10): Polymorphism detected by each marker system in the six conifers

Marker number	Marker system		Monomorphic bands	Polymorphic bands	Unique bands	Total	Polymorphism %
1	Protein		2	18	3	23	91.30
2	Peroxidase isozyme		0	13	7	20	100.0
3	RAPD	OP-F01	9	1	1	11	
4		OP-F05	9	1	1	11	
5		OP-F08	7	6	3	15	
6		OP-Z01	7	5	5	17	
7		OP-C11	9	2	0	11	
	Total RAPD bands		41	15	10	66	37.9
8	ISSR	A98	11	7	1	19	
9		HB08	11	7	2	20	
10		HB10	9	6	2	17	
11		HB12	4	5	0	9	
12		HB13	8	6	2	16	
	Total ISSR bands		43	31	7	81	46.91
	Total number of bands		86	77	27	190	
	Mean polymorphism %						54.74

3.4.Genetic relationships based on protein, peroxidase, RAPD-PCR and ISSR-PCR analysis.

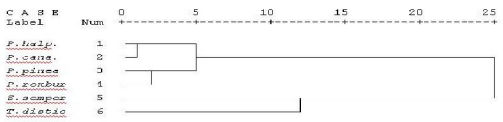
The matrix of similarity index for the six conifers under investigation is presented in Table (11). The maximum similarity coefficient value (91.8%) recorded between *P.halepensis* and *P.canariensis* followed by (91.1%) observed between *P.pinea* and *P.roxburghii*, then (90.5%) between *P. canariensis* and *P.pinea* followed by (90.0%) between *P.canariensis* and *P.roxburghii*. However, the lowest similarity coefficient value (75.3%) was noticed between *P.halepensis* and *T.distichum*. Similarity coefficient range value between *Pinus* species was observed between 91.8% (between *P.halepensis* and *P.canariensis*) and 87.7% (between *P.halepensis* and *P.pinea*), while similarity coefficient between *S.sempervirens* and *T.distichum* was 85.4%. The range of similarity coefficient between *S.sempervirens* and *Pinus* species was between 77.4% (with *P.roxburghii*) and 79.1% with *P.pinea*. On the other hand, the highest similarity coefficient value between *T.distichum* and *Pinus* species was 79.4 (with *P.canariensis*) and the lowest value (75.3%) with *P.halepensis*

Table (11): Similarity coefficient among the six conifers as estimated by protein, peroxidase isozyme, RAPD and ISSR analysis.

Species	P.halepensis	P.canariensis	P.pinea	P.roxburghii	S.sempervirens	T.distichum
P.halepensis	1.00					
P.canariensis	0.918	1.00				
P.pinea	0.877	0.905	1.00			
P.roxburghii	0.895	0.900	0.911	1.00		
S.sempervirens	0.784	0.779	0.791	0.774	1.00	
T.distichum	0.753	0.794	0.775	0.780	0.854	1.00

Data illustrated in Fig. (6) exhibit the dendrogram of the genetic distance between the six investigated conifers, they are grouped into two main clusters, at a distance of 25. The first cluster included *T.distichum* and *S.sempervirens* and the second cluster involved the four *Pinus* species which subdivided into two groups, at a distance of 0.5, the first group included *P.roxburghii* and *P.pinea* and the second group contained *P.canariensis* and *P.halepensis*.

Fig. (6): Clustering dendrogram of the genetic distance between the six conifers, based on proteins, peroxidase, RAPD and ISSR analysis data.



4. Discussion:

Characterization of the genetic diversity and examination of the genetic relationship among conifers are important for the sustainable conservation and increase use of plant genetic resources. In our study, Genetic polymorphism was investigated in six conifers representing four *Pinus*

species, i.e(P.halepensis, P.canariensis, P.pinea, and *P.roxburghii)which* belong to *family Pinaceae* and two members of family *Taxodiaceae, (Sequoia sempervirens and Taxodium distichum).* Genetic biochemical (proteins and isozymes), as well as molecular (RAPDs and ISSRs) analysis were investigated. Proteins and peroxidase banding patterns resulted in extensive polymorphism among conifers under investigation.

The needle leaves protein banding profile was separated using SDS-PAGE of the six genera and species of conifers. The highest number of bands was 16, detected in *Pinus roxburghii* while the lowest number of bands was 8, identified in *Taxodium distichum.*

The protein assay permitted the identification of only three conifers under investigation by unique positive and negative markers. In this regard, Piovesan, *et al.* (1993) stated that the genus *Pinus* has maintained a considerable homogeneity, may be attributed to speciation processes mainly due to gene mutations in which hybridization plays a major role.

In addition, isozyme profile permitted the identification of three conifers under investigation, *i.e. Pinus roxburghii*, *Sequoia sempervirens* and *Taxodium distichum* by the presence of two unique markers found in peroxidase isozyme with *P. roxburghii*, four with *Sequoia sempervirens* and absence of three bands and the presence of one with *Taxodium distichum* with absence of one unique band.

In this respect, González-Andrés, *et al.* (1999) could distinguish between *P.canariensis, P.halepensis, P.pinaster* and *P.pinea* by using *ACP*, *GOT* and *SOD* isozymes banding patterns. They found that *P.canariensis* and *P.pinea* had similarity level of 0.6, while *P.halepensis* presented the lowest similarity level with the other species.

RAPD assay permitted the identification of the six conifers under investigation by unique positive and / or negative markers, as well as the polymorphic markers. Our results revealed that the RAPD marker produced 66 bands with mean polymorphism 37.88%, out of them 10 unique markers were recorded across the six conifers under investigation, besides of 15 polymorphic markers. Each of *S. sempervirns* and *T. distichum* produced the highest unique markers (seven positive markers with *S. sempervirens* and three positive markers with *T. distichum*) followed by *P. canariensis* (one negative marker), while the other *Pinus* species showed no unique markers. In this concern, Cuesta, *et al.* (2010) postulated that stone pine (*Pinus pinea*), the exceptionally low genetic polymorphism of the species has been confirmed in studies applying different markers, such as isozymes, chloroplast and nuclear microsatellites and RAPD. Moreover, Klaus (1989) noted that *P.pinea, P.canariensis* share many cone and vegetative characters, while Frankis (1993) combined *P.canariensis, P.halepensis* in one subsection, *Pinaster*, but he still placed *P.pinea* in a separate subsection. However, Wang, *et al.* (1999) grouped *P.pinea* together with *P.canariensis* and *P.halepensis* in the same subsection.

ISSR results confirm the role of fragments polymorphism on conifers identification. The results were in harmony with those recorded by Wang, *et al.* (2009), and Wang, *et al.* (1999), since they concluded that the ISSR markers are believed to be distributed throughout the whole genome. Most of them may have no direct effect on morphological phenotypes because these DNA sequences are not amplified from functional genes. Also, results suggested the ISSR genetic diversity did not necessarily match the morphological trait difference among the used species (*Dendrobium*). Application of multiple DNA marker systems would help reveal more accurately the phylogenetic relationships among the species based on differentiation of their whole genome organization.

In this investigation, the observed polymorphism in different biochemical (proteins and isozymes patterns) as well as in molecular patterns (RAPDs and ISSRs) recorded with the six conifers, exhibited different similarities between some *Pinus* species which does not match those of taxonomy. This could be explained on the bases of adaptations to the local environmental conditions associated with selection processes through many generations or may be attributed to the occurrence of mutational events that alter the performance of genes encoding some isozymes as well as changes in the annealing site of a random primer. This suggestion is in agreement with Rottenberg, *et al*. (2000).

Newton, *et al*. (2002) postulated that pines, genetically were among the most variable of organisms and characterized by high variation both within and between populations, as indicated by assessments of both quantitative and isozyme variation. The high diversity generally recorded within populations of pines was attributed to reproductive characteristics such as wind pollination, high reproductive capacity, effective mechanisms of seed dispersal, and flexible mating systems which permit inbreeding and selfing in isolated trees. Pines were monoecious, and in most species of the genus, mechanisms of self-incompatibility appeared to be lacking. However, rates of out crossing were generally very high, which appeared to be mentioned by partial self-sterility.

Kusumi, *et al.* (2000) concluded that *Sequoia* were formed in a clade with *Metasequoia* and *Sequoiadendron*, while *Taxodium* formed another clade together while *Glyptostrobus*, both in the family *Taxodiaceae*.

On the other hand, Gadek, *et al*. in the same year (2000) related *Taxodium* and *Seqouia* to two subfamilies (*Taxodioideae* and *Sequoioideae*), respectively under the family *Cupressaceae*.

On the other hand, Liston, *et al.* (1999) found that Himalayan *P.roxburghii* was paraphyletic to the Asian and Mediterranean hard pines, and that the strong

morphological resemblance of *P. roxburghii* to *P.canariensis* has promoted the classification of the two taxa into the same subsection, *Canarienses*. Klaus (1989) suggested that *P.roxburghii* originated from Mediterranean ancestors of P. *canariensis* which reached the Himalayan region and led to the rise of *P. roxburghii.* However, Mirove (1967) suggested an eastern Asian origin of *P.roxburghii* from where it purportedly migrated to the Himalayas and extended to the west, hence he proposed the closely related *P. canariensis* reached to the canary Islands. Moreover, Liston, *et al*. (1999) concluded that *P.roxburghii* might represent an ancestral stock to the Eurasian hard pines.

It is necessary to search extensively at genome scale for more ISSR markers or molecular markers of other types for molecular diagnosis tool specific for additional conifers genus and species.

The ISSR markers reported in the present study will facilitate the understanding of inter- species gene flow, genetic structure of species, genetic diversity and evolutionary relationships in the conifers under investigation. Remaining challenges, as incorporating additional nuclear loci into the molecular analysis, comparing and combining the molecular results with morphology-based phylogenetic analyses.

In conclusion, the present data distinguished the genetic relationship between the six conifers under investigation and established the genetic similarities. In fact, both biochemical and molecular identification were useful in the discrimination between conifers, generally characterized by a high level of polymorphism.

Study on immune response of quail for avian influenza vaccines

M.A.saad, A.I.Abd-Elhady, A.EL-nagar

Central laboratory for evaluation of veterinary biologics Quail influenza
Saad940@yahoo.com

Abstract: This study was a trial to evaluate: The immune responses of quails vaccinated with common avian influenza (AI) commercial vaccines in Egypt The results revealed that: There were high to moderate levels of maternal immunity against AIV (H5N1and H5N2) on the 1st, 5th day of age and low levels on the 7th day of age. There was no significant difference concerning the immune response of H5N1 and H5N2 AI vaccines ($P < 0.05$) in vaccinated quails. Vaccination at 8-days of age with 0.5ml of vaccine, gave satisfactory titers, on the 3rd week post vaccination. By the 4th week post vaccination quails exhibited highest titers and continued to the 5th week post vaccination(age of slaughter or marketing of quail) against AIV.

Keywords: immune response avian influenza - vaccines.

1. Introduction:

Avian Influenza (AI) is a disease of poultry that has occurred worldwide over the past 100 years (Easterday et al., 1997). Two clinical forms are seen in the field: a mild disease affecting the respiratory, reproductive and or urinary tracts, and a severe systemic disease, causing high morbidity and mortality. AI viruses are classified as highly pathogenic (HP), mildly pathogenic (MP) and a non-pathogenic (NP) based on the mortality rates (Senne et al., 1986; US Animal Health Association (USAHA, 1994). Over the past decade, the emergent HPAI viruses have shifted to increased virulence for chickens. HPAI viruses typically produce a similar severe, systemic disease with high mortality in chickens and other gallinaceous birds (Swayne, 2007). 26 epizootics of HPAI have occurred in the world since 1995. The largest of these outbreaks has been the H5N1 HPAI which has caused problems in poultry and some wild birds in over 60 countries of Asia, Europe and Africa since beginning in 1996 (Maines *et al.*, 2005). In Africa, H5N1 HPAI cases approved in February 2006 in several countries. It began in Nigeria then other African countries including Egypt. (Swayne, 2008). On 17 February 2006, the Egyptian government confirmed that bird flu had broken out in the nation's poultry.

Quails are migratory game birds belonging to the same family as the domestic fowl (Weatherbee and Jacobs, 1961). *Sccharomyces cerevisiae* yeast has the ability to reduce the toxic effect of AFB1 in quail. It was also apparent that the higher the inclusion rates of SC in the diet of quail (2.5 mg/kg) the more the effective it is.(Mariam et al.,2010)

Highly pathogenic avian influenza (HPAI) virus subtype H5N1 has caused significant losses in Thailand's poultry industry since its initial detection in January 2004 (Tiensin *et al.*, 2005). Chickens and quail are highly susceptible to HPAI H5N1 infection; however ducks, considered more resistant, are probable "Trojan horses" or carriers (Hulse-Post et al., 2005; Tiensin et al., 2005).

AI virus was detected in quail and chickens muscles and organs by indirect immunofluorescent assay (Antarasena,. et al. 2006).
The HI test against AI showing positive results in quail sera collected random samples from Egypt. (Elmahdy et al. 2009).

A formalin-inactivated oil-emulsion vaccine was prepared from a high-growth H5N1/PR8 virus (Chen *et al.* 2005). Vaccine candidates of influenza A viruses of H5N1 subtype have been generated in several laboratories (Lu *et al.*, 2007). In the face of disease outbreaks in quail industry and the potential pandemic threat to humans caused by the highly pathogenic avian influenza viruses (HPAIVs) of H5N1 subtype, improvement in biosecurity and the use of inactivated vaccines are two main options for the control of this disease, for that we designed our present study to measure the immune response of quail to AI vaccines H5N1 and H5N2.

2. Materials and methods

1-Quails: two hundred and fifty, one day old quail were used in this experiment.
2-AI Vaccine: commercial AI H5N1 and H5N2 vaccines, used for vaccination of quail.
3-Serum samples: quail blood samples were collected and sera were separated to apply HI test.

4- AI antigen: local inactivated HPAI virus was obtained from CLEVB and used as AI antigen with a concentration of 4 HA in HI test for the tested serum samples.
5- HA haemagglutination test: HA test were carried out according to (Anon 1971) to estimate the HA titer of used antigens.
6- HI haemagglutination inhibition test: Was carried out according to (Takatsy 1956) the test was applied to quantify AIV antibodies in sera according to OIE (2008)

Experimental design

Experiment 1
Maternal immunity: fifty quails were selected for determination of maternal immunity that acquired from vaccinated parents by HI test.

Experiment 2
Immune response of the vaccinated quail:
200 Quails were used for Determination of the immune response of quails by vaccinated S/C with either inactivated oil-emulsion H5N1 or H5N2 vaccines. Commercially available oil emulsion vaccines were used: H5N1 (subtype, Re-1 strain - A/chicken / China, Puerto - Rico) and H5N2 (Subtype chicken / England, Mexico) of = 10^4 EID50 haemagglutination antigen content. The dosage was 0.3ml at age 4-days and 0.5mlat age 8-days (inoculate at two different sites) Blood samples were collected 1, 2, 3, 4 and 5 weeks post vaccination. The flocks were arranged as follows:
A- Vaccination at 4 days old with 0.3ml of vaccine.
B- Vaccination at 8 days old with 0.5ml of vaccine.

titer of 2^6 HA units/ml. and was used at a final

3. Results and Discussion

Table 1: Maternal immune wading in quails § acquired from vaccinated parents by AIV inactivated oil-emulsion vaccines H5N1 and H5N2.

Age of Quail	H5N1	H5N2
	HI	HI
1 day	5.3	4.8
5 days	4.4	4.3
7 days	4.0	3.6
10 days	2.9	2.8
14 days	2.0	2.0

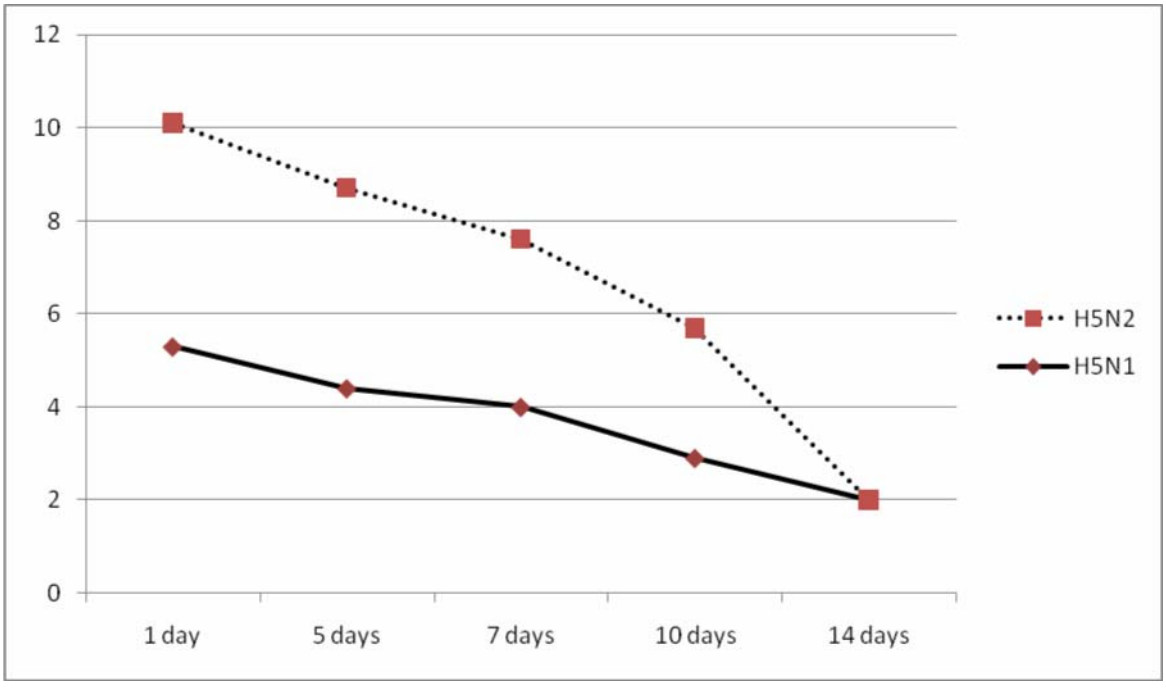

Figure 1: Maternal immune wading in quails § acquired from vaccinated parents by AIV inactivated oil-emulsion vaccines H5N1 and H5N2 .

Table 2: The immune response of quails vaccinated by AIV inactivated oil-emulsion vaccines H5N1 and H5N2 .

Group No.	Type of vaccine	Age of vaccine	Dose	HI titer post vaccination				
				1ST W	2ndW	3rd W	4th W	5th W
1	H5N1	4 days	0.3 ml	2.1	3.0	5.7	5.9	5.0
2	H5N1	8 days	0.3 ml	1.8	2.6	5.5	6.2	5.3
3	H5N1	4 days	0.5 ml	2.3	3.2	6.1	6.4	5.4
4	H5N1	8 days	0.5 ml	2.0	2.8	6.5	6.8	6.0
5	H5N2	4 days	0.3 ml	2.0	2.8	5.2	5.7	4.7
6	H5N2	8 days	0.3 ml	1.7	2.4	5.4	5.9	5.0
7	H5N2	4 days	0.5 ml	2.2	3.1	5.7	6.1	5.2
8	H5N2	8 days	0.5 ml	1.9	2.6	5.9	6.3	5.7

Now quails are raised commercially for meat and egg production and kept as pet birds and experimental birds in most parts of the world. (Lima et al., 2004). Quail are resistant to many diseases but they are susceptible to most naturally occurring viral diseases of chickens, especially when reared under poor management conditions. However the reports of the naturally occurring diseases are few when compared to those of chickens and this may be due to the fact that there are few quail farms (Ratnanohan, 1993). We have recently shown that quail are highly susceptible to infection with highly pathogenic H5N1 viruses isolated from geese. These viruses cause disease in quail; however, infected quail have a longer disease period than do chickens and thus are more likely to transmit the virus (Webster et al., 2003).

Table 1 and Fig.1 illustrated The results of maternal immunity,they show that:

1: There were high to moderate levels of maternal antibodies against AI (H5N1) and (H5N2) on the 1st and 5th day of age and low levels on the 7th day of age [HI mean values were 5.3, 4.4, 4.0, 2.9 and 2.0 (log-2) respectively] for H5N1. On the other hand, quails vaccinated by H5N2 at ages of one-day, 5-days and 7-days, were 4.8, 4.3, 3.6, 2.8 and 2.0 respectively (HI titer values).
2: After the age of 7 days the level of maternal immunity was greatly reduced and it was fade at the age of 14 days.
3: There was no significant difference concerning the immune response of H5N1 and H5N2 AI vaccines ($P < 0.05$).

Determination of immune response in quails vaccinated with inactivated oil-emulsion H5N1 and H5N2 vaccines Vaccination at 4-days old:

In one hand, Table 2 Showed that: H5N1 and H5N2 vaccination at 4-days of age (0.3ml of vaccine) resulted in positive antibody response on the 1st week post vaccination (HI titers were, 2.1 and 2.0 (log-2) respectively). The antibody response was gradually increased up to the 4th week post vaccination (HI titers were, 5.9 and 5.7, log-2 respectively).while at 4-days of age (0.5ml of vaccine) resulted in positive antibody response on the 1st week post vaccination (HI titers were, 2.0 and 1.9 (log-2) respectively) The antibody response was gradually increased up to the 4th week post vaccination (HI titers were, 6.4 and 6.1, log-2 respectively)

Vaccination at 8-days old:

On the other hand, Vaccination at 8 - days of age with 0.3ml of vaccine,Gave satisfactory titers, 3 weeks post vaccination (HITiters were, 5.5 and 5.4 (log2) respectively), but highest Titers were exhibited on the 4th week post vaccination (HI Titers were, 5.9 and 5.7 (log2) respectively) and then Continued to the 5th week post vaccination. While 0.5ml of vaccine gave satisfactory titers, 3 weeks post vaccination (HI Titers were, 6.5 and 5.9 (log2) respectively), but highest Titers were exhibited on the 4th week post vaccination (HI Titers were, 6.8 and 6.3 (log2) respectively) and then Continued to the 5th week post vaccination.

Our results pointed out that, vaccines do not sufficiently reduce the probability of infection up to 3

weeks post vaccination and this is indicated by the low HI titers. Although H5N1 or H5N2 vaccination at the age of 8- Days, gave protection 3 weeks post vaccination where, The titer ranged from 4.2 to 5.7 (log2), but maximum Levels of HI titers occurred 4 weeks post vaccination (4.6 to 6.1, log2) and continue with protective titer to five weeks of quail age (age of slaughter or marketing of quail) .Our results agreed with (Swayne, etal. 1999). Study The influence of vaccine strain and antigen mass on the ability of inactivated avian influenza (AI) viruses to protect chicks from a lethal, highly pathogenic (HP) AI virus challenge were they affect the immune response to AV vaccine, and also our results supported by (OIE 2008) which referred that the positive HI titer must be more than 4 log2 for AI.

Further studied needed by application of challenge test to estimate the vaccine efficacy in quails but these test need critical high registrations to use the virulent AV virus to apply these test. Our results suggested in regard to The immune response of vaccinated quails Against AIV.that The ideal age for quails Vaccination by AI vaccine is between 4 and 8-days of age, otherwise quails maternal immunity should be considered if they vaccinated at one-day of age. Quails one-day old of age which have low or no maternal immunity should be vaccinated at one-day old (with a dose of 0.3ml, H5N2), followed by a second dose (0.5ml) at 15-21-days of age.

The effectiveness of the available commercial vaccines in protection against the disease required. Two main categories for the control of this disease:

1: The use of efficient inactivated vaccines (targeted Control strategies).

2: Improved, strict and satisfactory biosecurity measures.

Modification of Silk for Improvement of Weighting and Properties

S.M.Gawish*, A.M.Ramadan, S.M.Abo El-Ola

Textile Research Division, National Research Centre, Tahrir Street, Dokki, Cairo, Egypt
*Samihagawish@yahoo.com

Abstract: Silk was modified by 2-hydroxy ethyl methacrylate (HEMA) and glycidyl methacrylate (GMA) and GMA/ derivatives to increase the weight, improve silk properties, antibacterial and fungicidal activities. Thus silk was grafted using a chemical method to different percentage add-on HEMA and GMA. Modified silk / GMA were further reacted with Diethylene triamine (DETA) at 85ºC for one hour to yield bactericidal and fungicidal silk fabrics. The weight of silk was increased and the properties were improved including moisture regain, crease recovery angles, abrasion resistance, whiteness and decrease of yellowness index. Characterization of modified fabric was done by FTIR, thermal gravimetric analysis (TGA) and SEM.
[S. M. Gawish, A. M. Ramadan, S. M. Abo El-Ola. **Modification of Silk for Improvement of Weighting and Properties.** Journal of American Science 2010;6(12):1515-1520]. (ISSN: 1545-1003). http://www.americanscience.org.

Key words: modified silk, chemical redox method, HEMA, GMA/derivatives, weighting moisture regain, crease recovery angle, abrasion resistance, whiteness, yellowness index, bactericidal and fungicidal activities.

1. Introduction

Silk is one of the most expensive fabrics. It has excellent properties such as soft, smooth handle, pleasant luster and gives brilliant color shades on dyeing. Silk is used for the apparel women dressing and it is a traditional dress in some countries like India, Japan, and Sudan etc.

Nowadays, grafting modification of silk[1-7] is considered an alternative procedure for the old weighting technique using inorganic salts [8] which was used for a long time ago with the purpose to increase silk weight resulting from the demumming process. Graft copolymerization of active vinyl monomers onto silk by different techniques acquired a great interest on an industrial scale by researchers all over the world to increase silk weight and improve its properties.

In addition to the well known chemical redox method [9-13] and silk irradiation using electron beam or γ–rays[14] followed by grafting, other methods were investigated using micro-wave irradiation [15] or plasma grafting techniques [16].

Thus, silk grafting is not only an effective method to increase the silk weight but it is an excellent method for improving silk properties such crease recovery angle, abrasion resistance, photo yellowing, dimensional stability and inducing antimicrobial activity for biomedical applications.

In the present article, silk fabric was grafted by the chemical redox method with the aim of weighting, improving silk properties and inducing antimicrobial activity to the fabric. For this purpose ammonium persulfate (APS) was used as initiator followed by grafting GMA or HEMA. GMA was reacted with DETA to produce silk/GMA/DETA or silk/HEMA fabrics. Grafted silk fabrics were characterized by FTIR, TGA and SEM. The properties of silk /HEMA were evaluated including moisture regain, crease recovery angle (dry and wet). Abrasion resistance, whiteness and yellowness index, which were improved. In addition silk/ GMA/ DETA had imparted bactericidal and fungicidal activities to the fabric.

Experimental

2. Materials

Egyptian plain construction silk fabric (63 gm/m^2) was scoured by 2g/1 of monionic surfactant solution at 50ºC for one hour. The silk fabric was thoroughly washed with warm water, then with cold water and finally squeezed and air dried.

Reagents

2-hydroxy ethyl methacrylate (HEMA) and glycidyl methacrylate (GMA), were purchased from Aldrich Co. and were used without further purification. Potassium persulfate (PPS), ammonium persulfate (APS), copper sulfate (CuSo4, 5 H2O), Diethylene triarnine (DETA) and acetone were all analytical grade reagents.

Polymerization procedure

A graft coplymerization reaction was carried out by treating silk fabric with a solution (2% w/w) of PPS or APS for 20 minutes at room temperature. The fabric was removed, thoroughly washed with distilled water, squeezed and dried at room temperature.

Silk fabric pretreated with (PPS or APS) were introduced into a stoppered Erlenmeyer flask containing 100 ml of the solution. The solution consisted of water, monomer and copper sulfate. The stoppered flask was kept in a thermostated shaking water bath at the desired temperature during the polymerization reaction. After a desired time, the reaction mixture was then washed several times with warm water and then with acetone , dried in oven at 105ºC for one hr and cooled to room temperature in a desiccator until constant weight. The graft yield was calculated as follows.

$$\% \text{ Graft yield } (G^o) = \frac{W - W^o}{W^o} \times 100$$

Where W is the weight of grafted silk sample and Wº is the weight of original silk fabric.

Grafting silk with GMA derivatives

Silk was grafted with GMA using the previous conditions and gave a fabric of the following composition: silk/109.7 GMA. Then it is allowed to react with DETA solution at a liquor ratio 1:50 (the solution mixture is 30 ml distilled water and 20 ml DETA) in an alkaline medium (addition of 1gm pyrophosphate). The reaction temperature was adjusted at 85ºC for one hr. The dry weight increase of the fabric was determined and the fabric was of the following composition:
Silk/109.7% GMA/7.7% DETA

Measurements

FTIR Spectroscopy

The FTIR spectrums of the silk fabrics were recorded on a Pirken Elmer 781 Infrared Spectro-photometer, as KBr disks.

Thermogravimetric analysis

Thermogravimetric analysis TGA was carried out using Pirken Elemer 7 Series instrument. The samples were placed on an aluminium holder and covered with gold. The rate of heating was adjusted at 10ºC/min. The thermograms were recorded from 50ºC to 600ºC under normal atmosphere.

Crease recovery angle measurement

The crease recovery angle of silk was measured by an iron recovery apparatus (Type FF-07 Metrepex) for 10 min crease period. The sum of crease angles of the warp (W) and weft (F) directions were measured.

Abrasion resistance measurement

One hundred fifty cycles were used for each fabric sample using the Universal Textile Abrasion Tester (Custom type, ASTMD). The percentage weight loss was determined.

Yellowness and Whiteness Indexes

The yellowness and whiteness indexes of silk fabric were measured using Erichsen Model 299/300, Erichsen GMBH and Co, Germany.

Antimicrobial activity

Antimicrobial activity was done by the diffusion disc method. A sample of the fabric is placed in a Petri dish containing solid bacterial medium (nutrient agar broth) or fungal medium (Doxs medium) which has been heavily seeded with the spores suspension of the tested organism. After inoculation, the sample is incubated at 37ºC for 24 or 48 hrs. The diameter of the clear zone of inhibition surrounding the sample is taken as a measure of the fabric inhibition action against the particular test organism[18-21].

Scanning electron microscopy

SEM micrographs were done on JEOL Model JSM-T20 instrument operating at 19 KV Photos which were prepared at a magnification range 2500X. The samples were placed on aluminium holder and covered with gold.

3. Results and Discussions

Effect of cupric ions concentration

The effect of copper sulfate concentration on the percentage graft yield of HEMA onto silk fabric is shown in Figure1. It was observed that the presence of cupric ions played a significant role in increasing the grafting reaction. An increasing in the graft yield was achieved when Cu^{2+} ion concentration increased gradually and reached 100% at 0.1 m.mol/1. The presence of Cu^{2+} ion caused an accelerating effect on the decomposition of PPS and by further increasing of Cu^{2+} concentration, the graft yield became constant.

Effect of HEMA concentration on the graft yield

The effect of HEMA concentration on percentage HEMA graft yield onto silk fabric is shown in Figure 2. It was observed that the percentage graft yield increases by increasing the HEMA concentration to 1.2×10^{-4} mmol/1 and attains a corresponding graft yield of 78%.

FTIR Study

FTIR were done for the degummed silk Figure 3 (a) and for the modified silk ie silk/GMA (b), silk/GMA/DETA (c) silk/ HEMA (d).

In the spectrum (a) the ungrafted silk[17] shows the absorption bands at 1516 and 1647 cm^{-1} assigned for=C=O stretching of amide I and amide II respectively. The peaks at 2925 and 3301 cm^{-1} are attributed to the C-H stretching and N-H stretching deformation.

In case of spectrum (b) for grafted silk, it revealed new absorption bands of GMA-grafted silk at 1151 cm^{-1} which is attributed to C-O stretching and at 1734 cm-1 which is due to C=O stretching of ester groups and increase absorption bands of epoxide group at 1261 cm^{-1} and appearance of extra bands at 906 and 847 cm^{-1}. In case of spectrum (c) silk/GMA/TETA the appearance of the bands at 906 and 847 cm^{-1} which correspond to the unreacted epoxide group. For spectrum (d) silk/HEMA, it reveals the same previous ester bands and a sharp peak at 3296 cm^{-1} corresponding to the hydroxyl group of HEMA.

Effect of grafted HEMA on crease recovery angle

The result of this study revealed that both dry wet crease recovery angles were improved due to grafting of silk fabric with HEMA, even at low graft yield which agree with our previous work [1]. Thus as shown in Table 1, dry crease recovery angles increased from 159º to 198º (29.3% HEMA) and then slightly decreased to 191º as the graft yield increases to 35.5% of HEMA, which may be attributed to steric hindrance.

The dry crease recovery angles of silk were improved due to grafting of silk by HEMA even at low HEMA graft yield, which is shown in Table 1.

The wet crease recovery angles (wetted in 1% nonionic detergent and then well squeezed) increased from 106ºC for the ungrafted silk to approximately mean constant value of 119ºC for all the HEMA graft yield (9.48 to 35.5% HEMA) i.e. increase grafting has the same effect on the wet crease recovery angles.

Table 1. Effect of grafted HEMA on the dry and wet crease recovery angles of silk.

HEMA Grafted Silk %	Dry Crease Recovery Angle (W+F)º	Wet Crease Recovery Angle (W+F)º
Zero	159	106
9.48	183	115
15	189	121
29.3	198	122
35.5	191	116

Effect of grafted HEMA on the abrasion resistance of silk fabric

Grating of silk by HEMA increases the abrasion resistances as shown in Table 2. It was observed that the percentage weight loss decreases from 11.59 for the control silk fabric (ungrafted) to 1.25% for 35.5% HEMA grafted silk fabric. As a result of grafting, the percentage weight gains by grafting compensate the percentage abrasion weight loss. As a conclusion grafting of silk fabric by HEMA leads to improvement of its abrasion resistance.

Table 2. Effect of grafted HEMA on the abrasion resistance of silk fabric.

HEMA Grafted Silk%	Weight loss%
Control sample	11.59
9.48	7.26
15	3.5
29.3	2.4
355	1.25

Yellowness and Whiteness Indexes

It is shown in Figure 4 that the photo yellowing index of modified silk fibers is decreased from 14 (ungrafted silk) to 9 for (20% grafted HEMA). The reverse is clear with the whiteness since the whiteness index increases from 12.5 (ungrafted silk) to 19 for (35.5% grafted HEMA). Therefore it can be deduced that grafting silk with HEMA reduced the native silk yellowing and thus protected silk against sunlight damage.

Moisture Regain

Table 3 shows that the percentage moisture regain increased by increasing HEMA yield induced by grafting silk, i.e. it increased from the 7.3% (blank silk) to 8.31% (for 15% grafted HEMA). This can be attributed to HEMA itself as it is contains hydroxyl groups grafted in its chemical structure, which are hydrophilic in nature and consequently increase moisture absorption of silk.

Table 3. Effect of percentage grafted HEMA on the moisture regain of silk.

Grafted HEMA %	Moisture regain%
Zero	7.3
9.48	7.52
15	8.31

Thermo gravimetric analysis TGA

TGA Study Table 4 and Fig.4 revealed that grafted silk fabric with (silk/108.6% GMA/7.7% DETA is slightly increased at 374ºC to 600º. On the other hand the grafted silk fabric of composition 29.3% HEMA, its thermal stability slightly decreased than that of silk at temperature beyond 250ºC to 600ºC.

SEM

SEM micrographs of ungrafted and grafted HEMA 35.5% silk fabrics are shown in Figure 6 (a,b). The ungrafted silk fabrics (a) has a smooth surface compared to that of silk/HEMA grafted fabrics (b) which shows a large amount of side chains, confirming the grafting of silk.

Antimicrobial activity

The modified silk fabric of composition silk/109.6% GMA/7.7 DETA showed antimicrobial activity against *Escherichia* Coli (G^-) and Staphylococcus *Aureus* (G^+). Table 4 shows that the inhibition zones were 25 mm and 28 mm/cm fabric respectively for 24 hrs incubation. Also the same fabric gave fungicidal activity against *Candida Albicans and Saccharomyces Cereviseaes* and the inhibition zones were 24 and 26 mm/cm fabric respectively for 24 hrs incubation. Ungrafted Silk fabric was inactive against the above microorganism. These findings support the mechanism of the antimicrobial action whereby a hydrophobic polycationic chain penetrate bacterial cell membranes/ walls and fatally damage them [22-23]. The bactericidal modified silk prepared are active not only to pathogenic bacteria but to fungi as well.

Table 4. Effect of percentage grafted silk on the inhibition growth of bacteria

Samples	Inhibition Zones Diameter (mm/cm sample)							
	E. coli (G-)		S. aureus(G+)		C. albicans (Fungus)		S. cereviseae (Fungus)	
	24 h	48 h	24 h	48 h	24 h	48 h	24 h	48 h
Grafted silk	25	25	28	28	24	24	26	26
Blank	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

Grafted silk: 109.6% GMA/7.7% DETA; G: Gram reaction.

Table 5. Thermal Gravimetric Analysis (TGA) for grafted & native silk.

Temperature °C	Silk control	Silk/29.3% HEMA (2)	Silk/109.6% GMA/7.7% TETA (3)
	Residual weight %		
200	94.917	95.325	93.386
250	93.568	93.904	91.227

Abstract: Aim :Different bone resorption levels effect, and better understanding of the effect of implant design parameters such as implant length on the stability of implants, stress values and distribution in surrounding bone are targeted in this study. **Materials and Methods**: Nine cases (implant-bone conditions) were numerically analyzed in 3D by Finite Element Method (FEM). Three bone levels were tested versus three implant lengths, while one type of loading was applied. **Results** showed that implant stability decreases as bone level decreases. The level of instability depends on implant design parameters. Bone stresses increase as bone level decreases with varying values depending on implant parameters. Approximate design curves were obtained.

Key words: Bone resorption ,implants,

Introduction:

The resorption of the dental bones after the dental implant surgery is one of the main factors that lead to biological and/or mechanical failure of implant-supported dental restorations.

From the biomechanics point of view, bone resorption decreases the bone density, therefore leading to the reduction of the overall stiffness of the bone. This could worsen the stress/strain distribution and the bone's role as the support to the implant, and in some cases, cause bacteria to be trapped in the resorbed notch area, therefore further worsening the resorption phenomenon. Clinically, two factors are primarily identified and associated with the incidence of bone resorption: bacterial infection due to the plaque in the bone/implant interface; and occlusal overload in the newly formed bones in the gap between the implant surface and the hosting bone, thereby damaging mineralized cellular tissues and their responses, thus preventing proper osseointegration, Daniel et al., (2009).

The exact reason for bone resorption varies between patients and has not been pinpointed yet. In general, the crestal bone level remains more or less the same and does not change much. Nevertheless, several literature studies have reported the marginal bone loss following the dental implantation surgeries, Nowzari et al., (2006). It was reported the alveolar bone loss occurs at an average rate of 0.17mm per year after implantation, Corn et al .,(1989). While Kol et al (2003);Nowzari et al .,(2006) reported the alveolar bone loss between 0.2 and 0.4mm over the first twelve months of implantation, followed by an additional 0.1mm bone loss between months 12 and 18.Overall, it can be seen that the average dental bone loss due to resorption is approximately around 0.2-0.4mm over the first twelve months, and can be said to reach a more stable status after months 12 to 18. Clinically, the bone resorption usually occurs in the cortical region surrounding the neck of the implant. Micro-damage and macro-damage may be differentiated in such construct of artificial (implant) and natural (bone) biomaterials. A certain level of micro-damage in bone tissues could promote positive bone remodeling, while excessive micro-damage may lead to certain local micro-cracking of mineralized tissues and the loss of bone strength, consequently weakening the implantation as a whole. Thereafter, the damage could reduce the magnitude of stress and strain induction in such bone tissues. Bone remodeling on the other side is a damage repair process, Li et al.,(2007). Bone resorption can therefore be viewed as the result of excessive damage in the bone tissues, where the damage takes place at a rate too rapid for the bone to repair and remodel, McNamara et al.,(1997).

Currently, placement of dental implants is a gold standard for replacement of missing teeth. Although successful clinical treatments by dental implants have

been reported Andersen et al.,(2002). failure of osseointegration still sometimes occurs Chee and Jivraj (2007). In contrast to natural teeth, there is no periodontal ligament between dental implants and their surrounding bone. The periodontal ligament acts as a shock absorber between a root and surrounding bone and it also contains mechanoreceptors.
Without the periodontal ligament,
mechanoreceptors will also be absent. The absence of mechanoreceptors results in poor detection of bite forces with small magnitudes.
This subsequently increases the tendency of occlusal overloading, which can cause peri-implant bone loss and implant failure, Kim et al.,(2005). When dental implants are used, it is therefore advisable to remove the sources of occlusal overloading as much as possible.
The Finite Element Method (FEM) is frequently used to determine stresses in bone around dental implants, Dejak and Mlotkowski(2008). Complex FE analysis methods such as the FE contact analysis can be very beneficial for modeling different clinical situations,Lin et al.,(2008).
Modeling of a bone resorption level problem, can actually be done by employing FE contact analysis. With having the maxilla, mandible, periodontal ligament and all teeth placed in the actual positions. The main reason may be that the FE contact analysis is expensive since it needs both large human and computational resources. Nevertheless, studies of bone resorption levels by experiments, both in humans and animals, are even more difficult and more expensive. In fact, some information, such as stresses in human bone, can be very difficult to obtain from experiments. To obtain stresses in bone from experiments, strains in bone must be first measured and, after that, stresses can be computed from the measured strains. The measurement of strains in bone is complex and can be quite expensive. The difficulties in performing experiments discourage studies of premature contacts with varied parameters, Takayama et al.,(2001)

2.Material and Methods:

2.1.Materials:

2.1.1.Implant designs:

Fixed implant diameter of 3.9 mm, and three different implant lengths: 9, 11 and 13 mm were modelled. Vertical load of 100 N perpendiculars in the middle for implant head top surface and coincident with bone (cortical and spongy) centreline were applied. Cortical and spongy bones were modelled as two co-axial cylinders of 24 and 22 mm diameter, and 16 and 14 mm height respectively. Where cortical bone cylinder is hollow, and has a constant thickness of 1 mm.

2. 2. Methods:

2.2.1.Experimental design

-Three different bone resorption levels at: 0, 2, and 4 mm were studied.
-Four types of stresses: Tensile stress, Von Mises stress, Compressive stress and Shear stress were obtained and focused by this study.
-The modulus of elasticity and possion ratio for the cortical and spongy bone besides the titanium implant was provided to the F.E.package,Table (1).
-Boundary condition was just supporting the bottom level of the cortical bone cylinder.
-The solid modeling (Figure 1) and finite element analysis were performed on a personal computer Intel Pentium IV, processor 2.8 GHz, 1.0GB RAM. The meshing software was ANSYS version 9.0 and the used element in meshing all three-dimensional models is 8 nodes Brick element (SOLID45), which has three degrees of freedom (translations in the global directions) Peter Kohnke (1994)
Figure (2).

Table 1. Material properties used in the analysis

Material	Modulus of Elasticity (MPa)	Poisson's Ratio
Cortical bone [Ishigaki etal.,2003]	14,500	0.323
Spongy bone [Caglar etal.,2006]	1,370	0.3
Titanium [Mellal etal.,2004]	110,000	0.3

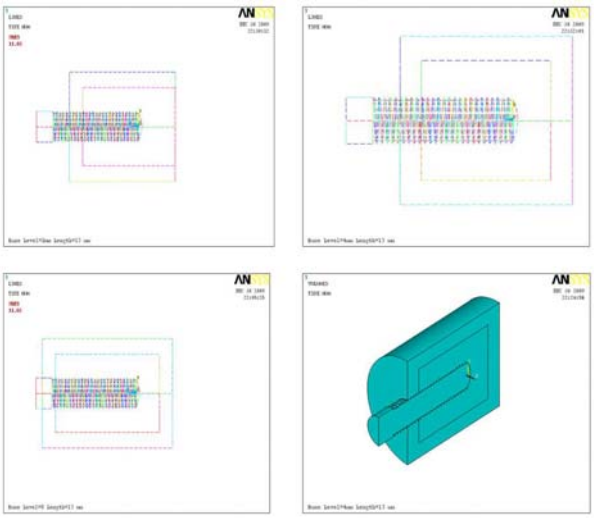

Figure 1: Different levels of bone resorption (screen shots from FE package)

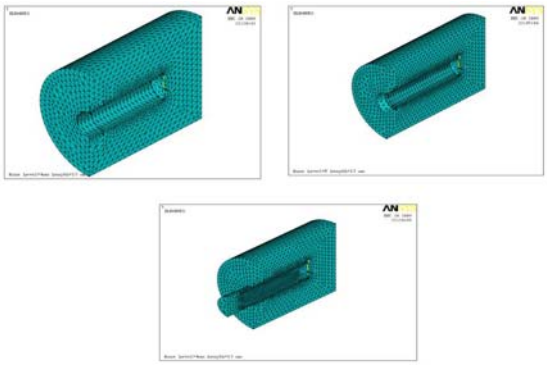

Figure 2: Meshed models for different bone resorption level

3.Results:

3.1. Running the F.E. package for the nine planned cases

This resulted in tons of data, and screen shots for the detailed analysis.

Figure(3)showed the maximum tensile stress generated on the 13mm implant at resorption level of 4mm. The maximum stresses were localized at implant-cortical bone interface. Generally all cases showed safe implant stresses levels, therefore, no further demonstrations for implant results presented in this study.

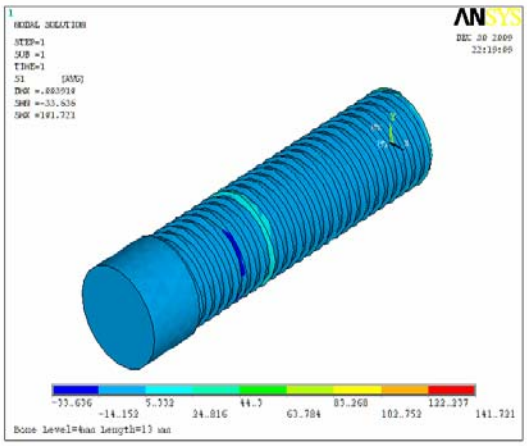

Figure 3: Maximum tensile stress in 13mm implant
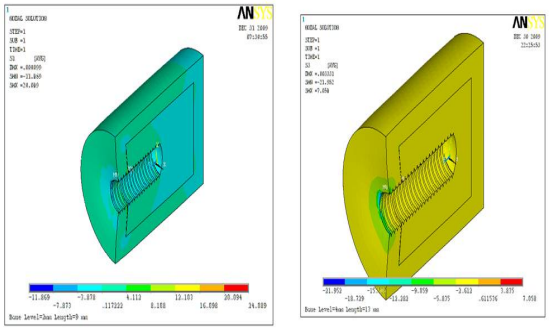
length, bone level 4mm

3.2. Bone stresses distributions and levels:

Bone stresses distributions and levels resulted on fixed stresses distribution where the maximum stresses were found at cortical bone interface with the implant (Figure 4).



(a) **(b)**

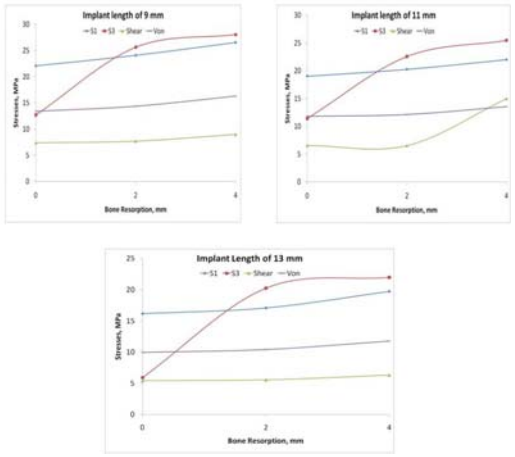
(a) 9mm implant length / 2mm bone level Maximum tensile Stress

b) **13mm implant length / 4mm bone level Maximum compressive Stress**

Figure 4: Spongy and Cortical bones stresses distribution

3.3.**Comparing stresses values with different resorption levels** :

This comparison could lead to approximate design curves, and solid conclusions. Figure (5) showed these comparisons between bone maximum tensile, maximum compressive, shear, and Von Mises.



Bone maximum stresses are generally increased with bone resorption level increase

Figure 5: Comparison between the nine cases

4.Discussion:

Consistently, the most prominent stress peaks occured in the bone (either cancellous or compact) near the protruding part of the stem. The values were probably under-estimated, since slip might occur between implant and tissue - contrary to the models' assumptions-thus at the least reducing amount of load transmitted by shear and tension. The resulting compressive stressed in the mandible were still locally approaching the upper limit of temporarily-acting physiological stresses, Borchers and Reichart(1983).

Crestal bone resorption primarily occurred during the first 4 weeks after uncovering, and although the cellular mechanism has not yet been identified, the micro-gap elicited an inflammatory response and subsequent bone loss, Xavier et al.,(2006). Pattern of stresses showed the distributions of stresses within the implant and the bone highlighting the location of the maximum and minimum values. An increase of all types of stresses occurred with higher bone resorption proportionate to degree of resorption. The compression stress showed an increased stress more than the others. For all bone levels the locations of maximum stresses were the same. On the other hand increasing implant length (in other words implant side area) ensured more stable fixation, and less stresses values which was preferred for weak bone patients. All stresses types could be said that it increased linearly with resorption level except maximum compressive stress (S_3). Which dramatically increased, by 100 to 400%, when resorption level increasing from zero to four millimetres.

Conclusions:

In the present study, the influence of a premature contact on stress and strain distributions in bone around an STDI was investigated. Bone resorption increased stresses for both implant & bone with all types of stresses namely, tension, Von Mises, shear & compression; with the later showing maximal increase. The increase of compressive stress in the bone showed more than one hundred percent increase. The location of the maximum stresses in the bone was the same for all levels of resorption in all implant designs. The increase of the implant lengths reduced the rate of increase in bone stresses with increasing bone resorption.

Diagnosis of Egyptian Bovine Meat Borne Zoonosis

Nawal, A. Hassanain; Mohey, A. Hassanain; Raafat, M. Shaapan; Hassan, A. Fadaly and Ashraf, M. Barakat

Department of Zoonotic Diseases, National Research Center,
nnawalah@yahoo.com

Abstract: Food borne zoonoses have a major health impact in both industrialized and developing countries. Meat might be infected with some bacterial and parasitic agents; that could be threatening on human health. One hundred and eight meat samples (20 buffaloes and 88 cows) were collected from different Cairo abattoirs and examined parasitologically and bacteriologically. Results showed that 16.67% and 34.26% of the examined meat samples were infected with bacteria and parasites, respectively. The bacterial isolates were non typhoid *Salmonella* (50%), *E. coli* (38.89%) and *Mycobacterium bovis* (1.11%). Three out of the *E. coli* isolates (16.67%) were identified as *E. coli* O157:H7. The liberated parasites were *Cysticercus bovis* (51.35%) and *Toxoplasma gondii* (48.65%). ELISA results showed that seroprevalence of toxoplasmosis was 47, 22.7 and 38.42% in human, cows and buffaloes, respectively. The immunoreactive profiles of *C. bovis* (167.82, 137.32, 88.839, 66.859, 59.851, 54.660 and 48.480 KDa) and *T. gondii* local tachyzoite (158, 111, 102, 86, 55 and 33 KDa) antigens probed with rabbit hyper immune serum showed one immunoreactive band at 55 KDa. While those of *E. coli* (182.01, 144.90, 72.558, 60.324, 28.312 and 18.392 KDa) and non typhoid *Salmonella* (91.967, 60.955 and 20.031 KDa) antigens displayed one common immunoreactive band at 60 KDa. It can be concluded that although immunoblotting help in identification of strains and detection of common cross reactive epitopes between different pathogens, there still exist many challenges and opportunities to improve the current technology of food pathogen detection.

Keywords: Meat borne, human health, parasites, bacteria, ELISA, SDS-PAGE, immunoblotting.

1. Introduction:

Food borne diseases continue to be a major public health problem and constitute an important cause of morbidity and mortality in both developed and developing countries. The annual incidence of some 1.5 billion episodes of diarrhea in children less than 5 years of age, and the more than 3 million resultant deaths are an indication of the magnitude of the problem (NIH, 2006). Most of these diseases are infections caused by a variety of bacteria, viruses and parasites (Smith, 2003).

Meat is an important source of protein and a valuable commodity in resource poor communities. In many developing countries, there is lack of appropriate slaughtering facilities, unsatisfactory slaughtering techniques and slaughtering places are frequently contaminated and may not be protected against dogs, rodents and insects. Meat products coming from such conditions are often deteriorated due to bacterial infection or contaminated, which may cause food poisoning or diseases in consumers. Moreover, in many developing countries, regulations concerning meat inspection and/or control are inadequate or non-existent allowing consumers to be exposed to pathogens including zoonotic parasites (Joshi et al, 2003).

In many countries of the world, bacterial food borne zoonotic infections are the most common cause of human intestinal disease **(**Thorns, 2000). Salmonellosis is the most common food borne bacterial disease in the world. *Salmonella* is a significant pathogen for food-producing animals and these animals are the primary source of salmonellosis. It is estimated that herd prevalence varies between 0% and 90%, depending on the animal species and region (Plym and Wierup, 2006). Shiga toxin-producing *E. coli* (O157: H7) usually do not cause disease in animals but may cause watery diarrhea, hemorrhagic colitis, and/or hemolytic uremic syndrome in humans. Cattle and other ruminants are the most important reservoir of zoonotic *E. coli* O157, which are transmitted to humans through the ingestion of foods or water contaminated with animal feces (Fairbrother and Nadeau, 2006). Mycobacterium bovis infections are of major importance in many developed and developing countries. Transmission of *M. bovis* can occur between animals, from animals to humans and vice versa and rarely, between humans. As with *M. tuberculosis*, transmission is most common by the aerosol route and also through the ingestion of milk and meat from infected animals. Infection acquired

through ingesting *M. bovis* is more likely to result in non-pulmonary forms of disease (Oloya et al., 2007).

Parasitic food borne diseases remain a major public health problem affecting hundred millions of people and animals, particularly in tropical developing countries (Tagboto and Townson, 2001). Bovine cysticercosis is a zoonosis caused by the larval stage (cysticercus) of the human tapeworm *Taenia saginata*. Humans get infected by eating raw or undercooked meat containing viable cysticerci. They penetrate the intestinal wall and invade subcutaneous tissue, brain, eye, muscle, heart, liver, lung, and peritoneum. Bovine cysticercosis occurs world-wide, but is at particularly high prevalence in Africa (Eddi et al., 2003). Meat borne toxoplasmosis in humans may result from ingestion of tissue cysts contained in meat of many different animals (Tenter, 2009). Up to 50% of *T. gondii* infections are transmitted by ingesting undercooked meat, making toxoplasmosis one of the most clinically significant food borne diseases in pregnant women (Ogunmodede et al., 2005).

The types of food borne diseases are constantly changing. A century ago; typhoid and Cholera were common food borne diseases. Improvement in food safety as pasteurization of milk, safe canning and disinfection of water has conquered those diseases. Today new food borne diseases took their place as *Salmonella Enteritidis*, *Campylobacter and E. coli* 0157: H7. In future, other diseases; whose origin is currently unknown may turn out to be related to food born infections. So, in this investigation we shall try to diagnose bovine bacterial and parasitic meat borne infections common in Egypt.

2. Material and Methods

1. Sample collection:

a. Meat samples: One hundred and eight cattle meat samples (20 buffaloes and 88 cows) were collected from different Cairo abattoirs and subjected for bacteriological and parasitological examination.

b. Blood samples: Two hundreds, 20 and 88 blood samples were collected from the contact persons, the investigated buffaloes and cows, respectively and used for the determination of the prevalence of *T. gondii* infection.

2. Bacteriological meat examination:

Samples were taken from the infected lymph nodes, lungs, liver, spleen and kidneys of the infected animals (buffaloes and cows) and inoculated on different bacteriological media {nutrient agar, MacConkey agar, blood agar, Salmonella Shigella (SS) agar, Lowenstein-Jensen}. Samples were also enriched with tryptone soya broth containing novobiocin and sub cultured on sorbitol MacConkey agar for isolation of *E. coli* O157. The inoculated plates were incubated at 37°C for 48hr but cultures on Lowenstein-Jensen were incubated up to 8 weeks. Suspected colonies appearing on the different media were identified according to Holt et al. (1994) and Roberts et al. (1991) for *Mycobacteria*. The recovered *Salmonella* isolates were identified serologically using the diagnostic polyvalent and monovalent antisera according to Kauffmann (1972). *E. coli* O 157 suspected colonies were tested by the *E. coli* O157:H7agglutination latex test (Oxoid).

3. Parasitological meat examination:

a. Cysticercus bovis cysts were collected from liver, heart and masseater muscles of infected cattle.

b. *T. gondii* local isolate was isolated according to procedures described by Dubey and Beattie (1988) after many trials of feeding 20 kittens with 250g meat samples from cattle carcasses and their feces examined daily for identification of *T. gondii* oocysts using concentration floatation technique with saturated NaCl solution (sp gr. 1.15). Sporulation of the recovered *T. gondii* oocysts were done and mice were experimentally infected with the recovered sporulated oocysts by oral inoculation (1000 oocysts / mouse) and After 6 - 8 days, the peritoneal exudates of these injected mice were examined to obtain the tachyzoites of *T. gondii.*

4. Preparation of parasitic and bacterial antigens:

a. *C. bovis* antigen: Crude whole cyst antigens were prepared by homogenization of cysts in phosphate buffer saline (PBS) and centrifuged at 10,000 g for 30 min. following the method of Cheng and Ko (1991). The supernatant was collected and its protein content was determined by the method of Lowry et al. (1951). **b. *Toxoplasma gondii* antigen**: Local isolate antigen (LA) of *T. gondii* tachyzoites was prepared using the method described by Waltman et al. (1984). Briefly, tachyzoites were repeatedly freezed and thawed to rupture the parasite wall, sonicated and centrifuged at 12,000 rpm for 45 min at 4°C. The supernatants were separately collected and its protein content was determined by the method of Lowry et al. (1951).

c. *E. coli* and *Salmonella* antigens: Whole cell protein antigens of the isolated and identified *E. coli* and non typhoid *Salmonella* from meat samples were prepared according to Khan et al. (1996). Overnight bacterial culture of each strain in brain heart infusion broth was harvested by centrifugation; washed with phosphate buffer saline (PBS), pH 7.2 and resuspended in sample buffer (6.25 mM Tris {pH 6.8}; 2% SDS; 5% B-Mercaptoethanol; 10% glycerol

and 0.002% bromophenol blue). The sample was boiled in a boiling water bath for 10 min. Protein concentration was determined according to Lowry et al. (1951).

5. Elisa:

The optimum antigen, serum and conjugate concentrations were determined by checkerboard titration and test procedures were carried out according to Lind et al. (1997) with little modifications. The cut off values of optical density (OD) were calculated according to Hillyer et al. (1992).

6. Rabbit immunization:

Two white New-Zealand rabbits were immunized with 400 µg protein per rabbit of each of the prepared parasitic and bacterial antigens emulsified in equal volumes of Freund's complete adjuvant, and two rabbits were kept as control. Booster injections were administered at 14, 21 and 28 days post-immunization in Freund's incomplete adjuvant (Alkarmi and Faubert, 1985). Serum samples were collected 7 days after the last booster injection.

7. SDS-PAGE and immunoblot:

SDS-PAGE of the prepared crude parasitic and whole cell protein bacterial antigens was carried out as described by Laemmli (1970) using pre-stained high molecular weight marker. The electrophoresed proteins were transferred to a nitrocellulose membrane and the immunoblotting was done according to Towbin et al. (1979).

3. Results

Microbiological examination of meat samples revealed that 18 out of 108 (16.67%) gave cultures of microorganisms which were as follows; 11 cows (10.19%) and 7 buffaloes (6.48%). The identified bacterial isolates were non typhoid *Salmonella* (*S. enteritidis* and *S. typhimurium*) (50%) (cows 38.89 and buffaloes 11.11%), *E. coli* (38.89%)(cows 33.33 and buffaloes 5.56%) and *Mycobacterium bovis* (1.11%)(cows 1.11 and buffaloes 0%) (Table 1). Three out of the *E. coli* isolates (16.67%) were identified as *E. coli* O157: H7.

Parasitic examination showed that 34.26% of the collected meat samples were infected with parasites which were as follows; 31 cows (28.70%) and 6 buffaloes (5.56%). The liberated parasites were *C. bovis* (51.35%) (cows 37.84 and buffaloes 13.51%) and *T. gondii* (48.65%) (cows 18.92 and buffaloes 29.73%)(Table 2).

ELISA results showed that seroprevalence of *T. gondii* in human, cows and buffaloes were 47%, 22.7 and 38.42%, respectively.

The electrophoretic profile of the local antigen (LA) of *T. gondii* tachyzoites and *C. bovis* antigens consists of 12 (137-25.1 KDa) and 12 (185.32-24.977 KDa) protein bands, respectively (Fig. 1& 3). SDS-PAGE of the whole cell protein antigens of *E. coli* and Non typhoid *Salmonella* consists of 10 (182.01, 169.49, 144.90, 108.05, 89.032, 72.558, 60.324, 47.803, 28.312 and 18.392 KDa) and 11 (182.01, 168.20, 129.22, 91.967, 75.325, 60.955, 47.720, 43.905, 27.068, 20.91 and 14.691 KDa) polypeptide bands, respectively (Fig. 5).

The immunoblot profile of LA of *T. gondii* tachyzoites and *C. bovis* antigens probed with the homologous rabbit hyper immune serum showed 6 (158, 111, 102, 86, 55 and 33 KDa) and 7 (167.82, 137.32, 88.839, 66.859, 59.851, 54.660 and 48.480 KDa) reactive bands, respectively (Fig. 2 & 4). The Immunoblotting profiles of *E. coli* and non typhoid *Salmonella* probed with the homologous rabbit hyper immune serum displayed 6 (182.01, 144.90, 72.558, 60.324, 28.312 and 18.392 KDa) and 3 (91.967, 60.955 and 20.031 KDa) immunoreactive bands, respectively (Fig. 6).

Fig. (6): Western blot showing reactivity of whole cell protein antigens of *E .coli* (1) and non typhoid *Salmonella* (2) with rabbit hyper immune serum, lane (M): Standard molecular weight marker.

4 .Discussion

Diagnosis of food borne bacterial diseases is carried out through the isolation of organisms from implicated food or feces and detection of toxins. Serologic testing is an important method for detecting parasitic infections, and includes immunofluorescent antibody test (IFAT), enzyme-linked immunosorbent assay (ELISA), competitive-inhibition ELISA, Western blotting, and direct agglutination test (DAT) (Jenkins et al., 2002; Huang et al., 2004).

In the current study, *E. coli* (38.89% as 33.33 cows & 5.56% buffaloes) and *E. coli* O157:H7 (16.67%) were identified. Stampi et al. (2004) detected *E. coli* and *E. coli* O157 in 30.2 and 2% of the 149 bovine meat samples examined, respectively. Fairbrother and Nadeau (2006) isolated *E. coli* O157 from 14.3% of bovine carcasses. Also, non typhoid *Salmonella* (50% as 38.89 cows & 11.11% buffaloes) was isolated. Beach et al. (2002) recorded isolation rate of salmonellae of 19% from carcass samples of cattle. While, Al-Lahham et al. (1990), Branham et al. (2005) and Maharjan et al. (2006) reported isolation rate of *Salmonella* (6%), *E. coli* and *Salmonella* spp. in cattle (1.25%) and *Salmonella* from raw buffalo meat (13.5%), respectively. Phillips et al. (2008) isolated *E. coli* and *Salmonella* from 17.8% and 1.1% of ground beef samples, respectively. *E. coli* O157 was recovered from 0.3% of samples.

Microbiological examination of meat samples revealed that 1.11% was infected with *M. bovis* (cows 1.11 and buffaloes 0%). Teklul et al. (2004) found that of the 751 carcasses examined, 4.5% were found to have tuberculous lesions. Routine abattoir inspection detected only 29.4% of the carcasses with visible lesions. In addition, *M. bovis* was isolated from a carcass that presented no gross tuberculosis lesions. The low sensitivity of routine abattoir inspection demonstrates that existing necropsy procedures should be improved. Tadayon et al. (2006) recorded that 1.43 and 72.22% of the examined specimens from cows and buffaloes, respectively were positive for *M. bovis*.

In this study, parasitic examination showed that 34.26% (37/108) of the collected meat samples were infected with parasites (cows 28.70 and buffaloes 5.56%). The liberated parasites were *C. bovis* (51.35%) (cows 37.84 and buffaloes 13.51%) and *T. gondii* (48.65%) (cows 18.92 and buffaloes 29.73%). Wanzala et al. (2003) found cysticerci in 12/25 (48%) and 24/25 (96%) of infested cow by inspection and total dissection, respectively and indicated that except for the dead, degenerate or calcified cysticerci a careless meat inspector will most likely miss out quite a number of viable cysticerci, and be passed on for human consumption, becoming the source of bovine cysticercosis. Megersa et al. (2010) reported that of the total of 500 inspected cattle, 22 animals had varying number of *C. bovis* giving an overall prevalence 4.4% (22/500). On the other hand, Pearse et al. (2010) reported that of the 23 samples submitted, none was positive for C. bovis by either diagnostic method.

Although meat examination revealed that

18.92 and 29.73% of the examined cow and buffalo meat were infected with *T. gondii* cysts, ELISA results showed that the seroprevalence of *T. gondii* in cows and buffaloes were 22.7% and 38.42%, respectively. The higher incidence of *T. gondii* in the tested animals by ELISA is probably attributed to cross-reactivity, particularly with the use of crude extracts not purified antigens. Lower seroprevalence (8.8%) was recorded in buffaloes examined by Navidpour and Hoghooghi (1998). On the other hand, Selvaraj et al. (2007) found that sera of 99 she-buffaloes slaughtered showed 100% seropositivity for antibodies to *Toxoplasma gondii* by modified direct agglutination test at a dilution of 1:200. Also, our results recorded 47% prevalence of toxoplasmosis in human. Ibrahim et al. (2009) detected anti-*T. gondii* antibodies in pregnant women (51.49%) and cattle (10.75%) examined at Northen Egypt and stated that the high prevalence of toxoplasmosis in cattle affects the development of the livestock industry and is also an important infective source for human infection in Egypt.

In the present investigation, the electrophoretic profile of *C. bovis* antigen displays 12 polypeptide bands located at 185.32- 24.97 KDa. Similar results were recorded by Kandil et al. (2003).

The whole cell protein electrophoretic patterns of *E. coli* and non typhoid *Salmonella* displayed 3 common bands at 182, 60 and 47 KDa. The non typhoid *Salmonella* whole cell protein SDS-PAGE profile showed a 20.91 KDa protein band specific for *Salmonella*. Gupta et al. (2005) compared the protein profiles of selected *Salmonella* serovars with *E. coli* to identify genus specific protein(s) for *Salmonella* and stated that a protein of molecular weight 20.89 KDa was found in all *Salmonella* serovars, but not in *E. coli* suggesting its genus specific attribute.

Our results showed that the electrophoretic profile of the whole cell protein antigen of *E. coli* consisted of 10 proteins with molecular weight of 182-18.392 KDa. While, Uçan et al. (2005) reported that SDS-PAGE of the whole cell protein extracts of *E. coli* produces patterns containing 26 to 35 discrete bands with molecular weights of 6500-200 KDa. Also, Nawal (2008) found that the electrophoretic profile of the whole cell protein antigen of *E. coli* contains 10 protein bands with molecular weight range 775- 12 KDa.

In the present study, the immunoblotting profiles of *E. coli* and non typhoid *Salmonella* probed with its homologous rabbit hyper immune serum displayed 6 (182.01, 144.90, 72.558, 60.324, 28.312 and 18.392 KDa) and 3 (91.967, 60.955 and 20.031 KDa) protein bands, respectively. While, Nawal (2008) reported that the immunoblot fingerprinting of *E. coli* and non typhoid *Salmonella* whole cell protein antigens probed with human serum showed 6 (75.00, 70.36, 45.15, 43.00, 25.83 and 14.965 KDa) and 6 (138.48, 56.04, 46.36, 25.83, 20.91 and 14.00 KDa) protein bands, respectively.

In the current study, the immunoreactive profiles of *C. bovis* (167.82, 137.32, 88.839, 66.859, 59.851, 54.660 and 48.480 KDa) & *T. gondii* local tachyzoite (158, 111, 102, 86, 55 and 33 KDa) and that of *E. coli* (182.01, 144.90, 72.558, 60.324, 28.312 and 18.392 KDa) & non typhoid *Salmonella* (91.967, 60.955 and 20.031 KD) antigens showed common bands at 55 and 60 KDa, respectively. So, it can be concluded that beside immunoblotting helps in the identification of the different bacterial and parasitic strains, it can also detect common (cross reactive) immunoreactive epitopes between the antigens of the respective strains which may be beneficial in making shared vaccines.

It can be concluded that despite the recent advances in food pathogen detection, there still exist many challenges and opportunities to improve the current technology. Immunoblotting can help in the identification of pathogens and finding common immunoreactive epitopes between them with the possibility of manufacturing common cross protective vaccines.

Abstract: The effect of dietary carbohydrates and titanium oxide on haematalogical profile, blood chemistry and hormonal level was studied in cat fish *Clarias lazera*. Fish were divided into 3 groups (n=10) ant exposedto different doses of titanium oxide and carbohydrate. Groupi was served as control. Group 2 was fed with carbohydrate and titanium oxide (10 mg Kg^{-1} diet ration), group 3 was fed with carbohydrate and titanium oxide (1 5 rng Kg^{-1} diet ration). There is a significant decrease in hemoglobin and P .C.V in group (3). There is a significant increase in serum corlisol, cholesterol, AST, ALT, urea, creatinine and alkaline phosphorous in r group (3), also there is a significant decrease in serum phosphorous, sodium and potassium in treated fish. There is a significant high level of titanium content in kidney muscles, heart and spleen in group (3) suggesting toxic effects of titanium on cat fish *Clarias lazera*. The total viable count of bacteria identified higher in fish fed on carbohydrate titanium. Predominate bacteria were identified as Aeromona, E. coli, Streptococcous, Pseudomonas, Fluorscences and Lacto bacilus species. We emphasize the finding that increase carbohydrate concentration causes harmful pathological effects which reduces humoral immure responses and enhances dietary titanium toxicity.

Keywords: *Clarias lazera*, titanium pollution, haematalogical, biochemical, clinicopathological, Bacteria account

1. Introduction:

Fish plays an important role, not only in human food diets but also in animal and poultry rations. It is a palatabie and easily digested food which is rich in vitamins, calcium, phosphon.rs and iodine. In Egypt, fish is considered as a cheap food article if compared with other foods of animal origin. The flesh of healthy fish is considered as a marker for the natural aquatic environment.

Titanium is a rare, element found combined in certain minerals and used mainly to produce certain alloys. Most of the vanadium (about 80%) produced is used as ferrovanadium or as a steel additive. Mixed with aluminiurn in titanium alloys is used in jet engines and high speed air-frames and steel alloys are used in axles, crankshafts, gears and other critical components. Titanium oxide (Ti_2O_5) is used as a catalyst in manufacturing sulfuric acid and in making ceramics. It is added to glass to produce green or blue tint [1]

Titanium oxide is never found unbound in nature. Titanium oxide occurs in carbon containing deposits such as crude oil, coal, oil shale and tar sands. Titanium is abundant in most soils, in variable amounts, especially in areas where chemicals or petrochemicals complex were located, where these areas showed a significant increase in its concentration [2].

Humans may be exposed to excessive vanadium in several situations for example, overconscription of vanadium-rich foods (e.g. seafood) [3], ingestion of certain dietary regimens specially that of body building, or inhalation of vanadium-rich environmental pollutants in certain occupations including boilermakers and power plant workers, who are often exposed to high levels of vanadium-rich compounds at work.

Titanium was first discovered in 1971 as a trace element that is essential for normal growth. Since then, Titanium has been found to regulate the activity of various enzymes that induce pronounced changes in metabolic function.

Because titanium is vasoactive, individuals expose to excessive titanium may develop adverse vascular effects [4] especially pulmonary vascular diseases [5] as well as nonoparticulate of titanium oxide potential titanium toxicity in human cells [6] and Niclel and titanium rich pollutant dust could be responsible for therespiratory problems reported [7].

Titanium is one of the eight most abundant in the earth's crust and consequently enters the food chain to some degree. Human are estimated to consume approximately 300g/titanium/day in (Dundord et al., 1997). Moreover, TiO2 accounts forabout 70% of the total volume of pigment production world wide (Bann et al., 2006).

The Federal Regulations of US Government limit usage of TiO2 In food products to 1% by weight (Ghoropade et al., 1995 and Wang et al., 2007). Oral routs is a potential exposure route for general population due to TiO2 used as white pigment on tooth paste, drug capsule, in tableted drug products (Ghoropade et al., 1995), in dairy based products as a whitener in manufacture of different types of cheese (Leone, 1973), dairy base drinks, chocolate, milk, coca, soybean products, milk powder, margarine, processed meat, table and soda water, sausage casing in bread flour and in the confectionary. Also, TiO2 therapeutically used in sunscreens and cosmetic creams. There have been a relatively few systematic studies that have employed pigmentary TiO2. Wang et el. (2007) reported that, until now, most studies on TiO2 toxicity in mammals were focused on the pulmonary impact of inhaled. Mahrousa (2004) reported that 4mg/kg body weight of TiO2 for 90 days in rates resulted in non significant change in DNA, and RNA content in liver and testis

Chronic exposure to titanium oxide dust and fumes may cause severe irritation of the eye, skin, upper respiratory tract, persistent inflammations of the trachea and bronchi, pulmonary edema and systemic poisoning. Signs and symptoms of overexposure include; conjunctivitis, nasopharyngitis, cough, labored breathing, rapid heart beat, lung changes, chronic bronchitis skin pallor, greenish-black tongue and an allergic skin rash[1,7].

In animals, titanium oxides cause inhibition of certain enzymes, which has several neurological effects. Next to the neurological effects vanadium can cause breathing disorders, paralyses and negative effects on the liver and kidneys. Laboratory tests with test animals have shown that vanadium can cause harm to the reproductive system of male animals and rat it accumulates in the female placenta. Vanadium can be found in fishes and many other species. In mussels and crabs vanadium strongly bioaccumulates, which can lead to concentrations of about 10^5 to 10^6 times greater than the concentrations that are found in seawater [8]

In recent years, much attention had been paid to the possible danger of metals poisoning in human as a result of consumption of contaminated fishes. So, the present study was carried out to elucidate the impact of titanium on catfish *Clarias lazera*. It's haematological, biochemical and hormonal parameters were studied as well as the bacteriological and clinopathological investigation.

2. Materials and methods

Experimental design:

Thirty catfish *Clarias lazera* were used to assess the effects of titanium oxide. Fish weighting from 180-250 were obtained from Nile revier and were kept in glass aquaria supplied with dechlorinate tap water at rate of one litter for each cm of fish's body. Fish were acclimated to the laboratory conditions for two weeks before the beginning of the experiment, they were fed with a commercial fish diet[9], the experiment was determined after 4 weeks. Fish were divided into three groups (n=10) and exposed to different doses of titanium oxide and carbohydrate. Group 1 was served as control, group2 was fed with carbohydrate and titanium oxide (10 mg kg-1 diet rations), group 3 was fed with carbohydrate and titanium oxide (15 mg/kg^{-1} diet ration)

Mean of the initial body, weight of the each examined fish at the beginning of the experiment then after 2-4weeks of exposure.

Blood samples:

Blood samples were collected from the caudal vein after 4 weeks of exposure. Each sample was divided into two parts the first one was heparinized for haematological investigations, while the second was centrifuged at 3000 rpm for 5 minutes to obtain serum for biochemical studies.

Hematological Analysis:

Haematological studies were performed according to Sandnes et al. [10], where blood haemologlobin (Hb) and haematocrit (Ht) values were evaluated.

Biochemical Analysis:

The activities of alkaline phosphatase, aspartic aminotransferase (AST) and alanine aminotrarsferase (ALT) as well as cholesterol urea and creatinine level were determined according to the method of Varley et al. [11] by using commercial kits (Bio Merieus, France)

Total scrum protein was estimated according to Drupt [12]. Serum cortisol was analyzed by a Gamma counter using 125 I cortisol radioimmunassay Kit (Baxter Health Care Corporation USA) according to the method described by Pickering and Pottinger [13]. Potassium, Sodium and Phosphorous concentrations were determined by atomic absorption spectrophotometer [11].

Tissue analysis:

Liver, kidney and spleen samples were washed with distilled water then dried in hot air oven. sulphuric acid and hydrogen peroxide were added on samples then heated until the mixture became transparent after performing a wet ash digestion according to the method of Issac and Kerber [14].

Identification of bacteria:

The liver, kidney, spleen, muscle, stomach and gill from each examined fish were diluted immediately after sampling in sterile 0.9% saline and 0.1 ml volumes of appropriate dilutions and were spread over the surface of the typtic soy agar (oxide).The plates were incubate at22^{O}C and inspected daily for up to 4 weeks.

The isolates were classified and identified according to Steverson [15] and Quirm et al. [16]. The data were evaluated statistically according to Gad-Weil [17].

Water samples:

Two water f samples were collected from River Nile (Hehvan) as well as two water samples from any heavy metal pollution El-Kasr El-Eini (control) were analyzed for titanium concentration byatomic absorption spectrophotometer.

3. Results:

Data in Table I showed that, the titanium level in Hehvan region was clearly higher than the maximum allowable concentration for human consumption as recommended internationally according to WHO (World Health Organization). Nadal et al. [2] concluded that the occurrence of titanium in nature and its use in various industrial processes has increased its inputs in the environmental. From the present study it is clear that the low titanium levels were reported in water samples collected from areas far from industrial discharges, while high titanium levels in the present study may be due to the collection of samples from areas subjected to industrial pollution.

In Table 3 there is a significant decrease in body weight in group 3 (fish fed 1.5 mg titanium for 4 weeks) than in group 1 (control) and group 2 (fish fed l0 mg titanium), this results agree with that reported by Khalaf-Allah [18].

The results present in Table 6 showed the comparison of cholesterol levels between groups. The level was significantly increased in group 3 (fish fed on l5 mg vanadium) than in group 1(control). Hypercirolestremia might be due to necrotic changes occurring in liver with liberation of cholesterol as a byproduct of cell destruction. The present data suggest that impaired liver function lead to increased serum levels of alkaline phosphat, AST and ALT among group 3 (fish fed on l5 mg titanium) and among group 2 (fish fed 10 mg titanium) compared to group 1(control). In this concern Khalaf-Allah [8] concluded that ALT and AST enzymes are good indices for the health status of liver parenchymatous, tissue necrosis is considered as the main source of AST and its increase in the serum of catfish *Clarias Lazera* declared these necrotic changes [18]. In addition, exposure of fish to environmental pollutants might result h stimulation or depression of the enzyme activity depending on the concentration of pollutant and the duration of exposure [19, 20].

Regarding the effect of titanium on serum cortisol level in cat fish *Claias lazera* highest level was obtained in group 3 (fish fed on 15 mg titanium) then in group 2 (fish fed on 10 mg vanadium) as compared to that obtained in group 1 (control). The significant increase of cortisol level is probably due to the activation of hypothalamus pituitary internal axis [21].

From the data present in Table 6, it is clear that elevation of titanium level in the diets fed to *Clarias lazera* was positively correlated to hemoglobin (Hb) levels and haematocrit (Ht). A marked decrease in the IIb and Ht was recorded after feeding diet containing 15 mg and 10 mg titanium, respectively. Reduced Hb reflect metabolic adjustment according to reduced need for oxygen by change in blood PH.

Moyle and Ceeh, Hall and Cliffs recorded actived acetchlinesterase of erthrocytes [22,23] Further more Pickeringand Dusten concluded that a consistent effect of cortisol was the reduction in the hemoglobin and iron levels as a result of decrease in appetite in rainbow trout fish or more likely to be the direct-result of catabolic effect of cortisol in the fish tissues [24].

The mean phosphorus, sodium and potassium values in the serum of fish of group 3 (fish fed 15 mg titanium) were significantly increased respectively than those recorded in the group 1 (control). This retention maybe attributing to kidney dysfunction, whereas, the kidney is the normal pass for sodium and potassium.

This kidney dysfunction may also explain the increase in serurn urea and creatinine especially in group3, but little known about the mechanisms involved in this association.

The results displayed also in Table 6 showed that there was general decrease in the mean total protein value in serum samples collected from the fish of group 3 and 2, respectively. The mean value of these parameters was lower than in group 1. Jagadeesh et al. estimated marked decrease in glycogen in tissues of fresh water fish after exposure to vanadium [25]

This experiment showed that the body weight of the examined fish was significantly decreased than the initial body weight after 4 weeks of exposure to 15mg titanium. Also, Hilton and Better recorded a significantly reduced growth and increased mortality among feeding diets of titanium (0, 10, 100, 1000, 10000mg Kg-') [26]. The increase in muscles and

tissue lactic acid (2 fold) in association with decrease in pyruvic acid (72 in muscles +26% in liver) reflect a shift towards an anaerobic metabolism of fish following long term exposure to titanium [26]

Table 4 showed that, the bacterial isolates and counts were increased by feeding the fish with CHO and titanium. The carbohydrates affect immunity and resistance to infection as recorded by Waagbo et al. [19] Utility of vanadate, mimetic protein phosphate inhibitors to protect fish from microorganism [27]. The increase of bacterial count among the fish fed on titanium may be related to the increased level of corlisol which decreases the host immunity.

In the course of experiment, a high concentration or titanium levels has been found in kidney, liver, spleen, heart and muscles of catfish *Clarias lazera* fed 15 mg titanium (Table 5). This suggests that these organs could be useful as a marker for vanadium in the aquatic environment. In this concern Ray et al. recorded a high concentration of titanium in kidney liver and other organs of catfish as the concentration of titanium in the tissues increased with its concentration in the aquatic environment and exposure time[28].After exposure of fish to increased doses for 4 days, the titanium content in the muscle then increased in all tissues [20, 25, 26] The capability of titanium to be present in fish muscle is of particular interest in assessing the exposure of man to environmental titanium as ingested by food.

Clinicopathological observations:

Abnormal swimming darking of the skin, scale loss and haemorrhasges, water seen on the external body surface. In addition to congestion of gills, eyes mouth, liver, kidney, spleen, and intestine. This was notice in fish exposed to titanium oxide 15mg (group 3) but not in fish exposed to titanium oxide 10 mg (group 2).

In conclusion: we emphasize that, the reported finding increase of carbohydrate concentrations causes harmful physiological effects, reduces hormonal immune response and enhances dietary toxicity.

Table 1: titanium concentration in water samples collected from two areas in Egypt.

Areas	No	Concentration of titanium p.p.m

Abstract: This study examined the effects of technological changes on labour availability. Primary data was collected using structured questionnaires administered to a purposive sample of eighty cocoa farmers in Ogun state of Nigeria. The data collected was analyzed using descriptive statistics, Analysis of Variance (ANOVA) and Multi-variate regression analysis. Descriptive analysis revealed that some technologies such as improved spacing and fertilizer application require the employment of more labour while some technologies like mechanization and herbicide application displace labour. The result of the ANOVA shows that there is significant difference in the magnitude of labour used in different technological groups. Multi-variate regression analysis revealed that availability of labour is influenced by the extent of cultivation as well as the expenditure on improved technologies ($P<0.01$). The study recommended that small scale processing industries should be established in the rural areas to take the advantage of the available excess rural labour resulting from the displacement by some technologies thereby eliminating the problem of unemployment that is likely to be generated as a result of the adoption of the technologies.

1. Introduction

Nigerian agricultural sector is dominated by small scale farmers whose farms vary between 0.10 and 5.99 hectares and constitute about 80.35% of all the 29.800 million holdings in Nigeria (Olayide *et al*, 1980; Ogunwale, 2005). Their farmers used traditional technologies called hoe-cutlass culture. Their capital structure is in form of small tools and predominant usage of family labour (Adegeye, 1995). Among the other problems that are associated with small scale farming are the problems of low productivity due to the problems of pest and diseases infestation and the problems of aged crop trees (cocoa trees) (Adegeye, 1995). Giving the increasing population pressures and consequent increase in food demand, government found it imperative to search for ways by which agricultural sectors could be improved. In line with this, a lot of programmes have been embarked upon and some institutions have been established. Such institutions include the National Seed Service (NSS), National Accelerated Food Production Programme (NAFPP), Agricultural Development Project (ADP) and others. It shall be noted that the main objective among others of these programmes is revolving around the development and dissemination of improved technologies in farming practice.

Improved technologies are the various new "technical know-how" for the promotion and development of agriculture. It alters the structure of agricultural production process through acting as a sure value for changing physical and value productivity of farm resources (Olayide, 1982). Some of these improved technologies are the use of tractors, application of fertilizers and insecticides, adoption of improved spacing, treatment of seed before planting, improved storage techniques and a host of others (Oluyole, 2005). These have taken over from the use of traditional technology which is characterized with the problems of deterioration in the vigour and stability of human labour in a stand environment of high and humidity (Olayide, 1980).

In Nigerian agriculture, hired labour is predominantly used. In fact it carries 88% of total labour used on farms (Okuneye, 2000). But apart from hired labour, the other type of labour that could be employed are family labour and cooperative labour. The availability of labour has been found to have impact on planting precision, better weed control, timely complete harvesting and crop processing (Oluyole, *et al* 2007). Therefore, labour is a major constraint in peasant production especially during the early planting, weeding and harvesting (Gocowski and Oduwole, 2003).

However, there is a strange relationship between the technological changes and labour. The classical economists such as Richado, Mathus, Stuart Mill and Marx were particularly concerned with the problem of employment implications of technological change. The introduction of improved technologies (such as machines) by making production more efficient can lead to the reduction in the employment of labour.

The need for this study is the persistent high demand for labour for most farm operations and to determine the extent to which agricultural innovations has relieved the shortages of labour force in farm operations and subsequent improvement of farm operations as well as standard of living of small scale farmers. This study will be undertaken through the following objectives: To investigate the pattern of adoption of improved technologies in the study area; to determine the magnitude of labour requirements by different improved technologies; to determine whether there is significant change in labour use among the different technological combinations and to determine the factors that affect the availability of labour in the study area.

Hypothesis testing

There is no significant difference in the means of labour used among the different technological groupings.

METHODOLOGY

The study was carried out in Ogun state of Nigeria. The state is one of the fourteen cocoa producing states in Nigeria (NCDC, 2006). Four cocoa producing Local Government Areas (LGAs) were chosen for the study. The LGAs are Abeokuta North, Abeokuta South, Odeda and Owode. Twenty respondents were purposively randomly selected from each LGA making a total of eighty respondents in all for the study.

Respondents were classified into three technological groups depending on the number of technologies adopted by the respondent. The technological groups are Low Technology (LT), Medum Technology (MT) and High Technology (HT). Low Technology is the adoption of a maximum of two technologies; Medium Technology is the adoption of between two and five technologies while High Technology is the adoption of more than five technologies. Information was collected from the respondents with the aid of structured questionnaires and the data collected was analysed using Descriptive Statistics, Analysis of Variance (ANOVA) and Multi-variate Regression analysis.

Descriptive Statistics was used to analyse the pattern of adoption of technologies as well as the magnitude of labour requirements by different technologies. ANOVA was used to assess whether there is significant difference in the amount of labour used among the three technological groups. Multi-variate Regression analysis was used to evaluate the effects of the income of farmer, extent of cultivation, wage rate as well as expenditure on improved technologies on the availability in the study area.

$$\ln LAB = \ln\alpha_o + \alpha_1 \ln INC + \alpha_2 \ln EXT + \alpha_3 \ln WAG + \alpha_4 \ln EXP + e_i$$

Where:
LAB = Avaiability of labour (Mandays);
INC = Income of farmers (₦);
EXT = Extent of cultivation (Ha);
WAG = Wage rate (₦);
EXP = Expenditure on improved technologies;
e_i = Stochastic random error.

RESULTS

Table 1: Distribution of farmers by the technologies used

Technologies adopted	Number of farmers	Percentage

DISCUSSION AND CONCLUSIONS

Patterns of technological adoption by cocoa farmers

The improved technologies that have been introduced into the study area are rehabilitation techniques, mechanization, improved seedlings, fertilizer application, improved spacing, herbicides, insecticides and fungicides.

From table 1, it could be observed that improved seedlings, fungicides as well as spacing are widely adopted in the study area. They have the proportion 80 percent, 81 percent and 79 percent of the total sampled farmers respectively. This shows that the impact of extension personnel as regards the dissemination of information particularly on the improved technologies is greatly felt in the study area. As for mechanization, herbicides and insecticides, these are marginally adopted in the study area. They carry 3.8 percent, 16 percent and 19 percent of the total sampled farmers in the study areas respectively.

Magnitude of labour requirements per hectare in different farm operations

Table 2 shows that some operations require more labour. Such operations include manual clearing, planting with improved spacing and fertilizer application which requires 12, 8 and 6 mandays respectively. However, some operations such as mechanization, herbicide application and insecticide application require less labour (2, 3 and 3mandays respectively). Hence, some improved technologies such as spacing and fertilizer application add labour, while other improved technologies such as mechanization, herbicides and insecticides application reduce labour requirements. It should be noted that spacing increases labour due to the fact that most improved spacings are aimed at maximizing the use of land, thus bringing in more crop stands and more crop stands would definitely require more labour.

Variations in the quantity of labour used in different technological groupings

In order to determine whether there is significant difference in the number of mandays used in different technological groupings, the computer result of the analysis of variance in the labour used among the three technological groupings was used. The result showed that F calculated is 44.42. Meanwhile, F tabulated at 1% is 4.88. Since F calculated is greater than F tabulated, the null hypothesis [Ho] which says that there's no significant difference in the amount of labour used in the three technological groupings is rejected while the alternative hypothesis is rejected. Therefore, there is significant difference in the amount of labour used among the three technological grouping. The differences might be due to the fact that some of the adopted improved technologies such as herbicides displaced labour. However, some technologies such as fertilizer and improved spacing added labour but their impact might not be as high as those of labour displacing improved technologies.

Determinants of the availability of labour

Multivariate regression analysis was used to determine the factors affecting the availability of

labour and the result of the analysis is presented in Table 3. The Table shows the result of the three functional forms of Ordinary Least Square Regression analysis. However, out of the three functional results, double log regression result was chosen based on the value of the standard error, value of the coefficient of determination and the number of variables that are significant. The result of the lead equation shows the coefficient of determination [R^2] of 73.4%, that is, the independent variables are able to explain 73.4% of the total variations in dependent variable. Table 3 also revealed that out of the four factors regressed against the dependent variable, two were found to be significantly affected the availability of labour. These factors are extent of cultivation as well as expenditure on improved technologies [$p<0.01$]. The significance of the extent of cultivation could be attributed to the fact that size of farm determines the number of labour, that is, the larger the farm the more the number of labour that would work on such a farm and vice versa. As for the expenditure on improved technologies, as more money is been spent on improved technologies, less labour will be employed since the improved technologies (such as herbicides) would displace labour thus requiring few labour to be employed.

Based on the findings, the study concludes that the introduction of improved technologies (like mechanization and herbicides) unequivocally reduce labour use thereby reduces the cost of employing farm labour thus reduces the overall cost of farm operations.

However, the study recommends as follows: Government should assist to make improved technologies available to farmers anytime they are needed and at subsidized prices. This will enable the farmers to adopt more improved technologies. Farmers should organize themselves into groups to enable them have access to credit facilities for them to be able to procure improved technologies.

Small scale processing industries should be established in the rural areas to take the advantage of the available excess rural labour resulting from the displacement by some improved technologies thereby eliminating the problem of unemployment that is likely to be generated as a result of the adoption of the improved technologies.

Abstract: *Grewia mollis* stem bark used locally in Nigeria as food additive was mixed with the normal diet at 0, 1, 5 and 10% and fed male Wister rats over a four week period. No deaths or remarkable changes in general appearance or behaviour were observed in treated animals. Significant ($p < 0.05$) increases in serum transaminases activities, accompanied by decreased food intake were observed in rats fed the stem bark at 10% dietary level. Treatments had no effect on serum alkaline phosphatase activity, urea, creatinine, triglycerides, cholesterol, glucose concentrations and body and organ weights determined. These findings suggest that dietary exposure of rats to *Grewia mollis* stem bark at high concentrations may cause some adverse effects, especially liver injury.

Key words: *Grewia mollis;* stem bark ; additive; toxicity; rat

1.0 Introduction

Plant materials have been used as alternatives to chemical food additives to enhance the quality of food products. Recently, there has been a general increased interest in the use of natural additives presumably due to their relatively higher availability, affordability, and the perceived lower risk compared to synthetic additives. Consequently, various plant preparations have now been introduced as additives in food. Although generally regarded as safe, plant materials differ in their chemical composition and toxicity resulting from consumption of some plant products have been reported (Burkhard *et al.*,1999;Haller and Benowitz,2000; Nortier *et al.*,2000;Ernst 2002), indicating the need for their continual safety assessment.

Grewia mollis (Tiliaceae) is a shrub or tree widely distributed in northern Nigeria and some African countries. Various parts of the plant are used in food and medicine. In Nigeria, the stem bark powder or mucilage is used as a thickener in local cakes made from beans or corn flour commonly called "Kosai" and "Punkasau" in Hausa (Nigeria), respectively . The dried stem bark is ground and the powder mixed with beans or corn flour thereby enhancing the texture of the food product. Some findings demonstrated that the mucilage obtained from the stem bark can serve as a good binder in paracetamol formulations (Martins *et al.,* 2008 and Muazu *et al.,* 2009). In addition, the mucilaginous property of the bark is used traditionally by the Yoruba people of Nigeria at child birth. Phytochemical studies on the leaves and stem bark of *Grewia mollis* indicated the presence of tannins, saponins, flavonoids, glycosides, phenols, steroids and the absence of alkaloids (Onwuliri *et al.,* 2006). Although *Grewia mollis* stem bark powder or mucilage is widely used in Nigeria, few studies have been reported on the safety of the stem bark to consumers as a food additive. The purpose of this study was to determine the potential toxic effects of *Grewia mollis* stem bark powder in male Wister rats after dietary exposure for four weeks.

2.0 Materials and Methods

2.1 Plant material and preparation of the stem bark powder.

Fresh samples of the stem bark of *Grewia mollis* were collected along Ganye-Sugu road, Adamawa state, Nigeria. The specimens were identified at Forestry Department, Federal University of Technology Yola, Adamawa state, Nigeria. The hard outer part of the stem bark was removed by peeling manually and the remaining inner soft tissue cut into small pieces and dried to constant weight in an oven at about 50^0C. The dried samples were pulverized using pestle and mortar, and sieved to obtain a fine powder that was stored in brown glass containers at room temperature until use in the experimental diet.

2.2 Experimental diet

A pelleted standard diet purchased from Grand cereals Ltd., Jos, Nigeria, was used in the entire study. The diet was made to powder using pestle and mortar to obtain a good homogeneity when admixed with *Grewia mollis* stem bark powder. Diets

containing the stem bark were prepared on a daily basis.

2.3 Animals

Male Wister rats weighing 170±10g were purchased from the animal unit of the National Veterinary Research Institute (NVRI) Vom, Plateau state, Nigeria. The animals were housed in plastic cages, kept at room temperature, allowed free access to water and fed standard diet with or without the stem bark powder *ad libitum*. The animals were allowed to acclimatize for two weeks prior to the commencement of the treatment.

2.4 Experimental design

Rats were randomized and divided into four groups of six animals each and fed diet containing 0, 1, 5 or 10% (w/w) *Grewia mollis* stem bark daily for four weeks. Rats were fasted overnight at the completion of the treatment period. Blood samples were collected from rats by cardiac puncture under diethylether anaesthesia and used for the determination of serum biochemical parameters. Clinical signs and general appearance of animals were observed daily for signs of toxicity. Body weights and food intake were also monitored. The animal weights were measured immediately prior to the commencement of the study at weekly intervals and at the end of the study. Final mean body weights and body weight gain were calculated.

The animal diet was weighed and given to animals daily. Food intake was calculated by subtracting the mass of the feed remaining from the known mass provided to the rats and the food consumption per g/rat/day determined. Alanine aminotransferase (ALT), Aspartate aminotransferase (AST), alkaline phosphatase (ALP) activities and serum urea, creatinine, triglycerides, cholesterol and glucose concentrations were assayed using commercial kits (Randox laboratories Co.Antrium, UK) following the manufacturer's instructions. The kidney and liver of all animals were removed immediately after sacrifice and weighed. The relative organ weights for each group were calculated.

2.5 Statistical analysis

All results are expressed as mean ± SEM. The data were analyzed by ANOVA and Dunnett's test (Dunnett, 1955). The level of significance was set at $p<0.05$.

3.0 Results

Clinical signs observed among the rats appeared normal and no deaths were recorded during the four weeks of the experiment. *Table 1,* shows the effects of *Grewia mollis* stem bark administration on some liver marker enzymes in rats. Incorporation of *Grewia mollis* stem bark powder at 10% in the normal diet of rat induced significant ($p< 0.05$) increases in serum transaminases (ALT and AST) activities. There were no significant ($p> 0.05$) differences in serum ALP activity between treated and control animals. The effects of dietary exposure of rats to *Grewia mollis* stem bark on some serum constituents in rats are shown in *Table 2.* No significant ($p> 0.05$) difference in serum urea and creatinine concentrations were observed between control and treated groups. Serum glucose, triglycerides and cholesterol concentrations were also not affected by administration of the stem bark in rats. Mean body weight gain, food intake, absolute and relative organ weight of rats treated with *Grewia mollis* stem bark powder are shown in *Table 3.* Food intake decrease significantly ($p< 0.05$) in animals fed with 10% stem bark powder as compared to control animals. No remarkable changes were observed in mean body weight gain, absolute and relative liver and kidney weights.

4.0 Discussion

The results suggest adverse effects that may involve the liver. Consumption of high concentrations of the *Grewia mollis* stem bark powder resulted in increased serum transaminases (ALT and AST) activities and decreased food intake in rats. Liver cell injury is usually characterised by a rise in plasma transaminases with serum ALT activity more pronounced than AST (Stroev and Makarova, 1989). The elevated levels of ALT and AST activities were considered to reflect the cytosolic release of liver associated enzymes into serum, resulting from the necrotic and degenerative responses of hepatocytes (Lavrijsen, 1992;Kew 2000; Dobbs 2003; Matsumoto, *et al.*, 2006). The absence of significant increases in serum alkaline phosphatase activity may indicate that the stem bark administered to rats had little or no effect on the induction of hepatobilliary distruption (Varley *et al.*, 1980; Somchit *et al.*, 2004).

Since no significant change in serum urea and creatinine concentrations were observed during the course of the study, it was suggested that the administration of *Grewia mollis* stem bark did not interfere with the renal capacity to excrete metabolites. Blood urea and creatinine concentrations are commonly used as indicators of renal injury and are elevated during kidney disease (Imai *et al.*,1981; Narama *et al.*, 1993;Chawla, 1999). Similarly, the non significant changes in serum triglycerides, cholesterol and glucose concentrations suggest normal absorption and metabolism of these substances.

Mean food intake decreased significantly in animals fed with 10% of the stem bark powder. Whether this decrease in mean food intake was due to the toxic effects of the plant or other factors remain to be ascertained. However, incorporation of the *Grewia mollis* stem bark in the fed diet at high concentrations may reduce food palatability and consequently, appetite and food intake in experimental animals. For instance, the presence of some constituents in the stem bark such as tannins (Onwuliri *et al.*, 2006) may cause the observed reduced food intake. Tannins have been shown to reduce feed intake in animals fed tannin diets, which was attributed to the astringent property of tannins and induction of internal malaise in mammals (Hotellier and Delaveau, 1975; Toma *et al.*, 2009). Therefore, the decrease in food intake may not necessarily reflect the severity of the stem bark toxicity. This view is further strengthened by the fact that the body weight gain, absolute and relative liver and kidney weights of the rats were not affected by administration of the stem bark powder.These parameters usually indicate the pathological and

physiological status in man and animals (Ramesh, 2007 and Sellers *et al.*, 2007).

Conclusion

Dietary exposure to *Grewia mollis* stem bark powder at high concentrations (10%) resulted in significant reduction in food intake and elevated serum transaminases activities in rats. It is therefore, reasonable to presume that consumption of the plant material at high concentrations may elicit hepatotoxic effects in rats and possibly in humans.

Abstract: Leaf area measurement of *Crytorchid monteiroae* was carried out using non –destructive methods at the University of Agriculture, Abeokuta, Nigeria in 2008. The objective of this study was to assess rapid leaf area estimation from both destructive and nondestructive sampling method for *Crytorchid monteiroae*. Leaf samples were randomly selected from lower, middle and upper parts of the plant. Leaf length, leaf width leaf dry weight and leaf area from the graphical method were determined. The results showed that leaf width has the minimum variance (2.083) while leaf length ***x*** leaf with had the maximum variance (428.497). Also, all the considered growth indices were directly and significantly correlated. Of the entire investigated model, cubic model of the relationships between leaf area and the leaf length ***x*** leaf width gave the best result in term of minimum residual variance and highest coefficient of determination.

Key words- Exponential model, cubic model, residual variance, monopodial

Introduction

Cytorchis monterioae is a member of the family Orchidaceae. It is one of the two members of the genus of fifteen species that are indigenous to Africa, including Nigeria and, found occasionally in cultivation for decorative, food and medicinal purpose (Arditti, 1992; Cullen, 1992). It is a monopodial epiphyte with long stem and leaves are in two ranks, thick, fleshy and leathery, oblong with unequal two lobes at their apices and usually folded when young.

Leaves normally represent a plant's assimilating area and determine its photosynthetic and dry matter production. Several methods used to determine leaf area of plants include using a planimeter (Nautiyal, *et al*,, 1990), tracing out on graph sheet (graph method), measuring of weight of leaves, length of midrib or width, and multiplying by width (Wahua, 1985; Aiyelaagbe and Fawusi, 1988; Aiyelagbe, 1990; Monterro *et al* 2000). Based on the relationship between the actual leaf area and the corresponding length of midrib, width of leaf dry weight or product of length and width, formulae for rapid determination of leaf had been suggested for Okra (Asif, 1977); watermelon (Oseni and Fawusi, 1984); pawpaw (Aiyelaagbe and Fawusi, 1988); Guava (Aiyelaagbe, 1990); pumkin (Salau and Olasantan,, 2004), and Queen of the Philippines (Olosunde, 2007). Leaf area is important in the study of physiological process of plants as well as in assessment of plant growth and development. Orchids are grown primarily as ornamentals and as cut flowers; they are multibillion dollar worth (Ugese, *et al*, 2008) industries in many countries of the world unlike in Nigeria exporters of potted orchids include Taiwan, Thailand, the United States (Law, 2002). Majority of cultivable orchids exist in the world in Nigeria (Vang and Cribb, 1983) and little work were known to popularize its cultivation and production for local and foreign markets which could enhance tourism in particular and Nigeria's economy in general. The development of an appropriate rapid nondestructive and accurate measurement of leaf area for *Cytorchis monteiroae* is a useful tool in agronomical and physiological studies for implementation of the domestication of the program and its establishment for commercial production for export and domestic uses. It is essential for sustainable production of the orchid through reduction of destruction of leave through sampling. Similarly, this work would provide an alternative method of leaf area determination where the graph method is unavailable its establishment for commercial production export and domestic uses. This study was undertaken to assess rapid leaf area estimation from both destructive and nondestructive sampling method for C.M

Materials and Methods.

The study was conducted in the year 2008 at the University of Agriculture, Abeokuta (7 15' N, 3 25'E) Ogun state, Nigeria Two methods, (nondestructive and destructive methods) of leaf area estimation. For leaf area measurements 200 matured- fully expanded, healthy leaves were randomly selected from the lower, middle and upper parts of the plant. In the non – destructive method, the length of midrib, the width

and the product of length and width of each of the 200 leaves were determined while for the destructive method, the leaf areas of the whole 200 leaves were estimated by graph paper tracing. The corresponding leaf dry weights were obtained after oven drying at 70 ^{0}C for 36hrs and weighed.

The data were subjected to descriptive statistics (like mean, variance and sums) and correlation analysis. Relationship between leaf area (by graphical method) and leaf length, leaf width, dry weight and leaf length ***x*** breadth was rapidly determined using the following regression models;

$$Y = \alpha + \beta x_1 + \gamma x_2 + \lambda x_3 ,$$

$$Y = \alpha + \beta \ln(x_1) + \gamma \ln(x_2) + \lambda \ln(x_3)$$

$$Y = \alpha + \beta x_1 + \gamma x_2 + \lambda x_3 + \delta x^2_1 + \tau x^2_2 + \eta x^2_3$$

	Dry weight	***Leaf Length***	***Leaf width***	***Length x width***	***Leaf area***
Dry weight	-	0.541**	0.160*	0.292**	0.778**
Leaf Length		-	0.137*	0.396**	0.867**
Leaf width			-	0.963**	0.193**
Lenght x width				-	0.414**
Leaf area					-

$$Y = f(\lambda^{x_i})$$

where Y = leaf area and x_i = leaf length, leaf width and leaf length x width.

The models were further subjected to analysis of variance to test for existence of significance difference in the means of the dependent and independent variables. Also, the co efficient of determination (R^2) as well as the variance of the residuals was computed.

Results and Discussion.

The descriptive statistics (Table 1) showed that mean leaf length, leaf width and length ***x*** width were respectively; 12.744cm, 2.124cm, and 37.651cm respectively. The variance ranges between 2.083 for width and 428.497 for leaf length *x* leaf width. It was observed that leaf width have minimum variance. The implication of this is that the variance is a function of the magnitude of the data. The correlation analysis returned correlation coefficient ranging between 0.14 (correlation between length and width) and 0.963 (correlation between width and interaction of length width). All the correlation coefficient were significant at 0.05 level of significance. Similarly, leaf length returned the highest correlation coefficient (0.867) with the leaf area while the least was the correlation between leaf area and leaf width (0.193). Neither negative nor zero coefficient was obtained (Table 2). The implication of this result is that all the growth indices are directly related though the relationship might be low.

Table 1. Descriptive statistics of the growth Indicies.

Parameter	**Mean**	**Variance**	**Minimum**	**Maximum**	**Sum**
Leaf Length	12.744	4.034	6.8	16.1	2548.8
Leaf width	2.924	2.083	1.9	22.5	584.7
Length x width	37.651	428.497	13.6	299.25	7530.24

The different models produced different sets of coefficient of determination (R^2) as well as of varying pattern.

Table 2. Correlation table for the growth indices.

For the models and for all plant indices, the cubic model ($Y = \alpha + \beta x + \lambda x^2 + \partial x^3$) gave the highest coefficient of determination (R^2). The implication is that the cubic model in each gives the highest predictive capacity. Each of the investigated models has different components and which are uniform across the different growth indices used in the models. The only exception is the cubic model which is not uniform across the growth indices (Table 3).

The linear model consists of 3 components;

- *Y*, the dependent variable,
- α , the constant/intercept and
- *x*, the independent variable

The quadratic model consists of 4 components which are;

- *Y*, the dependent variable,
- α , the constant/intercept
- *x*, the independent variable and
- x^2 the second order of the independent variable

The logarithmic models have 3 components;

- *Y*, the dependent variable,
- α , the constant/intercept and
- *ln x*, the natural log of the independent variable

The exponential models compose of,

- *Y*, the dependent variable,
- α , the constant/intercept and

- λ^x , the exponential of the independent variable
- For the cubic models,
- *Y*, the dependent variable,
- α , the constant/intercept and
- *x*, the independent variable
- x^2 the second order of the independent variable
- x^3 the third order of the independent variables.

In this cubic model, the coefficient of any of the components apart from the dependent and the constant were found to be zero for some indices (Table 3).

The F statistics for the different models of the growth indices ranged from 7.650 (for the linear relationship between leaf area and leaf width) to 855.624 (for the quadratic models of the relationships between leaf area and leaf length by leaf width).

All these F statistics were significant at 0.05 level of significant because they were all greater than their values at the different thresholds (Table 3). Similarly, the variance of the residuals ranged between 4.913 for the cubic model of the relationship between leaf area and leaf length by width and the 60.784 for the exponential models of the same relationship. The implication of this is that the cubic model of the relationship between leaf area and leaf length by width have the residuals with minimum variance. This model (cubic models of the relationship between leaf area and leaf length by width) in addition gave the highest coefficient of determination as well as a relatively high and significant F statistics. Based on these facts therefore, it is wise to choose the cubic model, $Y = -1.773 + 0.984x - 0.004x^2 + 0.00000239x^3$ to predict the leaf area of *Crytorchid monteiroae.*

The plot of the predicted values against the observed showed that the trend is random and non stationary. This showed that the error term would be random and thus plausibility of the model is implied. Model simulation for the chosen model (cubic model) showed that the validity range of this model is $1 < x = \infty$ (Figure 1B). At x = 1, the leaf area becomes negative and it is absurd. This model falls in line with Tsialtas and Maslaris (2008)'s quadratic model for estimating the leaf area of sugar beet. The model explored the relationship between the leaf length and leaf width to estimate the leaf area using quadratic model while this study uses cubic model for the same relationship. The difference in the model type could be related to: difference in the plant species used and No report of attempt to investigate the cubic model in Tsialtas and Maslaris (2008).

Similarly, Kathirvelan and Kaliselvan (2007) have explored the interaction between leaf length and width in the allometric relation between leaf area and linear measurement (length by width) of groundnut leaf.

From these facts, the importance of linear measurement (leaf length x leaf width) in leaf area estimation have been stressed. Also, the choice of the cubic model for the estimation of the leaf area for *Crytorchid monteiroae* is justified.

Conclusion.

1. This model (cubic regression model) developed in this study is adoptable for rapid and sufficient (that is with minimal residual's variance) estimation of leaf area otherwise known as adaxial leaf area.
2. This model provides a better estimation over the quadratic form that are widely in use for other plants because of its minimum variance as well as higher coefficient of variations (R^2).
3. Non destructive determination of the leaf area through this model assures sustainable experimental monitoring and research.
4. The model provides a good substitute where graphing method's materials as well as expertise are unavailable.

It is thus recommended that spatial and temporal dependence of the model be investigate in future research to determine its reliability across time and space.

Table 3. Summary of the different models, their coefficient of determination and their residuals' variances.

Abstract: A total of 10 hybridomas were generated from five fusions of BALB/c mice immunized with *Cucumber mosaic virus* coat protein (CMV-CP) subgroup I. A modified reverse-transcriptase PCR protocol was used to amplify and sequence the V-genes' light and heavy chains. Database analysis of the sequences that encoded the V-genes showed that the light chains of the 10 hybridomas expressed the family Vκ2 gene, bd2, while four of the heavy chains genes expressed four genes of the V_H1/J558 family, three of V_H5/V_H7183, and three of V_H8/V_H3609. There was frequent addition of the N region and expected variation in the lengths of CDR3 regions which form the center of the antigen binding site. Somatic mutation, junctional diversity and alternative light chains collectively impart specificity to these serologically distinct epitopes. Apparent dissociation constants (K_d) of mAbs were determined by direct ELISA yielding K_d = 3.0-38.5 nM. We conclude that high-affinity CMV-binding antibodies can arise without extensive somatic hypermutation in the variable-region genes because of the expression of appropriate HCDR3s. This information permits analysis, not previously possible, of the relationship between antibody H and L chain genes and the antigenic domains on antigen. Knowledge of the specific immunoglobulin genes for common epitope may lead to insights on pathogen-host co-evolution and helps blocking the virus infections in plants

Keywords: Monoclonal Antibodies; *Cucumber mosaic virus*; antibody genes; affinity; ELISA

1. Introduction

Cucumber mosaic virus (CMV) is the type species in the genus *Cucumovirus*, family *Bromoviridae*. CMV has the broadest host range of any known virus, infecting more than 1,000 species of plants, including monocots and dicots, herbaceous plants, shrubs, and trees (Palukaitis et al. 1992). The antigenic structures of many plant viruses have been investigated through the identification of epitopes recognized by monoclonal and polyclonal antisera, which has been accomplished largely through the use of synthetic peptides, although early work was done with coat protein (CP)-derived peptide fragments and some information has emerged from sequence and mutational analysis. Serologically, the two subgroups are closely related, as shown by the cross reactions of polyclonal antibodies. Some monoclonal antibodies produced against the CPs of subgroups I and II can differentiate the two, indicating the presence of unique epitopes for each (Zein et al. 2007). Antibody genes from hybridomas, as well as diverse repertoires of antibody genes from immunised and non-immunised donors have been displayed in this way (Marks and Marks, 1996). Accurate diagnosis depends on the affinity and specificity of the antibody preparation used, and high affinity antibodies are essential for the detection of very small amounts of pathogen. Monoclonal and recombinant antibodies can be produced in potentially unlimited quantities, and the epitopes with which they react can be identified, thus making well characterised preparations of these reagents the preferred choice for inclusion in standard assays. Also, assay specificity can be designed to detect one or more antigens by incorporating several different antibodies (Zein and Miyatake, 2007). Previously, the molecular structure of CMV was determined at 23 Å resolution by cryoelectron microscopy and image reconstruction. In examining which capsid protein domains are clearly exposed on the virus, Liu et al. (2002) noted that the amino acid sequence of the βH-βI loop forms a conspicuous, negatively charged

electrostatic field on the surfaces of virions (Liu et al. 2002) and has fundamental aspects that are conserved among cucumoviruses: its structure plays a role in aphid vector transmission (Perry et al. 1998), A prominent feature on the surface of the *Cucumber mosaic virus* (CMV) capsid is a negatively charged loop structure, the βH-βI loop. Six of eight amino acids in this protein loop are highly conserved among strains of CMV and other members of the cucumovirus family. Liu et al. (2002) individually changed five of these amino acids to alanine or lysine (positively charged), creating nine mutants. The mutants formed virons and accumulated to wild-type levels, but eight of the nine mutants were defective in aphid vector transmission. Since the disruption of charged amino acid residues in the βH-βI loop reduces or eliminates vector transmissibility without grossly affecting infectivity or viron formation, they proposed that this sequence or structure has been conserved to facilitate aphid vector transmission. The long-term goal of generating CMV-resistant transgenic plants using antibody genes depends on the molecular basis of antibody structure and diversity. Knowledge of the molecular structure of epitopes provides the possibility to predict *in silico* the cross-reactivity of antibodies.

The epitopes can directly be used to screen the databases for identical or similar sequences, either by performing a general search or a specific search among family members. Antibody-based resistance is a novel strategy for generating transgenic plants resistant to pathogens (Schillberg et al. 2000). Ectopic expression of recombinant antibodies (rAbs) has great potential to prevent viral infection. The strategy of using antibodies to increase pathogen resistance has been successfully demonstrated for human viruses (Marasco 1995) but the application in plant virology has been limited. Recent advances in gene isolation and an understanding of 'antibody-based resistance', an approach in which expressed antibodies bind to essential proteins, were used to interfere with pathogenesis. The introduction of antibodies is an attractive alternative and effective resistance against a number of plant viruses has been demonstrated (Zimmermann et al., 1998) as well resistance against other phytopathogens including fungi (Peschen et al., 2004).

The aim of this work was to examine the molecular structure, in particular, the nucleotide sequences of the heavy and light chain genes which are specific to CMV-coat protein (CP) specific for subgroup I, and their respective affinity. We also attempt to understand the antibody structure and the immunoglobulin genes that encode the biding sites of antibodies against CMV-CP, the high affinity heavy V_H and light V_L chains variable regions (Fab) of these antibodies for long-term CMV resistance of important transgenic crop plants.

2. Material and Methods

2-1 Plant material and virus purification

Tobacco plants (*Nicotiana tabacum* cv. 'Xanthi-nc') and *Nicotiana benthamiana* plants at the five-leaf stage were used for inoculation. The pepo strain of CMV (subgroup IA) was originally obtained from *Cucurbita pepo* in Japan; CMV propagated in tobacco was purified as described by Nitta *et al.* (1988). Plants were inoculated mechanically with purified CMV strain pepo, diluted to a final concentration of 50 μg ml^{-1} in 100 mM phosphate buffer, pH 7.0. Inoculated plants were grown in a growth chamber (NK systems) at 24°C with a 14 h light/10 h dark cycle.

2-2 Immunization

Immunized eight-weeks old BALB/c mice (Nippon SLC Co., Japan) were injected subcutaneously with 100 μg of purified CMV strain pepo in 0.1 ml phosphate-buffered saline (PBS; 0.01 M phosphate and 0.015 M sodium chloride, pH 7.5), which was mixed with an equal volume of adjuvant containing TDM plus MPL (Sigma). Three injections were administered at two-week intervals. Three days after the fourth injection, the mice were given a peritoneal injection of 200 μg of virus in 0.2 ml PBS. The mice were sacrificed three days later and their spleens were harvested. Fusion experiments were carried out in which lymphocytes from the spleens of the immunized mice were mixed at a 5:1 ratio with non-secreting P3X63-Ag8-U1 myeloma cells in polyethylene glycol 6000 (50%, w/v). The cells were distributed to 96 well plates at a concentration of 10^5 cells/well with HAT medium (100 μM hypoxanthine, 0.4 μM amino protein, 16 μM thymidine, 6 mM Hepes, and 200 μM 2-mercaptoethanol). Clones that successfully secreted antibodies specific to CMV were examined by both ELISA and western blotting. Furthermore, these positive hybridoma cells were subcloned by a limiting dilution method in the presence of thymocytes of BALB/c mice as feeder cells according to standard protocols (Harlow and Lane, 1988).

2-3 Production of monoclonal antibodies (mAbs)

mAbs were produced following the intraperitoneal injection of 10^7 hybridoma cells into intraperitoneal cavities of BALB/c mice primed two-weeks previously with 0.5 ml pristine (2, 6, 10, 14-tetramethylpentadecane), and the antibodies were

purified from the isolated ascetic fluid by affinity chromatography protein.

2-4 Preparation of IgG

The immunoglobulin (IgG) fraction was separated from ascitic fluid by using protein A affinity purification kit (Bio-Rad, Hercules, CA). Ascitic fluid was diluted with binding buffer 1:2 (v/v), centrifuged, and filtered through a PF syringe filter, 0.2 μm Acrodisc. Nine milliliters of the diluted ascitic fluid was applied to a column filled with 3 ml of sorbent and then allowed to flow through the chromatographic column with immobilized protein A. The column was washed with 10 bed volumes of washing buffer, eluted with 3-4 bed volumes of eluting buffer, and neutralized with Tris-HCl buffer. After dialysis against PBS buffer, the IgGs were incorporated into indirect ELISA to establish assay parameters of the respective antibodies.

2-5 Determination of the real binding Affinity mAbs to CMV-CP

The binding affinity of each mAb was determined by virus inhibition, with each mAb used at an appropriate concentration that gave 50% maximal binding (Fujii et al., 1998). Diluted optimum concentrations were prepared: mAbs-(4, 5, 8, and 52) used 100 ng/ml; mAb-(6 and 7) used 200 ng/ml; mAb-8 used 400 ng/ml. These dilutions were preincubated for 2 h at room temperature (RT) with an equal volume of buffer containing a range of CMV-CP concentrations (1, 3, 30, 90 μg/ml). Competitive ELISA was performed on 96-well microtiter plates coated with CMV-CP at a constant concentration (1 μg/ml in carbonate buffer (100 μl/well) at 4°C overnight. Wells were aspirated and remaining free sites on the microtiter plates were then saturated using 1% Block Ace (Nippon SLC Co., Japan) in TBS (200 μl/well), and incubated for 2 h at RT. Using polypropylene tubes, the CMV-CP was concentrated to(1, 3, 30, 90 μg/ml) into optimum concentrations of antibody solution, and the amount of free mAb in the antibody inhibitor mixture was placed for 30 min at RT using CMV-precoated plates. The average mAb affinity was calculated according to the method of Bobrovnik (2003).

1-6 RNA isolation and cDNA synthesis

Total RNAs prepared from about 10^7 hybridoma cells were cultured in minimum essential medium containing 15% (v/v) fetal bovine serum, 2% (v/v) glutamine (200 mM), and 1% (v/v) gentamicin (10 mg/ml) in a 5% CO_2 humidified incubator (BIO-RAD) using ISOGEN RNA extraction buffer (Nippon Gene Co., Tokyo, Japan). Chloroform was added, followed by vigorous agitation, and incubated at RT for 2-5 min, centrifuged, and the upper aqueous phase was retrieved then incubated with isopropanol at RT for 10 min to precipitate the RNA. The RNA pellet washed with 75% ethanol, air-dried, and dissolved in 0.1% diethylpyrocarbonate water (Sigma). RNA concentration and purity were gauged using $OD_{260/280}$. The mRNAs were isolated on Oligotex-dT30 (Super) columns (Takara, Kyoto, Japan), as specified by the manufacturer's instructions. The primers used in PCR amplification were based on data by Huse et al. (1989): for V_H, 5′-AGGTCCAACTG**CTCGAG**TCAGG-3′ and 5′-AGGCTT**ACTAGT**ACAATCCCTGGGCACAAT-3′, where the underlined portion of the 5′ primers incorporates an *Xho*I site and that of the 3′ primer an *Spe*I restriction site. Primers for the Vκ genes were 5′-CCAGATGT**GAGCTC**GTGATGACCCAGACT-CCA-3′ and 5′-GCGCCG**TCTAGA**ATTAACACT-CTTCCTGTTGAA-3′ where the underlined portion of the 5′ primer incorporates a *Sac*I restriction site and that of the 3′ primer an *Xba*I restriction site for amplification of the Fd and κLc regions, respectively. First-strand cDNA was synthesized from mRNA template with the Moloney murine leukemia virus M-MLV Reverse Transcriptase kit (Takara, Kyoto, Japan) using oligo-dT20 primers (Pharmacia Biotech). Variable heavy and light chains were amplified from first-strand cDNA using Ex-*Taq* DNA polymerase with 30 cycles of PCR (1 cycle = 1 min at 94°C, 1 min at 55°C, and 2 min at 72°C) in 50 μl of the following reaction mixture: 78 mM Tris-HCl (pH 8.8), 17 mM $(NH_4)_2SO_4$, 10 mM β-mercaptoethanol, 2 mM $MgCl_2$, 0.05% W-1 detergent (Takara, Kyoto, Japan), 0.2 mg of BSA/ml, 200 mM each of dATP, dCTP, dGTP, and dTTP, 1 mM of each primer, 10 ng of cDNA, and 2.5 U of EX*Taq* DNA polymerase (Takara, Kyoto, Japan). The PCR products were analyzed on a 2% low-melting-point agarose-Tris acetate-EDTA (TAE) gel and visualized with ethidium bromide. PCR products of expected size about 650 bp were excised from the gel and purified with a QIAGEN gel extraction kit as specified by the manufacturer. The amplified fragments were cloned into pGEM-T Easy Vector (1:1, 3:1, 10:1) respectively, according to manufacture protocol (Promega, Biotech) and ligated with Ligation High Kit (Takara, Kyoto, Japan), for the purpose of transforming into competent *E. coli* DH5α cells.

2-7 DNA sequence of variable region of the heavy and light chain genes

Direct sequencing of the treated DNA fragments was made using M13 primer and ABI PRISM BigDye Primer Cycle Sequencing Kit reagent following the manufacturer's instructions (Applied Biosystems) and run on an ABI Prism 310 Genetic

Analyzer (Applied Biosystems) using ABI Prism Sequencing Analysis 3.7 software for data analysis. The PCR product was analyzed and sequenced using M13 primer sequencing of the V regions. Cyclic sequencing of these DNAs was performed in both directions using a commercial kit (Thermo Sequence kit, Amersham Pharmacia Biotech), M13 forward (5′-CACGACG-TTGTAAAAACGAC-3′) and reverse (5′-GGATAACAATTTCAC-ACAGG-3′) primers set (Pharmacia, Biotech). Fd or Lc sequences were "blasted" against the publicly accessible "Ig-Blast" database of mouse Ig sequences at the National Center for Biotechnology Information (NCBI; http://www.ncbi.nlm.nih.gov/igblast) to determine the closest germline gene of origin, and to identify potential mutations. CDR position and numbering adopted Kabat numbering (Martin, 1996) and CDR definition was adopted from Andrew's web site (www.bioinf.org.uk/abs/).

3. Results

3-1 Production and characterisation of CMV-CP specific mAbs

Immunization of nonautoimmune BALB/c mice with native CMV-CP–stimulated antibodies was intriguing. Hybridoma technology allows the production of hybrid cell lines from B cells that secret a single monoclonal antibody with specific binding, and can potentially produce unlimited quantities. The serological differentiation of CMV isolates is important in plant breeding for disease resistance and to study disease epidemiology. Specific mAbs have been developed, and one of the goals in their development being to provide tools for serotyping viral isolates. mAbs with serotype specificity have been previously described (Hsu et al. 2000). The antibodies bind a broad variety of antigens with high affinity and specificity and the structural information about the molecular interactions between them helps us to understand the effect of mutations on the affinity and specificity of the antibodies.

In this study, 10 mouse hybridoma cell lines secreting monoclonal antibodies specific to CMV-CP subgroup I were established, and the immunoglobulin classes and subclasses for each were determined (Table 1). The antibodies were produced in ascites fluids in mice, and the optimum dilution of the antibody solutions for use in ELISA ranged from 0.05 to 0.4 µg/ml (Table 1). In testing the recognition specificity of the mAbs, the binding affinity and specificity of each mAb were examined with ELISA and western blotting (data not shown).

3-2 Measurement of the Affinity constant of mAbs to CMV-CP by ELISA

The affinity constant of MAbs to CMV-CP was measured by ELISA binding specificity by demonstrating that soluble CMV-CP inhibited mAbs interactions with immobilized CMV. The mAb was incubated in solution with the antigen until equilibrium was reached. Then, the antibody, which remains free at equilibrium, was captured by binding to antigen on the microtiter plate and measured by classical indirect ELISA. The binding constant was calculated from the experimental curve with equation [1/Ai vs. (A0-Ai)* Li] plot linear regression analysis according to Bobrovnik (2003) (Figure 1). Two mAbs, -5 and -8, showed the highest binding activity, 3.0 and 5.0 $\times 10^{-9}$, respectively while the binding activity of mAbs-(4, 52, 521, and 6) against CMV-CP was 1.36, 1.43, 2.7, and 3.85 $\times 10^{-8}$, respectively (Table 1). This method was valuable for measuring true dissociation and was found to be simple, reproducible, and accurate. It is therefore possible to assess the contribution of different germlines in the assay by affinity maturation even when they have

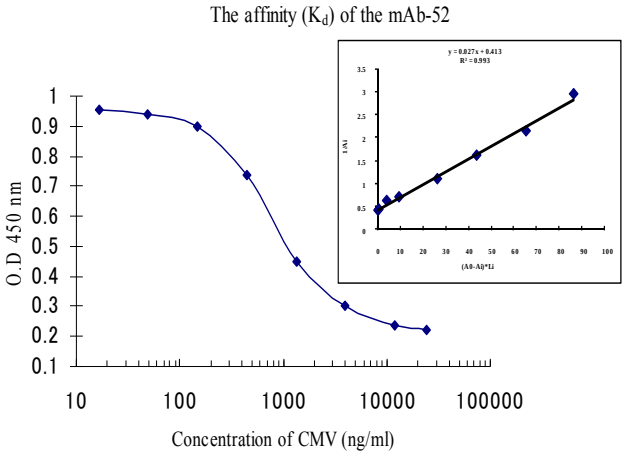

Figure 1. Competitive-ELISA for measuring the binding affinity of CMV-specific mAb-52. Different concentrations of CMV were incubated with a constant concentration of MAb-52 (0.45 µg/ml). The binding constant was calculated from the experimental curve with equation [1/Ai vs. (A0-Ai)* Li] plot linear regression analysis according to Bobrovnik (2003).

3-3 Utilization of the V gene segments of the H and L chain genes

The V_H and Vκ regions of 10 CMV-specific mAbs generated from three different fusions of BALB/c mice were sequenced. These sequences were almost homologous with corresponding germline genes published in the GenBank database, outlined in Table 2, which summarizes the V_H, D, and J_H fragments of variable heavy chain genes and Vκ, and Jκ of variable light chain genes. The nucleotide and deduced amino acid sequences of the expressed light chain germline gene assignments confidently to very restricted germline family Vκ2, gene bd2 (ten mAbs), GenBank accession nos. (**EF672211**, **EF672212**, **EF672213**, **EF672214**, **EF672215**, **EF672216, EF672217, EF672218**, **EF672219**, and **EF672220)** (Table 2). The identity of the V genes used was determined by searching the GenBank database for homologies to known V genes using the BLAST protocol (Altschul et al., 1997). On the other hand, the nucleotide and deduced amino acid sequences of the expressed V_H genes of the 10 anti-CMV antibodies are shown in Figs. 2, 3, and 4. The V_H genes belong to the following GenBank accession nos.: V_H1/V_HJ558 (four antibodies) (**EF672206**, **EF672197**, **EF672202**, **EF672203**); V_H5/V_H7183 (three antibodies) (**EF672198**, **EF672205**, **EF672201**); V_H8/V_H3609 (three antibodies) **(EF672199**, **EF672200**, **EF672204**) (Table 2). In addition, the V_H genes of the IgG antibodies were more somatically mutated. D segment usage also appears to be restricted with 7 mAbs of V_H using the DSP2 segment, while three mAbs were used for another segment, DFL16 (Figs 2, 3, and 4). On the other hand, it does not appear to be an obvious restriction in J_H segment usage. Interestingly, most antibodies could group into three sets based on their use of the same or highly similar V_H and V_L genes. Gene rearrangement entails the joining of heavy-chain V, D and J germline genes followed by the joining of light-chain V and J genes. The heavy chains belonged to three different families classified into three subgroups. The first included four mAbs (4, 9, 11, and 521) and belongs to the V_HJ558 germline family with different genes; the homology of the amino acid sequences were: $V_HJ558.51$ (89%), $V_HJ558.51$ (93%), $V_HJ558.45$ (94%), and V_H104B (99%) (Table 2; Cohen and Givol, 1983; Haines et al., 2001). The second subgroup included three mAbs-(5, 8, and 52) whose V_H gene segments were from the V_H7183 germline family (Gubbins et al., 2004). The mAbs-(5 and 52) V_H genes were derived from the same germline gene $V_H7183.14$ with 97 and 95% amino acid homology, respectively (Table 2; Chukwuocha et al., 1994). The third subgroup included mAbs-(6, 7, and 122) V_H genes which were derived from the same V_H3609 germline family, CB17H.10 gene (Gubbins et al., 2004) with 96, 96, and 95% homology, respectively (Table 2).

3-4 Somatic mutation and affinity maturation

Based on the sequence analyses of V genes in specific acquired immune responses to foreign antigens, somatic hypermutations were found to occur mainly in complementarity-determining regions (CDR) of V genes during the process of affinity maturation. The combined processes of immunoglobulin gene rearrangement and somatic hypermutation allowed for the creation of an extremely diverse antibody repertoire. V_H-521 showed 16 mutations, five of which were silent, while 11 others led to the mutation of amino acid no. 6 glutamine in germline to glutamic acid ($Gln6^HGlu$); $Ala9^HPro$; $Ser31^HLys$; $Thr54^HSer$; $Glu58^HAsp$; $Asp65^HGly$; $Ala71^HVal$; $Gln80^HGlu$; $Ser82^HHis$; $Ala94^HThr$; and $Arg95^HAsn$ (Fig. 2F). V_H-(4 and 9) showed 18 mutants, 7 silent and 11 amino acid replacements: $Thr19^HLys$; $Lys23^HArg$; $Ser25^HLue$; $Gly26^HIle$; $Met34^HVal$; $Asp52^HLue$; $Glu53^HGly$; $The54^HAsn$; and $Gly56^HAsn$; $Arg82A^HSer$; and $Lue94^HAsn$. The only difference between two antibodies is a one-point mutation in the V_H gene in CDRH2 $Lys65^HIle$ and another in the DSP2 segment of $Phe99^HTyr$ (Fig. 2H). In contrast, V_H-11 reveled only two substitutions, the first in CDRH2 with $Cys54^HSer$ and the second in FW3 with $Arg94^HIle$ (Fig. 2D). V_H-5 revealed 7 mutants: 2 were silent and 5 were substitutions: $Ser55^HGly$; $Tyr56^HSer$; $Arg75^HLys$; $Arg83^HLys$; $Lue89^HMet$. V_H-52 revealed 10 mutations: 3 were silent and 7 were substitutions, 5 being typical as Fd-5 with two more substitutions; $Thr50^HTyr$ and $Ser62^HThr$ (Fig. 2C). V_H-6 has 10

mutants, 3 silent and 7 substitutions: Asn33^{H}Gly; Ile35A^{H}Val; Asp56^{H}Ser; Ser62^{H}Ala; Ser74^{H}Tyr; Thr82A^{H}Ala; and Thr82B^{H}Ser. V_H-72 showed 11 mutants, 3 silent and 8 substitutions, similar to Fd-6 substitutions, except for Trp52^{H}Lue and Thr82B^{H}Asn. V_H-122 showed 13 mutants, 3 silent and 10 substitutions, similar to Fd-72, except for Asn33^{H}Asp and Ser41^{H}Pro; Ala49^{H}Lue. As the frequency of the PCR error used in this study was one in 5000-10000 nucleotides, the intraclonal sequence heterogeneity observed here might not be derived from PCR errors.

3-5 CDR3 length, D regions, and number of N insertions

The length of the H-CDR3 varied from 27 nucleotides in mAb-4 to 51 nucleotides in mAb-6 (Table 3). It has been suggested that the presence of Tyr and Trp residues in H-CDR3 confer flexibility upon the Ab molecule. Consequently, V_H-(6, 7, and 122) has five Tyr residues in this region, while the other V_H has three (Table 3). There are different D and J_H regions used in the CMV-specific V_H and the number of N insertions between these regions (Table 3). On the basis of N insertions at both the V-D and the D-J_H junctions, a third subgroup, V_H showed 10 nucleotides on the V_H-D side and three nucleotides on the other side, D-J_H. V_H-(5 and 8) showed 6 and 4 nucleotides on the V_H-D side, respectively, while only one nucleotide on the D-J_H side. V_H-52 showed 7 nucleotides on the V_H-D side and 5 nucleotides in the D-J_H side. V_H of the first subgroup showed only one sided V_H-D, with 7 or 5 nucleotide insertions.

Contribution of N- "random nucleotides insertion between V_H and D, D and J_H"

4. Discussions

Antibody fragments may have advantages for treatment of infections due to their small size and lack of Fc portion. It has been known for some time that small Ab molecules such as Fv's could have the potential for therapeutic application. However non-covalently assembled V_H and V_L tend to dissociate in the range of 10^{-4}-10^{-7} M depending on the sequence of interacting complementarity-determining regions (King et al., 1995). Therefore techniques have been developed to covalently link both V regions and stabilize them for *in vivo* applications. Using data from known crystal structures of Antibody and computer modeling, a series of linkers were designed and evaluated as potential candidates to genetically connect the V_H and V_L regions. The resulting scFv molecules were evaluated for their functional activities and relative affinity (Wörn and Plückthun, 2001). Very little molecular characterization of CMV with monoclonal antibodies (mAbs) has been achieved so far. Three different clones of a human synthetic antibody library specific to CMV-CP have been isolated; their V_H belongs to the human V_H1 family (Ziegler et al., 1995). A ScFv phage display library was constructed from mice immunized with CMV specific to the subgroup of both isolates I and II. V_H belongs to germline family V_HJ558 and subfamily V130.3, while the V_L gene belongs to germline Vκ4/5, gene ap4. Synthesis of an scFv antibody targeting CMV-CP, V_H belongs to germline family V_HI/J558, gene V_HF102, while V_L belongs to germline Vκ4/5, gene at4 (Chae et al., 2001). Several clones with high reactivity against CMV-CP were isolated from a large semi-synthetic scFv phage display library based on chicken immunoglobulin genes (van Wyngaardt et al., 2004). Due to the activation of the immune system as a response to a foreign antigen, maturation of the antibody response takes place, resulting in the production of specific, high-affinity antibodies. Therefore, specific antibodies can be selected using a relatively small, random combinatorial V-gene library derived from an immunized donor. Briefly, the procedure followed included the isolation of the variable heavy and light chain domains of the murine monoclonal antibody from mRNA of hybridoma cells, followed by cloning, sequencing and characterization of the Fab. V_H-gene. Usage was determined and compared to V_H-genes used by antibody fragments of a germline database. The V_H and Vκ regions of 10 anti-CMV mAbs generated from three different fusions of BALB/c mice were immunized with native CMV-CP, and the V_H, D, J_H, Vκ, and Jκ were determined (Table 2). Based on nucleotide sequence homology of the mAbs, V_H and V_L genes were classified into three subgroups. All the antibodies were found to derive from distinct B cells because they had utilized diverse V_H, D_H, and J_H gene combinations, and because the length of the CDR3 region ranged from 7 to 17 amino acid residues (Table 2). An abundance of V_H genes from the J558 family was observed (4/10) but each represented a separate member of the family (Table 2). CMV-CP is capable of inducing a variety of B cells that have distinct phenotypic and genotypic paratopes. Antibody-binding kinetics measured by surface plasmon resonance showed that antibodies from 'naïve' repertoires have comparable on-rates for antibodies from immune repertoires but faster off-rates (Winter et al., 1994). Frequently it is necessary to improve the affinity of antibodies isolated from a 'naïve' library by affinity maturation techniques that include chain shuffling, error-prone PCR (Fujii et. al., 1998), or parsimonious mutagenesis (mutagenesis in a few sites in which most residues remain parental) (Glaser et. al., 1992). Interestingly, the high affinity antibody specificity was encoded by germline genes such as mAb-8 (Figure 1). Furthermore, analysis of the affinity measurements and nucleotide sequences shows a strong correlation with the germline heavy chains, in which mAbs-(5, 52 and 521) were derived from V_H7183, showing high affinity to CMV-CP (Table 1). Although it is unlikely that all of these mutated residues are involved in CMV binding, increasing mutation in the heavy chain CDRs with increasing affinity of the antibodies is quite striking. It is difficult to determine the contribution of the CDR3 of the heavy chain, or of individual amino acids to affinity. Higher affinity scFv were produced by evolving the center of the antigen binding pocket by sequentially randomizing amino acid residues located within the heavy and light chain CDR3. Amino acid residues conferring higher affinity were located in loops within the CDRs and had solvent accessible side chains. In contrast, residues known to have a structural role were conserved. Isolation of higher affinity antibodies required a stringent selection process using limiting concentrations of soluble biotiylated antigen, use of a biosensor-based screening process

to identify higher affinity antibodies, and optimization of elution conditions (Schier et al., 1996).

One of the important aspects of V_L and V_H amino acid sequences is the study of the structural analysis of the antigen binding loops by molecular modeling and simulation of molecular dynamics (research currently in progress). Through these findings, it will be suggested that amino acids residues may play a crucial role in the antigen-antibody interaction.

Knowledge of specific immunoglobulin genes for a common epitope may lead to insight on pathogen-host co-evolution and help block a virus from infecting plants over the long-term, which is useful for antibody-based resistance. CMV-CP domains are clearly exposed on the virus; in addition, the amino acid sequence of the βH-βI loop forms a conspicuous, negatively charged electrostatic field on the surfaces of virions, which is a fundamental aspect that is conserved among *Cucumoviruses*, and this structure plays a role in aphid vector transmission (Liu et al., 2002). The βH-βI loop of the CP is a critical determinant of viral pathogenicity and has been shown to contain major immunodominant neutralization domains (He et al., 1998). The decapeptide sequence DDKLEKDE (aa198–205) probably contains essential contact residues, in which K (lysine) and E (glutamic acid) are both hydrophilic and negatively charged and might be important to constitute the epitope (Liu et al., 2002). Tyrosine side chains that exist in the antigen combining site might be capable of mediating most of the contacts necessary for high-affinity antigen recognition, and, thus, it seems likely that the overabundance of tyrosine in natural antigen-binding sites is a consequence of the side chain being particularly well suited for making productive contacts with antigen (Fellouse et al., 2004). Interestingly, the genes encoding the heavy chain variable region of these antibodies displayed evidence of only minimal somatic hypermutation. The crucial role of heavy-chain CDR3 in high-affinity CMV recognition is suggested. We propose that high-affinity CMV-binding antibodies can arise without extensive somatic hypermutation in the variable-region genes because of the expression of appropriate HCDR3s. We consider that the negative charge on the acetate group in the CMV-CP was partially neutralized by a hydrogen bond with the phenolic hydroxyl group of tyrosine, which exists in HCDR3. We consider that the negative charge on the acetate group in the CMV-CP was partially neutralized by a hydrogen bond with the phenolic hydroxyl group of tyrosine that exists in HCDR3. Therefore, we speculate and expect that the HCDR3-peptide be used as tool for plant virus resistance depending on the peptide-neutralizing epitope.

Abstract: today, the role and importance of the human body antioxidant defense system in prevention of many diseases has been proved completely on the other hand the need to strengthen the immune system is inevitable that the consumption of synthetic antioxidants in numerous adverse effects Experts are always following the use of natural antioxidants in this regard must recommend extensive research to find natural resources and the needs of modern human antioxidant is ongoing results of many studies have shown that marine resources are rich in antioxidants are the blue swimmer crab research in this respect were fractions antioxidant extracted from muscle tissue extracts such, antioxidant capacity showed significant antioxidant addition fractions such significant effects in inhibiting oxidative stress, including inhibition hemolysis of red blood cells and protection of Thiol groups of blood showed in a laboratory.

[Ashraf Jazayeri, Ahmad savari, Mehran Hossein-Zadeh, Forough papan, Manijeh kadkhodaei. **Including Effectiveness of the blue crab (*portunus pelagicus*) antioxidants inhibit oxidative stress.** Journal of American .http://www.americanscience.orgScience 2010;6(12):1565-11569]. (ISSN: 1545-1003).

Keywords: antioxidant capacity, blue crab, oxidative stress

1. Introduction

The human body in a state health system, a balance between free radicals and anti oxidant rate each factor that causes interference can be above the equilibrium incidence of some diseases cause. Including atherosclerotic cancer and premature aging recent research necessary to strengthen the body's antioxidant system through diet or supplements nutritional shows, although the late twentieth century as the only plant sources of natural antioxidant sources are identified in the recent decade extensive research on fish showed that some species of marine plants and animals significant amounts of anti-tumor compounds, anti-viral and contain antioxidants, blue crab research in the Gulf of antioxidant capacity consideration Therefore, the species was muscle tissue above the isolation and the environment was then Buffering homogenize blue crab muscle tissue for extraction process Sequestration antioxidants ammonium sulfate and dialysis, and then it was sad, extract the above route by the end of gel from 150, then the maximum for the fraction of total antioxidants was selected in 5 different concentrations Measurement for efficacy in inhibiting oxidative damage was used in this section of the human red blood cell model used and the effectiveness of the blue crab fractions antioxidant in human erythrocyte hemolysis inhibition and the amount of blood Thiol protecting groups was Calculated reviews and tests show that the blue crab at the level of antioxidants can significantly inhibit human erythrocyte hemolysis and blood Thiol protecting groups are the results of this study blue crab as a rich source of natural antioxidants that can be defined as the a source of marine biotechnology in food production complexes and compounds for drug prevention and treatment of disease pathogenesis that free radicals are used.

2. Material and Methods

Crab fishing by trawler were incubated with samples of ice and immediately transferred to the laboratory, the samples described tissue, muscle separation and buffer Tracy (5%, 5.7PH =) transferred along with muscle tissue was then centrifuged buffer homogenize iceman temperature for 10 minutes c 40 and g × 6000, was centrifuged, sedimentary layer was discarded, for the separation layer supernatant Sequestration method was used proteins thus under the terms of the first magnetic mixer adding the necessary amounts of solid ammonium sulfate saturation level was 50 percent, after centrifugation (g × 6000, c40) for 30 min, sedimentation at this stage was maintained and sup layer according to the previous stage saturation of 70 percent required rate of solid ammonium sulfate was added after this stage centrifugal sedimentation with sediment before step combined amount of the buffer size after mixing Tracy added, for 12-hour dialysis, the dialysis bag was transferred (input buffer during the dialysis, buffer was Tracy was replaced every 2 hours) after dialysis Inundation by sucrose for 10 hours was the end result of solution outside the dialysis bags to human transmission found and the

potential for antioxidants extraction chromatography was used in the first chromatography column containing seeds Pharmacia diameter 5.2 cm and 60 cm in height, Tracy salt buffer mobile phase, flow rate 40 ml per hour was elected , fractions obtained by the end of the device fraction collector column, were collected (170 fraction) then all the above fractions light absorption wavelength 280 nm and 540 nm was read and help protein and Bioret kit by Randox rate Each antioxidant was calculated fractions (122-117 and 97-93 and 58-52 and 26-20), which had the maximum amount of antioxidants to second column purification transferred to the second phase chromatography column containing DEAE cellulose column diameter 5.1 cm and 60 cm height Tracy salt buffer mobile phase, flow rate was 40 ml per hour by the end of the column device 150 fraction collector raised before the rate matching step, the amount of total protein and antioxidants, all calculated fractions was then fractions (89-84 and 71-68 and 48-42 and 27-25 and 16-12), which had the maximum amount of antioxidants microbial filter method, is sterile in order to review the effectiveness of the inhibition of oxidative damage were used.

2.1. The impact on blue crab antioxidants inhibits oxidative damage in a laboratory

2.1.1. Liz inhibition of red blood cells
A - **Suspension the blood**:

The blood in healthy individuals heparin pipe and then collected by centrifugation, plasma was separated from red blood cells, Rbc above three times by saline washing, and ultimately pure red blood cells were prepared from pure erythrocyte above dilution method in phosphate buffer salt, 2 percent suspension (equivalent hematocrit 12) was prepared.

B - Hemolysis of red blood cells

Of antioxidant fractions sterile, the pipe with concentrations (100%, 75%, 50%, 25%) was produced (with dilution buffer were PBC), then pipe that includes Prepare the mixture for 2 hours the temperature was then incubated with 370 centrifuges (g × 1000) of 10 minutes and the upper layer of light absorption wavelength 415 nm was read (represents the amount of hemolysis) and the control tube (No extract fractions) the rate of hemolysis were compared with values based on percent inhibition of hemolysis in the vicinity with fractions, compared to the control rate (percentage of hemolysis showed percent) was calculated.

2.2. Protection of Thiol groups

After the suspension of red blood cells, 50 micro litter of the suspension Rbc 1000 Tracy and 50th micro litter buffer fraction antioxidant (concentrations of four) the composition and light absorption wavelength of 4 micro litter 12 nm was read then pipe above 20 micro litter reagent DTNB added and 30 minutes and then incubated in the laboratory temperature optical absorption was read at 412 nm, pipe controls included buffer suspension cells and introduced Tracy DTNB prepared and its optical absorption 413 nm was read , then read the values in light absorption were the following formula according to the amount of computation protected Thiol groups were obtained Thiol protecting groups for the amount of each of the five branches fractions antioxidant concentrations separately tested and was measured at the end of percentage protection for each concentration fractions Thiol groups compared with control was calculated.

3. Results

Determine the antioxidant capacity of a blue crab: After chromatography, fractions from each stage (gel filtration, ion exchange) levels of total protein and total antioxidant were analyzed (Tables 1 and 2).

3.1. effect of antioxidant fractions blue crab in the inhibition of hemolysis of red blood cells

Fractions group of the A_1 the most total antioxidants were also dilution, fractions with total antioxidant levels (12, 9, 6 and 3 and 2 / 1) mmol liter in the equivalent concentrations (100, 75, 50, 25 and 10) respectively were prepared, then each fraction cells were in the vicinity, after adding a certain amount of AAPH for 2 hours incubation period temperature was 37 degrees then created hemolysis rate for all pipes and pipe control (No fraction antioxidant) spectrophotometric method at 415 nm wavelength was read and the percentage hemolysis inhibition was calculated (compared to control samples), all the numbers obtained in 0.05> p was considered significant (Table 3).

As is clear in Table 3 fractions antioxidant concentration of 100 percent blue crab (the amount of antioxidants in 12 mmol L) no effect on hemolysis of red blood cells did not fraction concentration of 75 percent (total antioxidant levels in 9 mmol L) maximum effectiveness in inhibiting the rate of hemolysis showed 95 percent plus extract dilution effects of the above reduction in hemolysis fraction the lowest effect concentration and the rate of 10 percent antioxidant 2 / 1 mmol l showed that (a rate 7 / 19 percent).

Table 1: Results of total protein and total measured antioxidant derived from gel filtration chromatography blue crab muscle tissue

step purification	fraction	Total protein(mg/l)	Total antioxidant (m mol / Lit)
(sephadex G100)	crude tissue extract	1360	42.5
	group A (26-20)	580.5	21.2
	group B (58-52)	204.9	6.8
	Group C (97-93)	405	14.7
	Group D (122-117)	167	5.3

Table 2: Results of measurement of protein and total antioxidant fractions A group from ion exchange chromatography

stage purification	fraction	Total protein (mg/l)	Total antioxidant
DEAE cellulose	group A (26-20)	580/5	21/2
	A_1	199	12
	A_2	105.4	7.3
	A_3	174	10.2
	A_4	59.5	5.1
	A_5	29	4.6

3.2. The effectiveness of the blue crab fractions antioxidant protection Thiol groups (-SH) blood

In this section the concentrations of five triple antioxidant fractions blue crab was prepared the same step, then any effects in protecting blood Thiol groups were determined according to procedures based on mg protein vs control calculation, all numbers obtained in 05/0p <are considered significant. (Table4).

Table 3: The rate the effectiveness of the blue crab fractions antioxidant in inhibiting hemolysis of red blood cells

Fraction	Total antioxidant (mmol/l)	Inhibition percent
control	0	0
concentration 100 percent (Group A)	12	0
concentration of 75 percent	9	98.5
concentration of 50 percent	6	89.2
concentration of 25 percent	3	75.9
concentration of 10 percent	1/2	46

Table 4: Effect of blue crab fractions antioxidant protection Thiol groups fraction type and amount of antioxidant

fraction type and amount of antioxidant	Protein (mol/mg)	Percent to control
control	930	100
12	920.7	99
9	890	95.7
6	821.1	88.3
3	605.4	65.1
1.2	404.5	43.5

4. Discussion

The antioxidant capacity measurement showed that blue crab fractions muscle tissue from this species contain considerable quantities of antioxidants average 5 / 10 mmol were lit. Toresin and Kerstin 1998 (8) also reviews some fish, including salmon successful extraction of synthetic antioxidants were Astaxantin name. Clark and colleagues (1998), while reviews of gel were able to jack in the antioxidant properties of these prove. Smith and Bell 1996 (9), while crab carcinus menas review declared that Super oxide enzyme extracted from a laboratory in such a strong antioxidant properties shows. According to World Health Organization (WHO 2007) standard rate of serum antioxidant capacity in normal individuals, 1.03 - 1.77 mmol l that this value depends on the age, sex,

nutrition and the geographical conditions of the Hang the tea and colleagues Watch 2007 (16) antioxidant capacity in such a way the average shrimp Penaeus monodon have announced 4 compared with values above antioxidant capacity blue crab is significantly more.

For measuring the effectiveness of antioxidants blue crab model of red blood cells were used. Cruz Silva and colleagues (2000) (17) red blood cell model ideal model to evaluate stress Oxidative laboratory environments experience and introduced them announced that free radicals attack cells, causing lipid per oxidation and membrane proteins and eventually to hemolysis are, in this study results showed that fractions A1 (100 percent concentration and antioxidant levels in 12 mmol L) not only to prevent blood cell hemolysis, but also has had the effect per oxidant.

1999 Partasaraty and colleagues announced that the antioxidants in different concentrations can be different effects of antioxidant vitamin E Per oxidant even have the same feature to update itself, State hawthorn 1998 (18) showed that concentrations of vitamin C in 60-100 property antioxidant concentrations, but not more than this amount will Per oxidant properties, Frag and Partners 1999 (19) announced that its antioxidant properties and chemical components of each combination of concentration is related. Other fractions blue crab concentrations 75, 50 and 25 percent respectively, the values 9, 6, 3 and 1.2 mmol l antioxidants were all showed inhibition of addition, as Table 3 shows the reduced dose antioxidant effect Atpase considerably reduced. Burton and colleagues 2009 declared that what proteins Thiol groups who are building cell membranes and how those buildings hemoglobin (especially glutathione) exist, a very important factor in membrane stability and are soluble oxidative stress during this groups to the oxide and formation of disulfide bond to protect the cells against free radicals are combined, so if Thiol groups against oxidation in the cell's ability to protect against oxidative stress is taken up.

This study showed that blue crab fractions antioxidant to protect the good Thiol groups have a protective effect above fraction dilution and reduced antioxidant capacity, it declined (Table 4).

Considering the importance of antioxidants and their role in prevention of the pathogenesis and treatment of disease free radicals (13) The results of this study showed that blue crab having significant amounts of antioxidants in this area is of great import can be a natural source of antioxidant should be exploited.

Abstract: PSTVd-$_{EG}$ strain was isolated from infected potato plants cv. Diamond during autumn season. The PSTVd-$_{EG}$ was eliminated from these plants by different methods. The meristem-tip culture with size (0.25 mm) gave the high percentage of plantlets PSTVd-$_{EG}$-free was 83.33%. The chemotherapy with ASA, 2-TU and Virazole was applied in culture media with concentrations 10, 20, 30, 40 and 50 ppm. It was found that, the percentage of PSTVd-$_{EG}$-free plantlets was increased by increasing chemical concentrations. The thermotherapy of plantlets in jars (21, 3-4, 5, 8 and 21 $^{\circ}$C /4 mon. due to PSTVd-$_{EG}$ elimination). In addition to, the combination cold treatment of tubers plus meristem-tip culture is more effective for PSTVd-elimination *in Vitro*. As well as, the exposure of the tubers for electricity 5/5, 5/10, 10/5, 10/10, 15/5 and 15/10 mA/min. due to PSTVd-$_{EG}$ elimination particularly the exposure at 10/10; 15/5 and 15/10 mA/min. The results were confirmed by dot-blot hybridization assay.

1. Introduction

Potato Spindle Tuber Viroid (PSTVd) is the type member of the genus *Pospiviroid* (Family *Pospiviroidae*) (ICTV, 2008). It is a circular single-stranded, RNA molecule, measuring between 356-361 nt. in length and un-encapsidated (Schnöelzer *et al*. 1985). Higher percentage of PSTVd-free was obtained from apical domes, followed by meristem and lower percentage from shoot tips (Lizárraga *et al*. 1982 and Salazer *et al*. 1985).Lower temperature (cold therapy) due to reduce or stopping viroid replication and translocation through phloem tissue (Helms & Wardlaw 1976). Whenever, PSTVd-$_{EG}$ was not detected in plantlets grown at 5ºC for 3 and 6 mon. and low light intensity but viroid was present in tissue when plantlets was transferred to 25ºC for 1 mon. (Lizárraga *et al*. 1980).

There are many antiviroid chemicals such as piperonyl butoxide (Singh, 1977); Silver nitrate and ethylene (Conejero, 1982)**;** Ribavirin (Belles *et al*., 1986); ethephon against Citrus exocortis viroid (CEVd) infection (Belles *et al*., 1990). In addition to, Chitosan (1-4 glucosamine polymers) has been shown to stimulate different responses in plants (Ryan, 1988). Amantadine, Ribavirin and Thiouracil used to eliminate viroids from infected plants (Kryczyński 1992). *Potato Virus X* was eliminated by exposure potato stems to 5, 10 or 15 mA for 5 or 10 min. followed by immediate planting the axillary buds tips *in vitro*. The highest TE values were obtained at 15 mA for 5 min. under these conditions, 40% to 80% of the buds regenerated and 60% to 100% of the regenerated plantlets tested virus negative Lozoya *et al*. (1996).

The first concern of the present study was production of PSTVd-$_{EG}$-free potato plantlets from infected tuber potato through applied meristem-tip, chemotherapy, thermotherapy electrotherapy techniques and combination with them.

2. Materias and Methods

Two-month-old PSTVd-$_{EG}$ infected potato plants (*Solanum tuberosum* L.) cv. Diamond growing under greenhouse conditions were used for PSTVd elimination by meristem culture, chemical anti-viroid, thermotherapy and electrotherapy.

Detection of Potato viruses and viroid

DAS-ELISA technique was applied for detection potato viruses (PVX, PVY, PLRV, PVS, PVA, CMV and TRV) as described by Clark and Adams (1977) using an ELISA kits (completely ready for use supplied by Sanofi, Sante Animals, Paris, France).

Dot-blot hybridization for detection PSTVd was done according to (Owens *et al*., 1986).

Sterilization of stem nodes

The stem nodes were cut from PSTVd-$_{EG}$ infected potato plants cv. Diamond. Nodal cutting and sprouts were washed in running tap water for 1 h. and then transferred to 5% solution of commercial bleach (sodium hypochlorite 5.25% active ingredient) containing 0.1% tween-20, Then were rinsed 3 times with sterile dsH_2O at 2, 5 and 15 min. sequently.

Meristem-tip culture

Twenty-five shoots (2-3 cm length) under the steromicroscope (CETI WF 10X) the outer leaves and leaf primordia until the youngest leaves (2 primordia) were removed. The dome with two leaf primordia was excised with 0.25 mm length by scalpel. Excised the dome meristems were cultivated on MS-medium containing (0.1 mg/L NAA + 0.5 mg/L kinetin + 2.25 gm/L phytagel) (Edriss *et al*., 1996) then incubated at 25ºC and light intensity 2.000 Lux for 16 h. lightday. After 21 days, the plantlets were transferred to MS propagation medium until rooting.

Chemotherapy

Stem cuttings with one leaf node were cut from potato plants cv. Diamond (6 wks-old) infected with PSTVd-$_{EG}$ and healthy. The stem cuttings were cultured on MS medium solidified with agar (8 gm/L) in jar (250 ml vol.). Jars were incubated at 18ºC/16 h. daylight. The plantlets were multiplied *in vitro* as nodal cuttings in jars vol. 500 ml (5 subcultures). The nodal cuttings were transferred on MS media containing three antiviroid separated [1-β-D Ribofuranosyl- 1, 2, 4-triazole-3-carboxamide (Ribavirin or virazole), (ASA) and 2-TU]. Thirty nodal cuttings were cultivated on Paper Bridge in jars (500 ml) for each concentration. The jars were incubated on the same mentioned conditions. Percentage of survival cuttings were counted for each conc. after 30 days. The survival nodal cuttings were transferred in anti-viroid free media. After 4 wks. plantlets were detected by dot-blot hybridization against PSTVd-$_{EG}$.

Thermotherapy

Fivety-six PSTVd-$_{EG}$ infected tubers of cultivar Diamond and PVX, PVY and PLRV virus tested as well as four healthy ones was used in this study. Tubers were storaged at different temperatures and periods (3-4, 5, 7-8 ºC/4 mons. in refrigerators and 21±0.2ºC/4 mons. in incubator. Fourteen tubers/treatment from each temperature. The tuber sprouts were separated and meristems with two leaves primordia were excised. The sprout and meristem tips were cultured on MS media and were incubated as above mentioned. The percentages of survival and PSTVd-$_{EG}$-free plantlets were counted post storage for 4 mons.

Electrotherapy

Seventy-two PSTVd-$_{EG}$ infected tubers cultivar Diamond were exposed to electrictherapy treatment (Lozoya-Saldaña, 1996) The tubers were treated as following: current intensity-time combinations: 5, 10 or 15 (mA) for 5 or 10 min. Electricity was applied by an electrophoresis power supply (consort 600V-500 mA E865). Immediately after treatment 12 sprouts per treatment were removed from tubers. Sprouts were excised and were planted *in vitro* in a semi-solid MS medium. Then growing tips 1.9 mm long were excised and were planted in medium consisting of basic MS salts and supplemented with 0.25 ppm GA_3, 2.0 ppm calcium pantothenate (B_5), 3% sucrose and 2.25 mg/L phytagel (Espinoza *et al*., 1985). After 30 days the plantlets were transferred to shoot differentiation medium containing the basic MS salts supplemented with 0.3 ppm IAA, 0.3 ppm kinetin, 4% sucrose and 2.25 gm/L phytagel (Lozoya and Dawson 1982). The plantlets were incubated at 16 h. daylight/18ºC, for 30 days in the shoot differentiation medium. The percentages of survival and PSTVd-$_{EG}$-free plantlets were recorded.

- Viroid detection by Dot-blot hybridization

Dot-blot hybridization was used for PSTVd-$_{EG}$ indexing of plantlets arised from tissue culture experiment after micropropagation reindexing was performed after meristem-tip, chemotherapy, thermotherapy and electrotherapy treaments.

3. Results

Dot-blot hybridization assay was used to detect PSTVd-$_{EG}$ in potato plants and tubers cv. Diamond virus tested which used to produce PSTVd-$_{EG}$ -free plants as well as micropropagated plantlets. These plants were divided into three groups. Group one: was used for excised meristem-tip, Group two: for treated chemotherapy of plantlets

micropropagated *in vitro* and Group three: PSTVd-$_{EG}$- infected tubers were treated with cold and electrotherapy treatments.

Meristem-tips size 0.25 mm was excised from PSTVd-$_{EG}$ potato plants cv. Diamond under stereomicroscope. They were cultivated on MS medium and incubated under convenient conditions. After four subcultures the meristems were developed to shoot (Fig. 1), the survival of potato plantlets was 75% and percentage of PSTVd-$_{EG}$-free plantlets was 83.33%. These results were confirmed by dot-blot hybridization (Table 1).

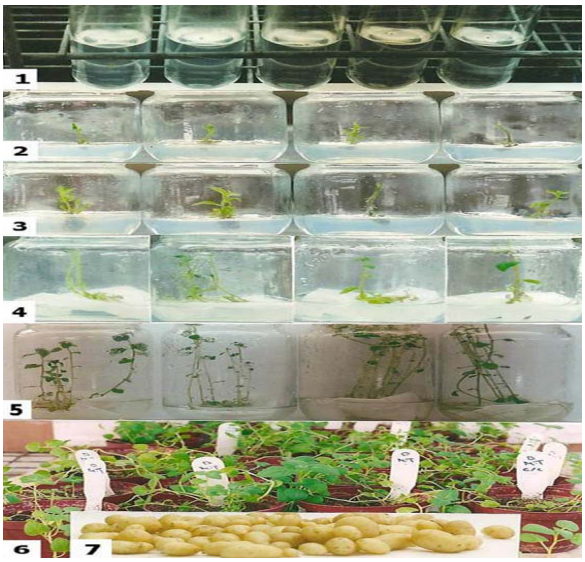

Figure 1. Micropropagation of PSTVd -free potato plantlets by meristem tip on MS-media.

1- Meristem-tip (0.25 mm size), 2, 3- Establishment stage. 4- Multiplication stage, 5- Rooting stage, 6- Adaptation, 7- Minitubers.

The plantlets were cultured on MS media treated with three different anti-viroid compounds. These compounds [Ribavirin (Virazole), 2-TU and ASA were incorporated individually into MS medium with concentrations 10, 20, 30, 40 and 50 ppm. The plantlets were incubated for 30 days. Incorporation of anti-viroid virazole, 2-TU and ASA in culture medium at conc. of 10, 20, 30, 40 and 50 ppm progressively increased the percentages of viroid-free plantlets to 57; 71.4; 77.7; 87.5 and 87.5 for virazole, 50, 63.63, 66.6, 77.7 and 85.7 for 2-TU and 42.8, 50, 71.42, 75 and 83.3 for ASA respectively. In addition, the percentage of survival decreased with increment conc. of the chemical antiviroid (Table 1).

Table 1. Effect of chemotherapy and meristem-tip on production of PSTVd-$_{EG}$ -free plantlets *in vitro*.

Chemotherapy treatments	% survival*		% viroid elimination
	H	I	
Meristem-Tip••(0.25 mm)	75.0	75.0	83.3
Chemotherapy •			
10 mg/L virazole	100	100	57.0
20 mg/L virazole	87.7	73.3	71.4

* Jar contaiing 30 plantlets. •Total number of tested plantlets 240 (8 jars x 30 plantlets), ••Total number of tested plantlets 25 (one meristem per tube).

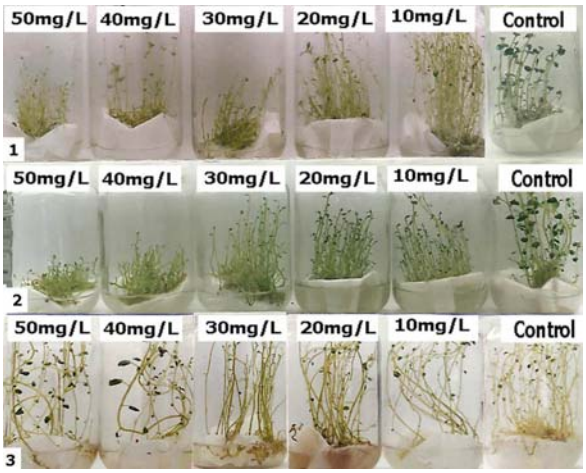

Figure 2. Micropropagation of plantlets on MS media treated with different concentrations of virazole. 1- Healthy plantlets treated with different concentrations of virazole, 2- PSTVd infected plantlets treated with different concentrations of virazole., 3- Re-subculture of plantlets on fresh media without virazole.

On the contrary, the effect of chemical antiviroid on the development plantlets was different such as virazole proved to be somewhat phytotoxic in

highest concs. 40 and 50 ppm causes severe stunting in plantlets, thin stem and stunted leaflets. Whereas, concentrations 30, 40, 50 ppm from 2-TU cause deleterious effects on growth of potato shoots, and concentrations 20, 30 and 40 ppm from ASA cause stunting of plantlets and concs 30, 40 and 50 ppm encourage formation of callus in some plantlets, while conc. 50 ppm induced formation of microtuber *in vitro*. But this phytotoxic effect was removed when subcultured on fresh medium without antiviroid-compunds. These results were confirmed by NASH (Table 1) and (Figures. 2, 3 and 4).

Potato tubers cv. Diamond infected with PSTVd-$_{EG}$ isolate were exposed to low-temperatures and cold therapy in refrigerators at 3-4; 5, 8ºC/4 mon. and incubator 21ºC/4 mon. (Table 2). Sprouts were excised with 0.5 mm buds. As well as, meristem-tip (0.25 mm) separated from sprout then micropropagated on MS media. It was found that percentage of sprout survival was 100%. Whenever, PSTVd-$_{EG}$ elemination percentages from sprouts were 61.50, 71.4, 71.4 and 64.2 at temperatures 21, 3-4, 5 and 8ºC respectively. On the other hand, meristem-tip excised from sprouts exposured for low-temperatures 3-4, 5, 8ºC for 4 mon. were the best treatments for viroid elimination which gave 100%, whereas 21ºC/4 mon. gave 77.7 %. However, survival rate of meristem-tip was 85.7; 71.4, 57.1 and 57.1% for temperatures 21, 3-4, 5, 8ºC for 4 mon. respectively (Table 2). These plantlets were indexed for PSTVd isolate by dot-blot hybridization assay.

Each 12 potato tubers cv. Diamond infected with PSTVd-$_{EG}$ isolate were exposed to 5, 10 and 15 mA for 5, 10 min. The sprouts of these tubers were excised and cuttings with 0.5 mm (explant). The explants were planting on MS media. The shoot-tips of plantlets were excised from plantlets and planting on MS media. It was found that treatments 10/10; 15/5 and 15/10 mA/min were the more effective for PSTVd-$_{EG}$ elimination (100 %) (Table 2). While, 5/5; 5/10 and 10/5 mA/min treatments gave 66.7; 0 and 0 % respectively. On the other hand, it was observed that regeneration Increased in treated sprouts with electrically compared with untreated electrotherapy ones. On the contrary, the survival rate decreases with increase electricity and treatment time (Figure 5 and Table 2). These results were confirmed by NASH.

Figure 3. Micropropagation of plantlets on MS-media treated with different concentrations of 2-TU.

4. Discussion

The size 0.25 mm of meristem-tips was excised from PSTVd-$_{EG}$ infected potato plants cv. Diamond under stereomicroscope and was cultured on meristem-tip media**.** The meristem- tip was developed of complete plantlets with 75% the survival of potato plantlets.

*****Plantlets survived/Total of treated samples.
** Plantlets PSTVd–free/Total Plantlets survived.

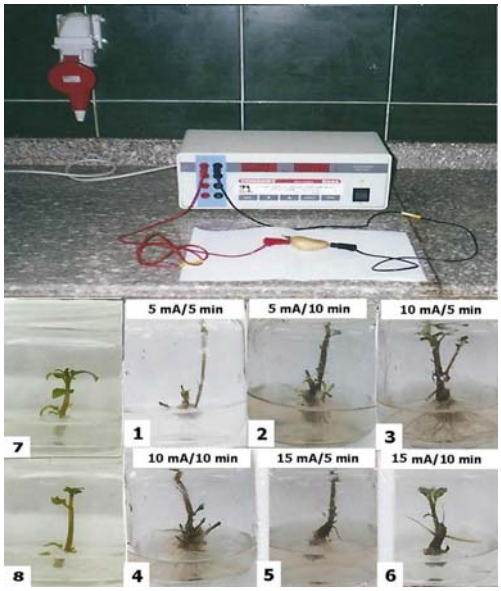

Figure 5. The electrotherapy procedure of PSTVd infected tubers and micropropagation of sprouts on MS media, 1-6) Sprouts of treated tubers cultured on MS media, 7) Sprout of untreated healthy tuber, 8) Sprout of untreated PSTVd- infected tuber.

As well as, the plantlets survived PSTVd-$_{EG}$-free were 83.33%, where as gave negative result against PSTVd-$_{EG}$ by dot-blot hybridization. The same results were obtained by (Stace-Smith, 1989 and Edriss *et al*., 1996) who mentioned that viroids were eliminated from shoot apical meristems with ranging size 0.2 to 0.5 mm long, but not obtained from longer ones. Lizáraga *et al*. (1982) and Salazar *et al*. (1985) showed that eradication of PSTVd was higher in the smaller tissue reactions and the higher percentage of eradication PSTVd was obtained from apical domes, followed by meristem-tip and in lower percentage from shoot-tips. They discussed this result where PSTVd no infection meristem cells since no phloem elements are found in apical domes and phloem elements disconnected from the rest of the plant vascular system are present in meristem-tips larger portions of apical tissue (like shoot-tips) already contain sieve tubes which are connected to the vascular system of the plant.

Three different anti-viroid compounds namely virazole (Ribavirin), 2-TU and ASA were incorporated individually into MS-medium with 10, 20, 30, 40 and 50 ppm. Potato explants (Nodal cuttings) were taken from PSTVd-$_{EG}$ infected potato plants cv. Diamond and were cultured on media. It was found that, using concentrations of 10, 20, 30, 40, and 50 ppm progressively increased the percentage of PSTVd-$_{EG}$-free plantlets for three compounds. But on the contrary, the percentage of survival decreased with increment concentration compared to the control. Thus, was found that Virazole proved to be somewhat phytotoxic in highest concentrations (40 and 50 ppm) and it causes stunting in plantlets, thin stem and stunted leaflets. The same results were obtained by many authors Kryczyński (1992) explained that the virazole inhibited viroid multiplication by RNA breaking. Also, they found that Ribavirin has been successful in reducing PSTVd concentration in *Scopolia sinensis* plants, but in shoot-tip culture or cuttings grown from Ribavirin-treated plants, viroid conc. rapidly reappears. Belles *et al*. (1986) showed that Ribavirin has been tested against viroids; it was active in eliminating *Citrus exocortis viroid* from *Gynura aurantiaca* as foliar applications. They found that concentrations. The lower than 30 mg L^{-1} was not effective, while phytotoxicity occurred at concentrations of 1600-2000 mgL^{-1}.

It was found that the highest concentrations 30, 40 and 50 ppm of 2-TU cause deleterious effects on growth of potato shoots. These results were similar with Commoner and Mercer (1951) who

reported that 2-TU (Pyrimidine analogue) is a powerful inhibitor of virus synthesis and replication. Also, Clerence & Agrawal (1972) mentioned that 2-TU affect on the metabolism of the plant itself; the young leaves become pale and apical growth is arrested**.** Kryczyński (1992) mentioned that amantadine, ribavirine and thiouracil used to eliminate viroids from infected plants.

In related to, ASA it was found that concentrations 20, 30, 40 and 50 ppm cause stunting of plantlets and concentrations 30, 40 and 50 ppm encourage formation of calli in some plantlets, while concentration 50 ppm induce formation of microtubers *in vitro***.** These results agreed with those reported by Malamy and Klessig (1992) who observed that ASA improve callus growth and/or regeneration in some culture media. Yu *et al*. (1997) found that ASA induce systemic acquired resistance (SAR). It has been proposed that SAR is mediated by an endogenous signal that is produced in the infected leaf and translocated in the phloem to other plant parts where it activates resistance mechaisms SAR is often induced by avirulent pathogens carrying an avirulence (*avr*.) gene. The production of an *avr* gene is recognized by the production of a resistance *R*-gene in plants (gene-for-gene recognition). In the case of viroid infection, however, involvement of *R*-genes is unlikely since viroids do not encode proteins. Therefore it will be of great interest to elucidate the PSTVd-activated pathway that is cross-linked with a SAR pathway to activate common down-strain genes encoding PR-1 and β 1, 3 glucanse (Itaya *et al*., 2002). Our results indicate that PSTVd-$_{EG}$ can be more successfully eliminated by treated PSTVd-infected plants cv. Diamond under conditions of low temperature and more efficiency when used a combination of low temperature treatment and subsequent meristem-tip culture. Thus showed that PSTVd-$_{EG}$ elimination percentage from sprouts were 61.50; 71.4; 71.4 and 64.2 at temperatures 21; 3-4; 5 and 8ºC respectively. On the other hand, meristem-tip excised from sprouts exposured for low temperatures 3-4; 5; 8ºC for 4 mons. were more efficiency for viroid elimination (100%) than in those at 21ºC/4 mon. (77.7%). Whenever, the percentage of sprout survival was 100% for meristem-tip was 85.7; 71.4; 57.1 and 57.1% for 21, 3-4; 5 and 8ºC/4 mons. The same result was obtained by (Lizàrraga *et al*., 1980). Hadidi *et al*. (2003) who mentioned that cold treatment of tubers, cuttings and plants must be pronged, even for mons. to increase the percentage of viroid-free plantlets, propably, the length of the treatment could be reduced when applied to *in vitro* cultured germplasm. The reduced size and tenderness of plant tissue could increase the effect of temperature allowing it to reduce the time of exposure. Also, the percentage of viroid elimination differed according to the isolate. Paduch-Cichel and Kryczński (1987) reported that prolonged a low temperature therapy (longer than 3 mon.) in eradication of PSTVd. The PSTVd-free plants were obtained from meristem-tips of sprouts from infected tubers after 6 months of therapy at 6 to 7ºC in the dark. The efficiency of 6 mon. therapy varied from 18.5 to 80% depending on viroid and plant material. A 3 mon therapy period at the same temperature proved to be too short.

Potato tubers cv. Diamond infected with PSTVd-$_{EG}$ were exposed to 5, 10 and 15 mA for 5; 10 min. followed by immediate planting the sprout *in vitro* then shoot-tips were excised and cultured on MS media. Temperature was increased from 4 to 10ºC in the tissue during the exposure to the electricity. After a 40 days growing period, electricity was influenced by the severity of treatment since organogenesis and viroid elimination were both stimulated by the electricity. The highest PSTVd-$_{EG}$-free values were obtained at 10/10; 15/15 and 15/10 mA/min. On the contrary, the survival rate decreases with increase electricity and treatment time. These results were compatible with that found by. Hadidi *et al*. (2003) mentioned that the viroids also may be eliminated if plants are treated simultaneously at low (2-5ºC) or high (37-38ºC) temperatures, especially if plants are exposed simultaneously to low irradiance lighting followed by shoot-tip culture. Also, Lozoya-Saldaña *et al*., (1996) who observed that *Potato Virus X* was eliminated by exposure potato stems to 5, 10 or 15 mA for 5 or 10 min. followed by immediate planting the axillary buds tips *in vitro*. Temperature increased from 4 to 10ºC in the tissues during the exposure to the electricity. After 60 days growing period, therapy efficiency (TE = % plant regeneration X % virus-free resulting plants) was influenced by the severity of treatment, since organogenesis and virus elimination were both stimulated by the electricity. The highest TE values were obtained at 15 mA for 5 min. under these conditions, 40% to 80% of the buds regenerated and 60% to 100% of the regenerated plantlets tested virus negative.

Abstract: The aim of this study is to assess the impact of industrial agriculture on the environment in Rwanda taking at Mulindi tea plantations as a case study. Soil samples collected in three zones of Mulindi Valley were analyzed in the laboratory through PH Meter and the results showed that pH of all soil samples is less than 5 (pH<5), which implies that the soil in that valley is acidic. During this study, soil erosion caused by deforestation has been noticed and the sediments carried down and deposited in valley were became a peat after process of acidification. On the another hand, the analysis of water samples from the tank in polyethylene of three streams of Mulindi using spectroscopic techniques revealed a high concentration of elements like: Na, Ca NO^{3-}, H^{+}, H_2NO_3, Cu and S. and elements with low concentration : Fe, NO_3, K, and $al^{3.}$ This pollution may be due to agrochemicals used. Finally we proposed the methods which can be applied in the country in order to ensure a sustainable tea agriculture and better environmental conservation**.**

1.Introduction

The environment which is defined as an area in which something exists or lives (WordNet3.0@ Princeton University, 2006) must be imperatively protected and every effort is important. In Rwanda, one of the smallest countries in Africa with a land area of 26 338 km^2 (with water: 1,390 km^2 and land: 24,948 km^2), many factors make it difficult to conserve the environment. The country's hilly topography is the reason why it is called a land of thousand hills. Most of the Rwandan area lies at high altitudes. The average elevation throughout the country is about 5,200 feet; 1,585 meters above sea level .The Rwandan topography (Figure1) includes steep hills, densely forested mountains, plateaus and savannas. The country has five regions which are: (i) The Vilunga mountains region in the north-west with five volcanoes: KALISIMBI the highest point of the country with 4, 507 m; BISOKE with 3,710 m; SABYINYO with 3,636 m, MUHABURA with 3500 m and GAHINGA with 3300 m. (ii) The Albertine Rift Valley region which is a branch of Great Rift Valley, it's located at the western border of country with an altitude between 3000 m and

3300m. (iii) The Congo-Nile Ridge with an altitude between 2500m and 3000m. (iv) The Central plateau which consists of gently hills with an altitude between 1500m and 2000m

(v) The Eastern savanna and Lowland of the south-west with an altitude between 900 m and 1500 m. (Thomas Streissguth , 2000)

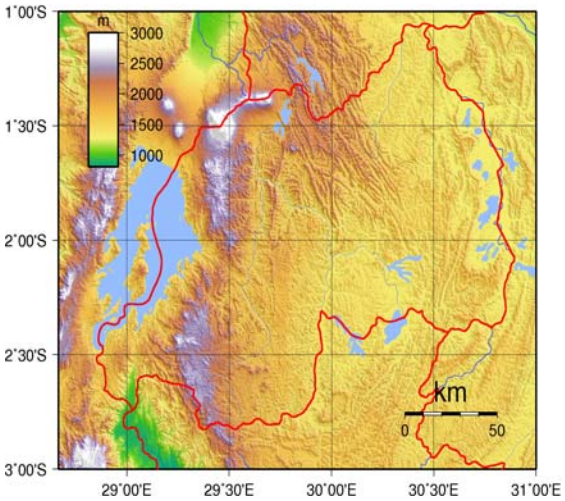

Figure 1 Topographic map of Rwanda (Wikipedia, 2009)

Another factor is the population density. Rwanda is one of the most densely populated countries in Africa with a population density of about 310 inhabitants per km^2 and an annual population growth rate of around 3.1% (MINISANTE/ONAPO,2003). In 1999, about 91% of her population earned their living, directly or indirectly, from agriculture; this is only applicable especially in some mountainside, in the alluvial valleys and in the volcanic soils of the northwest. About 1.1 million hectares (2.8 million acres) are under cultivation. Subsistence agriculture predominates, and the basic agricultural unit is the small family farm about one hectare (2.5 acres) (*nationsencyclopedia.com/Africa, 2009*). Rwanda's industrial agriculture is dominated by tea, coffee and Pyrethrum.

Tea agriculture requires a large area, in 1999 the total area for tea cultivation was 12,541 ha and 14,394 ha in 2008 with 1,407ha not exploited (Rwanda Privatization 2009, Lawrence w. Reed, 2002). Although Rwanda had made modest attempts to grow tea since the Second World War, it was only in the 1960's that the industrial cultivation of tea was really established.

Under the impulse of the FED, which considered tea as "a major agricultural opportunity" for Rwanda; the first tea unit was created in 1960 at Mulindi (Ex Byumba province actual Northern Province). Ten years later, already six tea units were functioning.

In 1964, the Office for Industrial Cultivation in Rwanda (Office des Cultures Industrialles du Rwanda - OCIR) was established, with the mission to manage the tea and coffee branches. Mulindi Tea plantation covers the largest area with 1,909 ha and its factory is the biggest in the country. Tea agriculture has positive and negative impacts on the environment. This is why this paper intended to provide a preliminary investigation of the environmental impact of industrial agriculture in Rwanda, particularly the case of Mulindi tea Plantations. This study shows the impact of tea plantation in Rwanda through the following factors: soil degradation, deforestation and soil erosion, air pollution and water pollution in Mulindi river, agrochemical use, tea agriculture methods, and finally it proposes the methods and techniques or strategies which can be used for conserving the environment and ensure sustainable development.

2. Materials and Methods

The study area: General state of Rwanda

The Rwanda is a small country located in Great lakes region of east central Africa, bordered by Uganda to the north, Tanzania to the East, Burundi to the South and Democratic Republic of Congo to the West where it is separated by Lake

Kivu and Ruzizi river (Siuberski, Philippe, 2008).This small country is also located near the centre of Africa, a few degrees south of the Equator. By this localization, the climate in Rwanda is cooled by the high altitude. It is warm throughout most of the country but cooler in the mountains. There are two rainy seasons: mid January to April and mid October to mid December (RICP, 2008). The capital, Kigali, is located in the centre of the country. In 2006, it was announced that they had located the longest headstream of the River Nile in Nyungwe forest (Team researches Nile's true source, 2006); the relief is mountainous with altitude declining from west to east. The country has few natural resources and its economy is based mostly on agriculture by local farmers using simple tools. It is estimated that 90% of the active population are in the agriculture and this sector occupied about 39.4% of GDP in 2006 (Special report on Rwanda, 97). Crops grown in the country include coffee, tea, pyrethrum, bananas, beans, sorghum and potatoes; but tea and coffee are the major cash crops for export (WTO Doha Round Bulletin , 2004)

Brief story of tea agriculture in Rwanda

Tea growing was introduced in Rwanda as an industrial crop and purely for export purposes to generate foreign income as early as 1960. Black tea manufacturing followed in 1965 at Mulindi tea factory in the actual Northern Province. Since then the tea sector has become the most important source of export earnings after the coffee market plunged in recent years. Tea is now number one export earner; contributing up to 34% of the total national exports. Today, the tea sector in Rwanda consists of six state owned production units, Gisovu, Kitabi, Mata, Mulindi, Shagasha, Gisakura and four private owned production units, Cyohoha (SORWATHE), Pfunda (Pfunda Tea Company), Nyabihu and Rubaya (Rwanda Mountain tea). Nshili-Kivu is another private owned production unity with a factory which is still under construction. The current tea sector consists of 10 tea factories, 8 governments owned plantations known as Blocs Industrials (BI), 3 tea cooperatives known as Coopthés and 11 tea small holders associations known as Thé Villageois, spread in the country as indicated in Table 1.The total planted area is 12,989 ha but only 12,862 hectares are exploited. The factories installed capacity is 15,500 tones of made tea per annum. The tea sector provides employment to 52,838 people, tea farmers and workers together (OCIR –THE , 2006)

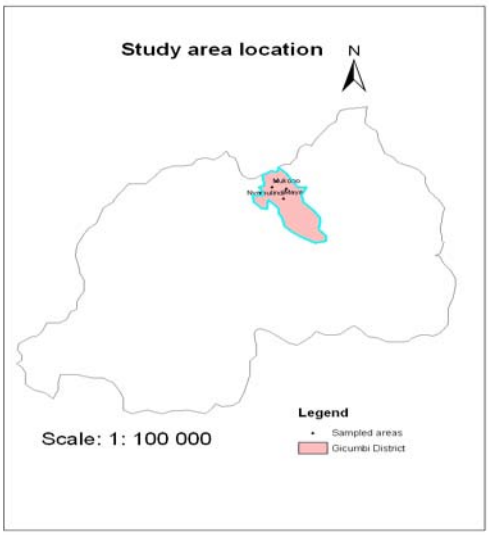

Figure 2 Study Area locations

Mulindi tea plantation is located in Gicumbi district in Northern Province and is home to about 47,000 people. Its capital is Byumba, which is also the ex provincial capital. The district lays due-north of Kigali, straddling the major road from Kigali to Kampala. It is a hilly district and is divided into 21 sectors called Imirenge in local language (Francis, 2008). Tea plantations are located in eleven Administrative sectors among 21 sectors of Gicumbi district which are: Kaniga in which Mulindi tea factory is located, Mukarange, Cyumba, Rushaki, Bwisige, Nyankenke, Manyagiro,

Byumba, Rubaya, and Shangasha. Mulindi tea factory is located at 14km to Gatuna board and at a 1 hour journey from Kigali and at 5 km from Kigali-Gatuna road in Kaniga Sector. The factory is the biggest in terms of production but as it does not have its own plantations; it depends on COOPTHÉ and Village's Tea which is called COOTHEVM for its green leaf supply. The COOPTHÉ constitute 35% with 585 ha exploited, and Village's Tea, 55% with 1150 ha.

The industrial block has only 174.4045ha; it means a total of 1909.4045 ha. All these tea plantations are distributed around ten agriculture sectors (Nyamulindi, Rushaki I and II, Bushara, Kaniga, Maya, Ngondore, Muturirwa, Rubaya and Mukono). About 90% of this area is located in valley or swamp and 10% only is located on versants of mountains. The factory was built in 1962 with capacity of 3200T. During 1994-1996 the factory and tea plantations were rehabilitated following the war. The factory only has 224 ha of woodlands that are not sufficient, the reason why the factory is obliged to buy the wood fuel from the population around.

Methods

The first phase of this study used a survey among the governmental and private tea factories through different plantation management companies (Coopthe, village's tea and estates tea plantations which called B.I).

During this phase, a questionnaire was used to collect information about different activities carried out in tea plantations such as plucking, drainage, pruning, fertilization etc. This questionnaire was sent to 11 tea plantation managers, representing the total number of the tea factories in the country. This questionnaire was also helpful in getting information concerning pesticides and types of fertilizers used in Rwanda's tea plantations. It was also designed in order to identify different techniques used to fight against erosion and to protect the environment. Lastly the questionnaire was used to get information about the evolution of tea production. All tea plantation managers submitted their completed responses.

The second phase of this project concerned particularly Mulindi tea plantation, where we took soil samples by dryer (or Terri ere in French) on three locations which are Nyamulindi, Maya and Mukono for getting information relating to soil degradation through laboratory analysis using pHMeter. We also took water samples by tank in polyethylene and we put on bottles very clean for a good transportation from three locations of Mulindi streams (Nyamulindi, Maya and Mukono) for analyzing and quantifying water pollution resulting from tea preparation activities in laboratory.

These water samples were acidified with purified nitric acid and were analyzed through atomic mass spectroscopy. The measure of pH in the solution used the followings elements: ammoniumacetae ammonia (pH 6-8), sodium acetate- acetic acid (pH 3-6), and hydrochloric acid-glycine (p h 1-3).

The analysis of the relationship between production and utilization of wood fuel in factory has been carried out using SPSS, Origin pro 7.5 and excel. The deforestation in that region is remarkable, and sediment deposition and different floods was a good indicator of the presence soil erosion in region.

The water samples taken in three streams of Mulindi River using the tank in polyethylene before rinsed with ultra pure water and it was taken 1L by location. This study started from 1st April 2008 and it was planned to get all responses of the questionnaire by 30th April 2009; by chance, all the respondents submitted their responses on time. The final report was completed by the 20th June 2009

3. Results

State of tea plantations and Evolution of production.

Tea plantations in Mulindi region are divided in two categories. A big part of all tea plantations around 90% are for private sector which are called Cooperatives with COOPTHE and COOTHEVM, and the small part of tea plantations (10%) which are called BI are controlled by Tea factory headed by Rwanda Tea Authority (Ocir the). Coopthe Mulindi is a cooperative with one thousand members and produces about 35% of green leaves. Tea plantations in this Cooperative get a special treatment like regular sarclage, good table of plucking and regular drainage. It is the same for the small plantations under the control of the Tea factory.

The Coothe.VM is a villages' cooperative with around three thousands members and every member has his field and he is responsible for all activities except plucking and transport.

The coothevm produces about 55% of green leaves. In general, all tea plantations in these villages' cooperatives do not receive good services and support such as drainage, plucking and pruning. Most of Mulindi tea plantations are composed by the stamps and few clones from Kenya. About 5000 workers are employed in tea plantations including those who work in the tea factory in different activities; accounting for about 10.64% of all people of Gicumbi District and 25% the active population of that District. Tea plucking is the first activity which employs many works, about 3500. Others activities (pruning, drainage) are occupied by about 1500 people. In Mulindi valley composed by Maya, Mukono, Nyamulindi, Ngondore and Muturirwa, they are many empty spaces caused by erosion and regular floods between April and May every year.

4. Discussions

During 13 years from 1996 to 2008, the production of green leaves at Mulindi tea plantations (table 2) increased by 10396156kg (316.74816%). During that period the using of wood fuel had an increase of 9684tones or 313.39806% while the use of fertilizers increased from 0 kg in 1996 to 370385kg in 2008. The total area was around 1900ha in 1996 but only 921.4ha were rehabilitated, and it was 2298ha in 2008 including the young tea and empty area inside of tea plantations but only 1909.4045ha give a production. By the Figure3 it was noticed that the years 2007, 2001 and 2008 were very productive with the

following production respectively 13904538 kg in 2007, 13750123 kg in 2001 and 13678308 kg in 2008.The good climate with enough rainfall, high quantity of fertilizers and good plucking are the favorable factors which can explain that increase of production. Also we found that the first three years from 1996 to 1998, had low production of green leaves because of it was a short period after genocide; many tea plantations were not taken care, few workers and it was difficult for the country to get fertilizers

Agrochemical: The use of chemical fertilizers led to the decline of soil fertility (Fared, 1996). To determine the impact of fertilizers in addition to laboratory experiment, in this study, we tried to use previous studies carried out in other study areas. For example, studies in India have shown that as much as 70% of soil biota has been lost on tea plantations The Figure 4 show that the use of fertilizers at Mulindi Tea Plantation was not regular; this can be explained by the following factors: Some farmers cannot afford the cost of fertilizers while others lack knowledge about the importance of fertilizers to nearby natural habitat, especially in areas that workers and machinery pass over (Senapati et al. 2002). In general, Rwanda tea plantations and at Mulindi in particular, they use NPK 25-5-5 +1Mg and NPK 26-6-8 +2Mg very frequently as fertilizers. Other pesticides which are used in different tea plantations are Round up for eliminating of weed; urea, methane and dime thane for young tea or in nurseries. .It was found through the Fig. 5 that the high quantity of fertilizers implies high productivity of green leaves. During the three most productive years 2001, 2007 and 2008, the use of fertilizers was also at very high rate, carried out in other study areas. For example, studies in India have showed that as much as 70% of soil biota has been lost on tea plantations as compared to nearby natural habitat, especially in areas that workers and machinery pass over (Senapati et al. , 2002). In general, in Rwanda tea plantations and at Mulindi in particular, the farmers use NPK 25-5-5 +1Mg and NPK 26-6-8 +2Mg frequently as fertilizers. Other pesticides which are used in different tea plantations are Round up for eliminating of weed; urea, dithane and dime thane for young tea or in nurseries

Soil Degradation at Mulindi was among the Main objectives of this study; for itsmeasurements, we used pH as indicator. For that case pHMeter was used to analyze the soil acidity. It was found that the pH of soil samples collected on three locations of Mulindi valley was 5.2 at Nyamulindi, 4.8 at Maya and 4.6 at Mukono. This means that the pH of soil in all Mulindi valleys is less than 7 and all soils are classified among the acidic soils. This acidic of soil can be explained by the following factors. First, the rock in which the soil came from, Mulindi valley belongs to the sedimentary rock. And then the using of fertilizers with NO_3^+ and an augmentation of aluminums ions and H^+ in soil. (www.document: calibrate a pHMeter, 2009). .

The concentration of major elements in water at Mulindi valley varied by site. The result in table 3 showed that the concentration of Na, H^+, H_2NO_3, Al^{3+}, No_3, NO_2, Mg, Ca, Fe, K, P, and S were important in all sites with 31.85, 26.4, 13.2, 13.1, 2.06, 1.14, 20.3, 12.17, 46.12, 0.18, 3.8, 0.26, 20.18 respectively at Nyamulindi, with 28.3, 38.6, 6.3, 11.6, 3.15, 1.64, 19.6, 13.05, 51.87, 0.14,9.3, 0.65, 18.9 respectively at Maya, and with 33.3, 21.9, 8.4, 10.8, 4.04, 0.96,26.4, 14.46,41.04, 0.09, 8.1, 0.48, 19.3 respectively at Mukono. The study also showed that the concentration of Fe, NO_3, K, Al^{3+} were no important than other elements in all Mulindi valley, but the concentration of Ca, Na, H^+, NO_2, S, H2NO_3 and cu ere highest in all valley and this concentration indicate that the water in Mulindi Valley are acidic and the pollution has its origin from oxide of nitrate (NO_2) and the use of many fertilizers with high level of MPK+ Mg . Note that this instrument (experimental) technique has been

used by many researchers in environmental studies such as (Filgueiras et al; 2002) and several schemes are existing (Smichowski et al; 2005).

Deforestation impact on Soil Degradation

Soil degradation is also associated with off-site problems of sedimentation, carbon emissions affecting climate change (Smyth and Dumanski, 1993). Soil degradation accelerated by erosion is a big problem in Rwanda and the erosion is caused by not only the topography of the country but also by deforestation. At Gicumbi district, particularly on the mountains around Mulindi where the climate is classified as tropic, we observed serious erosion caused by deforestation. From 1996 to 2008, the use of wood fuel in Mulindi tea factory was increasing as the production increased. Because of deforestation for example, over the years, the lands of Rebero (Figure 6) one among regions surrounding Mulindi tea plantation in Gicumbi District north of the Rwanda were washed away by rainfall. The study in India showed that the production of eucalyptus can vary from 11.9T/hm^2 in three year old plantation to 146T/hm^2 in 9 year old plantation in moist region and from 5.65t/ha in 5 year plantation to 135.5T/ha in 9 year old plantation in dry tropic region (Vijan Rawat, et. al, 2004) From 1996 to 2008, Mulindi tea factory used around 137 643 T of wood fires of eucalyptus, and it was noticed that the production of eucalyptus was 170t/ha for 7 year old plantation; it means that 809.66471ha of forests were cut in 13 years. If we consider that a forest is able to give a good production after 7 years, it is clear that an area equals to 404.83235ha of forest were cutting after 7 years; Its means that 57.833193 ha of forest were cutting every year for only Mulindi tea factory. Because of the deforestation we found a high quantity of peat in all valleys which surrounding Mulindi tea plantations caused by soil erosion through many types of sediment from the mountains. Mulindi tea factory has 227ha of forest and the government of Rwanda tried to mobilize its population about forest protection and environmental protection. In order to prevent soil erosion, this government tried also to mobilize its people to plant trees as a necessary call to restore the lost forest cover in Rwanda. Selected seedlings are planted in all provinces of the country by environmentalists in collaboration with all stakeholders and local community (Ministry of Lands, Resettlement and Environment, 2003).

This study through Figure 7 shows that the increase of quantity of wood fuel used is highly influenced by the increase of tea production and the deforestation is among the crucial problems that affect conservation in developing countries in which Rwanda is included. The human pressure on natural resources, poverty, low education level and lack of integration of local population in environmental protection activities are the major barriers for environmental conservation in those countries. Note that the use of wood fuel is not only for the tea factories but also in general the rural population use wood fires in preparation of their food. Also wood fires are used by different institutions like schools, hospitals and prisons. In Gicumbi district the use of high quantity of wood fires was also identified in GIHEMBE Refugees Camp.

5. Conclusion & Recommendations

Industrial tea agriculture introduced in Rwanda from 1960 has a negative impact on environment .The soil and water samples taken from Mulindi tea plantation indicate that this part of the country has been polluted by different contaminants.The fertilizers used in the tea plantations were the cause of soil degradation and through those fertilizers the water was polluted. Also the deforestation resulted in soil erosion which led to floods and the deposit of sediments on the valley. For that case, some recommendations have been proposed. First, the government should apply

lime on Mulindi tea plantations and on other tea plantations which have big quantities of peat. Second, anti-erosion canals should be dug around all tea plantations which are located on mountainside. Third, find alternative sources of energy for treating tea other than wood fuel in order to protect the environment. And finally to proceed by analysis of all rivers streams in order to ensure the quality of drinking water.

ACKNOWLEDGEMENTS

Our thanks go directly to the Government of Rwanda for their financial support, to National University of Rwanda and China university of Geosciences for laboratories, Prof Bukome Itangwa and Dr. Habumugisha Jean de Dieu (NUR) for their helpful comments and suggestions.

Abstract: *Waltheria indica* is used in Nigeria traditional medicine for the treatment of diarrhoea, infertility, skin diseases, gonorrhea and for relieving pains. Phytochemical analysis revealed the presence of steroids, tannins, saponins, and cardiac glycosides in all parts of the plant; flavonoids were detected only in the leaves and stem, while terpenoids and alkaloids were detected in the leaves only. No part of the plant showed the presence of anthraquinones. Antimicrobial activity of different parts of the plant on *E.coli, Pseudomonas aeroginosa and Salmonella typhi* showed the leaves having highest activity against *E.coli and pseudomonas aeroginosa* with the stem having the lowest activity against the three organisms. Column chromatography of crude extracts of the leaves gave fractions I, II and III that were eluted with ethylacetate/methanol benzene/methanol and acetic acid/methanol respectively. Of these extracts, fraction III showed highest activity against *E.coli and Salmonella typhi.* These findings support the traditional use of the plant as an anti diarrhoeal agent.
[Zailani, A. Hauwa , Jada, S, Mahmud and Wurochekke, U Abdullahi. **Antimicrobial Activity of *Waltheria Indica***. Journal of American Science 2010; 6 (12):1591-1594]. (ISSN: 1545-1003). http://www.americanscience.org.

Key words: *Waltheria indica,* phytochemical analysis, antimicrobial activity, *E.coli, Pseudomonas aeroginosa,* and *Salmonella typhi.*

1. Introduction:

The plant *Waltheria indica* belongs to the family *Sterculiacae*. It is widespread in West Africa (Akobunda and Agyakwa, 1998). Locally, the plant is called 'hankufah' or 'hankubah' in Hausa, 'kafafi' in Fulfulde, 'korikodi' in Yoruba and 'efu-abe in Nupe (Hutchinson and Dalziel 1958; Irvine, 1961). The uses of the plant are diverse; it is used in Northern Nigeria by the Hausas for the treatment of skin diseases, impotence, and infertility, as an aphrodisiac, and as children's medicine at birth and during teething (Mohammed *et al.*, 2007). In the Fulani community, the aqueous extract of the root is used in relieving aches and pains during the 'Sharo' festival. Among the Yoruba, the aqueous extract of the root and stem is used in treating syphilis, internal haemorrhage, and as a restorative during the labours of harvesting (Mohammed *et al.*, 2007). Yerra *et al.*, (2005) investigated the inhibitory effects of the flavonoids isolated from *Waltheria indica* on the production of nitric oxide (NO), tumor necrosis factor alpha (TNF)-a and interleukin 12 (IL)-12, the study supports the use of the plant for the treatment of inflammatory diseases in traditional medicine. The extract of *Waltheria indica* was among the six plants from Northern Cote D'voire that showed promising *in vitro* antibacterial activity against *pneumococcus* including strains resistant to penicillin (Kone *et al.*, 2007). The analgesic activity and/or anti-inflammatory effects have been reported with flavonoids as well as tannins content of the plant (Ahmadiani *et al.*, 1998). Here we present the antimicrobial activity of the crude and partially separated extract of the plant.

2. MATERIALS AND METHODS

Plant material

The whole plant of *Waltheria indica* was collected from uncultivated farmlands located at Yola South Local Government, Adamawa State, Nigeria. The plant was identified and authenticated at the department of Biological sciences, Federal University of Technology, Yola, Nigeria.

Micro-organisms

The micro-organisms used were obtained from the Department of Microbiology, Federal University of Technology, Yola, Nigeria. The organisms include: *E.coli, Pseudomonas aerogenosa,* and *Salmonella typhi.*

Extract preparation

The different parts of the plant namely: leaves, stem and root were removed from the whole plant and air dried separately at room temperature for five days. The dried parts were ground to powder and 50g of each was macerated in distilled water and left overnight. The mixtures obtained were filtered and evaporated using a rotary evaporator.

Phytochemical analysis

Chemical tests were carried out on the aqueous extract and on the powdered samples using standard procedures to identify the constituents as described by Sofowora (1993); Trease and Evans (1989).

Antimicrobial activity testing

The crude extract and individual components were tested using the method of Emeruwa (1982). Wells were made on the surface of 19ml nutrient agar plates previously seeded with 0.1ml of 10^{-6} test organisms. 0.5ml of each extract was aseptically introduced into the wells made. 0.5ml of distilled water was used as control in a separate well. The plates were allowed to stand on the work bench for 30 minutes and were then incubated for 24 hours at 37^{o} C in an incubator. The presence of zone of inhibition was regarded as the presence of antimicrobial activity. From the inhibition zones, the antimicrobial activity was expressed in terms of average diameter of the zone of inhibition that was measured.

Separation of crude extract

The method of Nok *et al*., (1993) was used. Slurry was prepared by dissolving 30g silica gel in 100ml methanol: water (1:1) and packed in a column (1.5x30cm). The column was loaded with 15m of the crude extract and sequentially eluted with ethyl acetate/methanol (19:1) benzene/methanol (9:1) and acetic acid/methanol (1:1). The fractions were collected separately and concentrated under pressure using a rotary evaporator.

Result

Phytochemical analysis:

The screening of leaves, stems, and roots of *Waltheria indica* using aqueous extract and powdered samples was carried out to determine the presence of tannins. Saponins, flavonoids, steroids, alkaloids, terpenoids, cardiac glycosides and anthraquinones. The results are presented in table 1.

Antimicrobial activity of crude extracts

The antimicrobial activity of crude extracts of leaves, stem and root were tested on *E.coli, Pseudomonas aerogenosa, and Salmonella typhi.* The diameter of zone of inhibition is summarized in table 2.

Table2: Diameter of zone of inhibition of crude extracts (mm).

Chemical constituents	leaves	stem	root
E.coli	14	10	11
Pseudomonas aerogenosa	10	10	12
Salmonella typhi	12	8	10

Antimicrobial activity of the separated eluents of the leaves.

The recovered extracts from the column weighted 0.5, 0.6 and 0.5g for fractions I, II and III respectively. The antimicrobial activity of the separated eluents of the leaves is summarized in table 3 below:

Table 3: Antimicrobial activity of the separated eluents of the leaves.

	Diameter of zone of inhibition (mm)		
	Fraction I	**Fraction II**	**Fraction III**
E.coli	9	8	10
Pseudomonas aerogenosa	8	12	9
Salmonella typhi	8	7	20

Control (distilled Water) = 4mm
Fraction I=and ethyl acetate/methanol
Fraction II=benzene/methanol
Fraction III= acetic acid/methanol

Table 1: Result of phytochemical analysis of leaves, stem and root of *Waltheria indica*

Discussion

Phytochemical analysis of the extract of the plant revealed the presence of steroids, tannins, saponins, and cardiac glycosides in all parts of the plant. The presence of flavonoids in leaves and stem in this study is in contrast with the opinion of Mohammed *et al.*, (2007) who noted that flavonoids are only present in the leaves with no part of the plant showing the presence of anthraquinones (Table 1). The observed difference could be due to environmental changes where the plants were collected or seasonal changes that could have altered the plant components. It could also have been as a result of changes during extraction and/or storage. Antimicrobial activities of different parts of the plant were tested on *E.coli, Pseudomonas aerogenosa, and Salmonella typhi.*

The leaves showed highest activity against two organisms- *E.coli* and *Pseudomonas aerogenosa* (Table 1). This could be due to its high composition of cardiac glycosides. Genzolel and Mathel (1982) demonstrated that high composition of cardiac glycosides have been found to inhibit microbial growth and is capable of protection against microbial infection. The phytochemical screening results also

showed the presence of alkaloids and saponins, these classes of compounds have earlier been reported to have antimicrobial activity (Hostettman and Nakanishi, 1979). Therefore, these compounds may be responsible for the observed antibacterial activity of the leaves of *Waltheria indica*.

The root had the highest activity against *Pseudomonas aerogenosa* while the stem had the lowest activity against the three organisms (Table 2). The different components of the leaves i.e. fractions I, II, and III were tested using the same three organisms; fraction III had the highest activity on the organisms, more specifically on *Salmonella typhi.* The result suggests that water is not the most effective solvent for extracting the pharmacologically active compounds and it is a good indication that the most active ingredient of the *Waltheria indica* crude extract is contained in fraction III. It could also mean that the active ingredient maybe different for the different organisms. The fractions reduced the activity of the leaves against the organisms except fraction II, which increased the activity against *Pseudomonas aerogenosa* as compared to the initial crude extract of the leaves (Tables 2 and 3). The observed reduction in activity could have occurred during fractionation.

Gunners (1991) reported that different solvent extracts of some plants may exhibit different pharmacological properties against the same species of microorganisms. Crude extracts may be very active because of synergistic relationship between the components of the plant although sometimes the relationship maybe antagonistic. The observed pattern of antimicrobial activity of crude and various fractions of the plant parts underscores the need to study all parts of the plant before generalization is made on the plant's pharmacological and therapeutic potentials. This is more so because *in vivo*, biotransformation reactions would occur and may likely give rise to new results.

These findings confirm the basis of traditional use of *Waltheria indica* for treating diseases such diarrhoea. The mechanism of action of the constituents of *Waltheria indica* may be difficult to speculate; however, many antibacterial agents may exhibit their action through inhibition of nucleic acid, protein and membrane phospholipids biosynthesis (Franklin *et al.*, 1987). It is probable that the antibacterial agent(s) in the extract of *Waltheria indica* act via some of the above mechanisms. Further studies on the *in vivo* activity, isolation and structural elucidation of the component(s) and toxicological studies of the plant extract are recommended.

Abstract: The aim of the present research was focused on the allelopathic effects of *Azardirachta indica* and *Chromolaena odorata* via *in vitro* approach. The aqueous and organic solvents (water and ethanol) extracts from leaves of *Azardirachta indica* Adr.Juss (*Meliaceae*) and *Chromoolaena odorata* (*Asteraceae*) where tested against fungal pathogens of rotten tomato (*Aspergillus niger*, *Fusarium oxysporum*, *Rhizopus stolonifer* and *Geotrichum candidium*) by poisoned food method. The results showed promising antifungal activity against the fungi tested. Among the various solvents with varying concentrations, aqueous extracts of 80% *Azardirachta indica* was found to have more inhibitory effect (65.20%) against *Rhizopus stolonifer* compared with other concentrations of 80% *Chromolaena odorata* (52.60%). Ethanol extracts of 30% *Azardirachta indica* had the best inhibitory effect (83.30%) against *Aspergillus niger* followed by 30% ethanol extract of *Chromolaena odorata* (80.00%) against *Geotrichum candidium* comparatively, 20% ethanol extract of *Azardirachta indica* (75.20%) against G. candidium inhibited than 20% ethanol extract of *Chromolaena odorata* (69.80%) against *Geotrichum candidium*. This finding proved the potentiality of the plant extracts for the control of post harvest and transit fungal rot of tomato fruit.

Ijato James Yeni, Oyeyemi Sunday Dele, Ijadunola John Ademola, Ademuyiwa Justus Adeniran. **Allelopathic effect of leaf extract of *Azardirachta indica* and *Chromolaena odorata* against post harvest and transit rot of tomato (*Lycopersicum esculentum* L).** Journal of American Science 2010;6(12):1595-1599]. (ISSN: 1545-1003). http://www.americanscience.org.

Keywords: *Azadirachta indica*, *Chromolaena odorata*, allelopathy, tomato fungal rot, Pathogens.

Introduction.

Tomato (*Lycopersicum esculentum*) originated from the Central America where it was then cultivated as an ornamental plant. Tomato belongs to the family *Solanaceae*. As a common vegetable crop, it rated second in significance to potato in many countries. Tomato is an important commercial crop in the world. Nutritional value of tomato makes it a widely accepted vegetable by consumers. Nevertheless, tomato is a very perishable crop with a short shelf life as well as high vulnerability to mycotic diseases. During extended storage, tomato fruits are prone to post harvest disease caused by various fungal pathogens. Control of tomato fruit rot has been by application of synthetic chemicals. However, these days' consumers request less use of chemicals and still want food devoid of corruptions, microbial growth, toxins as well as other qualities-deteriorating factors (Lingk, 1991).

Ripe tomato fruit has high vitamin C and potassium. More importantly, previous researches indicated that consumption of cooked tomatoes reduced cholesterol related cardiac diseases (Simon and Schuster, 1996). Tomato is essential in human diet; it can be prepared into stew, puree, salad etc. Despite the human need of tomato, its low yield as a result of disease infestation has being source of serious concern. Natural plant products and their analogues have been found as important sources of agricultural bio-pesticide which serve as antimicrobial properties of plant extracts (Cardelina, 1995, Okigbo 2009).

Antifungal properties of *Azardirachta indica* and *Chromolaena odorata* on fungal rot pathogens of post harvest tomato fruits are therefore aimed at in this finding. This is to serve as a relative alternative to the use of synthetic chemicals to extend the shelf life of tomato so as to reduce or eliminate loss due to post

harvest rot caused by phyto pathogens mainly fungi and the resultant economic loss to the farmers, traders and consumers.

Materials and Methods.

Collection of tomato fruits

Tomato fruits with symptoms of rot were randomly collected from the market stalls at Ado-Ekiti, Ekiti state, Nigeria. Softness of tissues of tomatoes was identified as being biologically deteriorated. Fresh and healthy tomatoes were also collected and packed into a sterile polythene bag already lined with soft paper and taken to the laboratory for further studies.

Collection of plant materials.

Azardirachta indica and *Chromolaena odorata* were collected in the premises of the University of Ado- Ekiti, Ekiti state Nigeria. These plants were taken to the herbarium unit of the University for Identification

Isolation of spoilage fungi from rotten tomato fruits.

Pieces of tomato were washed in a running tap these were cut from the periphery of a rotten tomato, these were surface sterilized in the plate with 70% ethanol for just 1minute, dropped on sterile soft paper and culture out on (Potato dextrose agar) already mixed with streptomycin. A minimum of four replicates pieces from each of the rotten tomato were cultured out. The Petri-dishes were incubated at 28 $\pm$ 2^0c for five days and observed for fungal growth. Fungi associated were re-cultured to obtain pure culture and the pure isolates stored in slant for further use. The frequency of occurrence was determined using the method of Okigbo and Ikediugwu (2000).

Pathogenicity test.

Cylindrical cores of 1cm deep were taken away from different spots of a fresh and healthy tomato fruits with the aid of sterile 5mm cork borer and then disc of 4mm was taken from the periphery/ core of a colony of five days old test fungus was placed downward into each hole in the tomato fruit. The core of the tomato fruit was replaced after 2mm pieces had been cut off to compensate for the thickness of the agar inoculum and then replaced core sealed with Vaseline (jelly). Sterilized potato dextrose agar (PDA) was used in place of the culture discs in the control set up**.**

Preparation of leaf extracts.

Azardirachta indica (leaf) and *Chromolaena odorota* (leaf) were collected and washed thoroughly under running water and allowed to air-dry for 7 days. These were grounded separately. Thirty grams of each sample was added to 15ml of distilled water in separate flasks. This was vigorously shaken and left to stand for 24hrs. The sample was filtered with 3-layer cheese cloth and filtrate extract preparation of 80% and 60% concentrations were used as the extracts. The same procedure was used for 30% and 20% ethanol extract.

Effect of plant extracts on mycelia growth of fungi

The approach of Amadioha and Obi (1999) was used to evaluate the allelopathic effect of the extracts on fungal growth by creating four equal sections on each plate by drawing two perpendicular lines at the bottom of the plate. The point of intersection indicated the centre of the plates. This was done before dispensing PDA into each of the plates. The extracts were poured into the flask, plugged with cotton and heated for about 10minutes to avoid contamination (Madari and Singh, 2005). About 2ml of the extract of various plant materials was separated introduced into the Petri-dish containing the media, (poisoned food method) (Nene and Thapilyal, 2002). A disc of 4mm diameter of the pure isolate each was placed on the extract in plate with PDA at the point of intersection of the two perpendicular lines drawn at the bottom of the plate. Control experiments were without addition of any plant extract but sterile distilled water. Fungitoxicity was determined in term of percentage colony inhibition % = $\frac{DC - DT}{DC} \times \frac{100}{1}$

Where DC - Average diameter of control

DT - Average diameter of fungal colony with treatment

Results

"Table 1 Percentage inhibition of radial growth of rot fungi cultured in potato dextrose agar poisoned with aqueous plant extracts of 60% and 80% concentrations."

Table 1. Plant extracts (% inhibition of mycelia growth)

Rot Fungi	*Azardirahta indica*		*Chromolaena odorata*		Control (mm)
	60%	80%	60%	80%	
Aspergillus niger	59.90a	60.00a	52.20a	53.30a	16.00
Fusarium oxysporum	48.20bc	62.50a	42.80c	45.20b	15.00
Rhizopus stolonifer	56.40ab	65.20a	54.80a	52.60a	16.00
Geotrichum candidium	46.70c	59.20a	45.60bc	52.30a	17.00

Each of the data is a mean of three replications. Each data followed by the same alphabet along the columns not significantly different at P= 0.05, using (DMRT) Duncan Multiple Range Test to separate the means.

Table 2: Percentage inhibition of mycelia growth of rot fungi grown in potato dextrose agar poisoned with ethanol plant extract of 20% and 30% concentration

Rot Fungi	Plant extract (% inhibition of mycelia growth)				
	Azardirachta indica		*Chromolalena odorata*		Control (mm)
	20%	30%	20%	30%	
Aspergillus niger	63.30b	83.30a	50.00bc	72.60ab	15.00
Fusarium *oxysporum*	69.60ab	79.80a	62.00a	74.70ab	17.00
Rhizopus stolonifer	63.30b	83.60a	47.80c	70.20b	16.00
Geotrichum candidium	75.20a	80.20a	69.80a	80.00a	16.00

Each of the data is a mean of three replacements. Each data followed by the same alphabet along the columns not significantly different at P= 0.05, using DMRT Duncan Multiple Test to separate the means.

The isolated spoilage fungi from infected tissues included: *Aspergillus niger*, *Fusarium* o*xysporum*, *Rhizopus stolonifer* and *Geotrichum candidium*. The results of the pathogenicity test showed that these rot fungi were able to cause deterioration after 7 days of inoculation. Both aqueous and ethanol extracts of the test plants of *Azardirachta indica* and *Chromolaena odorata* were able to reduce the radial growth of the fungal mycelia. (Tables 1 & 2), 80% aqueous extract of both *Azardirachta indica* and *Chromolaena odorata* reduced the mycelia growth more than the compared 60% aqueous extract of the respective plants (Table 1). The same thing was recorded in 30% ethanol extract inhibited in both test plants than 20% ethanol (Table 2).

The highest of 80% aqueous extract of *Azardirachta indica* inhibition of 65.20% was recorded against *Rhizopus stolonifer* (Table 1). *Azardirachta indica* was able to cause inhibition up to 83.60% and 83.30% using 30% ethanol against *Rhizopus stolonifer* and *Aspergillus niger* respectively. Inhibition 75.20% was attained with 20% ethanol extract of *Azardirachta indica* against *Geotrichum candidium*. *Chromolaena odorata* using 30% ethanol extract had the highest inhibition of 80.00% against *Geotrichum candidium*. Higher concentration percentage of ethanol extract favoured better inhibition also aqueous extract. *Azardirachta. indica* seemed to possess more efficacy cumulatively than *Chromolaena odorata* irrespective of the extractive mode (solvents).

Discussion

The microbes linked with the post harvest deterioration in this finding were: *Geotrichum candidium*, *Rhizopus stolonifer*, *Fusarium oxysporum* and *Aspergillus niger*. Both the test plants: *Azardirachta indica* and *Chromolaena odorata* had inhibitory effect on post harvest rot pathogens of

tomatoes in aqueous and ethanol solvent of varied concentrations. Extracts of *Azardirachta indica* and *Chromolaena odorata* have been reported to have antimicrobial properties. *Azardirachta indica* of the family *Meliaceae* contains secondary metabolite of alkaloid and terpenes which can be used to cure dermal diseases.

The derivatives of *Azardirachta indica* are of great use in agriculture, public health, medicine, cosmetics and many more. Its leaves, bark, seed and flower are bitter, astringent, acrid, depurative, refrigerant, demulcent, insecticidal, expectorant, liver tonic etc. *Chromolaena odorata* of the family Asteraceae is used to cure diabetic mellitus and malarial. Hycenth (2008) reported the antifungal effect of *Azardirachta indica* against yam rot pathogens (*Rhizopus stolonifer*). Siva *et al.* (2008) used *Azardirachta indica* to inhibit *Fusarium oxysporum* (wilt pathogen) of *Solanum melogena* (egg plant). Nahed (2007) improved biological control of fusarium root rot in cucumber (*Cucumis sativum* L) by *Azardirachta indica*. Vigorous inhibition of soil borne pathogenic fungal growth using *Azardirachta indica* was reported by Paul and Sharma (2002). Okigbo and Ajalie (2005) inhibited some human pathogens with *Chromolaena odorata*. Amadioha (2000) was able to control rice blast *in vitro* and *in vivo* with extract of *Azardirachta indica.* In Nigeria, plant extracts have been used to inhibit fungal diseases of plants such as cowpea (Alabi, *et al* 2005),banana (Okigbo and Emoghene, 2004), yam (Okigbo and Nmeka 2005), cocoyam (Eunice, et al 2008), and sweet potato (Amienyo and Ataga, 2007) . The extracts of *Azardirachta indica* and *Chromolaena odorata* could be used as bio-pesticides against tomato fruit rot caused by fungal pathogens, these plants are economical and save to handle.

Abstract: Aminopeptidases participate in the development of flavour in food products. The present study aims at production of aminopeptidase(s) from the safe mammalian locally available rich sources. Three forms of alanine aminopeptidase AAP1, AAP2 and AAP3 isoenzymes were purified to homogeneity from the kidney cortex of water buffalo. The purification procedures involved anion exchange chromatography on DEAE-cellulose column and gel filtration through Sephacryl S-300 column. All of the purified isoenzymes turned out to be homogeneous as judged by native polyacrylamide gel electrophoresis. The molecular weights of the native isoenzymes AAP1, AAP2 and AAP3 were determined by gel filtration to be 120, 400 and 310 kDa. AAP1 was a homodimer of 60 kDa subunits. AAP2 was a homohexamer of 67 kDa subunits. AAP3 was a homohexamer of 53 kDa. AAP1, AAP2 and AAP3 displayed their maximum activity at pH 8, 7.8 and 7.8 and their isoelectric point (pI) values at pH 6.4, 6.2 and 6.6 respectively. The type of inhibition of AAP1 by dithiothreitol and AAP2 and AAP3 by 1,10 phenanthroline was found to be competitive. One binding site was deduced on each isoenzyme for its corresponding inhibitor.

Keywords: Alanine aminopeptidase; water buffalo; kidney

1. Introduction

Aminopeptidases are ubiquitously distributed in animals, plants, bacteria as well as in fungi and catalyze the sequential removal of amino acid residues from the amino termini of peptides, polypeptides and proteins (Matsui et al., 2006; Bogra et al., 2009; Mane et al., 2010; Renwrantz and Lam, 2010).

Aminopeptidases are also vital for metabolic pathway regulation, cell maturation and turnover of proteins, including utilization of exogenous proteins as nutrient substances and elimination of non-functional proteins (Liu et al., 2008).

Aminopeptidase N (APN; EC 3.4.11.2), also called alanyl aminopeptidase (AAP) that cleaves neutral amino acids from the N-terminus of oligopeptides (Gabrilovac et al., 2005).

Also AAP are widely distributed in mammalian tissues and body fluids such as human seminal plasma (Huang et al., 1997), human liver (Yamamoto et al., 2000), rat liver (Yamamoto et al., 1998), human placenta (Mizutani et al., 1993), human pancreas (Sidorowicz et al., 1980), human kidney (Mantle et al., 1990), porcine kidney (Itoh and Nagamatsu, 1995), human gallbladder bile (Offner et al., 1994) and human skeletal muscle (Mantle et al., 1983). These enzymes from mammals are considered to participate in the metabolism of hormones and neurotransmitters (Hiroi et al., 1992).

AAP is an enzyme that is used as a biomarker to detect damage to the kidneys, and that may be used to help diagnose certain kidney disorders. It is found at high levels in the urine when there are kidney problems (Flynn, 1990).

Aminopeptidases participate in the development of flavour in food products, either directly, by hydrolyzing bitter peptides which are generally rich in hydrophobic amino acids and therefore good substrates for its action, or indirectly, where aminopeptidases could be involved in the liberation of aromatic amino acids which are important precursors of aroma compounds identified in cheese (Martinez-Cuesta et al., 2001).

The main goal of our research project is the production of industrial enzymes from the locally available rich sources. In the case of such enzyme (AAP), there is a need to develop economical and large-scale production methods for use in food industries. This work is the first report describes a simple purification procedure and some properties of aminopeptidase from the water buffalo kidney as a safe mammalian locally available rich source.

2. Material and Methods

Kidney materials

Fresh kidneys from water buffalo Bubalus bubalis, were obtained fresh from a local slaughter-house. The cortex and medulla were separated.

Chemicals:

Ampholyte solution, pH 3.5-10, ampholyte solution, pH 3-7, DL-alanine *β*-naphthylamide,1,4 Dithiothreitol (DTT), *p*-Chloromercuribenzoate, *p*-Hydroxy-mercuribenzoate, 1,10 phenanthroline, Phenymethylsulfonyl-fluoride (PMSF), diethyl-aminoethyl-cellulose (DEAE-Cellulose), bestatin, puromycin, glutathione reduced form, N-Tosylamide- L-phenyl-alanine chloromethyl ketone (TPCK), *Na-p*-Tosyl-L-Iysine chloromethyl ketone (TLCK), Phenylmethylsulfonyl fluoride (PMSF), Pepstatin A, soyabean trypsin inhibitor and Sephacryl S-300 were purchased from Sigma Chemical Co. The other chemicals were of analytical grade.

Purification of the kidney AAP

1- Preparation of crude extract

All of the procedures were performed at 4˚C unless stated otherwise. Thirty gm of frozen kidney cortex or medulla were sliced and homogenized in omni-mixer (Sorvall DuPont Instruments), with two volumes (w/v) of 0.02 M Tris-HCl buffer pH 7.8 containing 1 mM $MgCl_2$ and 0.2 mM PMSF. After centrifugation at 12,000 xg for 30 min at 4˚C, the supernatant was saved and designated crude extract.

2- DEAE-cellulose column Chromatography

The crude extract was chromatographed on DEAE-cellulose column previously equilibrated with 0.02 M Tris-HCl buffer pH 7.8 containing 1 mM $MgCl_2$ and 0.2 mM PMSF. The proteins were eluted with stepwise NaCl gradient ranging from 0 to 1 M followed by 0.5 % Triton X-100 prepared in the equilibration buffer. Fractions of 5 ml were collected at a flow rate of 60 ml / h and the fractions of the peaks containing the alanine aminopeptidase activity were pooled.

3- Sephacryl S-300 column Chromatography

The concentrated material containing the AAP activity was applied onto a Sephacryl S-300 column (142 cm x 1.75 cm i.d.). The column was equilibrated and developed with 0.02 M Tris-HCl buffer pH 7.8 containing 1 mM $MgCl_2$ and 0.2 mM PMSF at a flow rate of 30 ml / h. 2 ml fractions were collected. The Sephacryl S-300 column was used for molecular weight determination of the buffalo kidney cortex native AAP according to the method of Andrews, (1964 and 1965). The above described Sephacryl S-300 column was calibrated with ferritin (440 kDa), catalase (240 kDa), *β*-amylase (200 kDa) alcohol dehydrogenase (150 kDa), bovine serum albumin (67 kDa), carbonic anhydrase (29 kDa), myoglobin (17.2 kDa), and cytochrome C (12.4 kDa).

Assay of aminopeptidase activity

(A) Using *β*-naphthylamide derivatives

The aminopeptidase activity was assayed according to Kawata et al., (1980) by measuring the liberated *β*-naphthylamine. The reaction mixture 1.5 ml contained; 100 mM Tris-HCl buffer pH 7.8, suitable dilution of the enzyme extract and 0.4 mM DL-alanine-*β*-naphthylamide HCl. The reaction was initiated by adding 0.1 ml of the substrate (6 mM stock solution). The reaction was terminated by the addition of 0.5 ml of Fast Garnet GBC solution (1 mg / ml) in 1 M Na-acetate buffer pH 4.2 containing 10% Tween 20. The absorbance of the liberated *β*-naphthylamine was determined spectrophoto-metrically at 525 nm. One unit of AAP activity was defined as the amount of the enzyme which catalyzes the liberation of 1 nmol of *β*-naphthylamine per hour at 37˚C. The specific activity is expressed in units / mg protein. The *β*-naphthylamine concentration was determined from a previously constructed curve for *β*-naphthylamine treated similarly.

(B) By using *p*-nitroanilide derivatives

The aminopeptidase activity was determined according to Niven, (1995) by measuring the liberated *p*-nitroaniline in 1 ml reaction mixture containing 100 mM Tris-HCl buffer pH 7.8 and suitable dilution of the enzyme extract. The reaction was initiated by addition of substrate; 5 mM amino acyl *p*-nitroanilide derivatives dissolved in dimethylsulfoxide (DMSO). The reaction was terminated by the addition of 0.5 ml 30 % (v / v) acetic acid and the mixtures were centrifuged for 10 min at 10 000 xg. The absorbance at 405 nm was recorded against control lacking the enzyme and the *p*-nitroaniline concentration was determined from a previously constructed standard curve for *p*-nitroaniline treated similarly.

Electrophoretic analysis

Native gel electrophoresis was carried out with 7% polyacrylamide gel according to Smith, (1969). SDS-PAGE was performed with 12% polyacrylamide according to Laemmli, (1970). The molecular weights of the purified AAP subunits were determined by SDS-PAGE as described by Weber and Osborn, (1969). The isoelectric point (pI) of the purified AAP was analysed on native 5% polyacrylamide vertical slabs (Robertson et al., 1987). The proteins were stained with 0.25% coomassie brilliant blue R-250.

Isoelectrofocusing marker proteins and their pI values; trypsinogen (9.3), lectin 1 (8.8), lectin 2 (8.6) lectin 3 (8.2), myoglobin 1 (7.2), myoglobin 2 (6.8), carbonic anhydrase 1 (6.6), carbonic anhydrase 2 (5.9), *β*-lactoglobulin (5.1), trypsin inhibitor (4.6)

and amyloglucosidase (3.6) were used to construct a calibration curve by plotting the distance from anode of each marker protein versus its isoelectric point pI value (Ubuka et al., 1987).

Staining of the AAP activity

Detection of AAP activity on gel was performed as described by Chien et al. (2002). After the native PAGE, the gel was incubated in the staining solution; 0.1 M Na-phosphate buffer pH 5.8 containing 1 mM $CoCl_2$, 0.06% DL-Alanine β-naphthylamide HCl and 0.06% Fast Garnet GBC until the development of the red bands. The stained gel was washed with water and then fixed in 7% acetic acid.

Protein determination

Protein was determined by the dye binding assay method (Bradford, 1976). Bovine serum albumin was used as a standard protein.

3. Results

Comparison of the AAP activity in the kidney cortex and medulla:

The AAP activity was assayed and compared in the kidney cortex and medulla. The AAP showed a higher specific activity in the cortex (1616.13 ± 91.77 units / mg protein) than the medulla (194.4 ± 10.7 units / mg protein) representing more than 8 folds Table (1). Therefore, the kidney cortex is selected for the AAP purification.

Table (1), AAP specific activity in the water buffalo kidney cortex and medulla.

Specific activity* of the water buffalo kidney AAP by using DL-alanine β-naphthylamide	
Cortex	Medulla
1616.1 ± 91.8	194.4 ± 10.7

Purification of AAP from the water buffalo kidney cortex

A typical purification scheme of the AAP from water buffalo kidney cortex is presented in Table (2). The procedure involved anion exchange chromatography on DEAE-cellulose column (Fig. 1) followed by gel filtration chromatography on Sephacryl S-300 column (Fig. 2 A, B and C). The starting specific activity in the crude extract was 1704.25 unit / mg protein. The chromatography on the DEAE-cellulose column revealed the presence of three peaks of the AAP activity eluted with 0.1 M NaCl (AAP1), 0.2 M NaCl (AAP2) and 0.5% Triton X-l00 (AAP3) (Fig. 1).

For further purification, the concentrated pooled fractions of AAP1, AAP2 and AAP3 were applied separately on a Sephacryl S-300 column. The column was equilibrated and developed with 0.02 M Tris-HCl buffer pH 7.8 containing 1 mM $MgCl_2$ and 0.2 mM PMSF. The elution profiles of AAP1, AAP2 and AAP3 (Fig. 2 A, B and C) revealed the presence of one peak of AAP activity in each one. After the gel filtration on the Sephacryl S-300 column the specific activity of AAP1, AAP2 and AAP3 were increased to 2972.1, 4038.06 and 11655.32 units / mg protein which represents 1.74, 2.36 and 6.83 fold purification over the crude extract with 5.18 %, 8.6 % and 51.31 % recovery respectively.

The molecular weights of the native AAPs were calculated from the calibration curve to be 120 kDa, 400 kDa and 310 kDa for AAP1, AAP2 and AAP3 respectively. The elution volumes (Ve) of AAP1, AAP2 and AAP3 are 190 ml, 140 ml and 146 ml respectively from the Sephacryl S-300 column (Fig. 2A, 2B and 2C) and the column void volume (Vo) was 132 ml as determined by the dextran blue (2000 kDa).

Characterization of the water buffalo kidney cortex AAPs

Electrophoretic analyses

` Samples from the different purification steps (crude extract, DEAE-cellulose and Sephacryl S-300 fractions) of AAP1, AAP2 and AAP3 were analyzed electrophoretically on native 7% polyacrylamide gel (Fig. 3). The isoenzyme pattern of the crude extract and the three isoenzymes confirmed that the water buffalo kidney cortex contain three distinct AAP isoenzymes. The AAP activity was visualized on 7% native PAGE. AAP1 and AAP2 isoenzymes migrated faster than AAP3 due to their higher negative charge (Fig. 4).

The native and denatured 12% SDS-PAGE confirmed the purity of water buffalo kidney cortex AAP1, AAP2 and AAP3 (Fig. 6). The subunit molecular weights of AAP1, AAP2 and AAP3 were estimated to be 60 ± 1 kDa, 67 ± 1 kDa and 53 ± 1 kDa respectively (Fig. 6).

Samples of the purified AAP1, AAP2 and AAP3 isoenzymes were electrofocused (Fig. 5). AAP1, AAP2 and AAP3 isoenzymes showed isoelectric points (p*I*) value at pH 5.6, 4.9 and 4.6 respectively.

Substrate specificity

The substrate specificity of the purified water buffalo kidney AAP1, AAP2 and AAP3 were screened toward various substrates and presented in (Table 3). The three isoenzymes AAP1, AAP2 and AAP3 cleaved preferentially alanyl residue (100 % relative activity).

The rate of hydrolysis of DL-alanine -*β*-naphthylamide HCl (0.311), (0.327) and (0.827) were more than the rate of hydrolysis of L- alanine *p*-nitroanilide (0.231), (0.244) and (0.763) for AAP1, AAP2 and AAP3 respectively.

Effect of pH on AAP1, AAP2 and AAP3

The enzyme activity of AAP1, AAP2 and AAP3 isoenzymes toward DL-alanine-*β*-naphthylamide HCl were measured in 100 mM Tris-HCl buffer of various pH values from 7.2 to 9. The optimum pH was found to be at pH 8, 7.8 and 7.8 for AAP1, AAP2 and AAP3 respectively (Fig. 7).

Table (2). A typical purification scheme of the water buffalo kidney cortex AAP.

Purification step	Total protein (mg)	Total units	Recovery (%)	Specific activity	Fold purification

Michaelis-Menten constant (Km) value

The purified AAP1, AAP2 and AAP3 isoenzymes were incubated with increasing concentrations of DL- alanine -*β*-naphthylamide HCl. The plots of substrate concentration [s] versus reaction velocity (v) (Fig. 8) were used to calculate the Michaelis-Menten constants (Km). The Km values were found to be 0.15, 0.17 and 0.125 mM and the corresponding maximum velocities (Vmax) were calculated to be 1694, 1143 and 66129 units / mg protein for AAP1, AAP2 and AAP3 respectively.

Effect of divalent cations on AAP1, AAP2 and AAP3

The purified AAP1, AAP2 and AAP3 isoenzymes were pre-incubated with 0.5 and 1.0 mM of each divalent cation at 37ºC and the activity was assayed. Table (4) shows the activity of AAP1, AAP2 and AAP3 in the presence of each cation. A control test based on the rate of hydrolysis of DL-alanine-*β*-naphthylamide HCl without any cation was taken as 100 % relative activity.

The activity of AAP3 was increased 112.5 % and 108.2 % in the presence of 0.5 and 1.0 mM $MgCl_2$ and 107.9 % and 100.8 % in the presence of 0.5 and 1.0 mM $CaCl_2$ respectively. The three isoenzymes were inhibited by the metal ions of Cu^{2+}, Mn^{2+} and Ni^{2+}, while Co^{2+} and Fe^{2+} have non-significant effect on AAP3 but have inhibitory effects on AAP1 and AAP2. The metal ion Zn^{2+} has a great inhibitory effect on the three isoenzymes AAP1, AAP2 and AAP3.

Effect of amino acids on AAP1, AAP2 and AAP3

Prior to the reaction initiation with the substrate, 1 mM of each tested amino acid was incubated with the enzyme in the assay reaction mixture. Table (5) presents the effect of the different amino acids on the purified water buffalo kidney cortex AAP1, AAP2 and AAP3 isoenzymes.

Almost all amino acids increase the activity of AAP2 except L- tyrosine, phenylalnine and L-leucine caused either slight or moderate inhibition of the enzyme. The isoenzymes AAP1 and AAP3 were inhibited 47.4 % and 32.9 % in the presence of 1 mM of tyrosine, 30 and 17.8 % by 1 mM phenylalnine and 25 % and 7.7 % by 1 mM serine respectively. The other tested amino acids caused slight inhibition of the isoenzymes AAP1 and AAP3.

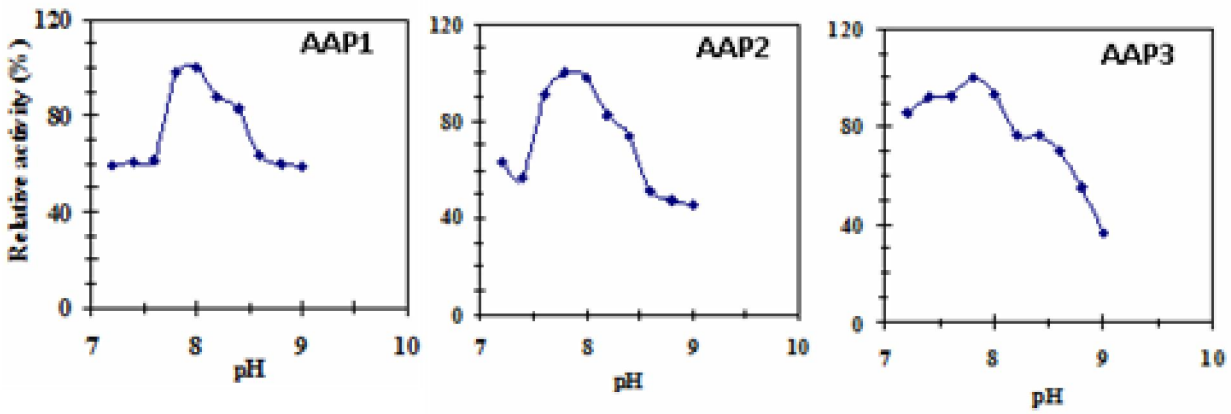

Figure 7. Effect of pH on the purified water buffalo kidney cortex AAP1, AAP2 and AAP3 using DL-alanine-*β*-naphthylamide HCl as substrate in 100 mM Tris-HCl buffer of various pH values from 7 to 9.

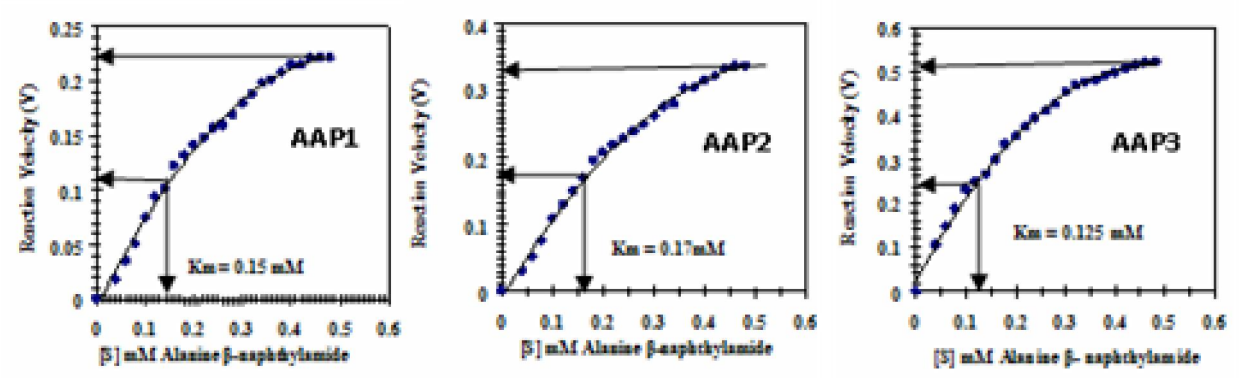

Figure 8. Effect of the substrate DL-alanine-β-naphthylamide HCl concentration in mM on the reaction velocity of the purified water buffalo kidney cortex AAP1, AAP2 and AAP3. The reaction velocity is the change in absorbance at 525nm per 30 min.

Effect of inhibitors on AAP1, AAP2 and AAP3

The purified AAP1, AAP2 and AAP3 isoenzymes were pre-incubated with a suitable concentration of each inhibitor at 37ºC for 5 min and the residual activity was assayed (Table 6).

The DL-dithiothreitol (DTT) was an obvious inhibitor of AAP1 since it caused 97.9 % inhibition at a concentration of 0.4 mM, while 1,10 phenanthroline was an inhibitor of both AAP2 and AAP3 since it caused 94.4 % and 96.5 % inhibition at a concentration of 10 mM.

The bestatin was a potent inhibitor of AAP1, AAP2 and AAP3 since it caused 72 %, 82.1 % and 79.56 % inhibition respectively at a concentration of 1 µM.

The isoenzymes AAP2 and AAP3 were sensitive to the thiol compound *β*-mercaptoethanol since it inhibited 60.13 % and 58.6 % of the enzyme activity at a concentration of 0.4 mM and also they were sensitive to reduced glutathione (GSH), which inhibited 57.69 % and 36.18 % of the enzyme activity respectively.

Kinetics of AAP1, AAP2 and AAP3 inhibition by DTT and 1,10 Phenanthroline

The effect of varying concentrations of DTT on the AAP1 activity is shown in Fig. (9). A maximum inhibition of AAP1 by DTT 92 % was reached at a concentration of 0.4 mM. A linear relationship was observed by constructing the Hill

plot for the inhibition of the purified water buffalo kidney cortex AAP1 by DTT, a straight line was obtained with slope of about 1.1 for AAP1 Fig. (9). Also, the effect of varying concentrations of 1,10-phenanthroline on the AAP2 and AAP3 activity are shown in (Fig. 10 and 11). A maximum inhibition of AAP2 and AAP3 by 1,10 phenanthroline 94.1 % and 91.2 % was reached at 10 mM 1,10-phenanthroline. The slopes of the Hill plot were found to be 0.95 and 0.78 for AAP2 and AAP3 (Fig. 10 and 11)**.**

Table (4**),** Effect of divalent cations on water buffalo kidney cortex AAP1, AAP2 and AAP3.

Reagent	**Final concentration (mM)**	**Residual activity (%)**		
		AAP1	**AAP2**	**AAP3**
Control	-	100.0	100.0	100.0
$CuCl_2$	0.5	64.7	87.6	74.1
	1.0	60.6	80.3	67.2
$MnCl_2$	0.5	45.5	84.3	88.9
	1.0	34.7	71.3	85.2
$ZnCl_2$	0.5	17.6	19.7	1.7
	1.0	15.0	11.8	0.0
$NiCl_2$	0.5	43.5	48.9	55.6
	1.0	37.3	34.3	40.0
$CoCl_2$	0.5	70.9	73.0	100.0
	1.0	65.2	75.2	99.1
$CaCl_2$	0.5	64.2	69.1	107.9
	1.0	61.6	67.4	100.8
$FeCl_2$	0.5	89.6	83.7	99.1
	1.0	86.5	86.5	95.6
$MgCl_2$	0.5	92.2	84.8	112.5
	1.0	86.5	87.6	108.2

The inhibition of AAP1, AAP2 and AAP3 by DTT and 1,10 phenanthroline were competitive type since the presence of the inhibitors did not alter the Vmax value but increases the Km value (Fig. 9, 10 and11).

The Ki value of AAP1 inhibition by DTT is determined to be 47 µM directly from the intercept of the X axis of the plot, while the Ki values of AAP2 and AAP3 inhibition by 1,10 phenanthroline are determined to be 1.3 mM and 1.9 mM respectively (Fig. 9, 10 and 11).

Table (5), Effect of amino acids (1 mM final concentration) on water buffalo kidney cortex AAP1, AAP2 and AAP3.

Amino acid	**Residual activity (%)**

L-Arginine	86.8	121.9	98.3
L-Glutamine	90.4	123.8	97.7
L-Serine	92.2	130.0	74.9

4. Discussion

Among various aminopeptidases, the alanyl aminopeptidases (AAPs) which preferentially liberate amino-terminal neutral amino acids, such as Ala, Met, Leu and Tyr of peptides are widely distributed in mammalian tissues and body fluids (Mane et al., 2010).

In this study, a simple, convenient and reproducible purification procedure of the water buffalo kidney cortex AAP is carried out by a combination of anion exchange chromatography on DEAE-cellulose column followed by gel filtration chromatography on Sephacryl S-300 column. The native enzyme was obtained since both the extraction buffer and the equilibration buffer of the DEAE-cellulose column contained 0.2 mM phenylmethylsulfonylfluoride (PMSF), a serine protease inhibitor to avoid the action of the endogenous protease.

On the basis of the protein charge, the chromatography on DEAE-cellulose column revealed the presence of three forms of water buffalo kidney

cortex alanine aminopeptidases AAP1, AAP2 and AAP3 (Fig. 1). A considerable yield and purity of the AAP isoenzymes from water buffalo kidney cortex was obtained (Table 2). The recovery % of the enzyme units was 9.1, 10.3 and 68.44 for AAP1, AAP2 and AAP3 respectively. The total recovery is more than 87%. The alanine aminopeptidase from chicken intestine has a yield of 3.43% (Mane et al., 2010).

Table (6), Effect of inhibitors on the purified water buffalo kidney AAP1, AAP2 and AAP3.

Inhibitor	**Final concentration**	**Inhibition %**		
		AAP1	**AAP2**	**AAP3**
Control		0.0	0.0	0.0

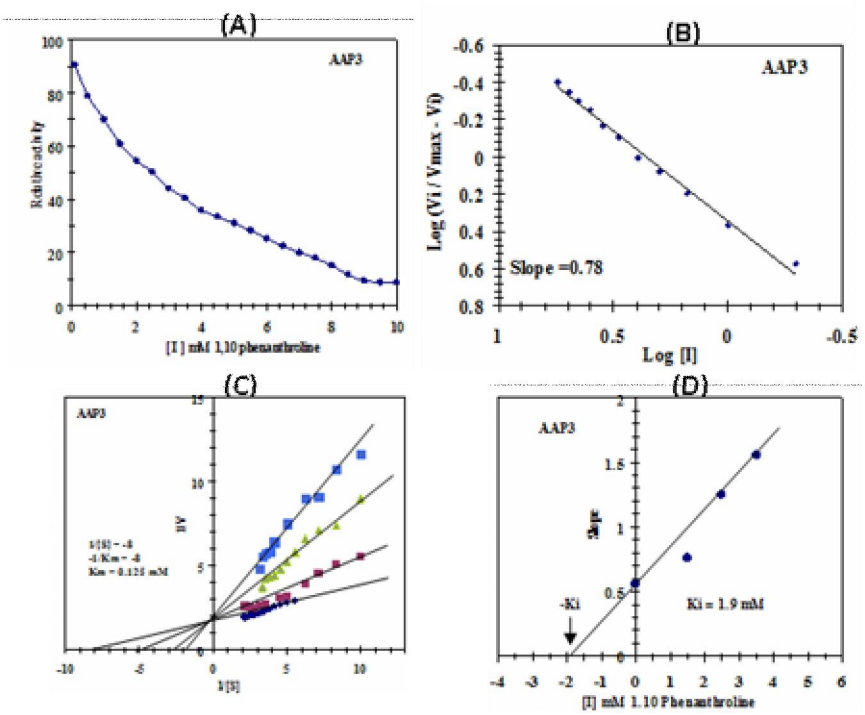

Figure 11. (A) Inhibition of the purified AAP3 by varying concentrations of 1,10-phenanthroline. (B): Hill plot for inhibition of AAP3 by varying concentrations of 1,10-phenanthroline. (C): Lineweaver-Burk plots showing the type of inhibition of AAP3 by 1,10-phenanthroline. (D): Determination of the inhibition constant (Ki) value for the inhibition of AAP3 by 1,10-phenanthroline.

The molecular weights of the native isoenzymes were determined by gel filtration to be 120 kDa, 400 kDa and 310 kDa for AAP1, AAP2 and AAP3 respectively (Fig. 2). The molecular mass of AAP1 was different from those of 180 kDa from chicken intestine alanine aminopeptidase (Mane et al., 2010), 153 kDa from human seminal plasma (Huang et al., 1997), 140 kDa from rat kidney (Watt et al., 1989), 106 kDa from porcine skeletal muscle (Flores *et al.*, 1996), 102 kDa from human skeletal muscle (Mantle et al., 1983) and 98 kDa from human liver cytosol (Yamamoto et al., 2000). The molecular masses of AAP2 and AAP3 were more or less similar to those of 420 kDa from gypsy moth *Lymantria dispar* (Masler and Kovaleva, 1997), 375 kDa from eosinophilic blood cells of *Mytilus edulis* (Renwrantz and Lam, 2010), 320 kDa from human placenta (Lampelo et al., 1982), 290 kDa from ostrich duodenal mucosa (Roos et al., 1993), 280 kDa from pig kidney (Wacker, 1976) and 236 kDa from human kidney (Kao et al., 1978).

All of the AAP1, AAP2 and AAP3 turned out to be homogenous as indicated by both native (Fig. 3) and SDS-PAGE (Fig. 6). Also, the single band of the enzyme subunit (Fig. 5) confirms the purity of the enzyme.

The subunits molecular weight of the purified buffalo kidney cortex AAP1 is determined by SDS-PAGE to be 60 ± 1 kDa indicating a homodimeric structure composed of two identical subunits, while AAP2 was 67 ± 1 kDa indicating a homohexameric structure composed of six identical subunits and AAP3 was 53 ± 1 kDa suggesting also a homohexameric structure composed of six identical subunits. (Fig. 6). However, aminopeptidases exhibit molecular weights ranging from 53–140 kDa per subunits and exist as monomers, hexamers and octamers (Božić et al., 2008).

The estimated p*I* values at pH 6.4, 6.2 and 6.6 for AAP1, AAP2 and AAP3 respectively (Fig. 5) are slightly higher than that described previously. The isoelectric point (pI) value is found to be 5.0 for membrane alanyl aminopeptidase (Riemann et al., 1999), between pH 4.5 and 5.8 for the soluble and surface-bound aminopeptidase in *Mytilus edulis* blood cells (Renwrantz and Lam, 2010) and 4.9 for that from rat liver (Hiroi et al., 1992).

The isoenzymes AAP1, AAP2 and AAP3 cleaved preferentially alanyl residue (Table 3)

The Km values using alanine *β*-naphthylamide as substrate were found to be 0.15, 0.17 and 0.125 mM for AAP1, AAP2 and AAP3 respectively (Fig. 8). These values were considerably

close to alanyl aminopeptidase from chicken intestine, since Km value of preferentially hydrolyzed Leu-β-NA was found to be 0.1 mM (Mane et al., 2010) indicating the high affinity of the buffalo kidney cortex AAPs toward the alanine β-naphthylamide.

The water buffalo kidney cortex AAP1, AAP2 and AAP3 displayed their optimum activity at pH 8, 7.8 and 7.8 respectively (Fig. 7). These pH values are similar to that of monomeric alanine aminopeptidase from bovine skeletal muscle which was optimal at pH 8.0 (Ye and Ng, 2011) and pH 7.9 for human pancreas alanine aminopeptidase (Sidorowicz et al., 1981).

The activity of AAP3 was increased in the presence of $MgCl_2$ and $CaCl_2$. The metal ion Zn^{2+} has a great inhibitory effect on the three isoenzymes AAP1, AAP2 and AAP3 (Table 4). High concentrations of Zn^{2+} (in the mM range) often inhibit metallopeptidases due to the formation of zinc monohydroxide that bridges the catalytic Zn^{2+} ion to a side chain in the active site of the enzyme (Božić et al., 2008). The chicken intestinal alanine aminopeptidase show that presence of cations (Zn^{2+} and Mn^{2+}) slightly activated the enzyme activity (Mane et al., 2010). The bovine skeletal muscle monomeric alanine aminopeptidase activity was totally abolished by Co^{2+} and Zn^{2+} ions, and almost completely inhibited by Mn^{2+}, the activity was strongly inactivated by Mg^{2+}, and Fe^{3+} ions. However the activity was not affected by Ca^{2+} (Ye and Ng, 2011).

The susceptibility of aminopeptidases to inhibition by free amino acids, suggesting in turn that the degradation of oligopeptides to amino acids may play a key role in control of the overall protein turnover process **(**Toldra et al., 1996). It has been suggested that the levels of the free amino acids within the cell may regulate the protein synthesis/degradation cycle, via a feedback inhibition type **(**Mader, 1988**)**; because aminopeptidase enzymes are in turn subject to inhibition by free amino acids **(**McDonald and Barrett, 1986**)**, it follows that the ultimate function of soluble aminopeptidases may be involved in the control of cellular protein turnover **(**Mantle, 1992**)**. Therefore, the effect of amino acids on the three isoenzymes AAP1, AAP2 and AAP3 was studied and presented in Table (5). The tyrosin inhibited the three isoenzymes obviously.

In the present study, the effect of different specific and characteristic inhibitors on the water buffalo kidney cortex AAPs is presented in Table (6). The purified isoenzymes are resistant to the serine protease inhibitors PMSF, N-Tosylamide-L-phenylalanine chloromethyl ketone (TPCK), Nα-*p*-Tosyl-L-lysine chloromethyl ketone (TLCK) and soya bean trypsin inhibitor indicating that the enzyme active site does not contain a serine residue and this was the reason why PMSF was added to the tissue homogenization buffer to inhibit the endogenous serine proteases. Also, they do not belong to the acid or thiol proteases groups since both the acid protease inhibitor, pepstatin A and thiol protease inhibitor, iodoacetic acid did not affect the purified AAP isoenzymes. The three isoenzymes AAP1, AAP2 and AAP3 are not cysteine proteases due to their resistance to the cysteinyl protease inhibitors, *p*-chloromercuribenzoic acid (*p*CMB), *p*-hydroxymercuribenzoate (*p*HMB) and N-ethylmaleimide (Table 6). Lack of enzyme inhibition with cysteine and serine protease inhibitors suggests that purified aminopeptidase does not have any endopeptidase activity (Pokharel and Rathaur, 2008).

The inhibition of the AAP isoenzymes by the thiol compound DTT indicates the role of sulfhydryl group in enzyme catalysis and their inhibition by 1,10 phenanthroline indicates that the isoenzymes are metalloenzymes.

Similarly, aminopeptidases from porcine liver (Imamura et al., 1983) and rabbit kidney (Oliveira et al., 1999) are found to be metalloenzymes. Inhibition by chelating agents such as 1,10-phenanthroline indicates the presence of at least one divalent zinc cation associated with the enzyme active site and should be considered as a zinc-aminopeptidase (Pokharel and Rathaur, 2008). Bestatin is not only LAP inhibitor but also a well-recognized inhibitor of membrane alanyl aminopeptidase although considerably less potent than amastatin or probestin **(**Tieku and Hooper, 1992). In this study, bestatin was found to be a potent inhibitor of the three AAP isoenzymes (Table 6) confirming that all of them are alanine aminopeptidase.

From the titration curves data a linear relationship was observed by constructing the Hill plot for the inhibition of the purified AAP1 by DTT and AAP2 and AAP3 by 1, 10 phenanthroline. The slope of the Hill plot was found to be 1.1 for AAP1 whereas 0.95 and 0.78 for AAP2 and AAP3 indicating the existence of one binding site for DTT and 1, 10 phenanthroline (Fig. 9, 10 and 11).

The type of inhibition of AAP1 by DTT, and AAP2 and AAP3 by 1, 10 phenanthroline were found to be competitive where the presence of DTT and 1, 10 phenanthroline did not alter the Vmax value but increased the Km value. For the determination of the Ki value, the slopes of the reciprocal plots lines were plotted against the DDT and 1, 10 phenanthroline concentrations. The Ki value of the AAP1 inhibition by DTT was determined to be 47 µM, whereas the Ki values of AAP2 and AAP3 inhibition by 1, 10 phenanthroline were determined to be 1.3 mM and

1.9 mM respectively directly from the intercept of the X axis of the plot (Fig. 9, 10 and 11).

The hexameric structure of AAP2 (400 kDa) and AAP3 (310 kDa) and their similar catalytic properties suggest that AAP2 may be a precursor of AAP3 and proteolytic modification is involved in the conversion of AAP2 to AAP3. On the other hand, AAP1 could be considered a unique isoform.

In conclusion, this study presents a simple, convenient and reproducible method for the purification of a well characterized alanine aminopeptidases from the water buffalo kidney cortex as a safe locally available rich source. Production of these enzymes on large scale will allow their use in various applications such as food industries and also investigation of the protein primary structure.

Engineering aspects and associated problems of flood plain deposits in Sohag Governorate, Upper Egypt

EL-SAYED SEDEK ABU SEIF* AND EL-SHATER, A.A.

Geology Department, Faculty of Science, Sohag University, 82524 Sohag, Egypt.
*e-mail: elsayed_71@Yahoo.com

Abstract: The flood plain sediments occurred on both sides of the River Nile course which are dominated by alluvial sediments. Signs of deterioration have been seen which characterized by cracking of the superstructures. This due to low bearing capacity, ground settlement and shrinkage and swelling of these soils. The sediments of the floodplain were accumulated during the annual inundation of the Nile causing deposition of fine materials before the construction of the High Dam. Five types of clay minerals were identified throughout the studied sequence, namely smectite and kaolinite were the predominant clay minerals present in all samples, mixed layer (smectite-illite), chlorite and illite. In general, for each unit the SPT "N" values increase downwards with depth. The high C_C values of the studied clayey soil (A-Unit) is ranged between 0.24 and 0.32, that indicated to the loose and very high compressible nature of this type of soil. The geotechnical associated problems of the River Nile flood plain sediments area: the low bearing capacity of the sediments, ground settlement and Shrinkage and swelling.

Keywords: Geotechnical problems; Standard penetration test (SPT); Undrained shear strength (S_U); Coefficient of compressibility (Co); Nile flood plain sediments; Clay minerals.

1. Introduction

Urban areas in Egypt occupy about 5 % of the territory and they are concentrated along the River Nile between Aswan and the Delta. The flood plain sediments occurred on both sides of the River Nile course which are dominated by muddy sediments in the upper most part. The average thickness of these mud deposits is 10 m between Aswan and Cairo.

Sohag is criss-crossed by a River Nile and most of the Nile Valley of the country is covered by of alluvial sediments. Due to insufficient accommodation for the increasing population. During the last three decades, a large numbers of structures include homes, schools, and offices in Sohag Governorate were built on soft alluvial soil of Nile flood plain sediments. Signs of deterioration have been seen which characterized by cracking of the superstructures. This due to low bearing capacity, ground settlement and shrinkage and swelling of these soils.

The suitability of soils for engineering purposes depends largely on their ability to remain in place and to support whatever loads may be placed upon them either by a permanent structure or transient loads. The civil engineer should be informed among other data of the quantity and type of clay minerals that are present and of their properties in order to evaluate their potential influence on the engineering project. Therefore, it is very important to determine the main geotechnical properties of these soil samples. When civil engineering projects are based on limited site geological conditions, geotechnical problems frequently arise and the work suffers cost increases and delays. To reduce such problems, investigation is recommended to correctly characterize the site and define land units with similar behaviour (Anonymous, 1972, 1976). This information allows the engineering geologist or the geotechnical engineer to develop a conceptual geological model (Fookes, 1997), useful to the site-specific project or to others in the same geological terrain. This model helps to understand site geological conditions, to identify the main geological problems, and to make realistic estimates of material properties.

This paper represents a comprehensive assessment of ground conditions and soil characteristics as well as causes of particular problems

2. Geological setting

From a geologic point of view, Sohag Governorate situated in the Upper Egypt occupying a major section (about 125 km long) from the Nile Valley with an average width varying from 16 to 20 km. Egyptian Nile Valley, where the Nile soil extended along the two banks of the River Nile for about 10 km. Sohag is located 467 km south of Cairo. To the east it is bounded by the Red-Sea Governorate and the Eastern desert and to the west by the New Valley Governorate and the Western desert (Fig. 1). It occupies a region including both the floodplain and the desert fringes between longitudes 31o 15' and 32o 15'E and latitudes 26o 00' and 27o 00'N. It is occupying a major section (about 125 km long) from the Nile Valley with an average width varying from 16 to 20 km, where the Nile flood plain soil extended

along the two banks of the River Nile for about 10 km. Contrarily, it constitutes only a very narrow strip along the eastern side and, moreover, it frequently disappears. Geologically the area has been studied by a variety of authors (e.g. Said, 1975, 1981, 1983, 1990; Issawi et al., 1978; Paulissen and Vermeersch, 1987; Issawi and MC Cauley, 1992; Mahran 1992 and 1993; Omer, 1996; Omer and Issawi, 1998 and Hassan, 2005). The sediments of the floodplain were accumulated during the annual inundation of the Nile causing deposition of fine materials before the construction of the High Dam These sediments are mainly muddy in nature and accumulated during the successive stages of the annual Nile floods for thousands of years till the construction of the High Dam.

3. Geotechnical investigation

3.1. Site soil conditions

The first step of site investigation was to collect undisturbed and disturbed samples of recent alluvial deposits from 0- to 30-m depth by drilling three boreholes extending along Sohag Governorate. The investigation sites from north to south are: Tema City (site I), Sohag City (site II) and Gerga City (site III), Theses samples were tested in the field and in laboratory to determine the index engineering properties. A subsurface profile is shown in Fig. (2). It is noted that the proportion of gravels and sands are increase downward at the expense of the proportion of silts and clays.

The alluvial deposits in the studied boreholes can be subdivide lithologically and geotechnically into three distinctive subunits (A, B and C). The soil sequences together with their Unified Soil Classification are given below:

Unit A (floodplain deposits): Inorganic clays of low to medium plasticity, sandy/silty/lean clays (CL): The top soil sequence is predominantly composed of sandy silt varying from one meter to 12 m in thickness especially in site III. This soil sequence is characterized by a low standard penetration test (SPT) resistance indicating a loose condition (Table 1). A floodplain is the low-lying, generally flat area adjacent to a River Nile channel which has been deposited during many thousands of years when river discharge exceeds the capacity of the channel, water rises over the channel banks and floods the surrounding low-lying lands. The average rate of sediment accumulation was about 9cm per century (Ball, 1939). Also, This type of soil are highly porous and permeable (El-Haddad and El-Shater, 1988).

Unit B (channel sands); Well-graded sand (SW): This zone is predominantly well-graded sands of channel sediments. The SPT 'N' values range from 10 to over 18 showing a general increasing downwards (Table 1). The shape of the grain size distribution curve of this type is considered "smooth.", C_U value > 6, C_C value from 1 to 3 is required (Fig. 3).

Similarly, unit C (channel gravels): Well-graded gravel (GW): This zone is predominantly well-graded gravels. The SPT 'N' values range from 18 to over 33 showing a general increasing downward (Table 1). The shape of the grain size distribution curve of this type is considered "smooth.", C_U value > 6, C_C value from 1 to 3 is required (Fig. 3).

The channel sands and gravels of Pleistocene age generally friable and highly porous and permeable. They represent the main aquifer which yields large quantities of groundwater in the Nile Valley. It has an average thickness of 150 m in Sohag area (Abdel-Moneim, 1992).

3.2. X-ray diffraction (XRD)

The XRD test was done on ten representative samples were chosen for mineralogical investigation from the three selected sites. Each sample was examined in three forms: as an oriented clay sample (untreated); as an oriented clay sample treated with ethylene glycol; and as an oriented clay sample heated to 550°C for 2h. The clay particle sizes in the samples were <2µm. The identification of the clay minerals was based on the basal reflections (001), according to the X-ray powder diffraction results of Weaver (1958 and 1967), Carrol (1970), Millot (1970), Chen (1977) and the ASTM cards. Five types of clay minerals were identified throughout the studied sequence, namely smectite and kaolinite were the predominant clay minerals present in all samples, mixed layer (smectite-illite), chlorite and illite (Table 1, Fig. 4). These results were agreed with a number of studies have previously been made on clay fractions in the alluvial soils of Egypt (Hamdi et. al., 1968; Abdel-Kader and Abdel-Hamid, 1974 and Hanna and Beckmann, 1975). According to these investigations, the dominant minerals in the clay fraction as a whole are smectite, kaolinite, and illite. They (op. cit.) found the mineralogical composition of the clay fractions is nearly the same.

3.3. Standard penetration test (SPT-N) and undrained shear strength (SU)

Engineering properties can be determined by means of tests carried out in the field and laboratory. In order to avoid certain difficulties during sampling processes in coarse-grained soils and the disturbance of the sampling in fine-grained soils, in situ tests are frequently used. The standard penetration test (SPT) is used for soil exploration in geotechnical applications and foundation design (Sivrikaya and Toğrol, 2006). The SPT has the advantages with the easiness of the test procedure and the simplicity of the equipment employed. This test is the most commonly used penetration test in Egypt. In geotechnical engineering, the engineering properties of soil layers must be known down to the required depths. The SPT is widely used around the world. The SPT test is carried out in various types of soils ranging from soft clay and loose sand to very stiff clay and dense sand. It is possible to estimate the undrained shear strength of fine-grained soils from SPT data.

SPT "N" values, are used to calculate important engineering properties of soils such as the internal friction angle (ϕ′), relative density (Dr), and bearing capacity and settlement of coarse grained soils (Schmertmann and Palacios, 1979; Kovacs *et al.*, 1981; Farrar *et al.*, 1998). The undrained compressive strength (qu) is an important characteristic for fine-grained soils and it gives an idea about their consistency. In addition, it is used to estimate both the undrained shear strength (Su) and the sensitivity of clays (Sivrikaya and Toğrol, 2006).

The SU-values based on the SPT "N" values and the consistency of the studied samples were calculated according to Tschebotarioff (1973) as shown in Table (1). The SPT "N" values range between 3 and 12 in the case of clayey soil (Unit A) that indicating a loose condition. SPT "N" values vary from 10 to 18 in the case of well graded sand soil (Unit B) and ranged from 18 to 33 in case of well graded gravels (Unit C).

In general, for each unit the SPT "N" values increase downwards with depth.

3.4. Compressibility characteristics of clayey soil

The compressibility of a soil is conditioned by the capacity of the soil voids to decrease in volume under a pressure. It is also assumed that the pore volume decrease due to a large degree of packing of soil grains. Settlement is the most common reason for failure of foundation and it is therefore of great importance to understand the mechanics of settlement. Compressibility of clayey soils is due to mechanical (deformation, reorientation and sliding of particles or domains with respect to one another, expulsion of pore fluid etc.) and physicochemical factors. Physicochemical factors may play dominant role in the compressibility of clayey soils depending on the clay mineral composition and the type of exchangeable cations present in the exchange complex (Blot 1956; Olson and Mesri 1970; Mitchell 1993).

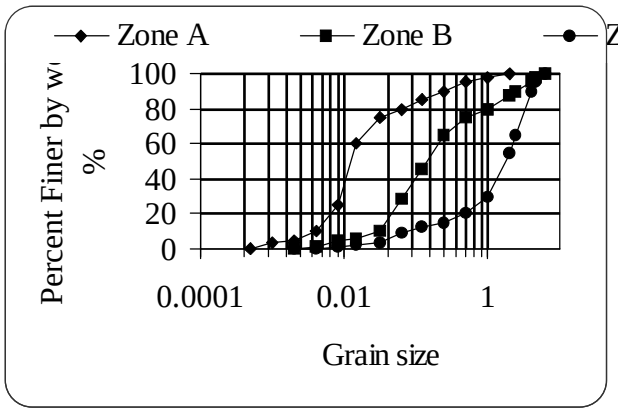

Fig. 3: Grain-size distribution curves for studied sediments.

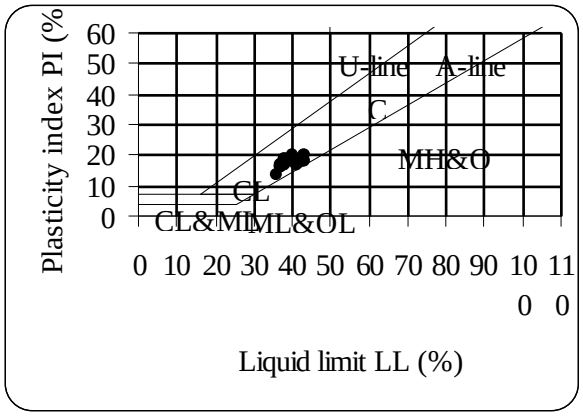

Fig. 4: XRD chart of clay minerals of unit A sediments.

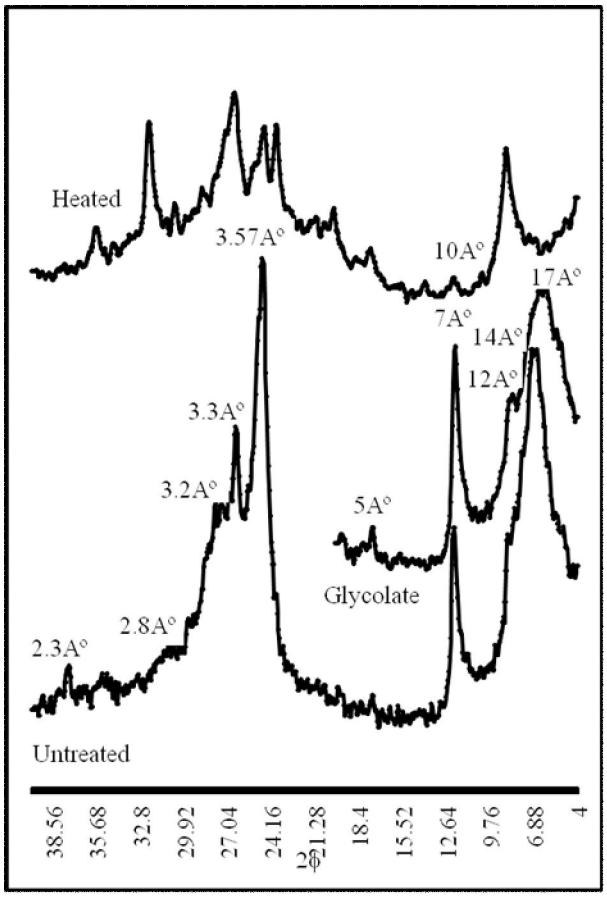

Fig. 5: Swelling potential classification of unit A sediments.

Plasticity and compressibility are typical properties of clays. Atterberg's limits of a clayey soil reflect the clay content and clay type of a soil. Compression index is also a clay dependent parameter. Among different correlations between the engineering and index properties of soils, which are often used to lessen the work load of a soil investigation program, Skempton's relationship (1944) between compression index (CC) and liquid limit (wL) given as Cc=0.009 (wL-10). The CC values were calculated using the Skempton (1944) formula: Co=0.009 (LL-10). The high CC values of the studied clayey soil (A-Unit) is ranged between 0.24 and 0.32 (Table 1, Fig. 5), that indicated to the loose and very high compressible nature of this type of soil (Maslov, 1987)

4. Geotechnical associated problems

Many parts of the world suffer from constructing problems that associated with flood plain clay soils. These problems include, ground settlement, low bearing capacity and swelling. These problems which greatly affect the safe and economic land utilization of the plains.

Alluvial deposits are generally granular and present favorable conditions, however, development activities in Egypt on these deposits are encountered with numerous geotechnical problems which greatly affect the safe and economic land utilization of the plains. These geotechnical problems: the low bearing capacity of the sediments, ground settlement and Shrinkage and swelling

.

4.1. Bearing capacity of soils

The low bearing capacity of the studied soils is the principal foundation problems in Sohag Governorate which related to the low resistance of the underlying soil to shearing resistance. Low bearing capacity is a problem that mainly affects the clay soil (CL) A-Unit of the flood plain sediments. Building foundations on these soils in this area must take into account the low shear strength of sediments and accordingly there are two frequently-used solutions. For low rise buildings, the most commonly used is a raft foundation, 1 or 1.5m deep and 60 to 80 cm thick. This type of foundation has the advantage of better support for differential ground settlement. Because the flood plain sediments are heterogeneous, geotechnical properties vary greatly over a short distance. In practice, various types of shallow foundations such as pad, strip and compensating types are used for light structures with pressures ranging from 25 to 40 kPa at depths between 1.5 and 3.0 m (Delgado, *et. al*., 2003).

The soil top layer (A) is unsuitable soil for carrying spread foundations safely. Soil improvement techniques are suggested. If these methods prove to be more economic than using deep foundations, they will be adopted:

1-It is economic to remove this layer and replace it with compacted sand or gravel.

2-Soil improvement techniques include compaction, deep compaction, preloading accompanied by sand drains, use of stone columns, injections, and concrete piles. Selection of the suitable methods depends on economy and nature of project.

4.2. Ground settlement

Ground settlement constitutes the principal geotechnical difficulty of the fine grained flood plain sediments. This problem is associated with fine sediments because the compressibility of sands and gravels is generally low (Smith and Smith, 1998). Settlement is particularly important in the flood plain sediments. Settlement is another major foundation problem in Sohag Governorate related to the loose and compressible nature of the surficial soil. The compression index, extracted from the record, ranged between 0.24 and 0.32 (Table 1). That means the surficial clay soil is of loose and very high compressible type (Maslov, 1987).

Structural settlement in the Sohag Governorate varies from a few centimeters to more than 50cm. Where, loading is high, deep foundations are usually used to reduce settlement. Another solution is ground improvement by vibro-replacement (gravel columns) of the ground to a depth of up to 10–15 m (Delgado, *et. al.*, 2003).

4.3. Shrinkage and swelling

Shrinkage and swelling are well-known phenomena causing damage to building foundations, roads, aircraft runways, underground service lines, etc. It is caused by a deficiency or excess of water (Youssef *et al.*, 1957; Popesco, 1980). Shrinkage and swelling soils are often characterized by high LL and PI caused by a variable content of more active clay minerals. Plasticity values of the studied soils are given in Table 1. The data are not strictly comparable because they are collected at different sites.

Undisturbed representative samples were chosen (Table 1), to determine swelling pressure as well as swelling percent using oedometer test. The Swelling pressure of the studied fine-grained soil of flood plain sediments varies from 1.8 to 2.4 kg/cm^2 (medium expansion, Chen, 1975). The free swell test was carried out typically as described by Holtz and Gibbs (1956), the free swell values of the studied samples ranged between 65 and 70% (Table 1). Ranganatham and Satyanarayana (1965) (quoted by Derriche *et. al.,* 1998) used plasticity index (PI) as classification indicator, PI-values of the studied clayey soil ranged from 14 to 20 (low swelling potential). Swelling measurements values are indicative of the low-medium swelling potential. For light structures, this can cause excessive uplift pressure inflicting damage. The problem of swelling can be handled, among others, by designing structures sufficiently rigid or flexible to accommodate the anticipated movement. Therefore, footings, piers, foundations, etc. should be placed at sufficient depths. It is common to place compacted sand (or sand and gravel or pit run gravel) cushion as buffer flexible layer between the foundation and the swelling clay.

9. Summary and Recommendations

This work can be considered as a simple geotechnical model of the Nile flood plain sediments in Upper Egypt. Thus, the following four points are of special interest and should be connected with the future projects.

(1) The geological features of the Nile flood plain soil in Sohag Governorate, Upper Egypt, had a great influence on the evolution of ground conditions and soil properties.

(2) Soil test data from the development projects cover almost the entire Nile flood plain soil in Sohag

Governorate indicate that the subsoil is dominated by sandy clay and sandy materials. A typical subsurface profile shows that the cover has a variable thickness comprising soft fine-grained cohesive soils graded down ward into well-graded sandy soil. There are broad similarities with respect to the textural composition over large distances..

(3) Sohag Governorate especially in flood plain region has encountered numerous specific construction problems because of its unique sedimentation history. The top most soils are too weak to support heavy foundations.

(4) A sufficient safety factor must be done in the design of any construction founded on this soil type.

Sajad.farahani@gmail.com

Abstract: In this paper, we propose a mixed integer programming formulation for a location distribution problem. We have a two layer supply chain, central warehouses/stocks, regional warehouses and customers. Stocks should satisfy the multi-commodity customers demand. Our objectives are to minimize transportation cost of goods, from stocks to regional warehouses and from regional warehouses to customers, and installing cost of warehouses and to maximize average service level of customers. Our model determines a set of Pareto optimal solution for considering these two conflicting objectives. We have a three type alternatives for both stocks and regional warehouses with varying installing costs and capacities. Regarding the long term decision making for a location problem, we consider time value of money to have more assumptions of real worlds. As a result, a case study is indicated to show efficiency of model to solve the industrial problems; a sensitivity analysis is also implemented upon the rate of return and the life of cycle of the supply chain system.

Keywords: Supply chain, facility location, mixed integer programming, time value of money

1. Introduction

Supply chain management (SCM) is the process of planning, implementing and controlling the operations of the supply chain in an efficient way. SCM spans all movements and storage of raw materials, work-in-process inventory, and finished goods from the point-of-origin to the point-of-consumption (Council of Supply Chain Management Professionals 2007, Simchi-Levi et al. 2004).

There are more works in literature considering concepts of SCM in variant areas that we state some of them as follows. Altiparmak et al. (2006) developed a multi-objective genetic algorithm (MOGA) to find a set of optimal pareto solution for Supply chain network (SCN) design. Thanh et al. (2008) proposed a mixed integer programming (MIP) formulation to design and plan a production – distribution system along the supply chain. Pujari et al. (2008) presented an integrated approach for incorporation of location, production, inventory and transportation issues within a supply chain. Shu and Karimi (2009) developed two heuristic algorithms for considering concept of safety stock in supply chain networks. Kaminsky and Kaya (2008) proposed effective heuristics for inventory positioning in supply chain networks involving several centrally managed production facilities and external suppliers. Monthatipkul and Yenradee (2008) introduced an MIP model to find an optimal inventory/distribution plan (IDP) control system for a one-warehouse/multi-retailer supply chain system. Chauhan et al. (2009) designed a heuristic for Multi-commodity supply network planning and a branch and price for large-sized problems. Khouja formulated a three-stage supply chain model and investigate effect of change from two-stage from three-stage in cost reduction. Seliaman and Ahmad consider three-stage supply chain with stochastic demand to optimize inventory decision. Santoso et al. (2005) proposes a stochastic programming formulation for supply chain under uncertain environment. Newly, a single vendor and multiple retailers supply chain retailers is modeled (Darwish and Odah, to be published). For more detailed study, Gunasekaran and Ngai (2009) and Minner (2003) can be useful.

Facility location is and has been a well established research area within Operations Research (OR). Numerous papers and books are witnesses of this fact. The development of SCM started independently of OR and only step by step did OR enter into SCM. As a consequence, facility location models have been gradually proposed within the supply chain context (including reverse logistics), thus opening an extremely interesting and fruitful application domain (Melo et al. 2009). Here, some previous researches worked on location within supply chain, are described. Gebennini presented a model for location-allocation problem to optimize safety stocks and customer service level. Snyder et al. (2007) proposed a stochastic version of the location model with risk pooling (LMRP) that include location, inventory, and allocation decisions under uncertainty.

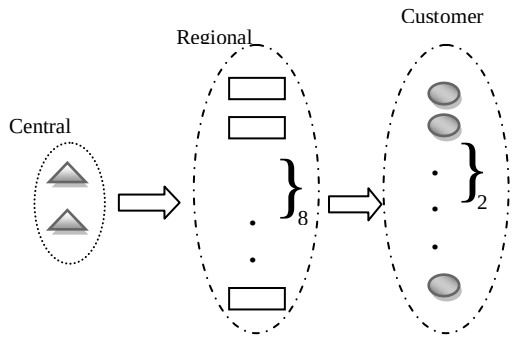
Syam (2002) extend facility location problem considering several concepts of logistic as holding, ordering, and transportation costs. He used two lagrangian relaxation and a simulated annealing (SA) based heuristics algorithm for comparing experimental results. Thanh et al. (2008) consider facility location problem in supply chain within planning horizon. Melo et al. (2009) reviewed facility location problem in a well-organized way that it can be useful for being depth in this area. There are other problems derived from facility location problem as transfer point location, hub location and etc.

In this paper, we present a multi-objective mixed integer programming formulation for location within network distribution problem considering time value of money, TVM. Objectives are to minimize total cost including establishment and transportation cost and to maximize customer satisfaction. The problem describes two location layers in single period. We determine the volume of the inventory in both stocks and middle warehouses. There is a few resea considering TVM as Rastpour and Esfehani (2010). They proposed a mathematical formulation for input/output point of department in facility layout considering time value of money. The remainders of paper are as follows. Model description is stated in section II. In, Section III, mathematical model is formulated, computational results are indicated in section IV and conclusions are discussed in section V.

2. Model formulation

The Components of supply chain such as are illustrated in Figure 1 are introduced. Central warehouses: the main stocks of supply chain that demands are supplied here. There are two potential location for central warehouses, capital of country and south port. Regional warehouses: stocks between central warehouses and customers that demands are distributed here. There are 8 potential locations for regional warehouses that they are in the capital of provinces. Customers: there are 28 customers that are located in the cities of the provinces. Goods: Five types of commodities can be supplied for the customers demanding five families of cars.

Figure 1. Components of supply chain



Assumptions of problem are as follows:

1. There are two potential central warehouses that at least one of them should be located,
2. There are limited capacities for both central and regional warehouses.
3. Transportation cost per unit is as a coefficient of distance between central and regional warehouses and between regional warehouses and customers.
4. There is a minimum level of customer satisfaction.

There are two objectives for supply chain, minimizing total cost including establishment and transportation cost and maximizing customer satisfaction.

Sets and indices

P Sets of central warehouses $(|P|=p, k \in P)$,
M Sets of regional warehouses $(|M|=m, j \in M)$,
N Sets of customers $(|N|=n, i \in N)$,
O Sets of good types $(|O|=o, t \in O)$, .
L Sets of type of warehouses $(|L|=L, l \in L)$,

Variables

v_{kl} is 1 if the potential point k is selected as a stock with capacity type l, otherwise 0.
u_{jl} is 1 if the potential point of j is selected for a regional warehouse with capacity type l.
x_{ijt} Percentage of demand customer i for commodity t that is supplied by regional warehouse j,
y_{jkt} Percentage of demand regional warehouse j for commodity t that is supplied by central warehouse k

Parameters

M Number of month in a year,
a_{it} Demand of customer i for commodity t,
b_{ijt} Capacity of regional warehouse j with type l for commodity t,
c Cost of transportation per unit,
d_{ij} Distance between regional warehouse j and customer i,
d'_{jk} Distance between regional warehouse j and central warehouse k,
e_{ktl} Capacity of central warehouse k with type l for commodity t,
P Coefficient of total cost in objective function,
q_{kl} Cost of installation central warehouse k with type l,
S_{it} Minimum level of customer satisfaction i for commodity t
W_{jl} Cost of installation regional warehouse j with

type l,

$$\min z_1 = P.\sum_{t=1}^{o}\sum_{j=1}^{m}\sum_{i=1}^{n} cd_{ij}a_{it}x_{ijt} + P\sum_{t=1}^{o}\sum_{k=1}^{p}\sum_{j=1}^{m} cd'_{jk}a_{it}y_{jkt} + P\left(\sum_{l=1}^{L}\sum_{j=1}^{m} w_{jl}u_{jl} + \sum_{k=1}^{p} q_{kl}v_{kl}\right)(A/P, i/M\%, nM)$$

$$\max Z_2 = (1-P)\sum_{t=1}^{o}\sum_{i=1}^{n}\sum_{j=1}^{m} x_{ijt}/no$$

$$\sum_{t=1}^{o}\sum_{i=1}^{n} x_{ijt} \le no\sum_{l=1}^{L} u_{lj} \qquad \forall j \qquad (1)$$

$$\sum_{t=1}^{o}\sum_{j=1}^{m} y_{jkt} \le mo\sum_{l=1}^{L} v_{lk} \qquad \forall k \qquad (2)$$

$$\sum_{t=1}^{o}\sum_{i=1}^{n} a_{it}x_{ijt} \le \sum_{t=1}^{o}\sum_{l=1}^{L} b_{jtl}u_{lj} \qquad \forall j \qquad (3)$$

$$\sum_{i=1}^{n}\sum_{j=1}^{m}\sum_{t=1}^{o} y_{jkt}a_{it} \le \sum_{l=1}^{L}\sum_{t=1}^{o} e_{ktl}v_{kl} \qquad \forall k \qquad (4)$$

$$\sum_{j=1}^{m} x_{ijt}a_{it} \ge s_{it}a_{it} \qquad \forall i,t \qquad (5)$$

$$\sum_{k=1}^{p} b_{jtl}y_{jkt} + \sum_{i=1}^{n}\sum_{t=1}^{o} a_{it}(1-u_{jl}) \ge \sum_{i=1}^{n} a_{it}x_{ijt} \qquad \forall j,t,l \qquad (6)$$

$$\sum_{i=1}^{n} x_{ijt} \le 1 \qquad \forall j,t \qquad (7)$$

$$u_{jl}, v_{kl} \in \{0,1\}$$

First objective Z_1, is summation of present cost, installation cost, and annually cost, transportation cost: Transportation cost between central and regional warehouses, $\sum_{t=1}^{o}\sum_{j=1}^{m}\sum_{i=1}^{n} c.d_{ij}a_{it}x_{ijt}$ Transportation cost between regional warehouses $\sum_{t=1}^{o}\sum_{k=1}^{p}\sum_{j=1}^{m} c.d'_{jk}a_{it}x_{ijt}$ and customer, Installation cost for central warehouses, $\sum_{l=1}^{L}\sum_{j=1}^{m} w_{jl}u_{jl}$ and Installation cost for regional warehouses, $\sum_{l=1}^{L}\sum_{k=1}^{p} q_{kl}v_{kl}$ that is multiplied by weighted coefficient P. Second objective, Z_2 is the summation of the level of the customer satisfaction that is multiplied by $(1-P)$. Constraints (1) and (2) states if regional warehouse j or central warehouse k satisfy the demand, it has been installed. Constraints (3) and (4) show capacity restriction for each regional warehouse. Constraint (5) implies that there is a minimum level of customer satisfaction i for commodity t. Constraint (6) considers that amount of supply should be greater than amount of demand. Finally, constraint (7) state that for service level of each goods for each customer is less than 100%.

3. Computational Results

We run the model without considering TVM and with considering TVM. Table 1 and 2 show the results of the model. We show Pareto set of solution the model both before and after TVM (Figure 2) and we show effect of rate and life cycle in the service level (Fig. 3).

4. Conclusions

In this paper, we present a new mixed integer programming formulation for multi-capacity multi level location distribution problem. Regarding, location problem is a long term, so we consider time value of money in period of using SCM system. We consider different cost of installment for each size of warehouses and stocks according to real world assumptions. Computational results show effect of TVM in objective function. As future research, we suggest to present a multi capacity multi period location distribution problem in which we have a different demand in each period. We show Pareto set of solution the model both before and after TVM (See Figure 2) and we show effect of rate and life cycle in the service level (Fig. 3).

Abstract: Background: Today, researchers pay special attention to patient satisfaction with emergency care services, the first line of hospital healthcare services. However, the nature of emergency medicine (EM) has changed significantly in recent years, and related factors in patient satisfaction have changed over time. The aim of this study was assessment of patient satisfaction and its related factors with emergency care services in six Iranian military hospitals. **Materials and Methods:** In this cross-sectional study, the satisfaction levels of 360 patients of emergency care services in six military hospitals of Iran in 2007 were assessed. After discharge from the emergency ward, a checklist of basic information and a 12-item questionnaire about satisfaction levels was completed for each patient. A 5-level Likert scale was used for the responses. Scores from 20-100 were allocated to each response (completely dissatisfied to completely satisfied), respectively. **Results:** 3,559/4,220 responses (82.4 percent) were completely satisfied or satisfied. In respect to priority, "Observation of ethical issues," "giving information “and” behavior of reception personnel" had the highest scores. "Variety of medical specialists," "emergency ward facilities," and "speed in calling doctor" scored the lowest. The total satisfaction score reported by patients older than 35 year ($p=0.022$), insurance coverage ($p=0.002$) and with history of previous referring to that emergency ward ($p=0.017$) was significantly higher than others. Gender, marital status, and educational level had no statistical correlation with the total satisfaction score ($p>0.05$). **Conclusion:** The findings of this study revealed favorable satisfaction levels for patients receiving emergency care services at military hospitals. However, using a variety of expert physicians and more facilities and also improving the process of calling doctors into the emergency ward are aspects that need more attention from healthcare managers in emergency centers.

1. Introduction

Respect for patients’ needs and wishes is critical to any healthcare system (Gani et al, 2007; Soufi et al, 2010; Nguyen et al,2002). The quality of health services has traditionally been based on professional practice standards. However, over the last decade, patient perceptions about healthcare have been predominantly accepted as an important indicator of healthcare quality and a critical component of performance improvement and clinical effectiveness (Woodring et al, 2004; Kikwilu et al, 2009). Since the 1990s, measuring patient satisfaction has come to be regarded as the method of choice for obtaining patient views about care and has been widely adopted as an indicator of quality of care (Soufi et al, 2010; Hjortdahl et al, 1992). Measuring healthcare quality and improving patient satisfaction have become increasingly prevalent, especially among healthcare providers and purchasers of healthcare as consumers become more knowledgeable about healthcare (Howard et al, 2007). Indeed, patient satisfaction is widely considered an integral part of quality of care (Bernard et al, 2007; Benson et al, 1987; Ball, 1996; Tamaki et al, 2005). Pascoe has defined it as a recipient’s reaction to salient aspects of his experience of a service. In his formulation, satisfaction consists of a cognitive evaluation and an emotional reaction to the structure, process, and outcome of healthcare services (Pascoe, 1983). So patient satisfaction is a quality indicator that can potentially provide valuable information about the care delivered by providers. This indicator is considered an important marker of quality by paramedics (Greenberg et al, 1997; Holt, 2006; Institution of Medicine of National Academy, 2008). Patient satisfaction is important outcome of healthcare services and can affect compliance with medical advice, service utilization, and the clinician-patient relationship (Hjortdahl et al, 1992; Howard et al, 2007; Pascoe, 1983). Most researchers agree that patient satisfaction is a multidimensional concept, but, no consensus exists regarding which dimensions of care should be evaluated to measure patient satisfaction (Acorn, 1999; Schulmeister et al, 2005).

Several approaches have been used to identify the factors contributing to healthcare satisfaction. A distinction is made between those based on expectations, those focusing on health service attributes, those emanating from economic theory, and those that are holistic in nature (Soufi et al, 2010; Moore, 1999; Ware, 1981).

Approaches based on health service attributes attempt to clarify the concept of satisfaction. They also focus on consumers' evaluations of health service attributes. These methods use reviews of the available literature or primary research to produce lists of critical features that affect healthcare satisfaction. These features are often incorporated into factor or principal-components analysis to validate definable dimensions of the care process. The resulting classifications may subsequently form the basis of the development of instruments to measure satisfaction (Eriksen, 1995; Greeneich et al, 1992; Bennan, 1995). In line with previous studies and the literature, demographics, socioeconomics, and patient health characteristics were explored(Laschinger et al, 2005; Sitzia et al, 1997).

Also emergency departments (EDs) provide emergency healthcare to all those who present with acute emergencies (Salazar et al, 2006; Ochoa et al, 2000). EDs are overcrowded with patients who often seem dissatisfied with emergency health services(Sinclair, 2007; Coughlan et al, 2007; McCarthy et al,2008). Objective information about patient satisfaction to ensure the quality of care delivered by emergency medical service systems is in demand by governmental agencies, insurance companies, and customers (Bernard et al, 2007; Moore, 1999). But the nature of emergency medicine has changed significantly in recent years with the advent of new treatment options and the availability of more medical technology [30, 31]. So related factors in patient satisfaction have changed over the time and standard quality indicators such as response time and outcome data may not reflect everything that patients consider important (Bernard et al, 2007; Greenberg et al, 1997). In this study, patient satisfaction and its related factors were examined through large data sets that were collected from emergency departments of Iranian military hospitals.

2. Material and Methods

In this cross-sectional study, subjects were randomly chosen from patients referred to emergency military hospitals located in six cities: Shiraz, Isfahan, Mashhad, Kerman, Kermanshah, and Tabriz in July and August 2008 . In total, 360 patients (60 patients from each emergency center) participated in this study. Inclusion criteria were: minimum age of 15 and admission to the ED for more than five hours. Exit conditions from the study were inability to answer questions (such as patients with decreased level of consciousness or patients with severe psychiatric disorders). After the ED stay was complete, subjects were interviewed by our colleagues. The interviewers completed the checklists (without name) that included information such as age, gender, marital status, education level, insurance type, history of previous admissions, and name of the city. This checklist was completed for all patients by interviewers.

The questionnaire determined satisfaction levels of emergency services for all patients. It let patients express their level of satisfaction with emergency care services through a series of 12 questions covering topics such as giving information, the reception process, speed in calling doctors, continuous presence of doctors and nurses at the patient's bedside, quick action by caring medical staff, diversity of medical specialties, reception personnel's performance and behavior, laboratory personnel's performance and behavior, financial personnel's performance and behavior, compliance with ethical issues by clinical staff, facilities of emergency ward, and emergency cleanliness.

The five-part Likert scale (completely satisfied, satisfied, not satisfied and not dissatisfied, dissatisfied, and completely dissatisfied) was the response vehicle for each item. Scores from 20-100 were assigned to each response (from completely dissatisfied to completely satisfied), respectively. Statistical analysis using SPSS 13 software was performed. A description of the qualitative variables and quantitative variables has been done by frequency tables and calculating of average (standard deviation), respectively. The independent samples test related to the level of patient satisfaction and two-way variables such as sex, age, marital status, insurance coverage, and history of referring. The ANOVA test was used for more than two variables such as educational level and the city. The significant level (p-value) was considered less than 0.05.

3. Results

3.1. Basic information

Of all patients, 228 (63 percent) were male and 256 (71 percent) were married. Regarding patient age, 202 people (56 percent) 35 years old or younger and 158 people (44 percent) were more 35 years old. For education, 147 people (41 percent) held lower educational diplomas, 122 people (34 percent) helped diplomas, and 91 people (25 percent) had higher than diplomas. In this study, 232 people (65 percent) have a history of previously referring people to the facility

and 39 people (11 percent) didn't have any insurance coverage as they entered the emergency centers.

3.2. Satisfaction with emergency different services

Of the 4,220 total responses, 1,320 responses (30.6 percent) were completely satisfied, 2,239 responses (51.8 percent) were satisfied, 585 responses (13.5 percent) were not satisfied and not dissatisfied, 137 responses (3.2 percent) were dissatisfied, and 39 cases (0.9 percent) were completely dissatisfied. Thus, from total of 4,220 patient responses, 3,559 responses (82.4 percent) were satisfied or completely satisfied with emergency care services received.

Table 1: Results of patient satisfaction quality and quantity with services provided in emergency centers for each service

Items	**Average (Standard Deviation)**	**Satisfaction levels**				
		Completely Satisfied	Satisfied	Not Satisfied and Not Dissatisfied	Dissatisfied	Completely Dissatisfied
Giving information	85/8± 13/9	145(40%)	184(51%)	22(6%)	9(3%)	0
Patients' reception process	82± 7/14	93(26%)	228(63%)	24(7%)	11(3%)	4(1%)
Speed in calling doctor	79/6 ± 16/2	93(26%)	186(52%)	167(18%)	10(3%)	4(1%)
Continuous presence of doctors and nurses at patient's bedside	80/5 ± 16/4	103(29%)	183(51%)	57(16%)	15(4%)	2(1%)
Acting quickly and caring medical staff	79/8± 16/4	98(27%)	178(49%)	71(20%)	9(3%)	4(1%)
Diversity of medical specialties	78/7± 18/4	95(26%)	187(52%)	46(13%)	25(7%)	7(2%)
Reception personnel's performance and behavior	82/4± 14/9	110(31%)	193(54%)	48(13%)	7(2%)	2(1%)
Laboratory personnel's performance and behavior	79/8± 0/17	100(28%)	180(50%)	62(17%)	14(4%)	4(1%)
Finance personnel's performance and behavior	82/1± 15/2	108(30%)	188(52%)	47(13%)	13(4%)	4(1%)
Compliance with Ethical issues	87/3± 15/2	176(49%)	153(43%)	22(6%)	4(1%)	4(1%)
Emergency facilities	79/5±15/7	93(26%)	178(49%)	78(22%)	10(3%)	0
Cleanliness	82/1± 15/2	106(29%)	201(56%)	41(11%)	9(3%)	3(1%)
Total satisfaction	81/6± 10/6	1320(30/6%)	2239(51/8%)	585(13/5%)	137(3/2%)	39(0/9%)

Thus, from total of 4,220 patient responses, 3,559 responses (82.4 percent) were satisfied or completely satisfied with emergency care services received. This number increases to 95.9 percent when blank answers are included. Based on mean (standard deviation) of satisfaction scores related to various sectors of service, "Observation of ethical issues," "Style of giving information," and reception personnel's performance and behavior in emergency centers had the highest scores with 87.3±15.2, 85.8±13.9, and 82.4±14.9, respectively. "Enjoy the diversity of medical specialties," "Emergency facilities," and acting quickly to inform the physician scored the lowest scores with 78.7±18.4, 79.5±15.7, and 79.6±16.2 respectively. Frequency and average (standard deviation) of the total satisfaction and satisfaction to each of the separate parts of the emergency services is shown separately in Table 1.

3.3. Factors associated with overall satisfaction score of patients with emergency services

The total satisfaction score reported by patients older than 35 years was significantly higher than those 35 years or less (p=0.022). The scores

reported from patients without insurance coverage were significantly higher than those from patients covered by insurance (p=0/002). Also total satisfaction scores reported by patients with a history of previous referrals to the emergency centers under study was significantly higher than others (p=0.017). The total satisfaction reported by men vs. women and single people vs. married showed no significant difference. Likewise, the total satisfaction reported from patients with less, equal, and higher education wasn't statistically significant (p>0.05) (Table 2).

Table 2: Factors associated with patients' satisfaction scores

	Sig. level	Subgroups	Total satisfaction
gender	9590/*	Men	81/7 ± 10/9
		Women	81/8 ± 9/2
Age (year)	0220/*	≥35	80/6 ± 10/5
		<35	83/2 ± 10/4

		keremanshah	79/8 ± 13/9
		Mashhad	79/1 ± 7/5
		Shiraz	87 ± 8/6
		Tabriz	79/9 ± 0/12

3.4. Comparing patient satisfaction with emergency services in various cities

The total satisfaction score reported by patients in different cities varied by a statistically significant amount (p<0.001). Closer examination of the results through post hoc tests reveals that patient satisfaction scores in Shiraz City was significantly higher than cities of Kerman (p=0.016), Mashhad (p=0.001), Kermanshah (0.003), and Tabriz (0.003). The patient satisfaction scores with emergency services weren't statistically significant in other cities (p>0.05) (Table2).

4. Discussions

This study showed that patient satisfaction with emergency services in Iranian military hospitals was desirable in more than 82 percent of all instances. Results of previous studies of this topic were completely different. Satisfaction with emergency services in previous studies found extensive variability - from 44-98 percent. Patient satisfaction with emergency services in some training hospitals that depend on Tehran University of Medical Sciences (44 percent) (Omidvari et al, 2008)., Tehran Imam Khomeini Hospital (62 percent)(Jalili et al, 2007)., Lorestan (64 percent)(Rezaei et al, 2002)., Ardebil (78 percent)(Entezariasl et al, 2003)., and Army (81 percent)(Khoshjan et al, 2005). were, in some cases, far lower than what this study found. On the other hand, patient satisfaction with emergency services in Tabriz training hospitals (88 percent) (Behshid et al, 2005)., and Gazvin (98 percent) was better what the present study found (Sarchami, 2001). Nevertheless, the dramatic differences in the findings from other studies call for closer examination. It's clear that these differences may be related to the emergency services provided in each ED under study. We must also consider factors such as differences related to the studied population, the frequency of emergency centers under study, and most important of all, different ways of measuring satisfaction (Trout, 2000).

As stated before, one application of patient satisfaction is to enable health managers to identify strengths and weaknesses and improve service quality(Sun et al, 200). In this study, the lack of diversity of expertise, facilities, and delay in calling doctors into emergency centers led to the highest dissatisfaction levels among emergency different services. A review of findings from previous studies revealed that, despite a variety of assessments, in the internal studies similar to this study, the largest cause of dissatisfaction stemmed from a lack of emergency facilities [Omidvari et al, 2008; Jalili et al, 2007; Rezaei et al, 2002; Sarchami, 2001).Therefore, healthcare managers and executives should pay added attention to this issue to noticeably increase patient satisfaction and ultimately enhance the ED. Also, in line with these results, patient dissatisfaction with personnel Acting quickly and wait times to receive emergency services were another matter that in all studies were among the main reasons for dissatisfaction (Omidvari et al, 2008; Jalili et al, 2007; Sun et al , 2001,2002). Patient wait times may occur in different stages - such as triage, encounter with a doctor, Para clinical services, the interpretation of

results, and finally a medical consultation and admission/discharge (Booth et al 1992). This is an important matter because lengthy waiting times lead as many as 30-60 percent of patients to leave an emergency before a medical examination is completed. On the other hand, faster wait times were associated with greater satisfaction - up to 75 percent in other studies (Krishel, 1993). Nevertheless, some researchers believe that patients' perceptions of wait times play a critical role in patient satisfaction than just the waiting time itself. (Sun et al , 2001; Hall, 1996). For instance a lengthy wait time can be mitigated by appropriate personnel behavior, communication/explanation, and estimation of wait times for patients (Hall, 1996). Therefore, emergency care managers should devise and implement solutions to reduce patient dissatisfaction with wait times.

This study also examined patient background factors and found that there were no meaningful statistical differences between men and women, singles and married, and different levels of education. However, older patients expressed more satisfaction with care services. Also, patients covered by insurance or who have a history of previous visits were more satisfied with services compared to others. In several earlier studies, the impact of patient demographics on satisfaction levels has varied(Taylor et al, 2004).Some studies reported that gender [Omidvari et al, 2008; Quintana et al, 2006). age (Omidvari et al, 2008; Hargraves, 2001), and level of education (Hedges et al, 2002) impacted patient satisfaction. Other studies reported that these factors were irrelevant to satisfaction (Jalili et al, 2007; Quintana et al, 2006). On closer examination, findings of Omidvarim et al.(Omidvari et al, 2008;)., the study within our country found that that men and older patients with lower education levels have more satisfaction. Marital status was irrelevant to satisfaction. However, Sarchami and Sheikh's study (Trout et al,2000) ("Patients' satisfaction level with quality of emergency services in training hospitals which depended on Qazvin University of Medical Sciences") found that women, younger patients, patients with history of previous referrals, and patients lacking insurance expressed greater satisfaction than other groups. These results showed noticeable differences - even the impact of background factors on patient satisfaction level was contradictory.

As mentioned, several causes could explain the differences among the various studies. The first factor is the differences among populations under study. Generally, the entry and exit conditions from the study had noticeable differences and common selection and measurement criteria were not used (Quintana et al, 2006). There are different ways to assess satisfaction in different studies, which may have led to the different findings. For example, the study of qualitative and quantitative satisfaction can lead to different findings regarding the impact of background factors. Hence, different methodologies may be necessary when studying patient satisfaction with healthcare.

The use of six different locations for this study of patient satisfaction with emergency care was a strength of this study. However, the use of more vague questions and the lack of variables such as disease type, severity, and clinical outcome were deficiencies of this study. We suggest that a confirming study must seek this additional information from a more comprehensive questionnaire.

The findings of this study revealed that patients' satisfaction level with emergency care services in military hospitals is desirable. Nonetheless, it seems to require skilled manpower and facilities and also reformed processes for referring physicians to emergencies. Managers, policy makers, and planners should pay special attention to these aspects of emergency care services

Abstract: Iron deficiency anemia among children and adolescents is a large health problem worldwide. Adolescence is characterized by a large growth spurt and the acquisition of adult phenotypes and biologic rhythms. During this period, iron requirements increase dramatically in both boys and girls. Anemia due to iron deficiency often coexists with zinc deficiency. Deficits in macronutrients or micronutrients can impair growth. Menstruation increases the risk for iron deficiency anemia among girls throughout their adolescence. The aim of the present work is to assess growth pattern in anemic boys and girls and to study relations between anthropometric parameters and hemoglobin, iron and zinc levels. The sample consisted of 60 anemic children and adolescents aged from 12- 14 years (30 boys and 30 girls) and 30 normal healthy children (15 boys and 15girls). Weight, height, mid upper arm circumference (MUAC), waist and hip circumferences were measured and body mass index (BMI) was calculated. Sex- and age-independent SD scores (SDS) were calculated for all anthropometric measurements with the use of the Egyptian reference data. Hemoglobin concentration, serum ferritin, iron and zinc were measured for patients and control. Anemic girls showed significant association between height SDS, weight SDS, BMI SDS and hemoglobin concentration level and also between MUAC SDS and zinc level. Anemic boys showed less marked growth delay. The study showed that growth delay was pronounced among anemic girls during adolescent growth spurt. Thus, age and sex are the factors most predicative of growth delay among Egyptian adolescents. The study emphasized that iron and zinc are essential micronutrients for normal growth and anemia has a negative impact on growth. The study suggests regular nutrition assessment of adolescents and recommends behavior modification to get dietary change among adolescents. The inhibited growth rate, induced by the iron-deficient diet could be reversed by giving a diet supplemented with iron.

Key words: Iron deficiency, phenotypes, Growth Pattern.

1. Introduction:

Adolescence is a time of intense physical, psychosocial, and cognitive development. During this period they gain up to 50% of their adult weight, more than 20% of their adult height, and 50% of their adult skeletal mass. Thus the nutritional needs for energy, protein, and many vitamins and minerals are increased. Inadequate stores or intake of nutrients during this period can have adverse effects on the physical growth and cognitive development. So adolescence is a vulnerable period for the development of nutritional anemia (DiMeglio, 2000; Chaudhary and Dhage, 2008).

Deficits in macronutrients or micronutrients can impair growth (Sen and Kanani, 2006). Iron and zinc deficiencies are the main micronutrient deficiencies of public health significance. The deficiency of these nutrients arise from inadequate intakes, impaired absorption and or utilization, excessive losses, or a combination of these factors and are exacerbated during times of greater physiological need such as adolescent (Ijarotimi,2004).

Anemia is a major public health problem at all ages worldwide (Maninder and Kochar, 2010). It may be due to iron deficiency; insufficient hematopoiesis due to deficiencies of folic acid or vitamin B 12; hemorrhagic anemia secondary to blood loss; hemolytic anemia with premature red blood cell plasma membrane rupture; hemoglobinopathies such as sickle cell anemia and thalassemia; or aplastic anemia with destruction of bone marrow. Iron-deficiency anemia is the most common type of several causes of anemia. Deficiencies of folic acid or vitamin B 12 can also cause anemia but are rare, and usually occur because of impaired vitamin absorption. Diseases of the bone marrow will also cause anemia. Fortunately, these conditions are rarer (Hoffman et al., 2008).

Iron deficiency anemia (IDA) is the main micronutrient deficiency that may affect adolescent. It is one of the most universally prevalent diseases in the world today particularly developing countries and

it is a major public health .Iron deficiency has been considered an important risk factor for ill health and is estimated to affect 2 billion people worldwide (WHO, 2002). Iron is essential for all tissues in a young child's developing body. It is present in the brain from very early in life, when it participates in the neural myelination processes. Beard (2001) and other authors (Haas and Brownlie, 2001) have been postulated other roles of iron that would affect growth and immune function. It is essential for the expansion of blood volume and muscle mass. Functions of iron include involvement in energy metabolism, gene regulation, cell growth and differentiation, oxygen binding and transport, muscle oxygen use and storage, enzyme reactions, neurotransmitter synthesis, and protein synthesis. Attention deficits, poor performance in intelligence tests, behavioral and mood changes, tiredness, and below-average school performance are associated with iron deficiency in adolescents (Amy et al., 2007).

Iron needs are highest in males during peak pubertal development because of a greater increase in blood volume, muscle mass and myoglobin (Hyder et al., 2007). However, after menarche, iron needs continue to remain high in females to replace menstrual blood loss (Paknahad et al; 2003). So an adolescent girl is 10 times more likely to develop anemia than a boy because of their irregular eating habits (caused by concerns about body image) compounded by normal menstrual blood loss. James et al., (2006) reported that Iron deficiency is the most prevalent micronutrient deficiency disease in the world and occurs in young women in the United States.

The detrimental effects of IDA on physical growth have been attributed to poor appetite, altered endocrinological profile and neurotransmitter metabolism consequent to iron deficiency. The appetite is seen to decrease in IDA independently of plasma leptin levels (Topaloglu et al., 2001). In IDA plasma norepinephrine as well as urinary excretion of epinephrine and norepinephrine is increased .An elevated cortisol and parathormone level along with altered metabolism of calcium, phosphorus and magnesium has also been observed (Campos et al., 1998). The effects of IDA on physical growth have been shown to be resistant even to the administration of growth hormone (Ceppi and Blum, 1994). The thyroid gland metabolism is also affected (Zimmermann et al., 2000) with impaired thermoregulation and a hyperadrenergic state is seen in hypothyroid individuals suffering from iron deficiency (Shakir et al., 2000).

Zinc, which is an essential cofactor for nearly 200 enzymes, participates in cellular growth as a cofactor for enzymes necessary for the synthesis of ribonucleic acid (RNA) and deoxyribonucleic acid (DNA), and controls, growth and development. Adolescents need more zinc/kg than adults, due to the role of this metal in growth and maturation. It is important to assess the levels of iron, and zinc in adolescents during the pubertal spurt (Urbano et al., 2002). Zinc deficiency has profound and far-reaching effect on health and well being of humans. There is convincing evidence linking zinc deficiency to childhood growth stunting (villalpando et al., 2003). Growth retardation has been associated with anemia and zinc deficiency in adolescent populations (Wajeunnesa et al., 2009).

Iron and zinc are essential micronutrients for human health. Deficiencies in these 2 nutrients remain a global problem, especially in developing countries. Anemia due to iron deficiency often coexists with zinc deficiency. It was apparently first recorded by Prasad et al., in that year (Nishiyama et al., 1998). Clinical findings included growth stunting, anemia, low serum iron and plasma zinc levels, low urine, sweat and hair zinc levels. Iron and zinc nutrition are often associated. Red meat is the most important common dietary source of bioavailable iron and zinc. Phytate inhibits iron and zinc retention. Consequences of these associations were first described by Prasad, Halsted and their associates in Egyptian and Iranian adolescents whose diets were nearly devoid of meat and were based on bread prepared from whole grain wheat flour rich in phytate (Paknahad et al., 2007). Instead, vegetables, whole grain cereals, legumes and nuts are their major food sources of these trace elements. However, these same foods also contain high levels of phytic acid and dietary fiber; components that may interfere with the absorption of iron and zinc, thus leading to decreased bioavailability The aim of the present study is to assess growth pattern in anemic boys and girls and to study correlations between anthropometric parameters and hemoglobin, iron and zinc levels.

2. Patients and methods:

The subjects of this study comprised a total number of 90 children and adolescents: 60 were anemic (30 boys and 30 girls), and 30 were normal healthy one and randomly chosen of both sexes (15 boys and 15girls). Their age ranged from 12- 14 years. A formal consent letter from the parents of each child included in the study was obtained after explaining to them the whole procedure. This study was approved by the Ethics Committee of the Hospital. They were attending the Pediatric Clinics of Al-Zahraa Hospital, Al-Azhar University complaining of easy fatigability, pale colour and decreased school performance. According to WHO criteria for diagnosis of anemia (Beard and Stoltzfus,

2001) the children with hemoglobin concentration< 12 g/dL were assigned to the anemic group and those with hemoglobin concentration ≥ 12 g/dL were assigned to the control group.

Children suffering from any chronic illness e.g. asthma, rheumatic heart disease etc, or receiving any long term drug treatment were excluded from the study. All Cases were subjected to: appropriate and thorough medical history, physical examination, routine laboratory investigations were also done including: Complete blood picture, erythrocyte sedimentation rate, and C-reactive protein. Hemoglobin concentration values and RBC indices were measured using automated hematology cell counter (Coulter T 890), serum iron values along with peripheral blood smear to study RBC morphology were analyzed. Serum iron was measured by method described by International Committee for standardization in Haematology and TIBC was measured by Ressler and Zak (1958) method. Transferrin saturation was determined by dividing serum iron by total iron binding capacity (looker et al .1995). According to the cut-offs values used by WHO the three indicators of abnormal iron status were applied: serum ferritin < 12 ng/mL, transferrin saturation < 16%, and red blood cell distribution width (RDW) >15%. Calorimetric test for the determination of Zinc in sera of all groups was performed by atomic absorption spectro-photometer (Gupta et al., 1992) using Zinc fluid Monoreagent (Centronic Gmbh-Germany).

The anthropometric measurements and instruments used followed the International Biological Programme (IBP) (Tanner et al., 1969). Measurements were taken on the left side of the body and included: weight, height, mid upper arm circumference (MUAC), waist and hip circumference. Body mass index (BMI; in kg/m2); and waist to hip ratio (WHR) were calculated.

Physical growth was assessed for each child by determining the standard deviation scores of weight, height, BMI and mid-upper arm circumference, using the Egyptian growth reference data (Ghalli et al., 2002), we calculated standard deviation score (SDS) independent of sex and age that is, child measurement minus population mean/population SD.

Waist to hip ratio was also calculated and compared to the control group in the present study. Statistical presentation and analysis of the results were carried out using SPSS software version 11. Statistical tests used included chi-square test, student's't' test , analysis of variance, and tukey tests. Correlations were tested between growth parameters and hemoglobin and serum zinc by linear regression analysis.

3. Results

Table 1 shows means of growth parameters SDS in anemic boys and girls. The values of SDS for the weight, height , BMI, and MUAC lied at the lower limits of reference Egyptian growth data with no statistical significant difference between boys and girls (P<0.188). However, girls had more delyed growth parameters than boys. Also, the waist to hip ratio had lower values, with no statistical significant difference between both sexes as well as when compared to the non anemic control group.

Table 2 shows means of growth parameters SDS in anemic girls. As the age of the girls increase the growth delay is more pronounced in all anthropometric parameters with no statistical significant differences between the age groups.

Table 3 shows means of growth parameters SDS in anemic boys. The values of SDS for height among the studied adolescent boys lied at the lower limits of reference Egyptian growth data nearly with the same lower value in all age groups, with no statistical significant difference between the age groups. However the SDS for weight, BMI, and MUAC showed lower values than Egyptian reference growth data, but at age 14 years the growth delay is more pronounced than that at age 12 years, with no statistical significant difference.

Fig. 1 shows the regression analysis between Hb (gm/dl) and serum zinc levels (µg/dl) among the studied anemic adolescents. The Hb values were negatively correlated with serum zinc in the studied anemic adolescents with significance (P<0.05).

Fig. 2 shows the regression analysis between Hb (gm/dl) and SDS for the weight in anemic girls. It shows significant correlation between Hb (gm/dl) and SDS for the weight in anemic females (P<0.05).

Fig .3 represents the regression analysis between Hb (gm/dl) and SDS for the height in anemic females. The Hb values were negatively correlated with SDS for the height in the studied anemic girls with significance.

Fig. 4 shows the regression analysis between Zinc and MUAC SDS among the anemic girls. Regression analysis shows significant correlation between Zinc and Z MUAC in anemic females (P<0.05).

The linear regression analysis in boys shows no significant correlations between the values of SDS for the weight, height, BMI, and MUAC, hemoglobin and serum zinc (P>0.05).

4. Discussion:

There exist general feelings in the society that adolescent years are normally free from major health problems. On the contrary it is a crucial period, because adolescent is still a developing child. Significant proportion of young people in developing countries suffers from nutritional anemia, in spite of impressive gains in the field of health and nutrition. Iron deficiency is the most prevalent micronutrient deficiency disease in the world (Stoltzfus, 2001). It affects more than 3.5 billion people in the developing countries (WHO, 2001). Twenty two percent of the Egyptian population is currently adolescents. A survey conducted in 1997 Ibrahim et al., (1999) found that 47% of adolescent girls and boys are anemic. El-Sahn et al., (2000) reported that the prevalence of anemia among adolescents in Egypt was 46.6 %. To address the high anemia rates, the Egyptian government and the Student Health Insurance Program (SHIP) began a targeted program to lower those rates through a dynamic school-based program. The task of improving the health and nutrition of adolescents by strengthening the preventive health program of SHIP was part of this work and was called the Adolescent Anemia Prevention Program. The program is implemented in all governorates all over Egypt.

High rates of anemia have been found in other developing countries, such as India (55%), Nepal (42%) and Cameroon (32%) (Kurz and Johnson-Welch, 1994). Among school children, the prevalence of anemia ranged from 32% in Bahrain to 78% in Oman (Verster and van der Pols; 1995). Irrespective of the severity, the prevalence of anemia ranges between 12-100% in the Region South-East Asian Countries (WHO, 2006). The prevalence of iron deficiency anemia was 6.2 ± 0.8% in Mexican American females and 2.3 ± 0.4% in non-Hispanic white females (Amy et al ,2000).

In the present study, the values of SDS for the weight, height, BMI, and MUAC among the studied anemic adolescents, showed values that represented the extreme lower end of the distribution of reference growth data of the normal age-matched Egyptian reference growth data (Ghalli et al., 2002). This is in agreement with the study of Kanani and Poojara (2000) on Indian adolescents, they recorded that anemia has a negative impact on growth and it may compromise pubertal growth spurt. Beard (2000) has been reported also, that iron deficiency anemia causes poor growth in humans especially among adolescents due to the increased iron requirements and growth spurt. Growth retardation has been associated with anemia in adolescent populations (Alton, 2005). The iron needs are high in adolescents because of the increased requirements for expansion of blood volume associated with the adolescent growth spurt. The low iron status among adolescents may limit their growth spurt. Poor eating habits are the main reason for the high rates of anemia among adolescents in Egypt. The typical Egyptian diet has few iron-rich foods, or foods that enhance iron absorption, and often considerable amounts of foods that inhibit iron absorption such as tea and whole wheat bread. WHO (2006) reported that anemia has a serious negative impact on growth and development. Studies conducted in different countries, reveal that nutritional deprivation affects almost all growth parameters and final adult body size resulting in thinness and stunting (Kanani and Poojara, 2000; Beard 2000; Alton, 2005; Hyder et al., 2007). However, the effect of malnutrition is more pronounced at the time of peak growth.

In the present study anemic adolescents displayed less development of circumferential measurements (waist and hip circumference) as compared to the non anemic control. Likewise, Colin-Ramirez et al., (2003) also observed that anemic subjects had lower waist and hip circumference than the non anemic subjects. Similar finding were noticed by Maninder and Kochar (2010) in anemic rural Haryanvi Jat women in India. It was observed that decrease in hemoglobin concentration reduces the availability of oxygen to the tissues, which in turn affects development of circumferential measurements among anemic subjects.

Muñoz et al., (2009) reported that adolescent iron requirements are higher in developing countries because of infectious diseases and parasitic infestations that cause iron loss, and because of low bioavailability of iron from diets limited in hem iron. Increased iron requirements, limited external supply, and increased blood loss may lead to iron deficiency anemia. Our findings suggest that physical growth spurt may be playing a larger role in causation of growth delay in anemic adolescents.

In our study the growth delay was evident within each gender across age groups in both boys and girls. However, regression analysis shows significant correlation between Hb (gm/dl) and SDS for the weight and height in anemic girls and no significant correlation in boys. This denotes that adverse impact of anemia on growth is more evident in adolescent girls than boys. This is in agreement with the study of Sen and Kanani (2006) on Indian adolescent girls and demonstrated adverse impact of anemia on growth. Bergstrom et al., (1995) evaluated iron status in healthy Swedish adolescents and found that low heme iron intakes increased the risk of low iron stores in girls but not in boys. They suggested that the differences in iron status between boys and girls in adolescence results primarily from biological

differences other than menstrual bleeding or insufficient iron intake. Moreover, adolescent girls have high nutrient needs and are susceptible to micronutrient deficiencies (Hyder et al., 2007). So boys are less at risk of growth delay secondary to anemia than girls who lose blood and as a result, iron through menstruation. The World Health Organization (2001) estimated that about 30-55% of adolescent girls suffer from anemia. Egypt Demographic and Health Survey conducted in 2000-2005 recorded the prevalence of anemia in adolescent girls and boys are 35.6% and 26% respectively (El Ashry, 2009). After menarche, iron needs continue to remain high in females to replace menstrual blood loss (Meier et al.، 2003). An adolescent girl is 10 times more likely to develop anemia than a boy because their irregular eating habits, caused by concerns about body image compounded by normal menstrual blood loss. The girl begins her adolescent growth spurt at an average of about 10 years and grows at peak velocity at about 12 years. The boy starts his adolescent growth spurt around 12 years of age and in a year or two overtakes the girl (WHO, 2006).This can explain another superimposed factor for growth delay in adolescent girls in the present study.

Iron and zinc are essential micronutrients for human health and normal growth. Their deficiencies usually coexist in the same individual and make anemia with worst effect on growth. By regression analysis, our study revealed significant positive correlation between Hb values and serum zinc levels in anemic adolescents, which was consistent with the observation of Paknahad et al., (2007) in Iran. However Kogirima et al., (2007) found a positive correlation between zinc intake and serum zinc levels. Serum zinc was significantly correlated with hematocrit and hemoglobin (P was 0.027 and 0.02 respectively). This is in agreement with the study of Cole et al., (2010) who reported that anemic African American children had an increased risk of zinc deficiency, and serum zinc is correlated with hemoglobin ($r = 0.24$, $P < 0.001$). Several studies have highlighted that supplementation of zinc along with iron improves hemoglobin level and is beneficial in iron deficiency anemia (Kolesteren et al., 1999). At the other hand zinc is clearly involved in several aspects of normal hematopoiesis by virtue of its role in many enzyme systems involved with DNA synthesis including thymidine kinase and DNA polymerase (Nishiyama et al., 1998). Zn deficiency should be considered as one of etiologic factors in some children with unexplained short stature. Oral Zn supplementation may be considered as the growth-promoting therapy for children with short stature once marginal zinc deficiency is established. Zinc is well known to be essential for somatic growth of children. Zinc has a close relationship with the endocrine system; it sustains normal growth (Kaji and Nishi, 2006). However, the interrelationships among Zn, growth, and GH-IGF-I axis appear to be complex and deserve further investigation.

In our study we didn't find any relationship between serum zinc and age. Villalpando et al., (2003) findings showed results similar to our study. Regression analysis showed significant correlation of zinc and MUAC SDS in anemic girls only. Consequently, zinc intake influence anthropometric measurements and has effects on the mid-upper arm circumference. Keith et al., (2005) findings showed results similar to our study. MUAC is a useful as an indirect measure of muscle size to determine whether a person has depleted lean body mass and is an excellent indicator of the severity of malnutrition (Rodriguez et al, 2000). An MUAC measurement was easier to perform on severely malnourished adults than BMI assessment. During famine; MUAC may be better suited to screening admissions to adult feeding centers than BMI. In rural Kenya Berkleyet al., (2005) found that MUAC is a practical screening tool that performs at least as well as WHZ in predicting subsequent inpatient mortality among severely malnourished children. Dasgupta et al., (2010) stated that the mid arm circumference measurement is a reliable and a feasible method of assessment of nutritional status of adolescents. The evidence indicates that adolescence boys have greater MUAC than girls in our study and anemic girls showed more growth delay during the adolescent growth spurt.

In conclusion, the anthropometric parameters are low in the anemic children as compared to Egyptian national reference data. Differences were evident within each gender across age groups. Several studies have suggested that lower growth rates and impaired physical performance are the adverse effects of iron deficiency anemia in children (Bandhu et al., 2003; Kanani and Poojara, 2000; Beard, 2000). Age and sex were the factors most predicative of anemia and growth delay among Egyptian adolescents. Boys had higher values of both hemoglobin and zinc concentrations than girls which may be due to the biological difference. Anemic girls were especially at risk of growth delay. A significant correlation between growth parameters and anemia in children, particularly girls during adolescent growth spurt was observed. Iron and zinc are playing a larger role in causation of growth delay in anemic adolescents. The inhibited growth rate, induced by the iron-deficient diet could be reversed by giving a diet supplemented with iron. Aggressive interventions are imperative to correct iron and zinc

deficiency and by so doing avoid their deleterious effect on growth. The main strategies suggested for improving adolescent nutrition can be food-based strategies like food fortification, for ensuring adequate nutrition at household level; addressing behavior modification to bring about dietary change in adolescents. This may be achieved through school-based nutrition interventions; regular nutrition assessment and counseling of adolescents; intersectional linkages at community level and building linkages with adolescent friendly health services.

[2] Hort. Dept. Fac. of Agric. Suez Chanel Univ. Egypt
fatenesmaeil@yahoo.com[*]

Abstract: The present investigation was carried out during 2008 and 2009 seasons in the experimental farm belonging to El-Kanater Horticultural Research Station, Kalyubeia Governorate Egypt to study effect of some nutrient elements on tolerance beachilyfolia pear rootstock to salinity. The following measurements were recorded: vegetative growth, nutritional status and some physiological properties of Beachilyfolia pear rootstock, irrigated with saline solution at 6000 ppm with 6 SAR and high chloride level (Cl : So4). Zinc at 50 ppm, Potassium at 250 ppm and Phosphorus at 250 ppm were used in this study to give more explanation about the protect against salt injury. The results revealed that, foliar spray treatments caused a significant increase of some growth measurements (stem height, root length, number of branches & leaves, leaf area, stem diameter and fresh & dry weights of plant organs), leaf photosynthetic pigments content (chlorophyll A, B and carotenoids), leaf mineral content (N, P, K, Na, Fe Mn and Zn), physiological properties (leaf succulence grade, leaf water potential and leaf relative turgidity) of beachilyfolia pear rootstock transplants during 2008 and 2009 consecutive seasons. On the contrary, leaf sodium and proline contents and leaf osmotic pressure took the other way around during the study.

Key wards: Beachilyfolia, pear, rootstock, nutrient elements, salinity.

1. Introduction:

Pear is one of the most important deciduous fruits in Egypt. For that, in recent years there has been a steady increase in the area cultivated with pear to meet the continuous rise in demand for pear fruits for local consumption in Egyptian markets.

Undoubtedly, the expansion of agricultural land needs a great amounts of suitable irrigation water which already is not sufficient to meet all the expected demands in this respect. In addition to that, the limited amounts of water is an ever growing crisis that may face us in Egypt in future due to the natural aridity in the region, the increasing population and land reclamation projects which represented a very important sector in the agricultural development programs for increasing the cultivated area. Salinity is one of the most serious and oldest environmental problems affecting approximately one third of earth's irrigation land. There are many factors affecting the salinity-yield relationship such as the physical and chemical conditions of the soil, climate and farming practices (Schreiner and Ludders, 1992).

The possibility of using saline water for irrigation, especially underground water is considered as a limiting factor and great value for the success of the projects of new land reclamation, which it is still very limited source until now, however many problems are expected to arise. These problems would be related to the excessive accumulation of saline salts in the soil because this water contains a considerable amount of harmful salts as an actual limiting factor for growth and productivity of transplants and fruit trees (Sharaf *et al.*, 2006).

There is a little of available information for fruit growers about the possibility of some pear and other deciduous rootstocks to grow under conditions of new reclaimed lands and probability of these rootstocks to tolerance for irrigation with saline water (Kabeel, 1985, Bondok *et al.*, 1995, Osman, 2005 and khamis *et al.*, 2008) on some deciduous rootstocks transplants.

The present study carried out to investigate the effect of spraying with some nutrient elements (K, P and Zn) on tolerance beachilyfolia pear rootstock to salinity.

2. Materials and methods

The present investigation was carried out throughout the two consecutive seasons of 2008 and 2009 in the experimental farm belonging to El-Kanater Horticultural Research Station, Kalyubeia Governorate, Egypt.

Uniform and healthy one-year-old transplants of *Pyrus beachilyfolia* rootstock was the plant materials used in this study. In both seasons of study and during the first week of February, pear rootstock transplants were transplanted individually each in clay pot of 35 cm. in diameter that previously

had been field with specific weight of media consisting of clay and sand at equal proportion (by volume). Mechanical and chemical analysis of the experimental soil from 0 to 30 cm. depth just before pear investigated treatments had been started are shown in Table (1). These standard methods used in this respect described by A.O.A.C, (1990).

Table (1): Physical and chemical analyses of the experimental soil.

Depth (cm.)	Sand %	Silt %	Clay %	Soil texture	Soil extract pH 1:25	E.C. (1:5) ds/m	Soluble cations				Soluble anions			
							Ca^{++}	Mg^{++}	Na^{+}	K^{+}	CO_3^{--}	HCO_3^{-}	Cl^{-}	$SO_4^{=}$
0-30	21.10	25.90	52.60	Clay loam	7.86	0.195	0.74	0.22	0.68	0.17	0.55	0.80	-	0.47

Irrigation with the saline solution was carried out twice weekly by adding (¾) liter per each pot starting from the first week of March until the last week of September throughout the two seasons of study. To prevent salts accumulation pots irrigated with tap water every 12 days, then rewatering with salt solutions applied the next day. Control treatment was supplied periodically two times every week with tap water only at (¾) liter/pot. The following treatments are used:

1- Tap water irrigation (control).
2- Irrigation with 6000 ppm saline solution of SAR6 and high Cl: SO_4 level plus tap water spray.
3- Irrigation with 6000 ppm saline solution of SAR6 and high Cl: SO_4 level + Zn at 50 ppm spray.
4- Irrigation with 6000 ppm saline solution of SAR6 and high Cl: SO_4 level + K at 250 ppm spray.
5- Irrigation with 6000 ppm saline solution of SAR6 and high Cl: SO_4 level + P at 250 ppm spray.

The different treatments arranged in a complete randomized block design where each treatment was replicated three times with two transplants for each replicate. Regarding the foliar spray solutions with some nutrition elements were periodically sprayed at one month interval beginning from mid- March until mid September. The abovementioned saline solution was prepared as shown in Table (2).

Salts added in grams were estimated as anhydrous form.

*SAR = Meq

$$\frac{Na}{\sqrt{\frac{Ca + Mg}{2}}}$$

Methodology as has been followed in this investigation is being determined as follows:

Table (2): Preparation of saline solution used.

	Saline solution (6000 ppm SAR6 high Cl)		
Salt added per liter	$CaCl_2$	g	1,67
		meq.	30,00
	$MgSO_4$	g	0,60
		meq.	10,00
	KCl	g	0,44
		meq.	5,84
	K_2SO_4	g	1,65
		meq.	8,96
	Na_2SO_4	g	0,45
		meq.	6,34
	NaCl	g	1,20
		meq.	20,51
	SAR*		6,00
	Cl meq./L		56,35
	SO_4 meq./L		35,29
	Cl / SO_4 ratio		1,60

Morphological characteristics (vegetative growth measurements):

On mid week of October during both seasons as the experiment was ended, the effect of the different studied treatments on some vegetative growth measurements were evaluated by the following growth parameters: Stem height (cm), Stem diameter (mm.), Root length (cm), Number of branches per plant, Number of leaves per plant and Dry weights of plant organs (leaves, stems and roots in gm).

Transplants of each replicate were carefully taken out from pots then washed with tap water and followed by distilled water to free them any residues. Thereafter, each transplant was divided individually into its three organs (leaves, stem and root) to be air dried in an electrical oven at 70 °C. until a constant weight then weighed then as average dry weight for each plant organ for every replicate was estimated and recorded.

Leaf physiological characteristics:

Determination of leaf osmotic pressure (in bar).

Adequate leaf samples were immediately frozen, the cell sap was extracted in the laboratory with a piston pressure. When the frozen tissue has been thawed. The sap total soluble solid (TSS) was determined by refractometer and the equivalent values of the osmotic pressure (in bars) were estimated according to Gusov (1960).

Leaf succulence grade (L.S.G.).

Leaf succulence grade (L.S.G.) was calculated as gms. H_2O/cm^2 of leaf according to the following equation according to Nomir (1994).

$$L.S.G. = \frac{\text{Leaf water content (gm.)}}{\text{Leaf area } (DC^2)}$$

Whereas, leaf water content (gm) =

$$\frac{\text{Fresh weight – dry weight of the leaves}}{\text{Number of leaves}} \times 100$$

Leaf relative turgidity (L.R.T.).

Discs of about one cm. in diameter were removed from each leaf sample to determine their fresh weight immediately, then placed in a closed containers (Petri dishes) until they became constant in weight (after 24 hours) at room temperature 22 ± 2° in shade. The discs were surface dried with paper and weighed for their turgid weight. Dry weight of each ten discs was determined after 24 hours. Leaf relative turgidity was estimated according to the following equation described by Nomir (1994):

$$L.R.T. = \frac{\text{Fresh weight – dry weight}}{\text{Turgid weight – dry weight}} \times 100$$

Leaf water potential (L.W.P.):

The method and the equation for the calculations have been suggested by Nomir (1994).

$$(L.W.P.) = \frac{\text{Fresh weight – dry weight}}{\text{Fresh weight}} \times 100$$

Chemical analysis:

In this regard, leaf photosynthetic pigments (chlorophylls A, B and carotenoids), leaf proline content and leaf mineral composition as well as shoot content of total carbohydrates in response to different studied treatments included were concerned.

Leaf photosynthetic pigments determination:

The quantitative analysis of photosynthetic pigments in response to treatments under study were determined and calculated according to the methods described by A.O.A.C. (1990).

Leaf proline content:

The proline content was estimated in fresh leaves according to the method described by Batels *et al*., (1973) and confirmed by Draz (1986).

Estimation of total carbohydrates:

Total carbohydrates in dry shoots (0.1 gm) were determined photometrically at 490 µm., according to the method described by the method of A.O.A.C. (1990).

Determination of leaf minerals content:

At last week of October in both seasons samples were collected and cleaned from adherent dust and dried at 70° C for 72 hours, ground to fine powder and digested according to Chapman and Pratt, (1961). The ground dried materials of leaf samples were analyzed for total nitrogen, phosphorus, potassium, sodium, iron, manganese and zinc by the method of A.O.A.C, (1990).

- Statistical analysis:

All data obtained during each season of this study were subjected to statistical analysis according to the method described by Snedecor and Cochran (1980). However, means values for every studied parameter were compared according to the Duncan's multiple range test (Duncan, 1955).

3. Results

Growth measurements:

Stem diameter, length of (stem and root); number of (branches & leaves per plant); average leaf area; fresh and dry weights of different plant organs

(leaves, stem and root) were investigated regarding their response to the treatments.

Regarding the effect of sprayed nutrient elements, results in Tables (3, 4, 5 and 6) declared that, all investigated growth measurements of the salinity stressed transplants were significantly increased by any of three nutrient elements however, Zn at 50 ppm foliar spray proved to be the most effective in this regard followed in a descending order by K and P each at 250 ppm foliar spray during two seasons of study.

Leaf physiological properties:

Four physiological characteristics (leaf water potential; leaf osmotic pressure; leaf relative turgidity and leaf succulence grade) were investigating regarding their response to effects of sprayed three nutrient elements (Zinc, Potassium and Phosphorus).

With regard to effect of sprayed three nutrient elements (Zinc, Potassium and Phosphorus), data in Table (7) revealed that, two conflicted trends were detected. Herein, leaf succulence grade, leaf water potential and leaf relative turgidity were significantly increased by any of three nutrient elements sprayed, but Zn foliar spray was more effective for (leaf water potential and leaf relative turgidity) and K spray showed the greatest increase in leaf succulence grade. On the contrary, the trend of response for leaf osmotic pressure as influenced by three nutrient elements (Zn, K and P) spray took the other way around; where characteristic was significantly decreased by any foliar application.

Chemical composition:

Photosynthetic pigments:

Leaf chlorophyll (A & B) and carotenes contents of salt stressed pear rootstock in response to effects of sprayed with nutrient elements were investigated.

The obtained results and tabulated in Table (8) revealed that, both (K and P) foliar spray each at 250 ppm and Zn at 50 ppm increased three photosynthetic pigments, while Zn foliar spray was more effective descendingly followed in this respect by (K and P) foliar spray during the study.

Stem total carbohydrates:

As for the effect of sprayed nutrient elements (Zn, K and P), it is quite clear that, total carbohydrates was increased. Zn foliar spray at 50 ppm was more effective followed in a descending order by K and/or P each at 250 ppm as increase in total carbohydrates (Table, 9).

Leaf proline contents:

With regard to effect of Zn, K and P sprays reduced significantly proline; however, Zn foliar spray was statistically the most depressive in this concern during the study (Table, 9).

Leaf mineral composition:

In this regard, effects of sprayed nutrient elements on leaf (N, P, K, Na, Fe, Mn and Zn) contents of salt stressed pear rootstock transplants were investigated. As for the effect of sprayed nutrient elements on leaf mineral composition of salt stressed pear transplants, data obtained in Tables (10 and 11) revealed obviously that, the response varied from one element to another. Foliar spray with Zn and K as well as P solely increased leaf N, P, K, Fe; Mn and Zn contents, but decreased leaf Na contents.

Table (3): Effect of some nutrient elements on some growth measurements of beachifolia pear rootstock transplants irrigated with saline water during 2008 and 2009 seasons.

Treatments	Stem height (cm)		Root length (cm)		Stem diameter (cm)	
	2008	2009	2008	2009	2008	2009

4. Discussions

Zn stimulated cell elongation by encouraging cell walls to stretch (Nason, 1950), as a result of its function for process of tryptophan biosynthesis, the precursor of the IAA plant auxin. Bouat *et al*., (1954) showed that, there was a continuous demand for phosphorus for best vegetative growth of Arbequine olive. Also, Miller and Deidda, (1975) demonstrated that some parameters of young olive trees were positively affected by phosphorus application.

On the other words, potassium not only ameliorated the harmful effect of salinity, but also encouraged the vegetative growth of the pear rootstock. Huffaker and Wallace (1966) found that, the high rate of K fertilizer prevent the absorption of Na by plants to which Na is not a nutritive element by plants that need a high ratio of (Ca + Mg) : (K +Na) in the nutritional requirements.

Moreover, Rajput *et al*., (1976) on mango trees who found that spraying $ZnSO_4$ at 0.2- 0.8% in January increased length of the terminal shoot. In addition, Khamis *et al*., (1985) on grape rooted cuttings and Osman (2005) on some apple rootstocks reported that, spraying saline stressed with P or K reduced the salinity damage and improved growth.

The present results pertaining the response to foliar sprays with some nutrient elements findings Omar (1996) on mango and apricot plants, Abd- El-Mageid (1998) on almond seedlings, Hasan (2005) on olive transplants and Osman (2005) on some apple rootstocks transplants gave a real support in this regard.

These results regarding the influence of nutrient elements and growth retardants application on leaf photosynthetic pigments of salt stressed transplants are in accordance with those found by Kucherova *et al*., (1979); Nomir and El-Deeb (2000) and Gowda (2002), all reported that, nutrient elements and growth retardants increased foliar pigments contents i.e., chlorophyll (A & B) and carotenoids compounds.

The present result regarding the response of total carbohydrates was in harmony with that found by Gowda (2002).

The present result regarding the effect of nutrient elements on leaf proline contents goes in line with those found by Anju-Thakur and Singh (1998).

Such results are in general agreement with finding of Khamis *et al.*, (1985) on Thompson and American grape rooted cuttings who found that, P foliar spray caused significant decrease in leaf N and K content and increased significantly leaf P, Fe and Mn content over that of salinity stressed rooted cuttings.. However, K foliar spray increased leaf – N content. In addition, Behairy *et al.*, (1985) reported that, foliar spray with Zn increased leaf N, Fe and Mn content and decreased leaf P and K content of salt stressed transplants. Also, Omar, (1996) on mango and apricot plants and Abd- El- Mageid, (1998) on almond seedlings gave a real support in this regard.

5. Conclusion:

Foliar spray Beachilyfolia pear transplants with Zn at 50 ppm caused a significant increase of some growth measurements, leaf photosynthetic pigments content (chlorophyll A, B and carotenoids), leaf mineral content (N, P, K, Na, Fe Mn and Zn), Physiological properties (leaf succulence grade, leaf water potential and leaf relative turgidity) of beachilyfolia pear rootstock transplants. On the contrary, leaf sodium and proline contents and leaf osmotic pressure took the other way around during the study.

Black Tea Forestalls Sodium Fluoride-Induced Neurobehavioral Toxicity in Laboratory Rats

Mervat M. Kamel[1*], Heba S. El-lethey[1], Iman B. Shaheed[2], and Gehan M. Kamel[3]

[1]Department of Animal Hygiene and Management, [2]Department of Pathology, [3]Department of Pharmacology, Faculty of veterinary Medicine, Cairo University, Cairo, Egypt, mevy58@yahoo.com*

Abstract: The present study aimed to investigate the main effects as well as the interaction effect of supplemental Na-F and black tea on emotional reactivity and learning and memory capacities in rats using a variety of behavioural tasks. Eighty weanling 32-days old Wistar male rats randomly distributed into four groups of 20 animals each, were supplemented with Na-F at 100 ppm and 2% black tea in a factorial pattern to constitute 4 experimental treatments. Brain tissue specimens, representing all treatments, were taken for biochemical and histopathological investigations. In the open field test, Na-F-treated rats displayed higher levels of anxiety that were significantly reduced when black tea was concomitantly administered. Marked impairment in habituation was a significant remark for Na-F group. A superior learning and memory ability was recorded for black tea-supplemented rats during classic maze test, where black tea significantly recovered the intervention observed in Na-F-exposed rats. Moreover, black tea significantly enhanced spatial cognition learning ability and successfully alleviated Na-F-induced spatial memory impairment. Rats administered Na-F displayed distinct neurodegenerative changes of nerve cells especially in hippocampus, accompanied by inhibition of brain acetylcholinesterase (AChE) activity with increased oxidative stress. Administration of black tea along with Na-F was able to afford protection against these Na-F-induced alterations. Our findings suggest a profound ameliorative effect of black tea on Na-F-induced adverse alterations in the brain of rats as indicated by hindrance of learning and memory performance, and argue for concurrent administration of black tea to Na-F-exposed individuals in order to help alleviate fluoride intoxication.

Key words: Sodium fluoride, black tea, SOD, TBARs, learning, memory, anxiety-like behaviour

1. Introduction:

Toxic effects of excessive intake of fluoride are matters of serious international concern (Verma et al., 2006). Fluorides are naturally occurring contaminants in the environment and commonly involved in toothpastes, mouth rinses, processed beverages and food as well as public water in order to prevent dental caries (Buzalaf et al., 2004). In humans, exposure to elevated fluoride drinking water in endemic areas has been found to cause headache, followed by lethargy and insomnia with reduced Intelligence Quotient (IQ) of children and lowered levels of mental work capacity of adults (Lu et al., 2000, Xiang et al., 2003, Sharma et al., 2009).

Since fluoride was evidenced to cross blood brain barrier, a link between excessive exposure to fluoride and dysfunction of the central nervous system has established (Blaylock, 2004, Ge et al., 2005). High levels of fluoride in drinking water (3-11 ppm) are known to cause definite harm to the central nervous system as manifested in diminished mental acuity with alterations in learning and memory processes directly without first causing the physical deformities of skeletal fluorosis (Wu et al., 2006, Chioca et al., 2008, Zhang et al., 2008). Rats exposed to fluorosis showed neuroinflamation in the brain, including demylinization, a reduction in the number of Purkinje cells, thickening and disappearance of dentrites, swelling of mitochondria and dilation of endoplasmic reticulum in neurons (Guan et al., 1998). Moreover, disturbances in brain development in offspring rats with chronic fluorosis have been reported (Liu et al., 1989).

Prolonged exposure to sodium flouride has been reported to induce deleterious effects on soft tissues (Patel and Chinoy, 1997, Purohit et al., 1999) and changes in behaviour through locomotor activity impairment (Ekambaram and Paul, 2001, 2003).

The central nervous system is principally more susceptible to oxidative damage due to its high oxygen consumption along with high tissue concentrations of iron and comparatively low levels of some antioxidants system (DrÖge and Schipper, 2007; Korkmaz et al., 2007). It has been emphasized that higher levels of fluoride provoke oxidative stress in the brain through excessive production of reactive oxygen species (ROS) free radicals taxing the compensatory task of antioxidant system with increased levels of lipid peroxidation, accounting for neuronal dysfunction with cognitive decline (Guan et al., 1998, Chirumari and reddy, 2007). Moreover, fluoride intoxication has been shown to induce changes in central neurotransmission presenting inhibited acetylcholinesterase (AChE) activity (Gao

et al., 2009). Thus, prevention of fluoride-induced oxidative damage to the brain is likely to be beneficial for the maintenance of cognitive function.

There is a growing awareness of the role of certain nutritional components including flavonoid polyphenols, a group of dietary-derived phytochemicals, found in fruits, vegetables and beverages like tea in maintenance of health and prevention of chronic diseases (Youdim et al., 2002). Flavonoids have been reported to induce improvement in memory, learning and cognition (Spencer, 2009). Several studies suggested that flavonoids might improve cognitive function by protecting vulnerable neurons against injury induced by neurotoxins, suppressing neuroinflamation, and enhancing existing neuronal function or by stimulating neuronal regeneration (Mandel and Youdim, 2004, Spencer, 2008, Rendeiro et al., 2009). Most of these studies have been conducted in rodents as models for human in order to predict effects of flavonoids on human cognitive performance (Casadesus et al., 2004, Lee et al., 2005, Williams et al., 2008).

Although six types of teas are distinguished, the three main types are black tea (fully fermented), oolong tea (semi-fermented) and green tea (non-fermented). Black tea accounts for 80% of the world's total tea production (Krisnamoorthy, 1991). While black tea is the most common type of tea consumed in Egypt and widely consumed beverages, second to water, few studies have investigated the effects of black tea on cognitive performance.

The type of flavonoid polyphenols founds in different types of teas, and constitutes 93% of total tea phenolic compounds (Lakenbrink et al., 2000), depends on the degree of fermentation during manufacture. Black tea contains more complex flavonoids than green tea. Although catechin content of black tea is lower (3-10%), but it has a higher content of theaflavins and thearubigins as a result of catechins enzymatic polymerization under substantial oxidation during processing (Unno and Hoshino, 2007). In addition, tea leaf also contains theanine, caffeine and other chemical components (Xu and Chen, 2002).

Tea flavonoids are brain permeable (Nakagawa and Miyazawa, 1997) and have been reported to possess potent cognitive protective effect through antioxidative and radical scavenging properties that can help to ameliorate neurodegenerative disorders such as Alzheimers and Parkinson diseases (Weinreb et al., 2004, Mandel and Youdim, 2004, Sutherland and Rahman, 2006).

In a previous study, clear deleterious effects of Na-F on the brain of rats were revealed as indicated by impaired cognitive abilities (El-lethey et al., 2010). Therefore, the present study was undertaken to evaluate the possible ameliorative effect of black tea, an important source of dietary antioxidants, against Na-F-induced alterations in the brain of rats with negative manifestation on learning and memory performance. For further investigation for the mechanisms of Na-F-induced cognitive disorders, and the potential protective effect of black tea on brain oxidative stress, the later parameter was also quantified in the current study.

2. Materials and methods

2.1. Animals and housing:

Since estrogen has been found to enhance memory in females, only male rats were employed in our study in order to eliminate estrogen related beneficial influence on memory (Wolf and Kirschbaum, 2002). Eighty weanling 32-days old Wistar male rats, approximately 45g weight were obtained from the Unit for Laboratory Animals at Faculty of Veterinary Medicine, Cairo University and used in our study. They were housed in standard polypropylene cages with stainless steel wire lids, bedded with wood shavings. Animals were maintained on a 12-h light/dark cycle at a room temperature of 20-22°c and 60% humidity with free access to feed (standard laboratory pellets) and water throughout the study. The procedures concerning animal care and experiment protocols were carried out in accordance with guidelines from Cairo University Policy on Animal Care and Use.

2.2. Experimental design:

All males were randomly distributed into four groups of 20 animals each, divided on 2 replicates and orally administered our treatments throughout the study till its completion at 106 days of age, in a 2 x 2 factorial design as follows:

Group (1) control (C), n=20: Weanling pups were administered plain water.

Group (2) Na-F group (F), n=20: Weanling pups were exposed to *ad libitum* supply of Na-F alone (Sigma Chemical Company) in drinking distilled water at 100 ppm on a mg/kg/day basis of 10.77 Na-F (Chioca et al., 2008).

Group (3) black tea group (T), n=20: Weanling pups were exposed to *ad libitum* supply of 2% black tea alone in drinking water (Trivedi et al., 2006). Twenty grams of black tea solids (Lipton Yellow label, Unilever Limited, India) and 1000 ml boiled drinking water were used to produce a 2% tea solution.

Group (4) ameliorated group (Na-F+T), n=20: Weanling pups were exposed to *ad libitum* supply of 100 ppm Na-F in combination with 2% black tea solution.

2.3. Behavioural assessment:

All behavioural testing were conducted by the same personnel throughout, started at 90 days and ended at 106 days of animals' age.

2.3.1. Open field test

The open field has been long established as an appropriate test for measuring situational anxiety in rodents (Millan, 2003). The process of habituation, a form of non-associative learning, was also measured in the open field test (Mello e Souza et al., 2000; Chioca et al., 2008). The open field used was a square wooden arena measured (90 x 90 x 25cm). The wood of the apparatus is covered with a plastic laminate (formica), which prevents absorption of fluids (urine of rats). The floor was divided by black lines into 36 small squares (15 x 15cm). All testing was conducted between 09:00 and 15:00 h. All treatment groups were tested at the same day in a random array. Rats were gently placed into a corner of the arena and allowed to confront this novel aversive situation (Belzung, 1999) for 3 minutes.

During the three minutes test duration, assessment of anxiety included measuring time spent freezing (immobility), exploratory behaviours in the form of ambulation (horizontal locomotion) and rearing (vertical activity) as well as non-exploratory measures comprising only vegetative behaviours in the form of number of faecal boluses (defecation) and number of times of urination (Kalueff et al., 2006). These parameters have all been labeled measures for anxiety (Ivinskis, 1970, Archer, 1973).

Ambulation (horizontal locomotion) is assessed in relation to lines drawn on the floor (the number of squares crossed). A crossed square was defined as the rat placing its two forepaws in the next square and moving forward (Chioca et al., 2008), whereas rearing was defined as the number of times an animal stood erect on its hind legs with its fore legs in the air or leaning against the wall of the open field (Brown et al., 1999). Hand operated counters and stop watches were used to score the behaviour of animals.

After the 3 minutes test session, the rat was returned to its home cage and the open field was cleaned using 70% ethyl alcohol (to avoid odour cues) and permitted to dry between tests. To assess the process of habituation to the novelty of arena, rats were exposed to the apparatus for a 3 minutes test session, on three consecutive days.

2.3.2. Classic maze test

Associative learning was assessed using classic maze test. The base of the maze measured (100 x 100cm) with walls height of 25cm. The entire maze was made of plywood with a glass cover in order to prevent escape of animals and allow observation. Testing was carried out between 09:00 and 15:00 h, where all groups were randomly allowed for testing at the same day in a randomized order. Rats were deprived from feed for a 23 hours period before start of testing. Rats were given their daily feed amount as a reward at the end of the maze. Animals were given one trial per day for five consecutive days. Time elapsed to locate the feed at the end of the maze and numbers of entries of blind alleys (errors) were recorded according to Staddon (1983).

2.3.3. Spatial Y-maze memory

The test was conducted only once for all treatment groups randomly divided on two consecutive days, between 09:00 and 15:00 h. The Y-maze apparatus consisted of three arms (labeled A, B and C). Each arm was 40cm long, 30cm high, 15cm wide and positioned at an equal angle converged in an equilateral triangular central area with 15cm at its longest axis. The maze has no floor, but placed on a clean sheet of paper on a table-top, where the sheet has to be changed for each animal in order to prevent the use of odour cues in maze navigation. Each rat, was randomly placed at the end of one arm and allowed to move freely through the maze for eight minutes session. Entry was considered complete when the hind paws of the rat had completely entered the arm. The sequence of arm entries was recorded (i.e. ABCABABCACABACAB, etc.). A spontaneous alternation behaviour, a measure of spatial memory, was defined as consecutive entries into all three different arms without repetitions in overlapping triplet sets (Rasoolijazi et al., 2007). Percentage of alternation was calculated as the ratio of actual to all possible alternations (total number of arm entries minus two) multiplied by 100.

2.4. Biochemical and histopathological examination:

On completion of all behavioural assessments, five rats per treatment were sacrificed by cervical decapitation under ether anaesthesia for whole brain tissue extraction. Brain tissue specimens were dissected out carefully and cut into two sagital sections for execution of biochemical and histopathological examination.

2.4.1. Biochemical estimation

Brain tissue specimens were homogenized (10% w/v) in ice-cold 1.15% KCl-0.01M, sodium potassium phosphate buffer (pH 7.4) using a Teflon mechanical homogenizer. The homogenate was then centrifuged at 4000 rpm for 15 min at 4^{o}C and the supernatant was used for the studied enzymatic assay.

2.4.1.1. Determination of acetylcholinestrase (AChE) activity

AChE activity (µmoles/min/mg protein) was estimated in the brain by an improved Ellman's colrimetric method, employing acetylcholine iodide as a substrate for the reaction (Darreh-Shori et al., 2002).

2.4.1.2. Determination of super oxide dismutase (SOD) activity

SOD activity (µmoles/min/mg protein) was measured according to Giannopolitis and Ries (1977), by means of SOD assay kit (Cayman, MI, USA). The kit utilizes a tetrazolium salt for detection of superoxide radicals generated by xanthine oxidase and hypoxanthine. One unit of SOD was defined as the amount of enzyme needed to produce 50% dismutation of superoxide radical. The SOD assay measures all three types of SOD; Cu/Zn, Mn, and Fe SOD. Enzyme activity was determined as the amount of the enzyme required to induce 50% inhibition of nitro-blue tetrazolium (NBT) reduction rate.

2.4.1.3. Determination of thiobarbituric acid reactive substance (TBARS) formation

The level of lipid peroxidation, in terms of TBARS formation (nmoles/min/mg protein) was determined (Esterbauer and Cheeseman, 1990). Tissue supernatant was mixed with 1ml of 20% trichloroacetic acid (TCA), 2ml of 0.67% thiobarbituric acid (TBA) and then heated at 100°C for 1h. After cooling, the precipitate was removed by centrifugation. The absorbance of the sample was measured at 535nm using a blank containing all the reagents except the sample. Since, 99% of TBARS was malondialdehyde (MDA), so TBARS concentrations of the samples were calculated using the extinction co-efficient of MDA, which is $1.56\times105\ M^{-1}cm^{-1.}$

2.4.1.4. Estimation of total protein

Total protein content (mg/100 mg fresh tissue weight) was identified in brain tissue homogenate as described by Lowry et al. (1951).

2.4.1.5. Estimation of lipids

Lipids were extracted from brain tissues using a mixture of (2:1 v/v) chloroform-methanol (Folch et al., 1957) and the contents were expressed as mg/100mg tissue.

Total cholesterol was estimated by the method of Zlatkis et al. (1953), where 9.9ml of ferric chloride-acetic acid reagent was added to 0.1ml of lipid extract, allowed to stand for 15 min, centrifuged and the supernatant fluid was collected. 3ml of conc. H_2SO_4 were then added to 5ml of the collected supernatant fluid. The colour developed was red after 20 min at 560nm against a reagent blank and values were expressed as mg/100mg tissue.

Triglycerides were estimated by the method of Foster and Dunn (1973). An aliquot of lipid extract was evaporated till dryness in glass tubes, 0.1ml methanol was then added followed by 4ml isopropranol and 0.4g alumina and centrifuged at 3000rpm for 15 min. 2ml of the supernatant fluid was transferred to labeled tubes to which 0.6ml of a saponification reagent was added, and then placed in a water bath at 65°c for 15 min for saponificatioin. 0.5ml of acetyl acetone reagent was added, mixed and the tubes were kept in a water bath at 65°c for 1h. The contents were then cooled and the absorbance was red at 420nm. The triglyceride content was expressed as mg/100mg tissue.

Low-Density Lipoprotein-Cholesterol (LDL-c) was calculated using Friedewald formula (Friedewald et al., 1972), based on the assumption that LDL-c is present in a concentration equal to one-fifth of the triglycerides. Values are expressed as mg/100mg tissue.

2.4.2. Neurohistopathology

The dissected brain tissue specimens were fixed in 10% neutral buffer formalin, processed by paraffin embedding method, sectioned at 4-5µm and stained with Hematoxylin and Eosin stain (Bancroft et al., 1996). Stained sections were fixed on slides, and lesions were then confirmed by microscopic examination.

2.5. Statistical analysis

Data analysis for all variables were carried out by means of analyses of variance (ANOVA) to judge the effect of administration of Na-F, black tea to rats as well as session factor for behavioural tests using the general linear models procedure in SPSS® statistical software (SPSS, 2006). After confirmation of significant effects in the overall ANOVA, data for different groups were compared using post hoc Tukey HSD test. For all tests, the criterion for statistical significance was $p<0.05$. Results are reported as mean ± SEM.

3. Results

3.1. Open field test:

Anxiety state of the animals was assessed on first occurrence in the open field test as shown in Table 1. Administration of Na-F to rats produced an anxiogenic profile of behavioural changes as indicated by increased time spent freezing ($F_{(1, 36)} = 19.35$; $p = 0.00$), higher vertical activity (numbers of rearing; ($F_{(1, 36)} = 36.16$; $p = 0.00$) as well as elevated defecation scores ($F_{(1, 36)} = 21.92$; $p = 0.00$). Also,

rats administered black tea solution alone displayed higher levels of anxiety-related behaviours than others in the control group. However, the level of enhancement noted for anxiety measurements was significantly different in individuals of Na-F group compared to counterparts in T group. On the other hand, our treatments had no significant influence on horizontal activity (numbers of crossed squares) as well as urination scores. Furthermore, administration of black tea along with Na-F significantly reduced levels of Na-F-induced anxiety. Similar levels of anxiety were recorded for rats in the ameliorated group and those in T group.

A significant degree of formation of memory of habituation over three sessions in the open field test was noted regarding time spent freezing ($F_{(2, 117)} = 11.61$; $p = 0.00$), horizontal activities (numbers of squares, ($F_{(2, 117)} = 27.16$; $p = 0.00$), vertical activity (numbers of rearing, ($F_{(2, 117)} = 11.34$; $p = 0.00$) and defecation scores ($F_{(2, 135)} = 9.57$; $p = 0.00$) for all treatments but not for Na-F group. In the later group, an equivalent assessment were significantly noted in the first day of induction compared to second and third test sessions ($p = 0.91$ and 0.08), ($p = 0.78$ and 0.09), ($p = 0.66$ and 0.16), ($p = 0.62$ and 0.27) for all previous parameters, respectively.

3.2. Maze test:

The ability of learning and memory of animals over the five days of maze test was presented in Table 2. Administration of Na-F to rats significantly increased both latency to locate the feed at the end of the maze ($F_{(1, 180)} = 122.87$; $p = 0.00$) and frequencies to enter the blind alleys ($F_{(1, 180)} = 127.82$; $p = 0.00$) compared to control group. In contrast, learning and memory were superior in group of rats exposed to black tea solution compared to the control group, as shown by reduced latency to end the maze ($F_{(1, 180)} = 62.83$; $p = 0.00$) accompanied with less numbers of errors (numbers of entries for blind alleys, ($F_{(1, 180)} = 90.19$; $p = 0.00$). Moreover, Administration of black tea to Na-F-treated rats significantly improved the parameters studied to the level of control group.

On testing the retention of the task over five days of maze test, rats in all treatments required steadily less time to terminate the maze ($F_{(4, 180)} = 16.46$; $p = 0.00$) with reduced numbers of errors ($F_{(4, 180)} = 21.01$; $p = 0.00$), except for Na-F-treated rats. Concerning Na-F group, values for latency as well as numbers of errors weren't significantly different during acquisition on first day when compared to their retention values on the four consecutive days of testing ($p = 1.00$, 1.00, 1.00 and 0.97), ($p = 1.00$, 0.61, 0.33, and 0.33), respectively, indicating poorer memory retention in Na-F treated rats compared to all other treatments.

3.3. Spatial Y-maze memory:

Spatial Y-maze performance was illustrated in Table 3. Spatial memory on the Y-maze was seriously impaired in rats administered Na-F as indicated by reduced percentages of spontaneous alternation behaviour in comparison with rats in all other treatments ($F_{(1, 36)} = 49.31$; $p = 0.00$). On the other hand, rats supplemented with black tea solution significantly improved spatial cognition learning ability than controls ($F_{(1, 36)} = 23.08$; $p = 0.00$). Furthermore, administration of black tea significantly alleviated Na-F-induced spatial memory impairment, where rats in the ameliorated group exhibited as better performance in the Y-maze test as their counterparts in the control group.

3.4. Biochemical analysis:

3.4.1. Brain acetylcholinesterase (AChE) activity:

The activity of AChE in the brain of rats was demonstrated in Table 4. Na-F-treated rats have shown a significant reduction in AChE activity compared to their counterparts in the control group. Administration of black tea has no significant influence on AChE level in the fluoride group. No significant differences were detected between rats in tea group and those in the control one.

3.4.2. Oxidative stress parameters:

SOD activity, TBARs formation as well as total protein contents in the brain tissues of rats were presented in table 5. SOD activity was significantly lowered in Na-F-exposed rats compared to Na-F-free rats. Significant alleviation of this reduction was recorded when black tea was concomitantly administered. Black tea alone significantly enhanced SOD activity in rats compared to the control group.

The Level of TBARs formation was significantly higher in case of Na-F-treated rats. This elevation was significantly diminished by administration of black tea. Compared to control rats, treatment with black tea alone had no significant influence on brain tissue TBARs level .

Total protein content was significantly decreased in brain tissues of rats administered Na-F when compared to those in the control group. The later reduction was significantly improved when black tea was concomitantly administered. The observed increase in total protein contents in black tea-treated rats, compared to control one, was not statistically significant.

3.4.3. Lipid profile:

Total cholesterol (TC), triglycerides (TG) and low density lipoproteins cholesterol (LDL-c) were significantly increased when Na-F was administered to rats (Table 6). Administration of black tea significantly lightened this noted increase in Na-F-exposed rats. Rats administered black tea alone have revealed a significant decrease in lipid profile parameters when compared to their counterparts in the control group.

3.5. Histopathological examination:

No histopathological changes could be detected in the brain of rats in both of the control and tea-treated groups.

Examination of fluoride-treated rats revealed severe pathological alterations as evidenced by congestion of the meningeal, cerebral and cerebellum blood capillaries, in addition to congestion of choroid plexus in the ventricle (Fig. 1). Large hemorrhagic areas were also detected in the cerebral cortex, cerebellum white matter as well as in the ventricles around choroid plexuses (Fig. 2). Neurodegenerative changes were noticed in nerve cells especially at hippocampus and large nerve cells of cerebral cortex, as represented by the accumulation of neurofilaments in the cytoplasm of nerve cells and axons (Fig. 3).

In addition, nerve cells of cerebral cortex revealed sever edema, central chermatolysis, atrophy, necrosis and neuronophagia (Fig. 4), whereas the pyramidal cells of Ammon's horn of hippocampus showed atrophy and necrosis (Fig. 5). Either focal or diffused Gliosis were noticed in the cerebral cortex with severe demylination of the nerve fibers in the neuropil shown in the cerebrum, and accompanied with axonal swelling (Fig. 6). Glial fibers was detected under the ependymal cells lined the ventricles. The cerebellum showed necrosis of Purkinje cells and edema with necrosis in the granular cell layer.

Concomitant administration of tea to fluoride-intoxicated rats resulted in mild to moderate pathological changes compared to their counterparts exposed to fluoride alone. Small hemorrhagic areas were noticed in the ameliorated group, especially in the ventricle around the choroid plexuses (Fig. 7). Only edema was detected in the large nerve cells of the cerebral cortex (Fig. 8). Few numbers of large pyramidal cells of hippocampus appeared slightly atrophied (Fig. 9). Focal glial cells and fibers were detected in few numbers of the ameliorated examined cases (Fig. 10).

4. Discussion:

For assessment of emotionality, the open field is one of the simplest and most popular tests currently in use (Weiss and Greenberg, 1996; Brain & Marrow; 1999; Crawley, 1999). The test is employed to assess anxiety-related conflict arising between the drive to explore by venturing into the center of the arena and safety by remaining in a corner or along a wall (Weisstaub et al., 2006).

To the best of our knowledge, few researches have implemented open field test to investigate Na-F influence on anxiety levels in rats. In compliance with our earlier study, rats exposed to Na-F spent more time freezing on the first exposure to open field test (El-lethey et al., 2010). Increased immobility in the open field is characteristic for increased levels of anxiety (Homberg et al., 2002; Fromm et al., 2004; Kalueff & Tuohimaa, 2004). Unlike horizontal locomotion, higher levels of vertical activity were detected in Na-F-treated rats. This finding supports the fact that vertical exploration is more sensitive to anxiety than horizontal locomtion (Lapin et al., 1995). Although the locality of the activities were not recorded here, the enhancement in vertical activity at first exposure might be on account of novelty-provoked more fear-related behaviour in rats such as activity in the corners and walls of the open field (Choleris et al., 2001). Moreover, rearing at the perimeter of the enclosure has been evidenced to indicate anxiety and an animal's attempts to escape; whereas rearing in the inner arena may be more indicative for curiosity, namely exploration of the upper parts of the apparatus (Anderson & Hughes, 2008). Although urination scores were not influenced by Na-F, our results revealed a profound increase in faecal boluses deposited in the field. These data were in agreement with Ivinskis (1968) who suggested that defecation is a more reliable measure than urination to assess emotionality in the open field. Also, Brain & Marrow (1999) have confirmed defection to be a satisfactory measure for anxiety, with increased defecation indicating higher anxiety. Taken together, these reports and the results presented here suggest a Na-F-induced increase of anxiety-like behaviour.

Where the decrement in exploratory response to successive exposure to a novel environment is taken as an index for memory of habituation, a non-associative learning task (Bolivar et al. 2000**;** Izquierdo et al., 2001; Winogard & Viola, 2004), an impairment in habituation was shown in Na-F-treated rats. Consistent with our finding, a decrement in habituation signifying learning and memory impairment was previously shown in rats exposed to 100 ppm Na-F, the identical concentration employed in the current study (Chioca et al., 2008; Pereira et al., 2009; El-lethey et al., 2010).

Tea consumption in many cases is the main source of caffeine (Haider et al., 1998). Caffeine content in black tea is greater than that in a green one, 3.86% versus 2.04%, respectively (Komes et al., 2009). The anxiogenic effect of caffeine has been documented in a substantial literature (Brice & Smith, 2002; Botella & Parra, 2003). Caffeine has been reported to elicit a dose-dependent, subjective feeling of anxiety, even at low doses (Kaplan et al., 1997). The stimulation of anxiety in response to caffeine may be as a result of increased levels of lactate in the brain (Tancer et al., 1991, 1994). Here, the enhancing effect of tea on rearing activity might be explainable in terms of caffeine-induced anxiety in a novel environment. In agreement with our findings, increased activity of animals was experienced after administration of low or moderate doses of caffeine (Buckholtz and Middaugh, 1987). Moreover, Haleem et al. (1994) have observed an increase in both home cage and open field activity in rats following low doses of caffeine. Enhancement of activity was not entirely due to caffeine per se, where presence of theophylline, another alkaloid present in tea, might be also attributable for promoting locomotor activity (Haider et al., 1998). In agreement with our data, no change on numbers of squares crossed in the open field was reported after four weeks of tea administration in rats (Haider et al., 1998). The stress effect of novelty on exposure to open field could suppress locomotor enhancing effects of stimulants present in tea, resulting in lack of effect on horizontal locomotion in our study. In addition, partial tolerance to the locomotor-enhancing effects of caffeine has been evidenced to develop following administration of high doses of caffeine for about a week resulting in lack of effect on locomotion (Haleem et al. (1994). Administration of tea to Na-F-treated rats brought about recovery in anxiety parameters almost to tea administration level alone, suggesting the potential ameliorative effect of tea on Na-F-induced symptoms of anxiety.

Although associative processes have been evidenced to play a real role in spatial learning, almost no studies have employed classic maze to address spatial memory (Leising, 2009). The animal must build a cohesive spatial representation of the maze to end with the food. On repeating the maze experiment several times, the changes in latency, and errors made to reach the food are indicators for learning and memory abilities of the rat. In the present study, the defective ability of Na-F-treated rats to navigate the maze for food reinforcement with higher errors on successive days of testing signifying inferior memory retention compared with other

treatments. Consistent with these findings, impairment in the learning capacity during classic maze was formerly experienced in Na-F-exposed rats (El-lethey et al., 2010). Bhatnagar et al. (2002) and Gao et al. (2009) have also reported poor performance of fluoride-intoxicated animals during maze test with increased inability to perform well with higher fluoride concentration in drinking water.

The alternation behavior observed during spatial Y-maze memory testing has been motivated by the detection of novelty, where animals are attracted to a stimulus that is novel relative to previous stimuli experienced, being a sign for the degree of learning ability in rats (Gaffan and Davies, 1982). Confirming the results of classic maze, more evidences for impaired cognitive capacity were derived from the data for Y-maze test, where Na-F provoked a remarkable hindrance in spatial memory of rats as indicated by a notable decrease in spontaneous alteration behaviour. Our findings are in accordance with previous reports from Niu et al. (2008) that have demonstrated a spatial memory deficit in rats during Y-maze after Na-F exposure.

Consumption of flavonoid-rich foods, such as tea that makes a significant contribution to dietary intake of flavonoids by 82% (Hertog et al., 1997), throughout life holds a potential to limit the neurodegeneration associated with a variety of neurological disorders and to prevent or reverse normal or abnormal deteriorations in cognitive performance. Interestingly, there is evidence to suggest that tea polyphenols can localize within the brain following dietary consumption and thus be available to promote actions resulting in cognitive improvements (Matsuoka et al., 1995; Suganuma et al., 1998). Our results are in line with these earlier reports, where administration of black tea has greatly improved cognitive performance during the two tasks applied here for evaluating spatial memory. Also, the observed attenuation in cognitive capacity in Na-F-exposed rats has been blunted to normal level when black tea was concomitantly administered. Accordingly, the potential cognitive protective effect of tea has been reported in various experimental animal models (Kim et al., 2004; Unno et al., 2004). Long-term administration of green tea catechins has been reported to improve the performance in radial maze tasks (Haque et al., 2006). Likewise, the effectiveness of tea extract in enhancing learning and memory, and hence, reversing age-related deficits in aged rats has been proved, as signified in performance in elevated maze and passive avoidance tests (Kaur et al., 2008).

The neuroprotective effect of dietary flavonoids involves a number of actions within the brain, including a potential to protect neurons against neurotoxins-induced injury, an ability to suppress neuroinflamation, and to promote memory, learning and cognitive function (Spencer, 2009). This multiplicity of effects appears to be attained by two processes. Firstly, flavonoids interact with important neuronal signaling cascades leading to an inhibition of neurotoxins-triggered apoptosis, as well as a promotion of neuronal survival and differentiation. Secondly, they induce peripheral and cerebral vascular blood flow in a manner leading to induction of angiogenesis, and new nerve cell growth in the hippocampus.

Complex mechanisms are underlying the neuroprotective effect of tea.

As regards tea catechins, possible mechanisms might involve their antioxidant and iron-chelating properties, as well as modulation of cell-signaling and cell survival pathways (Mandel and Youdim, 2004; Weinreb et al., 2004). As for black tea, since catechins undergo enzymatic transformation during fermentation, their amount is generally lower than in green tea (Luczaj and Skrzydlewska, 2005; Unno and Hoshino, 2007). Nonetheless, the conversion of catechins to theaflavins and thearubigins during fermentation does not significantly alter their free radical-scavenging activity, and both black tea and its components possess strong antioxidative properties (Leung et al., 2001; Henning et al., 2004)**.** In addition to tea polyphenols, theanine, an amino acid uniquely found in tea leaf, might also possess neuroprotective effect and enhance the positive cognitive effects (Nathan et al., 2006; Haskell et al., 2008)**.** Because tea leaf contains various other phytochemicals, including vitamin C, it is likely that the cognitive protective effect of tea is not due to a single compound but rather to the synergistic effect of many of its chemical components (Tze-Pin et al., 2008).

Acetylcholine is an important neurotransmitter present at cholinergic nerve terminal and plays a key role in cholinergic neurotransmission (Garcia-Ayllon et al., 2006). A tight correlation has been established between acetylcholinestrase (AChE) activity and cognition. Estimation of AChE, a substrate specific enzyme degrading neurotransmitter acetylcholine in nerve synapses, provides an easy and valuable assessment of cholinergic function. 90% of AChE in the brain is membrane bound and only 10% is in a soluble form (Atack et al., 1986; Mortensen et al., 1998). Since, estimation of the soluble form of AChE is a relatively simple and sufficiently reliable indicator of relative changes of AChE activity in the brain (Muller et al., 1985; Zakut et al., 1985), quantifying the soluble form of this enzyme was only considered in our study.

Here, the marked reduction in AChE activity experienced in brain tissue of Na-F-treated rats is in

agreement with previous findings in rats (Wang et al., 2004; Wu et al., 2006). Further studies have reported a significant decline in brain AChE activity after excessive intake of Na-F in mice (Vani and Reddy, 2000; Bhatnagar et al., 2006).

The observed inhibition of AChE might be attributable to the loss of neuron cell bodies in the hippocampus as well as loss of synaptic structures (Bhatnagar et al., 2003; Ge et al., 2005). Anion hydrolysis products of methyl phosphoric difluoride were also implicated to cause an inhibition of AChE in both rats and guinea pigs (Dahl et al., 1987). Toxic inhibition of the AChE will cause high concentration of acetylcholine to accumulate in the body, whereas excessive induction of the acetylcholine will lead to down-regulatory effects through more hydrolysis of the acetylcholine into acetate and choline in order to reduce the concentration of acetylcholine in the body and counteract excess acetylcholinergic activity (Teh et al., 2010). Therefore, the diminution in AChE level may lead to altered utilization of acetylcholine, thus interfering with the synaptic transmission in brain, being accountable for cognitive dysfunctions observed in our study (Wang et al., 2004).

Contrary to our findings, an elevated level of AChE activity was detected with severe brain tissue damage accompanied by high fluoride intake in rats and mice (Chen and Bai 1995; Sun et al., 2000). This contradiction in Na-F effect on AChE activity might be due to the exposed level of Na-F, where the inhibited activity of AChE activity is mostly induced with moderate fluorosis, whereas severe fluorosis may exert a stimulatory effect on the activity of AChE (Gao et al., 2009).

There are numerous reports about inhibitory effect of antioxidants, namely polyphenols, on AChE acivity. Kim et al. (2004) showed that tea polyphenols exhibit a dramatic inhibitory effect on AChE activity and might be useful in the treatment of Alzheimer's disease (AD). Additionally, Kulisic-Bilusic et al. (2008) reported about high inhibitory activity of aqueous tea infusions on AChE activity. In contrast to these earlier findings, there was a lack of influence of black tea on brain tissue AChE activity in our study. This discrepancy might be on account of different polyphenols production as a result of different degrees of fermentation during tea manufacturing as well as variation in place of origin.

The brain and nervous system are prone to oxidative stress, and also inadequately equipped with an antioxidant defense system to prevent ongoing oxidative damage (Halliwell, 2006). In addition, the brain consumes large quantities of oxygen that contributes to the formation of reactive oxygen species (ROS). In the current study, rats exposed to Na-F showed a significant reduction in the activity of antioxidant enzyme (SOD) and a concomitant enhancement in lipid peroxidation (TBARS), in accordance with earlier reports in brain tissues of fluoridated rats and mice (Mullenix et al., 1995; Vani and Reddy, 2000; Shivarajashankara et al., 2001; Bhatnagar et al., 2006; Chirumari and Reddy, 2007; Bharti and Srivastava, 2009). These detected alterations suggest Na-F-induced-oxidative stress in the brain thereby disturbing the antioxidant defense, in compliance with earlier findings (Chlubek, 2003; Inkielewicz and Krechniak, 2004). Increased oxidative stress could therefore be one of the mediating factors in the pathogenesis of Na-F-induced neurotoxicity experienced in the present work.

Tea polyphenols can pass through the brain-blood barrier to exert antioxidant activity and potent neuroprotective effects (Nie et al., 2002). One of the possible mechanisms may be their directly scavenging ROS produced either outside or inside the cell or both. Earlier data have shown that tea polyphenols can scavenge different kinds of ROS and organic free radicals, for example, superoxide anion, hydroxyl radical, singlet oxygen, and lipid free radicals (Zhao et al., 1989; Guo et al., 1996; Guo et al., 1999). Here, the elevated level of free radical enzyme (SOD) with lowered level of lipid peroxidation when black tea was administered to Na-F treated rats suggests the role of black tea in amelioration of Na-F-induced oxidative stress. This ameliorative effect of black tea may be due to the presence of monomeric catechins that affect plasma antioxidant biomarkers and energy metabolism (Williamson and Manach, 2005; Trivedi et al., 2006; Verma et al., 2006). Moreover, it has been reported that quercetin, a unique flavanol present in black tea extract, can reduce free radicals (Pietri et al., 1997). Polyphenols are also well known for their ability to reduce membrane lipid peroxidation that can prevent Na-F-induced-oxidative damage. Further support derived from former studies, where oral administration of a flavonoid-rich tea extract prevented iron-salt-induced lipid peroxide accumulation and suppressed age-related accumulation of neurotoxic lipid peroxides in rat brain (Inanami et al., 1995; Yoneda et al., 1995).

Brain protein is important to maintain normal brain physiological function and learning-memory ability (Liu et al., 1999). In the present study, protein contents have been shown to be reduced in the brains of rats subsequent to fluoride exposure. Decreased protein contents have been formerly reported in the brain of rats treated with Na-F (Wang et al., 2004; Wu et al., 2006). The Na-F-induced reduction in brain protein contents might be as a result of either increased proteolysis or decreased

rate of cellular protein synthesis through impairment of peptide chain initiation (Trivedi et al., 2007). Moreover, fluoride has been evidenced to inhibit oxidative decarboxylation of branched chain amino acids and simultaneously promote protein breakdown. Reduced activities of glutamine synthetase that catalyzing certain stages of amino acid biosynthesis as well as methionine activating enzymes of the liver have been also implicated in fluorosis-induced disturbance in protein synthesizing system (Zahvaronkov and Strochkova, 1981).

Brain triglycerides levels as well as cholesterol content were highly elevated in rats exposed to Na-F in the present study. In a study on rabbits, fluoride induced alterations in brain lipid metabolism similar to lipidosis, a disorder of lipid metabolism leading to abnormal fat accumulation in the body tissues, particularly in the liver and brain (Shashi, 1992). Fluoride intoxication-induced hyperlipidemia might occur due to enzymatic defect and inability of brain to degrade the lipid in the body. Furthermore, as lipids are transported in association with a carrier protein, a defect in lipoprotein metabolism as evidenced by reduced LDL-c in the current study might be on account for hyperlipidemia. Deficiency of a lipotropic agent has been evidenced to cause triglycerides to accumulate, leading to a decrease in free fatty acids synthesis during fluoride intoxication (Shashi, 1988; Shashi et al., 1989). Further evidence derived from a study for Trivedi et al. (2009) where accumulation of cholesterol and total lipids was reported in Na-F administered mice. Here, the observed hypercholesterolemia may be due to Na-F-induced deficiency of liposomal lipase which hydrolyzes cholesterol esters taken up by the cell, reducing the release of free fatty acids and glycerol as well as enhancing lipogenesis. (Shashi, 1992). The hypercholesterolemia and hypertriglyceridemia have been reported in previous studies to indicate excessive fat immobilization (Vatassery et al., 1980; Shashi et al., 1989). In our study, the alteration in lipid metabolism might also be due to increase in lipid peroxidation activity (Shivarajashankara et al., 2001).

In line with findings of Trivedi et al. (2009), amelioration of fluoride-induced rise in brain triglycerides and cholesterol contents by administration of black tea was recorded in our study. Black tea has been evidenced to inhibit the synthesis of cholesterol and decrease its concentration in the brain (Maron et al., 2003). Since the antilipogenic effect of black tea might be due to its radical scavenging activity, the alleviation of Na-F-induced alteration in brain by black tea might be due to its potent antioxidative properties (Katiyar and Mukhtar, 1997; Du Toit et al., 2001).

Given the crucial involvement of hippocampal activity in many aspects of learning and memory (Strack et al., 2000; Leussis & Bolivar, 2006), and since fluoride is known to accumulate in various parts of rat brain, especially in the hippocampus (Burgstahler and Colquhoun, 1996), detection of neurotoxic alterations in the hippocampus was monitored in the present study. Here, the demonstrated histopathological changes triggered by fluoride intoxication in the brain, especially hippocampus and cerebrum regions, are attributed to neurotoxic effect of fluoride. Previous studies have evidenced that accumulation of fluoride in the hippocampus generates neuronal dysfunction by mechanisms involving decreased aerobic metabolism with elevated levels of free radicals (Spittle, 1998; Chirumari and Reddy, 2007). Fluoride binds to antioxidants in the body such as N-acetyl cysteine and glutathione and other free-radical destroying enzymes, thereby disturbing the antioxidant defense, triggering oxidative stress that initiates nerve cell damage especially cell membrane and even cell apoptosis (Anuradha et al., 2001; Gao et al., 2009).

In the current study, presence of neurofilament in the nerve cells might be attributable to the interference of fluoride with various steps of protein synthesis inside nerve cells (Miu et al., 2003). Fluoride may also accumulate in both neurons and astrocytes, resulting in strong morphological changes such as clustering, degeneration and finally death (Mullenix et al., 1995).

In our study, the ameliorative effect of black tea on Na-F-induced histopathological alterations in the brain of rats could be explained on the basis of flavanoids-exhibited antioxidant activity via radical scavenging capacity (Trivedi et al., 2007).

In conclusion, our study demonstrated a potential effect of black tea drinking in protection against Na-F intoxication-induced cognitive decline in rats. Since, black tea is cheap, non toxic, and widely consumed, thus its regular consumption is greatly recommended in order to promote cognitive health and lessen the risk of cognitive impairment elicited by neurotoxins, particularly fluorides.

papajyde2000@yahoo.com

ABSTRACT: Cross-sectional studies of UTI among post menopausal women were carried out between January and June, 2009 using standard microbiological techniques. The result obtained showed that 42 (39.6%) out of 106 postmenopausal women had urinary tract infections with highest prevalence among women aged 56-60 and lowest among those aged ≥ 61 . Microscopic examinations of forty-two (42) mid-stream urine samples revealed the presence of 13(30.9%) epithelial cells, 5 (11.9%) phosphate crystals, 16 (38.1%) pus cell , 9 (21.4%) yeast cells, 7(16.7%) red blood cells and eggs of *Schistoma haematobium* 2(4.8%). Bacteria isolated were: *Escherichia coli* 20 (25.3%), followed by *Staphylococcus aureus* 16 (20.3%), *Pseudomonas aureginosa* 10 (12.7%), Coagulase negative *Staphylococcus* spp 9 (11.4%), *Streptococcus pyogenes* 6 (7.6%), *Serratia marcescens* 6 (7.6%), *Enterobacter* spp 5 (6.3%). *Klebsiella* spp. 4 (5.1%) and *Enterococcus faecalis* 3(3.8%). *E. coli* showed low percentage resistance to ciprofloxacin, ceftazidime and ceftriaxone. *Enterobacter* spp. were susceptible to ciprofloxacin and cotrimoxazole in 80%, respectively. Between 60-80% of *Pseudomonas aeruginosa* and *Enterobacter* spp were susceptible to all the tested antibiotics, while 4(66.7%) *Streptococcus pyogenes,* 6 (66.7%) CON-*Staphylococcus* spp and 4(66.7%) *Serratia marcescens* were sensitive to ceftazidime. All the *Enterococcus faecalis* and *Klebsiella* spp isolated were sensitive to ciprofloxacin. The phenotypic determination identified a low ESβL rate of 28.8 % (13 of 45 isolates). ESBLs were detected among the following species: 5 *Escherichia coli* (25.0%), 3 *Pseudomonas* spp (30.0%), 1 *Klebsiella* spp (25.0%), *Serratia marcescens*2 (33.3%) and *Enterobacter* spp. 2 (40.0%). The result also showed that 18.9 % of the bacteria were resistant to at least 3 antibiotics with (MAR) index ranging from 0.2 to 0.8. The results obtained in this study are statistically significant ($p \leq 0.05$). However, continuous surveillance to monitor the prevalence of UTI and antimicrobial resistance among post menopausal women is overwhelmingly necessary.

INTRODUCTION

The urinary tract consists of various organs of the body involved in the production, storage and excretion of urine. (Sotelo and Westney, 2003; Beer *et al*., 2006). Urinary tract infection (UTI) is caused by pathogenic invasion of the urinary tract, which leads to an inflammation of the urothelium. The invading microbes may affect the entire tract or be restricted to either the upper region or lower region (Stamm and Norrby, 2001). Urinary tract infection (UTI) is one of the most common causes of hospitalization and referral to outpatient, having an estimated figure of 150 million per annum worldwide. (Stamm and Norrby, 2001; Fakhrossadat and Narges, 2009). The urinary tract infections may be asymptomatic, acute, chronic and complicated or uncomplicated and the clinical manifestations of UTI depend on the portion of the urinary tract involved, the etiologic organisms, the severity of the infection, and the patient's ability to mount an immune response to it. Acute urinary tract infection is an extremely common entity that affects almost half of women in The United states of America (Foxman, 2002). The prevalence and incidence of urinary tract infection is higher in women than in men, which is likely the result of several clinical factors including hormonal effects, behaviour patterns or their having a short urethra and vaginal vestibule which can easily be contaminated (Harding and Ronald, 1994). Prevalence of UTIs increases with advancing age and in females the prevalence ranged from 3% in young girls under the age of 10 to a peak of 10% in post-menopausal women between the ages of 55 and 64 (Young and Koda-Kimble, 1995; Sotelo and Westney, 2003).The leading causes of acute and uncomplicated UTIs in patients have been reported to be due to *Escherichia coli, Staphylococcus aureus, Proteus spp,*

Klebsiella spp and *Pseudomonas aeruginosa* (Manges *et al*., 2006; Akram *et al*., 2007; Akortha and Ibadin, 2008). In Nigeria, *E. coli*, *Proteus spp* and *Klebsiella spp* have been isolated in 90% of UTI reposted cases (Obaseiki-Ebor, 1988; Foxman, 1990). The symptoms of UTIs which include fever, burning sensations while urinating, lower abdominal pain, itching, formation of blisters and ulcers in the genital area, genital and suprapubic pain, and pyuria generally depend on the age of the person infected and the location of the urinary tract infected (Amali *et al*., 2009). UTIs are associated with a high risk of morbidity and mortality and account for significant health care costs in spite of the availability and use of the antimicrobial drugs.

Hormonal changes that characterize menopause are likely to influence the habits of women. A number of observational epidemiological studies have dealt with risk factors of chronic diseases, namely cardiovascular disease (CVD), osteoporosis, and urinary tract infection. In post-menopausal women, susceptibility to UTI increases due to a deficiency of oestrogen (Foxman,1999). Sensitivity of bacterial to antibiotics shows a great geographical and historical variability due to different antibiotic treatments (Akinjogunla *et al*., 2009). So knowledge of the sensitivity pattern of common uropathogens according to local epidemiological studies is necessary for selection of appropriate antibiotics for empirical treatment. Researches have not been extensively carried out to determine the prevalence of symptomatic or asymptomatic bacteriuria among the postmenopausal women in this environment , this therefore necessitated this study that determined the prevalence and sensitivity pattern of uropathogens isolated from post-menopausal women in Uyo Metropolis.

MATERIALS AND METHODS

STUDY SETTING

This cross-sectional study was designed to cover post-menopausal women in Uyo metropolis. Uyo is the capital city of Akwa –Ibom State located in the South-South (S/S) part of Nigeria. Uyo metropolis was selected for the study due to its dense population. Demographic information such as age, and time of stoppage of their menstrual cycle of each post-menopausal woman obtained were kept confidential.

COLLECTION OF MID STREAM URINE SAMPLES

In a prospective study from January to June, 2009, a total of 106 mid-stream urine (MSU) samples from apparently healthy postmenopausal women who gave verbal informed consent were aseptically collected into sterile McCartney bottles and stored at 4^{o}C.

MICROSCOPIC EXAMINATION OF MID STREAM URINE SAMPLES

Two loopful of uniformly mixed uncentrifuged urine samples were aseptically placed on a clean grease-free slide and covered with a cover slip**.** The preparation was examined microscopically to detect the presence of pus cell, epithelial cell, red blood cell, yeast cell, phosphate crystal using 10x and 40 x condenser iris closed sufficiently to give good contrast.

ISOLATION AND IDENTIFICATION OF UROPATHOGENS

The uncentrifuged, uniformly mixed mid stream urine (MSU) samples were inoculated on Cysteine lactose electrolyte deficient (CLED), MacConkey agar (MCA) and Blood agar (BA) media and incubated at 37°C aerobically for 24 hrs. After incubation the cultures developed on media were observed and the colonies were counted by colony counter. Significant urinary tract infection (UTI) was defined as the presence of $\geq 10^5$ colony-forming units per millimeter in the culture of an appropriately collected urine sample. Standard identification procedures of colony morphology, Gram staining reaction, motility, catalase test, oxidase test, urease test, coagulase test, sugar fermentation, indole production and IMViC (Indole, Methyl red, Voges-Proskauer, and Citrate) tests were used to determine the uropathogens present in the urine samples.

THE ANTIBIOTIC SENSITIVITY TESTING

The antibiotic sensitivity of the bacterial species isolated from the mid stream urine samples was performed by disk diffusion method on Muller-Hinton agar plates as described by the National Committee for Clinical Laboratory Standards (presently called as Clinical Laboratory Standard Institute). 0.1 ml of each bacterial isolates was seeded into each of the Petri dishes containing Mueller-Hinton agar and were allowed to stand for 30 mins to enable the inoculated organisms to pre-diffuse. The commercially available discs containing the following antibiotics: Ceftazidime, (Caz,30ug), Streptomycin (Stp,30ug) Ciprofloxacin (Cpf,5ug) Ceftriaxone (Cef,30ug) and Cotrimoxazole (Cot, 30ug) (Oxoid, UK) were aseptically placed on the surfaces of the sensitivity agar plates with a sterile forceps and were incubated for 18 - 24hrs at 37°C. Zones of inhibition after incubation were observed and

the diameters of inhibitory zones were measured in millimeters. The interpretation of the measurement as Sensitive (S) and Resistant (R) was made according to the manufacturer's standard zone size interpretive manual. The percentage resistance was calculated using the formula *PR=a/b×100, where 'PR' was* percentage resistance, '*a*' was the number of resistant isolates and '*b*' was the number of isolates tested with the antibiotic. The percentage sensitivity was calculated using the formula *PS=c/d×100, where 'PS' was* percentage sensitivity, '*c*' was the number of sensitive isolates and '*d*' was the number of isolates tested with the antibiotic.

DETERMINATION OF MULTIPLE ANTIBIOTIC RESISTANCE INDEX (MAR)

Multiple antibiotic resistance index (MAR) was determined using the formula MAR=*x/y*, where *x* was the number of antibiotics to which test isolate displayed resistance and *y* is the total number of antibiotics to which the test organism has been evaluated for sensitivity (Akinjogunla and Enabulele, 2010)

ESBL SCREENING AND DETECTION

All the Gram negative bacteria that are resistant to either ceftazidime or ceftriaxone (≤15) were screened using double-disc synergy tests (DDST) to detect ESBL-producing isolates (Akinjogunla *et al*., 2010). 0.1 ml of each bacterial isolates was seeded into each of the Petri dishes containing Mueller-Hinton agar and were allowed to stand for 30 mins to enable the inoculated organisms to pre-diffuse. An augmentin was placed at the center of the Petri-dish and ceftriaxone (30 µg), ceftazidime (30) at 15mm from the augmentin. An inhibitory zone of 37 mm for ceftriaxone and 22 mm for ceftazidime indicated that the isolated strains are probably ESBL producers.

STATISTICAL ANALYSIS OF RESULTS

Frequencies and percentages were calculated for study variables. Chi-square ($\chi 2$) test was used to calculate probabilities and determine significance. A p-value of less than or equal to 0.05 was considered to be statistically significant ($p \leq 0.05$), while p-value more than 0.05 was considered to be statistically not significant (NS).

RESULTS:

The result obtained showed 42 (39.6%) out of 106 postmenopausal women included in the study had urinary tract infections and the prevalence was highest among post-menopausal women aged 56-60 and lowest among those aged ≥ 61 (Table 1) . Microscopic examinations of forty-two (42) mid-stream urine samples of post menopausal women with urinary tract infections revealed the presence of epithelial cell 13 (30.9%), phosphate crystals 5 (11.9%), pus cell 16 (38.1%), yeast cells 9 (21.4%), eggs of *Schistoma haematobium* 2(4.8%) and red blood cells 7(16.7%) (Table2).

Out of the 42 midstream urine samples of the post menopausal women with UTI, 79 bacterial isolates consisting both Gram positive and Gram negative bacteria were recovered using their morphological and biochemical characteristics such Gram's reaction, motility, catalase, oxidase, coagulase, indole, urease, indole, sugar and IMViC (Indole, Methyl red, Voges-Proskauer, and Citrate) tests (Tables 3 and 4). Of these, *Escherichia coli*. had the highest prevalence of 20 (25.3%), followed by *Staphylococcus aureus* 16 (20.3%), *Pseudomonas aureginosa* 10 (12.7%), Coagulase negative *Staphylococcus* spp 9 (11.4%), *Streptococcus pyogenes* 6 (7.6%), *Serratia marcescens* 6 (7.6%), *Enterobacter* spp 5 (6.3%). *Klebsiella* spp. 4 (5.1%), *Enterococcus faecalis* 3 (3.8%), (Table 4). The incidence of sensitivity of uro-pathogens isolated to five antibiotics routinely used to treat UTI infections are shown in (Table 5). *E. coli* as the predominant cause of UTI, showed low percentage resistance to ciprofloxacin in 25.0% , ceftazidime in 25.0% and the lowest resistance to ceftriaxone in 20.0%. *Enterobacter* spp. displayed a similar resistance pattern and were susceptible to ciprofloxacin and cotrimoxazole in 80%, respectively. Between 60-80% of *Pseudomonas aeruginosa* and *Enterobacter* spp. were susceptible to ceftazidime, streptomycin, ciprofloxacin, ceftriaxone and cotrimoxazole, while 4(66.7%) *Streptococcus pyogenes*, 6 (66.7%) CON-*Staphylococcus* spp and 4(66.7%) *Serratia marcescens* were sensitive to ceftazidime. All the *Enterococcus faecalis* and *Klebsiella* spp. isolated from post-menopausal women with UTI were sensitive to ciprofloxacin (Table 5). 13 (28.9%) out of 45 Gram negative bacterial species produced extended spectrum betalactamase with *Escherichia coli* producing the highest, followed by *Pseudomonas aeruginosa* 3 (30.0%), while *Klebsiella* spp, *Serratia marcescens and Enterobacter* spp had 1 (25.0%)., 2 (33.3%), 2 (40.0%), respectively.(Table 6). The result also showed that 15 (18.9 %) of the bacteria were resistant to 3 or more antibiotics with MAR index ranging from 0.2 to 0.8 in *Escherichia coli, Staphylococcus aureus* and CON-*Staphylococcus* spp., respectively. *Pseudomonas aureginosa and Enterococcus faecalis* had MAR index ranging from 0.2 to 0.6, while lowest MAR index of 0.2-0.4 was obtained in *Klebsiella* spp. and *Enterobacter* spp (Table 7).

Table 1: Age Groups and Occurrence of UTI among Post –menopausal women

Age / Yrs	No of Samples Collected	No / Percentages (%) Positive for UTI
≤ 50	30	11 (36.7)

DISCUSSION

Mid stream urine samples are among the most numerous of specimens sent for microbiological analysis in order to reduce the morbidity and mortality caused by UTI. Very few data exist concerning UTIs in developing countries, especially among the post-menopausal women in Africa. Microscopic examinations of mid-stream urine samples of post menopausal women with urinary tract infections revealed the presence of epithelial cell, phosphate crystals, pus cell, yeast cells, eggs of *Schistoma haematobium* and red blood cells. The presence of pus cell in mid-stream urine has been recorded by Merila et al. (1987). Occurrence of *Escherichia coli, Serratia marcescens, Enterobacter* spp, *Enterococcus faecalis, Klebsiella* spp. *Pseudomonas aeruginosa,* CON-*Staphylococcus* spp, *Streptococcus pyogenes* and *Staphylococcus aureus* in mid-stream urine samples in this study is similar to the previous reports by Ahmed et al (2000) . *E. coli* was isolated from highest number of cases, followed by *Staphylococcus aureus,* this results is similar with the previous studies by Brosnema *et al.*, (1993); Weber *et al.*, (1997) ; De-Mouy et al (1999); Ahmed et al (2000); Gupta et al (2001); Hryniewicz et al (2001); Hima-Lerible et al (2003). The frequency of occurrence of *Klebsiella* spp obtained from the mid-stream urine samples in this study is lower than the values obtained by Randrianirina et al. (2007).

There was occurrence of UTIs among post meno-pausal women with age less than or equal to 50 to age greater than or equal to 60. The occurrence of UTI among women above 60 years have also been recorded by Randrianirina et al (2007). The age distribution of UTIs among post meno-pausal women showed that the highest carrier rate was in the age group of 56-60 years (48.6%), and lowest among aged ≥ 61years .This result suggest that UTI is not an age moderated disease or infection.

The prevalent pathogens of UTIs have been found to be resistant to most chemotherapeutic agents, though the antimicrobial susceptibilities of these pathogens are highly predictable. Development of resistance to these antimicrobial agents in UTI cases will therefore affect future treatment and management of the infection with these drugs. Majority of the treatments begins or is done completely empirically, the knowledge of the organisms their epidemiological characteristics and their antibacterial susceptibility is therefore mandatory.

The isolated bacteria were resistant to streptomycin. This observed resistance to these drugs is a probable indication of earlier exposure of the isolates to these drugs. Shittu and Mandare (1999) in slight contrast to this study, reported *S. aureus* as 100% sensitive to cephalosporins**.** The high sensitivity of *Staphylococcus aureus, E. coli* and *Pseudomonas aeruginosa* to ciprofloxacin in this study is similar to the valued obtained by Ehinmidu (2003). The resistant of *Staphylococcus aureus* and *E. coli* to streptomycin in this study is in agreement with the result obtained by Ehinmidu (2003). Randrianirina et al (2007) reported the resistance to of uro-pathogens to third-generation cephalosporins and ciprofloxacin and this is in conformity with this study.

Multiple-antibiotic resistant bacteria are important pathogens and commonly express ESBL enzymes belonging to the SHV family; encoded by blaSHV genes (Jones et al., 2005). Many reports from different countries and regions have showed different prevalence rates of ESBLs producing *Enterobacteriaceae* causing urinary tract infections**.** The occurrence of ESBL-producing *Klebsiella* spp and *E. coli* in this study is similar to the results of Jones et al. (2005) and Ktari et al. (2006). Genes encoding

ESBL such as blaTEM, blaSHV, and blaCTX-M are usually located on conjugative plasmid. The increasingly prevalent of Extended-spectrum B-lactamases producing *E. coli* bacteria have been also reported (Naas et al., 2007; Akinjogunla et al., 2010). The prevalence of ESβL-producing isolates among the post menopausal women may be presumably due to overuse of some antibiotics resulting in selective pressure on new types of betalactamase antibiotics most especially cephalosporins. The production of extended spectrum β- lactamase (ESBL) among *E. coli* and *K. pneumoniae* also contributed significantly to the resistance of these isolates (Jenks *et al*., 1995). Multiple antibiotics resistance (MAR) index is a tool that reveals the spread of bacteria resistance in a given population (Krumpermann, 1983). An MAR index greater than 0.2 implies that the strains of such bacteria originate from an environment where several antibiotics are used. The MAR indices obtained in this study is similar to the valued obtained by Ehinmidu (2003), and this shows that a very large proportion of the bacteria isolates have been exposed to several antibiotics. Moreover these differences in sensitivity profile of the bacteria isolated may be attributed to practices of self medication, the drug abuse and indiscriminate misuse of antibiotics among the post-menopausal women, which has favoured the emergence of resistance strains.

In conclusion, therapy against UTIs should be guided by antimicrobial susceptibilities as increasing numbers of urinary isolates are developing resistance to commonly use antibiotics. Increasing antimicrobial resistance of uropathogens has led to reconsideration of traditional treatment of recommendations in many areas. This retrospective study should be followed by a multicentre study on antimicrobial resistance among post-menopausal women in Uyo and other regions as there is no data concerning the antibiotic susceptibility spectrum of bacteria isolated from Post-menopausal women with UTIs in South-South part of Nigeria have been published to date.

Morphology And Wall Structure Of Some Turonian Rudists (Bivalvia, Hippuritoida) Of Gabal Yelleg, Northern Sinai, Egypt

Hosni Hamama

Geology Department, Faculty of Science, Mansura University, Mansura 35516, Egypt
hamamahem@hotmail.com

Abstract: The Turonian succession exposed at the northern extremity of Gabal Yelleg at Northern Sinai yields many rudists. Most of these rudists exhibit polymorphism. Identification, systematic, wall structure and the biostratigraphy of the rudists are made. Rudists encountered are found to belong to: family RADIOLITIDAE Gray, 1848 which includes species related to subfamily RADIOLITINAE Gray, 1948: *Radiolites* cf *polyconilites* Orbigny, *Radiolites peroni* (Choffat), *Radiolites sauvagesi* (d'Holmis-Firmas), *Gorjanovicia costata* Polsăk and *Praeradiolites biskraensis* (Coquand); subfamily BIRADIOLITINAE Douvillé: *Milovanovicia heraki* Polsăk 1968; Subfamily SAUVAGESIINAE Douville´: *Suvagesia sharpie* (Bayle), *Durania* gaensis (Dacque), *Suvagesia nicaisei* (Coquand), *Durania barakatensis* nov. sp, *Durania cornupastoris* (Des Moulins) and *Durania arnaudi* (Choffat) and subfamily LAPEIROUSIINAE Kühn: *Lapeirousella aumalensis* (Douville´). From the family HIPPURITIDAE Gray, 1948 only species *Hippurites (Hppuritella)* cf. *castroi* Vidal was identified. One species among the rudists of Gabal Yelleg is suggested as new species: *Durania barakatensis* nov. sp. Fourteen thin sections representing the described Turonian rudists were prepared to study the wall structure of rudists, and the evaluation of such structure in classification of the studied rudists is discussed.
[Hosni Hamama. **Morphology And Wall Structure Of Some Turonian Rudists (Bivalvia, Hippuritoida) Of Gabal Yelleg, Northern Sinai, Egypt**. Journal of American Science 2010; 6(12):1682-1701]. (ISSN: 1545-1003). http://www.americanscience.org.

Key words: Turonian rudists, Bivalvia, Hippuritoida, Gabal yelleg.

1. Introduction:

General view:

Ghorab (1961) divided the Upper Cretaceous in Ras Gharib oil field into five formations, namely: Raha Fm., Abu Qada Fm, Wata Fm., Matulla Fm. And Sudr Chalk. Moon and Sadek (1921) studied the Cretaceous succession exposed at Gabal Yelleg starting from the Lower Cretaceous to the Campanian and Maastrichtian forming the ground of Gabal Yelleg.

Omran, A. M. (1997) divided the Upper Cretaceous succession of Wadi Um Said in the southeastern flank of Gabal Yelleg into Halal Fm. (Cenomanian), Wata Fm. (102.8m, Turonian), Matulla Fm. (63m, Coniacian- Santonian) and Sudr Chalk (77m, Campanian).The lower part of the latter formation, the Markha Member (40m) was assigned to Campanian and the upper part, the Abu Zenima Member (30.8m) was related by Omran to the Masstrichtian.

El-Sabbagh and El-Hedeny (2003) recorded seven radiolitids from the Upper Turonian of the Acteonella Series of Abu Roach. Theses are *Durania cornupastoris* (Des Moulins), *D. gaensis* (Dacque), *D. humei* (Douville´) *Lapeirousella aumalensis* (Douville') *Sauvagesia sharpei* (Bayle) and *S. toucasi* Pamouktchiev and *S. nicaisei* (Coquand).

Abdel-Gawad et al. (2004) recorded four species of rudists from Gebel Yelleg: *Praeradiolites irregularis* Douville´, *Durania arnaudi* (Choffat) and *Praeradiolites ponsianus* (d´,Archiac) from the Middle Turonian, Wata Formation, and *Eoradiolites liratus* (Conrad) from the Lower Cenomanian, Galala Formation).

Aly et al. (2005) identified 17 rudist species from the Cenomanian –Turonian rocks (Halal Fm. and Wata Fm.) of northern Sinai in sections of Gabal El-Minsherah, Gabal Yelleg and Gabal Maaza. These species belongs to genera: *Eoradiolites, Radiolites, Praeradiolites, Distefanella, Bournonia, Durania* and *Ichthyosarcolites.* The geological map of the Gabal Yelleg is given in (Fig. 1) after Omran, A. M. (1997).

In the present work a section was measured representing the topmost part of the Upper Cretaceous succession exposed at the northern flank of Gabal Yellig. A brief description of the measured section is given in (Fig.2):

Lithostratigraphy:

A section of about 130 meters of the Wata Formation was measured and divided into 18 beds. The lithology is mainly represented by marls and limestone and their intercalations. Marl and little shale, dominate the lower part of the section and limestone is the essential component all over the section. The limestone becomes gradually chalky toward the top of the section until it becomes entirely

chalk in the topmost part. Many rudist lisothsomes are encountered from which rudists are collected for this study. A bed of variegated sandstone attaining 3 meters in thickness found in the middle of the section is used as a marker bed. Accordingly, the section is tentatively divided into Lower Turonian and Upper Turonian. The top of the section consists of the chalk which probably related either to the Wata Formation or to the above formation.

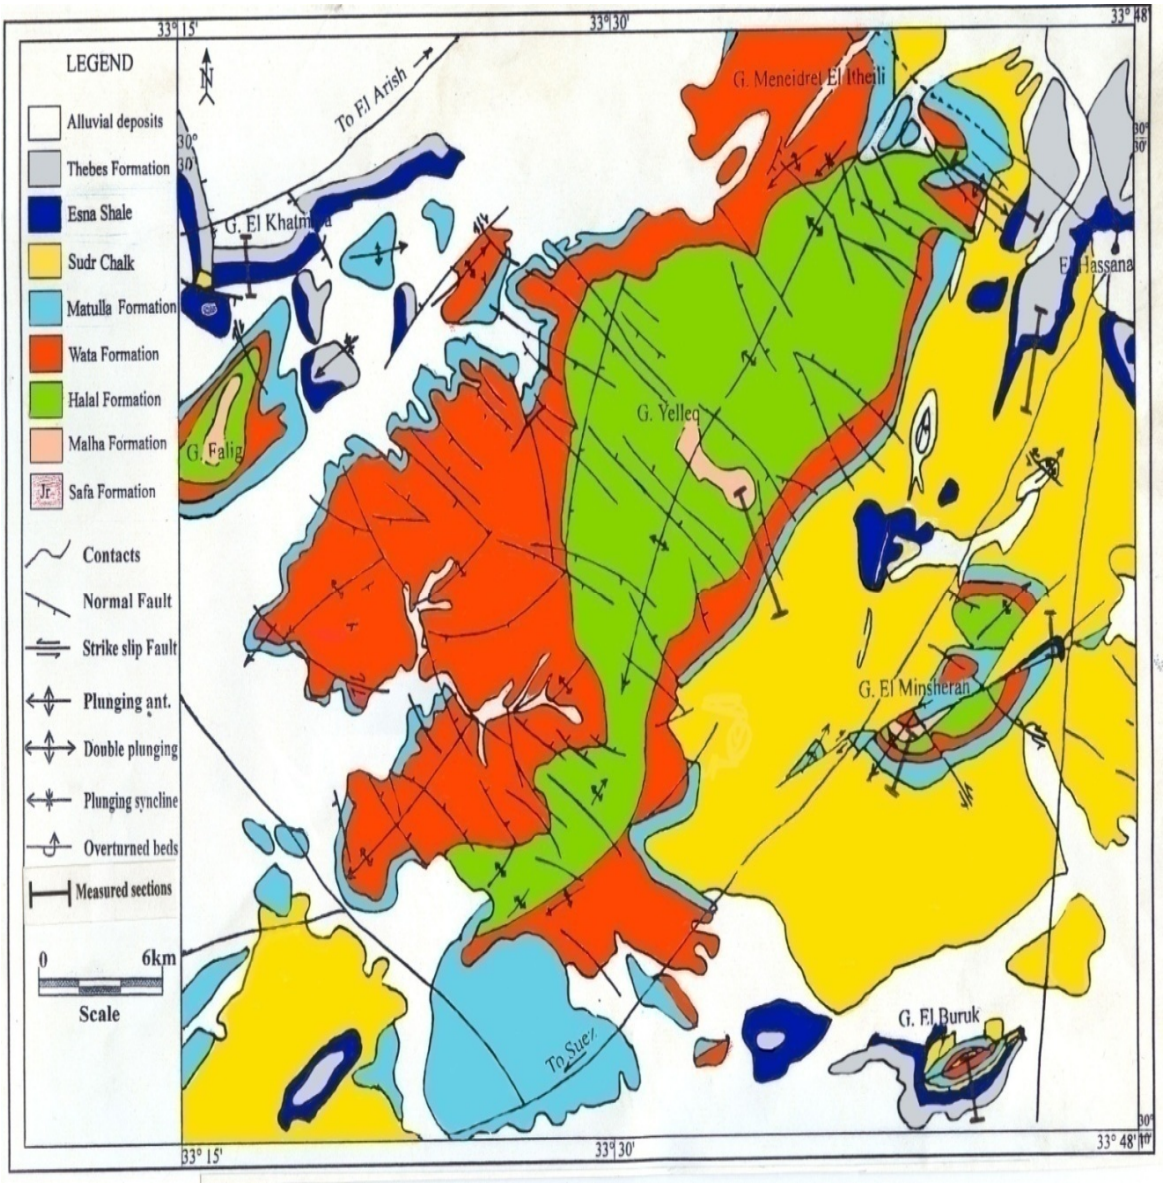

Fig (1): Geological map of Gabal Yelleg (After Omran, A. M. 1997)

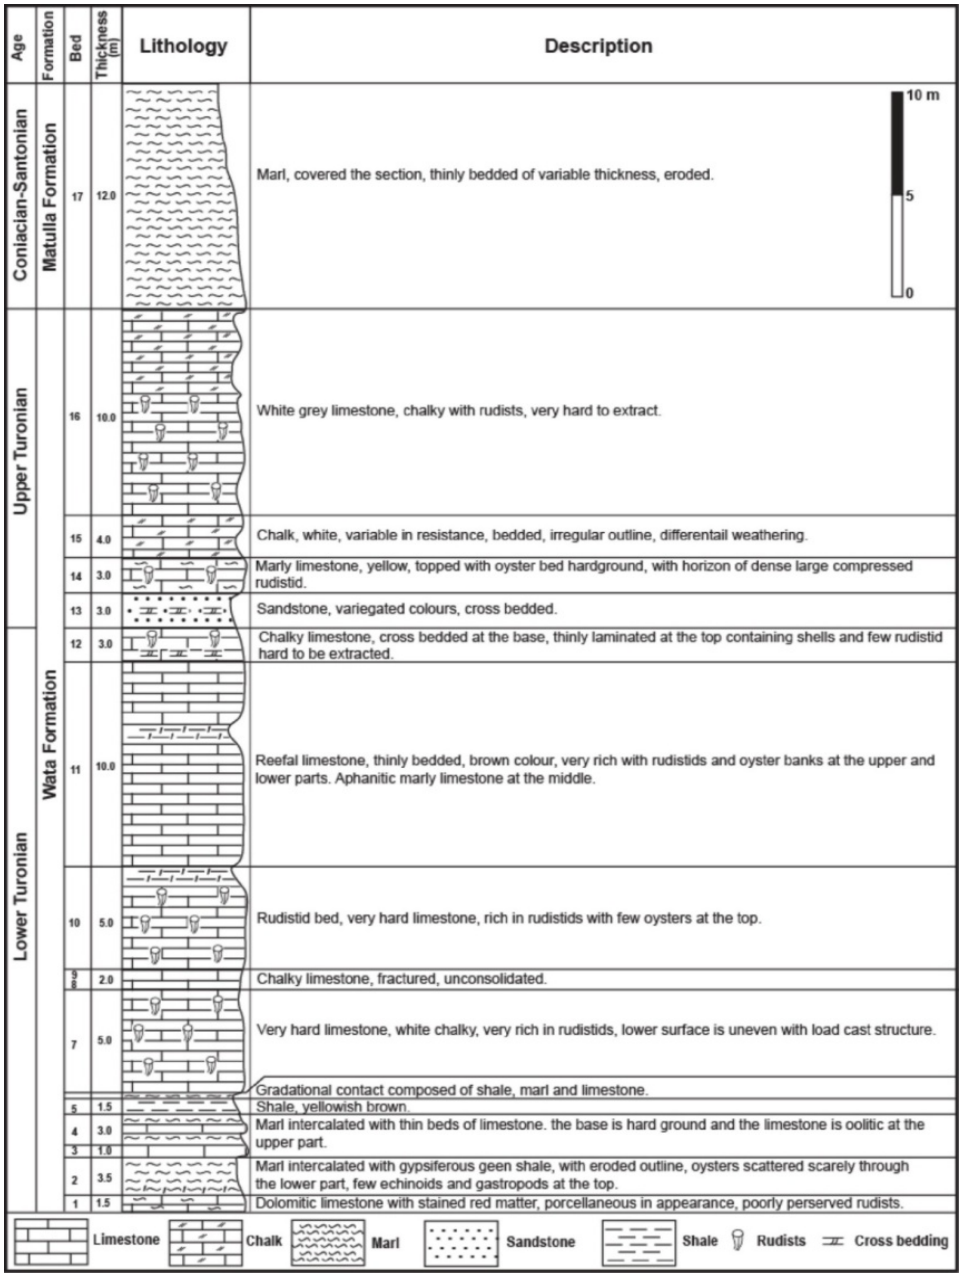

Fig (2): Stratigraphic column of Turonian succession at Gabal Yelleg, north Sinai, Egypt.

2. Materials and methods:

The shell of radiolitids consists of a hypostracum of aragonite and an ostracum of calcite (Zapfe 1937; Kennedy & Taylor 1968; Amico 1978; Cestari & Sartorio, 1995). In the attatched valve (AV) of most radiolitids, three outer layers of ostracum and an inner layer of hypostracum can be distinguished (Sanders, D. &Pons, J.M. 1995 & Sanders, 1999). Sanders recognized three layers in the wall of radiolitids: **(1)** an outermost ostracal layer of delicate calcite lamellae**, (2)** a thick layer of 'boxwork ostracum' built of radial funnel plates and cell walls, **(3)** a thin, inner 'ostracal layer **3'** of thick-walled boxwork, and **(4)** the hypostracum that formed the innermost shell layer (Fig. 3 after Sanders, 1999).

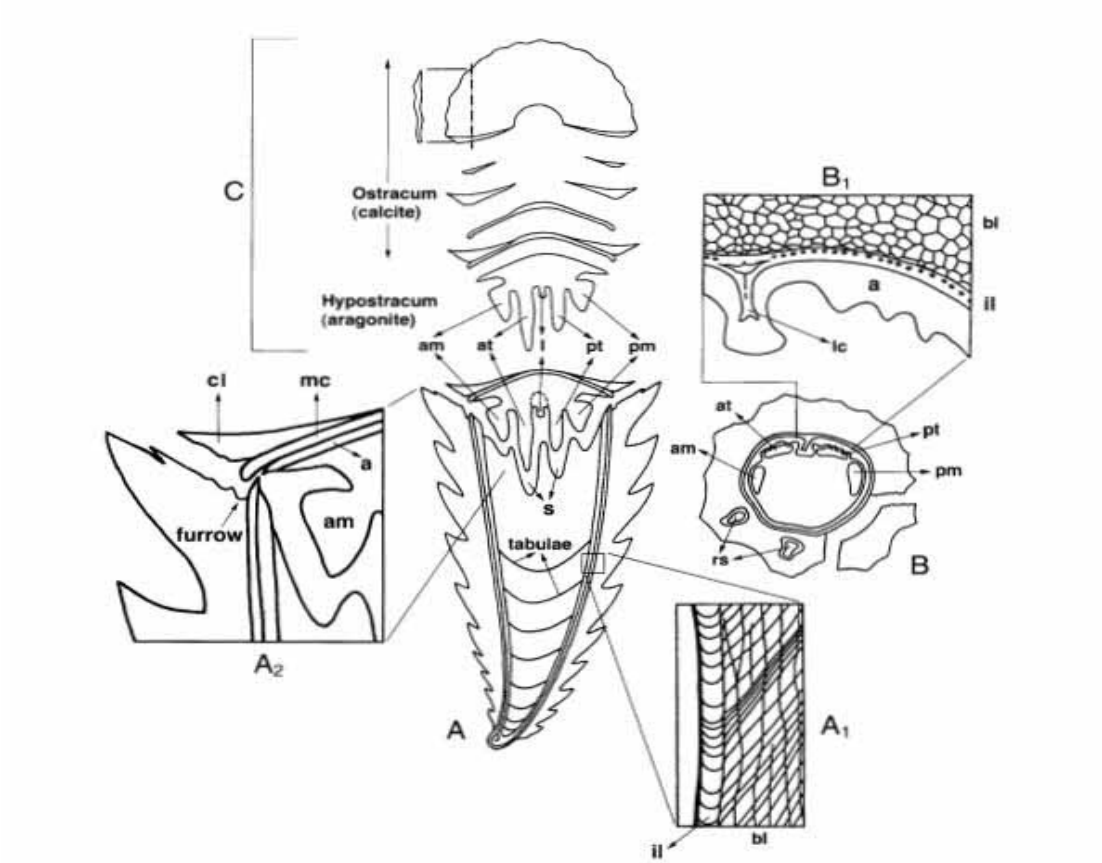

Fig (3): Main features of radiolitid shell (after Sanders, 1999) with some abbreviations: (s) socket; (am) anterior myophore; (pm) posterior myophore (at) anterior tooth; (pt) posterior tooth (L) ligament; (il) inner layer; (bl) thick outer layer of thin-walled boxwork; (a) the aragonitic hypostracum; (mc) layer of massive calcite; (rs) radial structures; ligamentary crest (lc).

The terminology used in description of rudistids in this paper is used after Moore (editor) in the Treatise on Invertebrate Paleontology- Mollusca, vol. 2, 1969, after Yanin, B.T. (1989).

Size: Concerning the size of the mature individuals, the scale proposed by Yanin was accepted, where:
Height (length) Small: up to 5cm; Medium: 6-10 cm, Large: 11-20 cm and Very large: 21-30cm. Bar in all text-figures equals 1mm.

Orientation**: AV:** attached valve**; FV:** free valve.

Ligamental Structures:

Ligamental groove**: (**Ligamental zone**,** LB**)** or furrow on the exterior of the shell on the lateral cardinal side of the lower valve.

Ligamental cavity**:** within the shell wall**.**

Ligamental ridge or pit on the interior of the shell.

L: Ligamental crest (truncated, small truncation and rounded).

Siphonal Structures (pillars, bands, pseudopillars, fossettes, and oscules):

Sp: first pillar

Ep: second pillar

Sb, **Eb**: siphonal bands (smooth, shallow depresses areas) in posterior-lateral side corresponding **S** and **E**.

Es and **Ss**: pseudopillars.

Myophore**:** am and pm, anterior and posterior myophore.

The material is deposited in the Geological Museum of Faculty of Science- Mansura University, Egypt.

SYSTEMATIC PALAEONTOLOGY

Class: BIVALVIA

Order: HIPPURITIDA Newell, 1965

Suborder: HIPPURITINA Newell, 1965

Superfamily: HIPPURITOIDEA Gray, 1848

Family: HIPPURITIDAE Gray, 1848

Genus *Hippurites* Lamarck, 1801

Type species: *Hippurites biloculata;* M

***Hippurites* (*Hppuritella*) aff. *castroi* Vidal (pl. 3, fig. 3)**

1960 aff. *Orbingnya vlasovi:* Bobkova, p. 117, pl. 25, fig.3

1977 *hippurites* (*Hppuritella*) *castroi* Vidal: Pons, pl. X

1989 aff. *Hippurites vlasovi* (Bobkova): Yanin, Pl. XIV, Fig S. 3-6.

Dimensions (mm)**:**				
Specimen no	Length	Width	Diameter opening	wall thickness
……29	61.50	25.40	30.30	?
…….. .30	72.00	22.10	22.10	7.50

Description:
Shell medium sized, LV curved cone to sub cylindrical form, wall thick; transverse section circular; surface covered with numerous longitudinal rounded smooth thin ribs, ribs regularly spaced forming network; anterodorsal aspect, growth laminae crowded in the lower part of the attached valve and widened near the commissure, at posterodorsal aspect four narrow concave siphonal bands and raised interbands having the same thickness as the bands.
Remarks: The described specimens has some affinity to *Hippurites vlasovi* (Bobkova, 1960), but the latter species is vey large and found in a higher stratigraphic level (Maastrichtian).
Locality: beds 15 & 16, Wata Formation, Upper Turonian, Gabal Yelleg.

Family: RADIOLITIDAE Gray, 1848
Subfamily RADIOLITINAE, Gray, 1848
Genus : *Radiolites* Lamarck. 1801
Type species: *Ostracites angeiodes* Picot De Lapeirouse, 1781

***Radiolites* cf. *polyconilites* Orbigny.**
(pl.1, fig.7)
1851: *Radiolites* cf. *polyconilites* Orbigny, pl.547, fig. 3 &4.
Material: one specimen of AV.

Dimensions:	Length (mm)	Width (mm)	commissural diameter	wall thickness
Specimen1.	87.82	22.22	36.50	?

Diagnosis: Horn-shaped AV, smooth with a triangular tooth and two coma shape sockets to receive the teeth of FV; concave radial bands and elevated ligamental ridge in between.
Locality: Gabal Yelleg, bed 1, Lower Turonian.
Geographic distribution: Cretaceous France; Cenomanian, Mexico.

***Radiolites peroni* (Choffat, 1886)**
(pl.1, figs.1a-b & 2)
1886 *Spheriolites peroni*: Choffat, p.33, pl. V, fig. 1-8.
1974 *Radiolites peroni* (Choffat): Atabican & Babkova (in Atlas fauna Azerbaijan), p.220, pl. 116, fig.3.
1981 *Radiolites peroni* (Choffat): Tzankov, p. 183, pl. XCII.
Material: 8 well preserved specimens of AV.

Dimensions:	Length	Width	commissural diameter	wall thickness
Specimen no.2	70.00	37.00	35.00	5.30
……..…..3	50.60	23.00	26.60	9.00
……4	52.80	21.18	24.68	5.70

Diagnosis: conical and horn-shaped AV, deep growth layers, irregular polygonal and vermiform cells, siphonal fossetes structures.
Description: Av medium size, elongate, curved cone, wall very thick, transverse section globular; external surface covered with thick raised folds, zigzag wavy growth laminae; external surface ornamented with longitudinal interrupted sharp ribs; siphonal zones large wide bands. Siphonal furrows longitudinal shallow. Wall structure with compressed elongate vermiform and smaller granular cells and fasciculate aspect (fig.4a-c)
Remarks: the described specimens differ from those identified by Aly *et al.* (2005) as *Eoradiolites sinaiticus* Douvillé: (pl.1, figs. 1-3) by their small size, coarse ribbing and development of fossetes siphonal structures of the outer layer; however a similarity in wall structure is sometimes obvious**.**
Locality: Gabal Yelleg, Wata Formation, bed 7, Lower Turonian.
Geographic distribution: U. Cenomanian: Middle Asia, Portugal, Libya, Egypt, Syria, Azerbaijan, Tajikistan, Little Caucasus; U. Cenomanian - L. Turonian: South France, Albania, Tunisia, Egypt, Iran, Karakorum; U. Cenomanian and L. Turonian: Albania, Tunisia, Egypt, Iran, Little Caucasus; Lower Turonian: Portugal, Armenia, Azerbaijan; Turonian: Albania; U. Turonian: Bulgaria, Romania, Greece, Tunisia, Iran, West China. Upper Cenomanian and Lower Turonian Azerbaijan, Upper Cenomanian Tadzhikistan, Lower Turonian Portugal, Upper Cenomanian – Lower Turonian south France, Albania, Tunisia, Egypt, Iran, Karakorum.(Ali-Zade,1988).

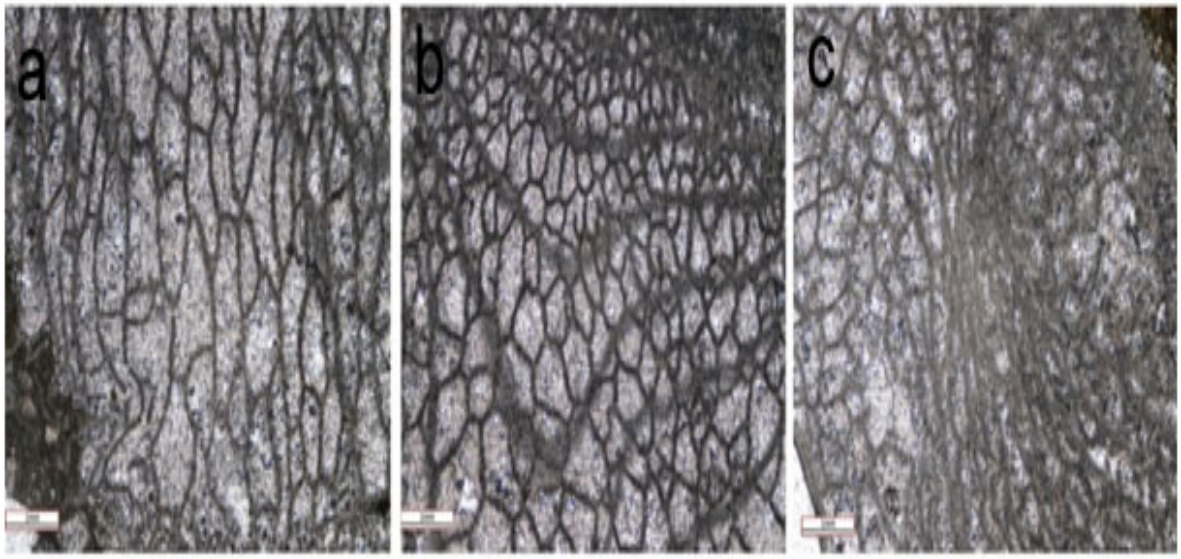

Fig (4) Transverse section in *Radiolites peroni* (Choffat, 1886): a- vermiform elongated cells; b- wavy plates and cellular polygons; c- siphonal fossetes structures. Bar equals 1mm.

2009: *Radiolites sauvagesi* (d´Holmis - Firmas); Gil, *et al*., p.533, fig.6
Material: 10 specimens.

Dimensions:	Length	Width	commissural diameter	wall thickness
Specimen no 5	99.70	39.22	39.22	11.20
…….6	5 0.40	39.60	39.60	12.30
……7	52.00	40.10	39.80	15.20

Diagnosis: dense growth laminae, horn and cylindrical shape, high amplitude wavy plates and closed funnels.
Description: Av medium size, conical and subcylindirical, thick recrystallized wall; transverse section circular; external surface covered with dense wavy zigzagged growth laminae; siphonal bands smooth, concave toward the commissure, Es and Eb well developed, Eb wider than Es., pentagonal cells and closed elliptical funnels of the outer shell layer (fig. 5).
Locality: Gabal Yelleg, Wata Formation, bed 7, lower Turonian.
Geographic distribution. The species was recorded from higher stratigraphic levels than the Turonian.

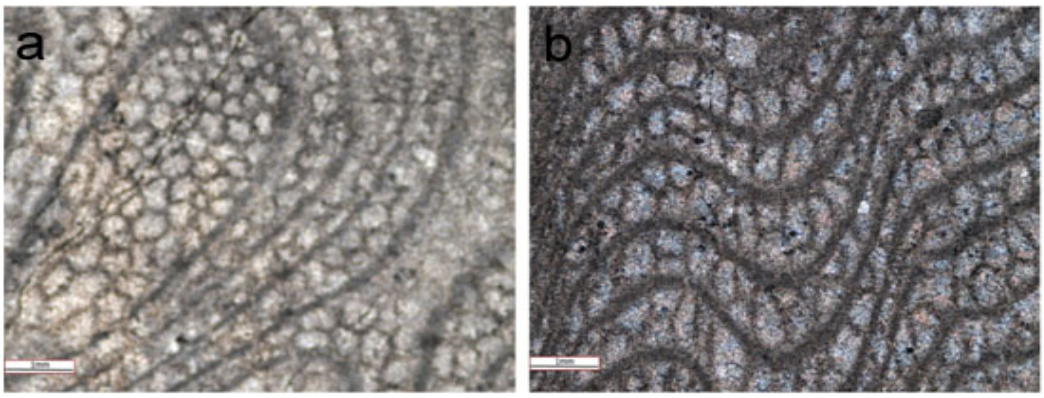

Fig (5) Transverse section of *Radiolites sauvagesi* (d´Holmis-Firmas): a- elliptical funnel plates; b- . ,nm, hz

Genus: *Gorjanovicia* Polsăk, 1968
Type species: *Gorjanovicia costata;* OD.
Gorjanovicia costata Polsăk, 1968
(pl.1, fig. 6)
1960: *Gorjanovicia costata* Polsak: Moore R.C. (ed.); Part N, vol. 2/3, Mollusca 6, N 808, fig E268-
Material: Tow well preserved specimens.
Dimensions: Length (89.66) Width (28.20), commissural diameter (20.50), wall thickness (8.30), specimen no 8.
Diagnostic feature: compressed subcylindirical Av, network of the outer shell layer composing of uniform rhombohedral cells, slightly undulation of plates.
Description: Av medium sized, thick-walled, elongate, cylindrical-conical, slender, slightly impressed with long dimension normal to the commissure and extending from the apex of the valve to commissure; longitudinal ribs salient, ribs thin and inter- ribs regularly spaced and relatively broad and deep, with fine zigzag growth layers, pointed upward; siphonal zones well developed Sb and Eb and Sb concave broader, both with dense flat laminae; ligamental groove in the exterior of the shell, very narrow pit on the interior of the shell; network of the outer shell layer composing of uniform rhombohedral cells; laminae with a definite pattern of arrangement of repetitions of two or three narrow spaced layers followed by fine distant layers crossed by muri; inner layer thin with fragments of disaggregate rod-like spines (fig. 6).
Remarks: The rhombs of the network differentiate the described specimen from the lamellar structure shown in *Sauvagesia nicaisei* (Coquand) figured by El-Sabbagh & El-Hedeny (2003, pl. 7, fig 2. Also the internal structure of *Praeradiolites* cf *irregularis* Douvillé described by Aly et al (2005) is similar to the present species; both are quite different morphology.
Locality: Gabal Yelleg, bed 11, Wata Formation, Lower Turonian
Italy, Yugoslavia and Turkey.

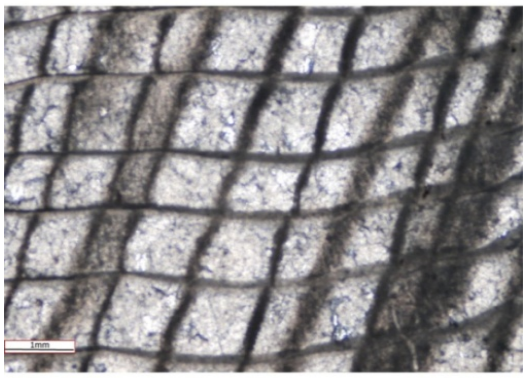

Fig (6) Transverse section of *Gorjanovicia costata*: compact rhombohedral network.

Praeradiolites Douvillé, 1902
Type species: *Radiolites fleuriaui* d´Orbigny, 1842
***Praeradiolites biskraensis* (Coquand, 1880)**
(pl. 3, fig. 1)
2004 *Praeradiolites biskraensis* (Coquand): Abdel-Gawad et al., p.292, pl.9, fig.1.
Material: one well preserved AV.

Dimensions:	Length	Width	commissural diameter	wall thickness
Specimen no 9	88.82	47.66	44.52	9.52

Diagnosis: Strong longitudinal regular folds, concave bands and prominent ridge.

Description: Attached valve (AV) medium size, conical shape, thick recrystallized wall, broad-rounded posterior margin and very narrow anterior margin; surface coarsely reticulate, ornamented with strong longitudinal regular folds, nearly 16 ribs pre diameter 20.5mm assuming bundle- shape of longitudinal digits, unequally spaced, condensed and sharp in early stage and large and divergent near commissure; growth laminae regularly spaced and crowded as growth proceeds ; growth laminae covered the surface, concave upwards at the ribs and convex downward in inter-ribs; siphonal furrow shallow longitudinal slit bounded by rounded raised prominent siphonal ridge; internal shell cavity narrow ellipse, anterior myophore (ma) large kidney- shaped tangent the inner wall, posterior myophore (mp) inclined at the inner wall.

Locality: Wata Formation, bed13, Upper Turonian, Gabal Yelleg.

Locality: Gabal Yelleg, Wata Formation, bed 7, Lower Turonian.

Subfamily SAUVAGESIINAE, Douvillé, 1908

2004 *Durania gaensis* (Dacqué): Abdel-Gawad *et al.*, p. 292, pl.9, fig.6.

Dimensions:	Length	Width	commissural diameter	wall thickness
Specimen no 20	88.82	47.66	44.52	9.52
……21	75.80	38.40	45.20	10.90
…….. …..22	77.10	31.4	48.90	14.20

Description: AV vase shape, conical to subcylindirical, shell beginning very narrow, after that increases by continuous accretion gradually during growth; radial bands deeply concave, very narrow, with fine chevrons, 5 in number, interband bud-shaped, broader than the bands; external surface ornamented with folded branching laminae; thick of regular polygons,, radial bands mostly with hexagonal polygons, ligamental pit in the interior of the shell (fig. 10)
Locality: Gabal Yelleg, bed 11, Wata Formation.

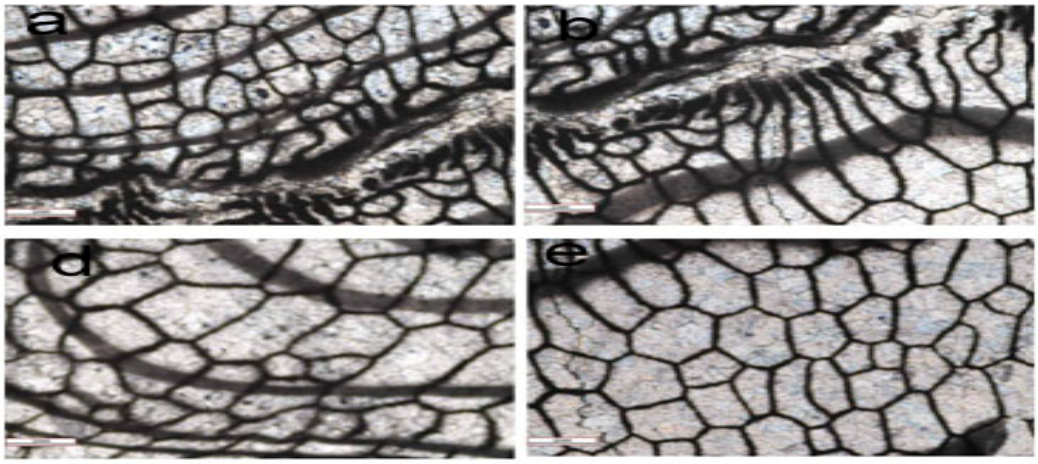

Fig (10): transverse section of *Durania gaensis* (Dacqu`) showing free muri (a &b) ending in subcircular bores, pentagonal, hexagonal or more faces and curved laminae (c & d).

Durania cornupastoris (Des Moulins)
(pl.3, fig. 3a-c)

Material: One good preserved specimen of AV.

Dimensions:	Length	Width	commissural diameter	wall thickness
Specimen no 23	82.20	16.20	34.80	9.4019

1969: ***Durania cornupastoris (***Des Moulins): Moore (editor), Mollusca 6, N.813, fig. E 272, 4.
2003: ***Durania cornupastoris (***Des Moulins): El-Sabbagh & El-Hedeny, pl.1, fig. 1-4.
Description: AV conical, curved, medium sized; transverse section oval; external wall ornamented with fine widely spaced ribs, inter ribs flat to slightly concaved; growth layers zigzagged with chevrons in the inter ribs and inverted chevrons across costae; ribs coarse in the ventral aspect; Siphonal bands Sb and Eb finely costulate, cells hexagonal in siphonal bands, normal the commissure, laminae folded (8 crenulations) in the outer part of the outer layer (fig. 11)
. **Locality**: Gabal Yelleg, Wata Formation bed 14, Upper Turonian.
Geographic distribution: Upper Turonian in the Tethyan Province.

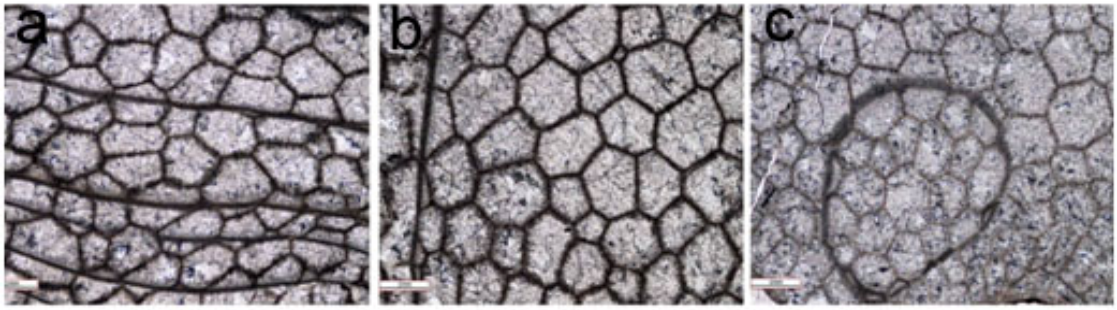

Fig (11): Transverse section of *Durania cornupastoris (*Des Moulins) showing: a-shell outer layer and superposed lamellae, b- one siphonal band with compact polygons (6-7 faces), c- ligamental pit.

Durania arnaudi (Choffat, 1891)
(pl.4, figs. 3-8 & 10-11)

1891 *Durania arnaudi:* Choffat, pp.203, 210 and 211.
1901 *Biradiolites arnaudi*: (Choffat); p. 138, pl. VI & pl. VII.
2004 *Durania arnaudi* (Choffat), Abdel-Gawad et al. p.289, pl 9, figs 4-5.
2005 *Durania arnaudi* (Choffat), Aly et al., p. 273, p. 10, Fig. 9.

Material: Ten complete and fragments of AV.

Dimensions:	Length	Width	commissural diameter	wall thickness
Specimen no 24	30.00	24.00	24.00	0.80
……25	26.00	25.oo	25.00	0.80
…… 26	55. 70	20.20	22.00	0.50
…… 27	71.90	30.00	38.00	0.70

Description: Shell medium sized, according shape three forms are presented: typical cylindrical, conical with curved anterior part and rounded commissure, conical with elliptical commissure; surface covered with sharp fine rounded radial uniform ribs with flat to slightly concave smooth inter-ribs; wall relatively thick, crystallized with finger print – like; ligamental cavity within the shell wall and ligamental ridge in the interior of the third mentioned form (fig. 12) and (pl. 4, fig.7b); siphonal structures with well developed Eb and Sb bands, the bands deeply concave separated by raised interband (ib).

Remarks: The conical form with broad commissure is similar to *Durania cornupastoris* (Des Moulins) described by El-Sabbagh & El-Hedeny (2003) in plate1, fig 2&4 from the Upper Turonian of el-Hassana Dome in Abu Roach area, but our mature shells are smaller in size. On the other hand, the typical cylindrical form is a typical the same species figured by Abdel-Gawad *et al.*, (2004) from the Middle Turonian of Gebel Yelleg and those of Aly *et al.* (2005) from the Turonian of the same locality.

Locality: Gable Yelleg, bed 11, Wata Formation, Lower Turonian.

Geographic distribution: Tethyan Province.

***Durania humei* Douvillé 1913**

(Fig. 13)

1913 *Durania humei*: Douville, p.254, pl.16, figs. 3-5

2004 *Durania arnaudi* (Choffat, 1891): Abdel-Gawad et al., p292, p. 9, fig.4-5.

Material: Two specimen of AV.

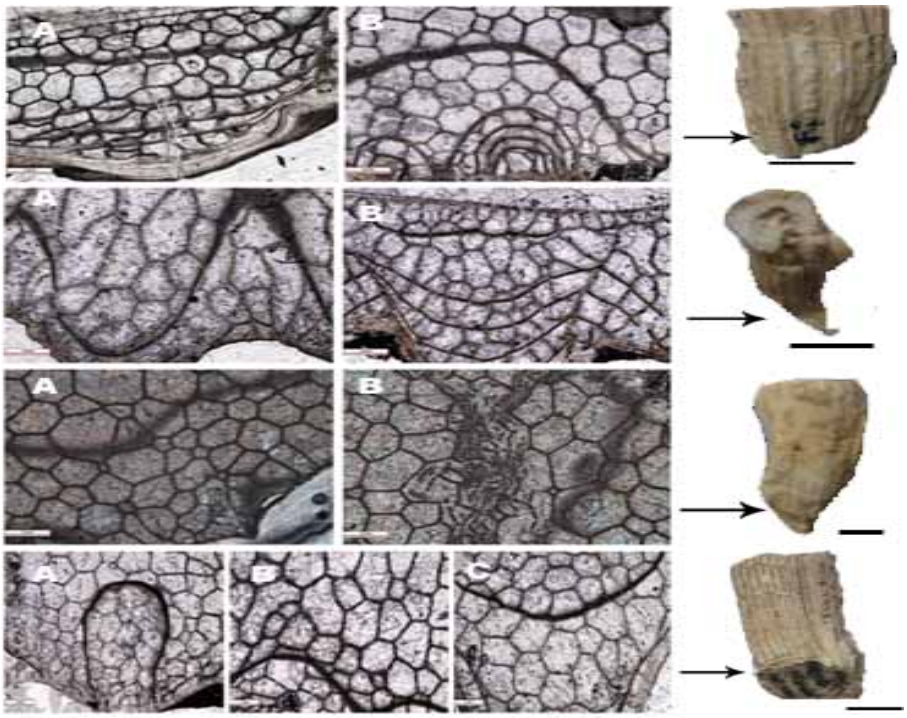

Fig (12) Transverse sections of *Durania arnaudi* (Choffat, 1891): first row- typical cylindrical form with radial structure (rs) in the outermost ostracal layer; second row- conical form showing the sockets for the teeth of the FV and ligament in between; third row-conical form with elliptical commissure showing relic shell by sapling of the ostracal layer; fourth row- typical cylindrical form showing the ligamentary crest (lc), with the hypostracal, aragonitic shell layer (a) indicated.

Dimensions LV (mm):				
Specimen no 29	Length	Width	commissural diameter	wall thickness
	62.00	40.5o	42.50	36.00

Diagnosis: Ligamental groove, deep narrow siphonal bands and different number in faces of polygons.
Description: Av conical shape, wall thick; surface covered with dense thin radial ribs; siphonal bands deep and narrow, Eb slightly deeper , interband broad, raised and broader than bands; presence of ligamental groove, pentagonal-hexagonal and pentagonal polygons, some cells oblique and normal to axial radial lamminae and the others parallel to lamminae (fig. 13).
Locality: bed 7, Wata Formation, Lower Turonian, Gabal Yelleg.

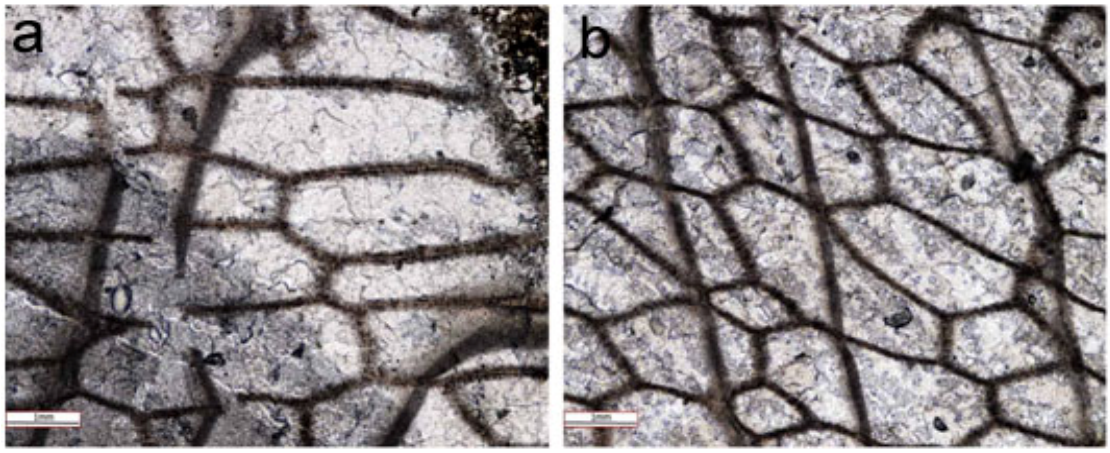

Fig (13): Transverse section of *Durania humei* Douvillé showing: a- elongated polygonal cells; b- polygons oblique to the siphonal bands.

2003 *Lapeirousella aumalensis* (Douvillé):El-Sabbagh & El-Hedeny, p. 250, pl. 2, figs. 3-4.
Material: 10 specimens deformed perpendicular to commissure.

Dimensions:	Length	Width	commissural diameter	wall thickness
Specimen no 30	90.00	50.00	50.00	10.00

Diagnosis: conical to subcylindrica with more or less regular longitudinal ribs, outer layer with braided and structure surrounding cavities, pseudopillar giving rise to ropy structure.
Description: AV medium to large size, elongate, subcylindrical, slender, deformed; transverse section elliptical shape, narrow squeezed; surface of the attached valve covered on the dorsal side with radial straight thin dense similar, longitudinal ribs strong and raised between bands on the ventral aspect; Sb and Eb shallow depressed separated by terraces which covered by radial costae, Eb wider than Sb (fig. 14).
Remarks: the described specimens have some affinity to *Durania bertholoni* Yanin which identified from the Upper Cretaceous of Azerbaijan.(1988, p. 288, pl. XVII, fig. 6, pl. XVIII, fig. 1-3 and pl. XIV, figs. 1-2)
Locality: Gabal Yelleg, Wata Formation, bed 14, Upper Turonian.
Geographic distribution: ? Upper Coniacian of Caucasus, Coniacian of Tunisia, and Turonian of Egypt.

MORPHOLOGIAL VARIABILITY AND SIGNIFICANCE OF WALL STRUCTURE

Cretaceous rudist formations have long been studied with respect to paleontology, sedimentology and diagenesis (e.g. Toucas 1903; Zapfe 1937; Kühn 1967; Skelton 1976, Skelton *et al.* 1995; Bebout &Loucks 1977; Pons 1977, 1982; Enos 1988; Minero 1988; Köch et *al.* 1989; Ross & Skelton 1993; Sanders 1998a; Sanders & Baron-Szabo 1997; Sanders ***et*** *al.* 1997; Sanders & Pons 1999.

In general radiolitids demonstrate wide intraspecific morphological variability (Gill, *et al.*, 2009; Senders, 1999; El-Sabbagh and El-Hedeny, 2003). Such variability markedly appears in rich assemblage, as the number of species and individuals increase the variability is well demonstrated. Concerning the studied specimens the some remarks of the variability in form and ornament are observed in the following species:

1- *Radiolites peroni* (Choffat, 1886): Two forms are recorded: horn and conical form with well developed concave tabulae and branched muri. The outermost ostracal layer is not preserved, it may be disintegrated. A thick layer of 'boxwork ostracum' is built of radial funnel plates and cell walls. The cells take two forms: cellular structure of pentagonal and hexagonal polygons and vermiform structure of elongated polygons with 2mm diameter. Very characteristic is the presence of siphonal fossetes structures (fig. 4).

2- *Radiolites sauvagesi* d'Holmis – Firmas, 1838): There are two forms, horn and cylindrical. Radial funnel plates are well developed, closed funnel is a characteristic feature for this species (fig. 5).

3- *Gorjanovicia costata* Pols˘ak, 1968: A profound feature of this radiolitids is network of the radial bands composing of rhombs of calcite and the narrow interbands (fig. 6).

4- *Milovanovicia heraki* Polsăk 1968: It is very large among all the studied specimens. Its wall is characterized by (a) an outermost thick ostracal layer of delicate calcite lamellae and the ligamental crests (lc). The latter penetrate the inner hypostracum that form the thin inner layer (il). The thick outer layer (bl) has a well developed radial band (rb) and interband (ib). Muri form what look-like ropy structure and the polygons are irregular hexagonal (fig. 7)

5- *Suvagesia sharpei* (Bayle): The cylindrical form is the only recorded form in this species. The Lamellar network and a well defined funnels are well developed (fig. 8).

6- *Durania barakatensis* nov. sp.: It is one of the large species in the rudist assemblage. The main features of the wall are highly laminated hypostracum with ligamental crests, rhombs of calcite, radial lamellae, branching muri, thick outer layer and branching funnels (fig. 9).

7- *Durania gaensis* (Dacqué,1903): The characteristic features of such species include a typical honey bee cellular structure of the inner layer, free muri ending in a vesicular pores and curved radial laminae(fig. 10)

8- *Durania cornupastoris* (Des Moulins): It has broad radial bands of hexagonal polygon and vesicular pore (fig. 11).

9- *Durania arnaudi* (Choffat, 1891): This species exhibits highest variability in form among the identified rudists. Three forms are recognized including conical form with rounded commissure, conical form with elliptical commissure and typical cylindrical form. The aspects include disintegrated laminae in the inner layer (fig, 12)

10-*Durania humei Douvillé* 1913: The large, oblique polygons and the developed radial bands are very characteristic features of the species (fig.13)

Barremian and Aptian Mollusca of Gabal Mistan and Gabal Um Mitmani, Al-Maghara Area, Northern Sinai, Egypt

HOSNI HAMAMA
Geology Department, Faculty of Science, Mansura University, Mansura 35516, Egypt.
hamamahem@hotmail.com

Abstract: A very rich assemblage of 40 Molluscan species was identified from the Lower Cretaceous succession of Gabal Mistan and Um Mitmani lying at the extremity of the northern flank of Gabal Al-Maghara, northern Sinai. These are used to date the investigated material as Barremian and Aptian. Comparison of the Sinai material with coeval deposits in the northern Caucasus and Western Europe signifies a possible direct marine connection between these areas.

[Hosni Hamama. **Barremian And Aptian Mollusca Of Gabal Mistan And Gabal Um Mitmani Al-Maghara Area, Northern Sinai, Egypt**. Journal of American Science 2010; 6(12):1702-1714]. (ISSN: 1545-1003). http://www.americanscience.org.

Keywords: Barremian, Aptian, Albian**,** Mollusca, North Sinai.

1. Introduction

Aim and Material: The stratigraphic boundaries of the Lower Cretaceous chronostratigraphic units are a matter of great deal. Ammonites are used successfully for this achievement. The author focuses attention to delineate the stages of Barremian, Aptian and Albian (Hegab *et al*.; Hamama, 1992, 1993 and 2000). Rich Molluscan specimens were collected by the author during field excursions from the area east of Gabal Lagama at Gabal Mistan and Gabal Um Mitmani. The identified molluscan fauna, especially ammonites were used to subdivide the Barremian and Aptian into substages and to determine some biozones of the Lower Cretaceous succession at the area of study.

Recent detailed important works on the Lower Cretaceous of north Sinai were made by Aboul – Ela *et al.* (1991), Aly, M. and Abdel-Gawad (2001 &2006), Hewaidy *et al.* (1998), Aly, M.(2006), Abu Zied R. H. (2006 & 2008), Mekawy, M. S. and Abu-Zeid, R. H (2008) at Gabal Manzour, Gabal Lagama and Gabal Abu Ruqum. The identity of the identified ammonite species with those of Northern Caucasus and Western Europe is taken as an indication to the presence of a marine seaway which connected North Sinai with Tethyan Province.

Stratigraphy: The measured Lower Cretaceous section of Gabal Mistan and Gabal Um Mitmani (Fig. 1) is represented by the Risan Aneiza Formation. The lower part of this formation consists mainly of sandstones, marls and intercalation of thin limestone beds, whereas the Upper part is composed mainly of marls and limestone with few sandstone intercalation. The Lower part of the succession was named Um Mitmam Member and the Upper part is Manzour Member (Hegab *et al.* (1989), Hamama (1992 & 2009), Hamama and Gabir (2001). The studied Mollusca were collected from Um Mitmam Member.

2. Systematic Paleontology

More than forty five species of ammonites, gastropods, Pelecyopods were identified. All the collected specimens were collected by the author and they were deposited at the Geological Museum of the Geology Department, Mansura University. The systematic of ammonites are adopted after Moore (1996), and for the Gastropods and Pelecyopods we use the systematic of Pcelincev and Korobkov (1960).

AMMONOIDEA
1-Order AMMONOIDEA Zittel, 1848
Suborder ANCYLCERATINA Wiedmann, 1966
Superfamily DOUVILLEICERATACEAE Parona & Bonarelli, 1897
Family DOUVILLEICERATIDAE Parona & Bonarelli, 1897
Subfamily CHELONICERATINAE Spath, 1923
CHeloniceras Hyatt, 1903
C. (*Epicheloniceras*) Casey, 1954a

***C.* (*Epicheloniceras*) *subnodosocostatum* Sinzow, 1954a**
(pl.2, fig. 1a-c)

1907 Kilian: *Douvilleiceras martini* Orbigny, pl. 2, fig. 5.
1915 Nikchitch: *Douvilleiceras seminodosum,* pl.1, fig. 9.
1960 Drushchitz, &. Kudriavteseva (Eds): *Epicheloniceras subnodosocostatum* Sinzow**,** p. 341, pl.XXI, Fig.3; pl. XXII, Fig 4&5.-b.
1989 Follmi: *Cheloniceras subnodosocostatum* (Sinzow), p. 134, Pl .6, Figs.17 – 20.

Remarks: The identified specimen is very similar to many *C.* (*Epicheloniceras*) species described by some authors. It differs by faint ribbing and distinct nodes from *Cheloniceras* (*Epicheloniceras*) *martini caucasica* described by Drushchitz &.Kudriavteseva (p.339, pl.

XVII, Fig.4a, pl. XX, fig3). The species is strongly similar to *Epicheloniceras tschernyschewi* described by the same authors (p.339, pl.XIX, Fig.2a-b), but it differs by distinct ventrolateral nodes. Moreover the described specimen may represent an embryonic stage of *C.* (*Epicheloniceras*) *tschernyschewi* described by Moore, (P. 269, Fig. 208, 5. C).

Age: Middle Aptian, *subnodosocostatum* Zone, Gabal Mistan.

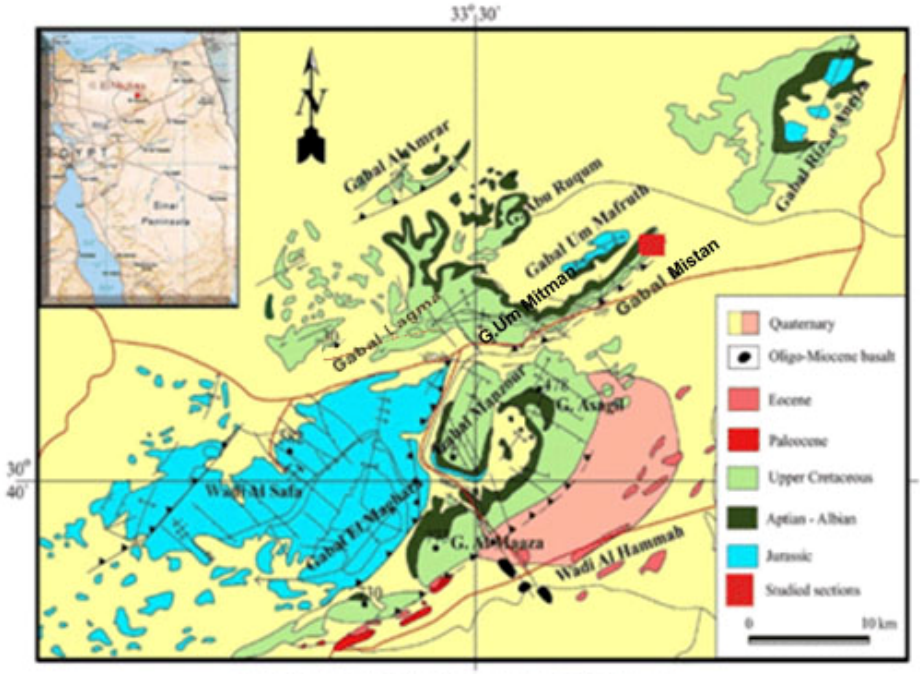

Fig.(1): Geological map of Maghara area, showing the study area
(After Geological Atlas of Sinai, 2004)

Text- Fig.1: Geological map of Al- Maghara area with Lower Cretaceous rocks surrounded the Al-Maghara Massif (after Geological Atlas of Sinai, 2004)

Superfamily DESHAYESITACEAE Stoyanow, 1949
Family DESHAYESITIDAE Stoyanow, 1949
Subfamily DESHAYESITINAE Stoyanow, 1949
Deshayesites Kazansky, 1914

***Deshayesites deshayesi* (Leymerie MS.) Orbigny**
(pl. 1, figs.1-2)

1842 Orbigny: *Ammonites deshayesi,* p. 288, pl. 85, fig. 1-4.
1936 Rengarten: *Deshayesites dechyi* Papp, pl. II, fig. 2
1960 Drushchitz, &. Kudriavteseva (Eds): *Deshayesites deshayesi* Leym, p.309, Pl .I, fig. 2 & 5.
1960 Casey: *Deshayesites d*eshayesi (ORBIGNY), p. 300, Text-Fig 106, *e, f. g.*
1996 Moore, R. ed.: *Deshayesites* deshayesi (Orbigny) p. 271, fig.211, 1a-c

Remarks*:* The described specimen is very similar to *D. Deshayesi* (Orbigny) var. *stringosus* Casey (p. 300, Text-Fig 106, h), but the latter has dens ribbing.

Age: Early Aptian, ***deshayesi*** Zone, Gabal Mistan.

***Deshayesites lavaschensis* Kazansky, 1914**
(pl. 1, fig.3)

1914 Kasansky: *Hoplites (Deshayesites) lavaschensis*, p. 105, pl. VI, fig. 87.
1960 Drushchitz, & M. P. Kudriavteseva: *Deshayesites lavaschensis* Kazansky, p. 311, p. lI, fig. 4a – b.
1964 Casey: *Deshayesites forbesi*, p.314, pl. XLVII, fig. 6a, Text-Fig 109, b & c.

Remarks: According Casey (1964, part v, p.314), the *D. forbesi* differs from *D. deshayesi* by an oblique umbilical wall and a more feebly ribbed nucleus, and from the earliest times it has been misidentified as *D. deshayesi.* The described specimen is similar to *Deshayesites multicostatus* Swinnerton described and figured by Casey (1964, p.304, pl. XLIII, fig. 5), however the latter has normal s-shaped ribs. The species is similar to *Deshayesites weissiformis* Bogdanova.

Age: Early Aptian, Gabal Mistan.

Superfamily ANCYLOCERATACEAE Meek, 1876
Family HAMITIDAE Gill, 1871
Hamites Parkinson, 1811

***Hamites intermedius* Sowerby 1814**
(pl. 2, fig. 10)

1889 Follmi: *Hamites intermedius* Sowerby, p. 124, pl.4, figs. 17-23.

Remarks: The ribs of the described species are thin relative to the Lower Aptian *Leptoceras biplex* Koenen (Drushchitz and Kudriavteseva, 1960, p.295, pl. XXXIX, fig., and 3). The described species is very similar to *Tonohamites aequicingulatus* (von Koenen) figured by

Casey (1960, part I, pl. IX, figs 2-4), but our specimen is slender with relatively thin and straight ribs.
Age: Early Aptian, Gabal Um Mitmani.

Family HAMULINIDAE Gill, 1871
Anahamulina Hyatt, 1900
Anahamulina lorioli Uhlig, 1883
(pl. 1, fig. 4)
1960: Drushchitz & M. P. Kudriavteseva.: *Anahamulina lorioli* Uhlig, p.265, pl. X, fig.
Remarks: From *Anahamulina subcylindrica* Orbigny, the described species differs by the presence of a pair of ventrolateral tubercles (Moore, 1996, p. 231, fig.181, 1a-c; Drushchitz & Kudriavteseva, 1960, p.364, pl. X, fig.2a-b).
Age: Barremian, Gabal Um Mitmani.

Suborder AMMONITINA Hyatt, 1953
Family DESMOCERATIDAE Zittel, 1895
Subfamily BARREMITNAE Breskovski, 1977
Barremites Kilian, 1913
***Barremites subdifficilis* (Karakasch, 1907)**
(PL. 1, figs. 5 – 7)
1907 Karakasch: *Desmoceras subdifficile,* p. 58, pl.6, fig.1a-b.
1960 Drushchitz & Kudriavteseva: *Barremites subdifficilis* Karakasch, 299, pl. XLII, fig. 2.
1974 Akobiana: *Barremites subdifficilis* Karakasch, p.269, pl. 92, fig. 8.
1996 Moore: *Barremites difficilis* (Orbigny), p.69, Fig.50, 1a-b.
Remarks: *Barremites difficilis* (Orbigny) and *Barremites subdifficilis* Karakasch is thought to be a dimorphic pair deferring in the height of the whorl section, one with very high whorl section and the other with relatively low section.
Age: Barremian, Gabal Mistan.

***Barremites charrierianus* Orbigny, 1840**
(Pl. 1, fig. 8)
1883 Uhlig: *Haploceras psilotatus*, p.226, pl. 16, figs. 2-3.
1960 Drushchitz & Kudriavteseva: *Barremites charrierianus* Orbigny, p. 300, PL XLII, fig. 4-5.
1974 Akobiana: *Barremites charrierianus* (Orbigny), p.270, pl. 92, fig. 5.
AGE: Barremian, Gabal, Um Mitmani.

***Barremites psilotatus* (Uhlig, 1883)**
(pl. 1, fig. 11)
1838 Uhlig: *Haploceras psilotatus*, p.226, pl. 16, figs. 2 and 3.
1960 Drushchitz & Kudriavteseva: *Barremites psilotatus* Uhlig, p. 73, 299, PL XLII, fig. 3a, b.
1972: Vasicek, Z: *Barremites psilotatus* Uhlig, p. pl. XII, fig.2, 3.
Remarks: The wide sinuous constrictions, the large size of the adult specimen, the presence of feeble lirae and the relatively low oval whorl section characterize the described specimen from the *Barremites difficilis* Orbigny described by Moore (1996, Fig 50, 1a-b) and Drushchitz & Kudriavteseva(1960, pl. XLII, fig. 1a-b).
Age: Barremian, Gabal Um Mitmani and Gabal Mistan

Subfamily PUZOSIINAE Spath, 1922
***Puzusia (Puzusia) matheroni* Orbigny**
(Pl. 1, fig. 12)
1916 Douville: *Puzusia matheroni* Orbigny, p.103, pl.XIII, figs. 1 – 7.
1960 Drushchitz & Kudriavteseva: *Spitidiscus seunesi* Kil., p. 306, pl. XLVII, fig.4.
1996 Moore: *Spitidiscus Rotula* (Sowerby), p.69, fig. 49, 1a-c.
Remarks: The described specimen is identical to that figured by Douville'. From *S. seunesi* it is relatively compressed. The three species of *Spitidiscus* Killian figured by Drushchitz & Kudriavteseva (1960, p. 305-306, pl. XLVII) seam to me as polymorphic forms of Lower Barremian ammonites. It is similar to *Puzosia quenstedti media* Seitz from the Albian of Poland by less inflated sides (1990, Marcinwski, pl. 6, fig.1).
Age: Upper Barremian-Early Aptian, Gabal Um Mitmani and Gabal Mistan.

Valdedorsella Breistroffer, 1947b
***Valdedorsella akuschense* (Anthula)**
(Pl. 1, figs. 15 & 16)
1960 Drushchitz & Kudriavteseva: *Valdedorsella akuschense* Anthula, p. 301, fig.3.
1996 Moore: *Valdedorsella akuschansis* (Anthula), p. 71, fig. 61, 2a – b.
Age: Late Aptian, Gabal Um Mitmani and Gabal Mistan.

Subfamily BEUDANTICERATINAE Breistroffer, 1953
Zuercherella Casey, 1954a
***Zuercherella* aff. *Zuercheri* (Jacob)**
(pl.1, fig. 13)
1996 Moore: *Zuercherella zuercheri* (Jacob), p.80, fig. 61, 2a – b.
Age: Late Aptian, Gabal Um Mitmani and Gabal Mistan.

Uhligella Jacob 1907
***Uhligella clansayensis* (Jacob)**
(Pl. 1, fig. 14)
1996 Moore: *Uhligella clansayensis* (Jacob), p.80, fig. 61, 3b-c.
Remarks: Although the described specimen is similar to *Uhligella walleranti* Jacob (Marcinwski, 1990, pl. 6, fig.5a-b), the latter species is highly inflated.
Age: Late Aptian, Gabal Um Mitmani and Gabal Mistan.
Suborder PHYLLOCERATINA Arkell, 1950
Family PHYLLOCERATIDAE Zittel, 1884
Subfamily PHYLLOCERATINAE Zittel, 1884

Macrophylloceras Spath
***Macrophylloceras ptychostoma* Benecke**
(pl.1, figs. 9&10)

1960 Drushchitz & Kudriavteseva: *Macrophylloceras ptychostoma* Benecke, p. 252, pl. II, fig. 6.
Age: Barremian, Gabal Mistan.

Phylloceras (*Hypophylloceras*) Salfeld, 1924
***Phylloceras* (*Hypophylloceras*) *velledae* (Michelin, 1842)**
(pl. 2, fig. 6)

1834 Michelin: *Ammonites velledae*, p.280, pl.35
1960 Drushchitz & Kudriavteseva: *Euphylloceras velledae* MICHELIN, p. 252, PL II, fig. 5a-b.
1990 Marcinowski & Wiedman: *Phylloceras* (*Hypophylloceras*) *velledae velledae* (Michelin), pl. 1, fig.1.
Remarks: It seems to me that the *Phylloceras semistriatum* ORBIGNY described by Douvillé from the Barremian of Sinai (1916, Pl. XII, fig 1.) is identical to *Euphylloceras Ponticuli* Rousseau described by Drushchitzs & Kudriavteseva (p. 251, PL I, fig. 9a-b.) from the Lower Barremian of Crimea. Also the described species is similar to *Euphylloceras velledae* Michelin, and it also collected from higher stratigraphic position comparable with that of *Euphylloceras velledae*.
Age: Middle Aptian, Gabal Mistan and Gabal Um Mitmani.
Age: Middle Aptian, Gabal Mistan

***Phylloceras* (*Hypophylloceras*) *moreti* (Mahmoud)**
pl.2, fig 4

1956 *Salfeldiella (Goretphylloceras)* Moreti Mahmoud; p. 67, fig. 44, pl. 5: 2-4
1964 *Phylloceras* (*Hypophylloceras*) *moreti* (Mahmoud): Weidmann, p. 200, fig. 46, pl. 19:2.
1990 Marcinowski and Wiedman:*Ph.(Hypophylloceras) moreti* (Mahmoud); p. 21, pl. 1, fig. 6.
Remarks: The species is known from the Lower and Middle Albian of the Sinai Peninsula (see discussion), and was recently described from the Aptian-Albian boundary of Solovakian Carpathians (Marcinowski and Wiedman), 1990. Therefore it used herein to determine This Contact in the studied section
Age: Late Aptian, Gabal Mistan and Gabal Um Mitmani.

Order LYTOCERATIDAE Hyatt, 1889
Suborder LYTOCERATINA Hyatt, 1889
Superfamily LYTOCERATACEAE Neumayr, 1875
Family LYTOCERATIDAE Neumayr, 1875
Subfamily LYTOCERATINAE Neumayr, 1875
Protetragonites Hyatt, 1900
***Protetragonites crebrisulcatus* (Uhlig, 1883)**
(pl. 1, figs. 19 – 21)

1960 Drushchitz & Kudriavteseva, *Protetragonites crebrisulcatus* Uhlig, p. 260, PL VIII, fig. 1a, b.
Remarks: It is probable that the *Protetragonites crebrisulcatus* Uhlig and *Protetragonites karakaschi* Druczczic are one and the same species (Drushchits & Kudriavteseva, 1960, pl.VIII, fig 1a-b and pl.VIII, fig. 2a-b). Both species were collected from the Upper and the Lower Barremian of Crimea respectively.
Age: Late Barremian, Gabal Mistan.

Superfamily TETRAGONITACEAE Hyatt, 1900
Family TETRAGONITIDAE Hyatt, 1900
Subfamily TETRAGONITINAE Hyatt, 1900
Tet1ragonites Kossmat, 1895
***Tetragonites (Tetragonites)* aff. *heterosulcatus* Anthula 1899**
(Pl. 2, fig. 3, 5 and 7)

1960 Drushchitz & Kudriavteseva: *Tetragonites heterosulcatus* Anthula, p. 260, pl. VIII, fig. 3a, b.
Remarks: The described specimens are differentiated from *Tetragonaites*(*Tetragonites*) *nautilodes* (Pictet) figured by Marcinowski & Wiedman (1990, pl. 1, figs. 12-13) by less inflated shell and much constrictions. The present species has affinity to the same species described by Drushchitz & Kudriavteseva , but it characterized by rectangular whorl section, little inflation and narrower venter.
Age: Middle - Late Aptian, Gabal Mistan and Gabal Um Mitmani.

Tetragonites Kossmat, 1895
***Tetragonaites(Tetragonites) nautilodes* (Pictet, 1847)**
(Pl.2, figs.8 &9)

1847 Pictet: *Ammonites Timotheanus* var. *nautiloides*, p. 296, pl. 3, fig. 2.
1967 Murphy: *T. (Tetragonites) nautilodes* (Pictet), p.27, pl. 2, figs. 5-10.
1989 Follmi: *Tetragonites nautilodes* (Pictet), p. 119, pl. 3, figs. 13, - 15.
1990 Marcinowski & Wiedman: *T. (Tetragonites) nautilodes* (Pictet), pl. 1, and figs.12 - 13).
Age: Late Aptian – Early Albian, Gabal Um Mitmani.

***Tetragonites* (*Tetragonites*) sp.**
(Pl.2, fig. 2)

Description: Small size, inflated shell with rounded sides and broad venter, whorl section rectangular.
AGE: Middle - Late Aptian, Gabal Mistan ..

Class GASTROPODA Cuvier, 1797
Order PROSOBRANCHIA Milne Edwards, 1848
Superfamily TROCHACEA Rafinesque, 1815
Family TROCIDAE Rafinesque, 1815
Subfamily TROCHINAE Stoliczka, 1868
Discotectus Faver, 1913
***Discotectus* (*Discotectus*) sp.**
(Pl. 3, figs. 6 &12)

Description: Very small size; low cone with relatively broad base; apex obtuse; surface ornamented with axial raised, intercostae flush and /or relatively depressed of width two times as costae.
Age: **AGE**: Middle - Late Aptian, Gabal Mistan.

Superfamily NERINEACEA
Family NERINEIDAE Zittel, 1873
Subfamily NERINEINAE Pcelincev
Nerinea Defrance, 1825
***Nerinea monocarinata* Pcelincev**
(pl. 3, fig. 18)

1960 Pcelincev and Korobkov (Eds): *Nerinea monocarinata* Pcelincev, p. 120, pl. XII, fig. 9.

1974 Collignon: *Nerinea* (*Ptygmatis) hottingera* Collignon, p.17, pl. 4, fig.7.

Remarks: The described species is very similar to *Nerinea archimedi* Orbigny identified by Pcelincev and Korobkov (P.123, fig 206) from the Lower Cretaceous , western Europe, but the latter has a wavy outline. Also *Nerinea* (*Ptygmatis) hottingera* Collignon described from Maroc meridional (Collignon, 1972. P.17, pl.4, fig. 7**)** has some affinity to the present identified species.

AGE: Late Barremian, Gabal Mistan.

Superfamily PSEUDOMELANIACEA Pcelincev, 1960.

Family TRAJANELLIDAE Pcelincev, 1953

Pseudomesalia Douville, 1916

***Pseudomesalia deserti Douville*, 1916**

(pl. 3, fig. 4)

1916: Douvillé: *Pseudomesalia deserti Douville*, pl. XVIII, figs. 18-25.

1949 Collignon: *Tympanotonus hourcqi* Collignon, P. 110, pl. XVII (V).

1991 Aboul Ela et al: *Pseudomesalia deserti Douvillé*, p. 208, pl. 2, figs. 10-11.

Remarks: Many species of *Pseudomesalia* recorded from the Cenomanian and Turonian of Armenia such as *P. brevis* Douvillé, *P. imbricate* Pcelincev, *P. angustata* Pcelincev differ from the present described *P. deserti* Douvillé by the presence of sharp strong spiral costae and depressed sutures (Okobiana, 1974, pl.119).

Age: Late Aptian, Gabal Mistan and Gabal Um Mitmani.

***Pseudomesalia* sp.**

(pl. 3, figs. 2 & 3)

1916 Douville': *Pseudomesalia bilineata* Douville', 1916, pl. XVII, fig.27)

Description: Very small, shell conical with acute apical angle, 6 to 7 rounded whorls with depressed sutures.

Remarks: The unknown *Pseudomesalia* sp. Is similar to *Nerinea mistanensis* Awad, 1952 descibed from the Middle Albian by Mekawy and Abu-Zied (2008, p. 316, pl. 4, fig. 20). But the latter species has slightly broader body whorl. If they may be encountered in the same horizon, they may probably represent a dimorphic pair.

Age: Late Aptian, Gabal Mistan.

Suborder MESOGASTROPODA

Family POTAMIDIDAE

Pyrazus Montofort, 1810

***Pyrazus* (*Echinobethra) magharensis* var. *rekebensis* Abbass.**

(pl. 3, fig. 8)

1991 Aboul Ela et al: *Pyrazus* (*Echinobethra*) maghareensis var. rekebensis Abbass, p. 208, pl. 2, fig. 21.

AGE: Late Aptian, Gabal, Mistan.

***Pyrazus* (*Echinobethra*) *sexangulatus* Ze'k**

(pl. 4, figs. 17-20)

2008 Mekawy and Abu- Zied: ***Pyrazus* (*Echinobethra*) *sexangulatus* Ze'k**, p. 208, pl. 4, fig. 13.

Remarks: This species is more or less typical to *Pyrazus valeriae* Vern. et Lor, however the axial nodes of the latter species is coarse forming alternating axial rows.

AGE: Late Aptian, Gabal, Mistan.

***Pyrazus valeriae* aff. *valeriae* (Vern.& Lor., 1868)**

(Pl. 3, fig. 9)

1916 Douvillé: *Pyrazus valeriae* Vern. et Lor., p. 136, pl. XVIII.

1972 Collignon: Confusiscala dupiniana (Orbigny), p.14, pl.2, figs.6 and 8.

Remarks: The described specimen has slightly fine axial ornamentation and smaller size relative to the original species.

AGE: Late Aptian, Gabal, Mistan.

Superfamily NATICACEA Forbes, 1883

Family AMPULLINIDAE (EUSPIRIDAE Cossman, 1907)

Tylostoma Sharpe, 1849

***Tylostoma (T.) canalliculata* Abdel Gawad**

(pl. 3, fig.1)

1991 Aboul Ela, et al: *Tylostoma (T.) canalliculata* Abdel Gawad, p. 210, pl. 3, figs.1 and 2,, Early Albian.

Remarks: This species shows a great affinity to species identified by Collignon as *Ampullospira (Euspirocrommium) exaltata* Goldf (Collignon, 1949, p. 104, Pl. XVI (IV), figs 9, 9a-b.

AGE: Late Aptian, Gabal, Um Mitmani

***Tylostoma (T.) maghareensis* Abbass**

(pl.3, figs. 13, 14, 16, 17; pl. 4, figs. 13 - 16)

1991 Aboul Ela, et al: *Tylostoma (T.) maghareensis* Abbass, p. 210, pl. 3, fig. 3.

Remarks: The described specimens are similar *to Natica laevigata* Deshayes from the Hauterivian of Crimea which described by Drushchitz & Kudriavteseva (1960, p. 159, Pl, VII, fig. 2)

AGE: Late Aptian, Gabal Um Mitmani.

***Tylostoma (T.) gloposum* Sharpe, 1849**

(pl. 3, fig. 21)

1991 Abdel – Gawad: *Tylostoma (T.) Gloposum* Sharpe, p. 211, pl.4, fig. 1.

Remarks: The described specimen is similar to? *Tylostoma* sp. Identified by Aboul-Ela *et al*. (1991, p. 211, pl. 4 figs. 2-3) of the Late Albian of Gabal Mannzur, but while the former is more globosely, the later species posses higher body whorl.

Age: Late Aptian - Early Albian, Gabal Mistan.

***Tylostoma (T.) zaghloulum* nov. sp.**

(pl.3, figs. 19 & 20)

Description: shell with short spire, consisting of four whorls; the body whorl incomplete, about one half of the spire; distribution of varices follows regular pattern when viewed in plan from above the apex as in Cassididae; aperture incomplete.

Derivation of name: The name of the species is derived in the memory of Professor Zaki Zaghloul.

Remarks: The nominated species has a short spire relative to Tylostoma sp. assigned to Late Albian by Aboul Ela *et al.* (1991, p.211, pl.3, fig. 5)

AGE: Late Aptian, Gabal Um Mitman.

Amauropsell Bayle, 1885

***Amauropsell holzapfeli* Cossmat.**

(pl.4, fig. 22)
1949 Collignon: *Amauropsell holzapfeli* Cossmat, p. 104, Pl. XVI (IV), figs. 8-8a.
Age: Late Aptian, Gabal Mistan.

Superfamily VOLUTACEA
Family VASIDAE
Tudicla Bolten, 1798
***Tudicla (Tudicla) spindllus* nov. sp.**
(pl. 3, fig.5)
Derivation of name: From the spindle - shaped y form of the shell.

Remarks: The species is identical to species identified by Aboul Ela, et al (1991, p. 211, pl.3, fig. 6).
AGE: Late Aptian, Gabal Mistan.

Superfamily SCALACEA
Family SCALIDAE
Confusiscala Boury, 1910
***Confusiscala dupiniana* Orbigny, 1842**
(pl. 3, fig. 7)
1960 Pcelincev and Korobkov (Eds): *Confusiscala dupiniana* Orbigny, p.173, fig 414, Albian France.
Remarks: The described species is very similar to *Scala* (*Criposcala*) primitive Collignon (Collignon, 1949, p.102, pl. XVI (IV), fig.4, but the costae of the second species is distant. Moreover, the costae of the present species are coarser than those of Confusiscala *dupiniana* Orbigny.
Age: Late Aptian, Gabal Mistan and Gabal Um Mitmani.

Superfamily PROCERITHIACEA
Family PROCERITHIIDAE Cossmann, 1905
Subfamily PARACERITHIINAE Cossmann, 1906
Cirsocerithium Cossmann, 1906
***Cirocerithium subspinosum* Deshayes**
(pl. 3, figs.10 &11)
1960 Drushchitz & Kudriavteseva: *Cirocerithium subspinosum*, p. 156, pl. VI, fig. 3a- b.
Age: Late Aptian, Gabal Mistan and Gabal Um Mitmani.

Order OPITHOBRANCHIA
Suborder TECTIBRANCHIA
Superfamily ACTEONACEAE
Family SCAPHANDRIDAE
Cylichna Loven, 1846
***Cylichna* sp.**
(pl. 3, fig. 15)
Description: obical cone, absent or very reduced spire, flat topped, smooth, aperture siphostomatus with canal.
Age: late Aptian, Gabal Um Mitmani.

Class BIVALVIA Linnaeus, 1758
Order HETERODONTA
Superfamily ASTARTACEA
Family Crassatellidae Ferussac, 1821
Crassatella Lamarck, 1799

1916 Douville: *Trigonia orientais* Douvillé, p.162, pl.XXI, fig.1, 2.

AGE: Late Aptian, Gabal Mistan.

3- Discussion and Conclusion

1: Vertical faunal distribution as an approach for Barremian and Aptian biozonation.

The identified ammonites (19 species), gastropods (15 species) and pelecypods (7 species) were used to subdivide the Barremian from the Aptian. These species help to subdivide these two stages and to establish tentatively some biozones. The measured Lower Cretaceous of Gabal Mistan and Gabal Um Mitmani are divided into the following stages:

Barremian: The Barremian is represented by about 100 meters of marl and sandstone comprising the lower part of Risan Aneiza Formation. Many species of ammonites characterized the stage including: *Barremites charrierianus* Orbigny, *Barremites psilotatus* (Uhlig), *Macrophylloceras ptychostoma*, *Puzusia (P.) matheroni*, *Barremites subdifficilis*, *Anahamulina lorioli* Uhlig and *Protetragonites crebrisulcatus* (Uhlig). The first four species record the Lower Barremian.

Aptian: The Aptian rocks attain a thickness of about 200 meters of clastic rocks intercalated with thin beds of limestone. The Lower Aptian is defined by the presence of *Deshayesites deshayesi* (Leymerie) Orbigny and *Deshayesites lavaschensis* Kazansky. The zonal index species *C.* (*Epicheloniceras*) *subnodosocostatum* Sinzow in addition to *P.* (*Hypophylloceras*) *velledae* (Michelin,) *T. (Tetragonites) heterosulcatus* Anthula define the Middle Aptian. The Upper Aptian is defined by the presence of ammonite species *Uhligella clansayensis* (Jacob), *Valdedorsella akuschense* (Anthula) and *Zuercherella* aff. *Zuercheri* (Jacob). The Aptian is characterized by rich assemblage of gastropods and pelecypods in addition to abundant sceleractinids.

Albian: worthwhile to mention that many authors in the old literatures assigned the Clansayesian to the Albian, therefore what was considered as a basal Albian is actually Upper Aptian. All the gastropods and pelecypods are collected from low stratigraphic position below the Middle and Upper Albian. The Albian fauna is outside the scope of the present study. In the studied section, it is difficult to define the Aptian/ Albian boundary in the absence of the Lower ammonite *Leymeriella tardefurcata* and *Douvilleiceras mammillatum*. The contact is based on lithological variation between Um Mitmam Member and Manzour Member. Herein the facies changes from dominant siliciclastic to become calcareous facies.

2: Paleobiogeography

The Aptian-Albian interval (124.5-97.0 Ma) was a critical time both globally and for the Tethyan domain. In the Tethyan domain it was the time when a united Neo-Tethyan subduction zone became established between the future site of the Alps and Southeast Asia and greatly accelerated the rate of north-south convergence throughout the Tethyan region **(**Naci Görür, 1991**).** This is had been confirmed in the area of study by the identity of the identified ammonites between north Sinai, the Caucasus and the Atlantic region. The ammonite distribution shows that the faunal composition is ecologically controlled **(**Fabrizio Cecca**,** 1998). The diversity of molluscs in the studied section reflects an increase of the number of niches.

Sinai Peninsula lies within the South Tethyan region (North Africa, Middle East, Iran) **(**Damotte, R., 1990). Generally, the faunal assemblages recovered from the studied sections have Tethyan affinities. They indicate rather warm waters of normal to slightly hypersaline conditions that represent a shallow, near shore environment in which the water depth did not exceed 100 m (Abu-Elaa, *et al*., 1991).

In many regions it is impossible to distinguish pre-Barremian stages (Louise Beauvais, 1992). In Sinai as a whole and in Egypt in general, the pre-Barremian interval is assessted on microfossil specially palynomorphs in some rare exposures and in many boreholes (**(**Mahmud, M.S. and. Moawad**,** A**.**M., 2000). Rare and signals on macrofauna were mentioned in literatures. The missing of some Barremian and Aptian ammonite index species in the area of study, in addition to the small sizes of the molluscan shells including ammonites refer to crises. Crises in species richness and abundance during the Early and mid-Cretaceous were coeval with oceanic anoxia associated with platform drowning. These crises can be attributed to regional environmental, induced by either oceanic anoxia or tectonic movements (Steuber, T. and and LöserH., 2000).

A step-wise demise of the carbonate platform biota transpired in the latest Aptian to Middle Albian interval was recorded by many authors (Iba, Y. and Sano, S.**,** 2007**;** Coccioni*, et al.***,** 2006). In the Pacific Province nerineacean gastropods disappeared at the Late Aptian to Early Albian transition (Iba, Y. and Sano, S.**,** 2007), hoever in the area of study, they are well represented. The missing of Barremian zonal index ammonites of the Tethyan Province such as *Colchidites securiformis* Sim, *Imerites densecostatus* Renng., *Matheronites ridzewski* Kar., *Acrioceras furcatum* Orb., …etc. may refer to such step-wise demise. Also the same phenomenon is confirmed in the area of study by missing the Aptian indes zonal ammonites of *Turkmenicera turkmenicum* Tovb., *Deshayesites weissi* Neum.,*Procheloniceas albrechtiaustriae* Hoh., *Dufrenoya furcata* Sow, *Colombiceras crassicostatun* Orb., *Parahoplites melchioris* Anth., *Acanthohoplites nolani* Seun*., and Hypacanthoplites Jacobi* Coll; in addition to absence of the most basal Albian *Leymeriella tardefurcata* Leym., and *Douvilleiceras mammillatum*.

In Tunisia, the so called "Aptian Crisis" of the south Tethyan margin is suggested by Adel Rigane *et al.* (2004) due to deficiency in organic deposits except where the medusa coral are encountered. The presence of red beds of the studied section, in addition to hard grounds may refer to the change from generally humid to arid climates during the Barremian. In Western Europe it is

though to have been linked to the lowering of the sea level (Ruffell and Batten, 1990). Many hard grounds forming ledges are encountered in the area of Gabal Mistan and Gabal Um Mitmani.

On a global scale, major transgressions were stepwise enlarged in space and time from the Neocomian, via Aptian-Albian, to the Late Cretaceous, and the post-Cretaceous regression was very remarkable. Tectono-eustasy may have been the main cause of the phenomena of transgression-regression in the Cretaceous (T. Matsumoto, T., 1980). According to El-Azaby and El-Araby (2005) and Abd-Elshafy**,** E. & Abd El-Azeam, S. (2010), the Lower Cretaceous sequence is dominated by sandy braided-river deposits with minor overbank fines and basal debris flow conglomerate.

Three second order depositional sequences were recorded in the carbonate platform of the eastern Levant. These three second-order depositional sequences mid-Cretaceous succession are: (MCEL-1: Upper Barremian–Lower Aptian, MCEL-2: uppermost Lower Aptian–middle Upper Aptian and MCEL-3: middle Upper Aptian–Middle Albian. Moreover eight third-order depositional sequences were observed in the Upper Barremian–Albian interval. They comprise successions of the inner ramp facies from open marine to restricted lagoons or tidal flats **(**Bachmann, M. and Hirsch, F., 2006)**.** In the northern Sinai Upper Aptian to Middle Cenomanian succession represents an example of a carbonate platform, 18 sequences superimpose the second-order sea-level change: 3 sequences in the Upper Aptian and 11 sequences in the Albian (Bachmann, *et al*., 2003). Without hesitation, there was a direct link between Caucasus and North Sinai.

fouzelantably@yahoo.com[*]

Abstract: *Streptococcus pneumoniae* is an important human pathogen that causes both serious invasive infections, such as septicemia, meningitis and pneumonia, as well as mild upper respiratory infections. The purpose of the study was to identify the *Streptococcus pneumoniae* using the conventional phenotypic methods and the PCR assay; especially, to evaluate their usefulness in the identification of the suspected pneumococcal isolates lacking one or more of their typical phenotypic characteristics. A total of 123 nasopharyngeal specimens obtained from children under five years of age, with acute upper respiratory tract infection were subcultured and identified by conventional and gene-technological methods. Forty-one isolates were identified as *Streptococcus pneumoniae*. Approximately (7.31%) were found to be atypical optochin-resistant, while, (4.87%) were bile insoluble. A 209-bp fragment indicative the pneumolysin (ply) gene was obtained from all typical and atypical isolates. The bile solubility test is more specific than the optochin test for identification of *Streptococcus pneumoniae*. Genetic test (PCR) for *ply* could be used to evaluate any isolates giving questionable results by any of the other phenotypic methods.

Keywords: *Streptococcus pneumonia*; optochin susceptibility test; bile solubility; *pneumolysin* PCR.

1. Introduction:

Streptococcus pneumoniae (pneumococcus) is a major bacterial infection worldwide, ranging from common infections such as otitis media to life threatening invasive infections such as sepsis, meningitis and pneumonia. Pneumococcus is the sixth most frequently isolated organism from human patients (Harakeh *et al.*, 2006). It has one of the largest public health and economic impacts of any bacterial infectious disease agent in both developing and industrialized countries (O'Brien *et al*., 2003). Pneumococcal disease kills over 1.6 million people each year. The vast majority of its victims come from the world's poorest countries (All-Party Parliamentary Group (APPG) on Pneumococcal Disease Prevention in the Developing World, 2008). It affects people of all ages, but its incidence is especially high in children less than 2 years and in adults more than 65 years (Domínguez *et al*., 2002). World Health Organization estimates that between 700 000 and 1 million children under five die from pneumococcal diseases each year (World Health Organization, 2005), and at least one child dies of pneumococcal disease every minute (All-Party Parliamentary Group (APPG) on Pneumococcal Disease Prevention in the Developing World, 2008).

Streptococcus pneumoniae is a member of the *Streptococcus mitis-Streptococcus oralis* group (the Smit group) of viridans group streptococci, which includes *Streptococcus mitis*, *Streptococcus oralis*, *Streptococcus cristatus*, *Streptococcus infantis*, *and Streptococcus peroris* (Arbique *et al*., 2004). There are now 90 recognised serotypes of *Streptococcus pneumoniae*, and the involvement of different serotypes in invasive disease varies between countries and between different age groups within the same country (Mckenzie *et al*., 2000). Most of the ninety pneumococcal serotypes immunologically distinguishable by their polysaccharide capsules are potentially pathogenic (García-Suárez *et al*., 2006).

Rapid and accurate diagnosis of pneumococcus infections plays an important role in treatment, effective management and control of outbreaks. The laboratory identification of

Streptococcus pneumoniae is based on the hemolysis pattern when it is cultured on blood agar plates and by confirmatory tests that include optochin (ethylhydrocupreine hydrochloride) sensitivity, bile solubility, miniaturized manual systems such as the API 20 Strep system, reaction with specific antisera, and PCR assays (Rudolph *et al*., 1993; Gardman & Miller,1998; Kellogg *et al*., 2001; Scott *et al*., 2003; Verhelst *et al*., 2003; Arbique *et al*., 2004; Messmer *et al*., 2004; Saukkoriipi et al., 2004; Slotved *et al*., 2004).

The purpose of the study was to identify the *Streptococcus pneumoniae* using the conventional phenotypic methods and the PCR assay; especially, to evaluate their usefulness in the identification of suspected pneumococcal isolates lacking one or more of their typical phenotypic characteristics.

2. Materials and methods

Bacterial strains:

A total of 123 nasopharyngeal specimens were obtained from children under five years of age suffering from acute upper respiratory tract infections defined as an illness having a sudden onset with rhinorrhea, pharyngitis, or cough, indicating mucosal involvement of the nose, throat, or bronchus. The cases were visiting the ENT Department of Ismailia General Hospital and the outpatient Department of Ismailia Fever Hospital. Samples were collected between September and November 2007. All specimens were immediately submerged into test tubes containing 2 ml of Skim-milk tryptone glucose glycerol (STGG) transport medium and cultured within 3-4 hours of collection.

Optochin sensitivity test: The suspected α-hemolytic colonies were touched with a sterile loop and streaked onto a tryptic soy agar plate with 5% defibrinated sheep blood in a straight line. Then, aseptically place an optochin disk (Oxoid) with a diameter of 6 mm containing 5 µg of ethylhydrocupreine HCl on the streak of inoculum. The plates were incubated in 5% CO_2 in a candle-jar at 35°C for 18–24 hours. Zone of inhibition of growth ≥14 mm in diameter indicated positive result.

Tube bile solubility test: Cells from fresh growth on agar plate were suspended in 2ml of sterile saline similar to that of a 2.0 McFarland or greater turbidity standard. The suspension was divided into two equal amounts (1ml per tube), 1ml of 0.9% saline was added to one tube (control), and 1ml of 10% sodium deoxycholate was added to the other. The tubes were shaked gently and incubated up to 30 minutes at 35°C. The tubes were visually compared; if clearing of turbidity occurred in the tube containing bile reagent, the tube was considered positive, indicating *Streptococcus pneumonia*e. Partial clearing was not accepted as a positive result (Messmer *et al*., 2004).

API 20 Strep system: Biochemical test was carried out according to the instructions of the manufacturer.

DNA extraction: Five to ten colonies were suspended in 100µl sterile distill H_2O and incubate at 100°C for 10 min. Then, a centrifugation at 12000g for 1 min was carried out. The supernatant was collected and stored at -20°C until used (Morrison *et al*., 2000; Mayoral *et al*., 2005).

Ply gene PCR assay: The oligonucleotide primers used for the amplification are IIa, (5'-CCC ACT CTT CTT GCG GTT GA-3') and IIb, (5'-TGA GCC GTT ATT TTT TCA TAC TG-3') amplify a 209-bp region of the *ply* gene. This target DNA sequence was used in developing the PCR assay according to Verhelst et al., 2003. The PCR mixture (20µl) contained 10µl of 2x TaqMix complete (Alliance Bio), 50 pmoles for each primer, 4µl Sterile distill H_2O, and finally 5µl of the extracted DNA was added. Amplification was performed using an automated thermal cycler (BIO-RAD) with the following parameters: Predenaturation 94°C for 10 min, followed by 30 cycles of (30 s at 94°C, 30 s at 55°C, and 30 s at 72°C for denaturing, annealing, and extension, respectively) with a final post-extension at 72°C for 6 min. Approximately 10 µl of each PCR amplicon was electrophoresed using a 2.0% agarose/1XTAE buffer gels and subsequently stained with ethidium bromide and visualized with a UV transilluminator. Amplified product size was determined by comparison with a 100bp ladder DNA marker (Axygen biosciences).

Control strain: A positive control (*Streptococcus pneumoniae* ATCC 49619) was included in all assays.

3. Results

Out of 123 isolates**,** 41(33.3%) isolates surrounded by a greenish zone of α- hemolysis after incubation on tryptic soy blood agar medium plates in a 5% CO_2 atmosphere for 18-24hours. Thirty-eight of them had typical pneumococcal colonial morphology and showed optochin inhibition zones: range, 18 to 22 mm with a clear zone, and they were bile soluble. Three isolates (7.31%) were found to be atypical optochin-resistant with no inhibition zone: Two isolates of them (4.87%) were small, dry colonies and bile insoluble, while, one isolate was typical colonial morphology and bile soluble. The API 20 Strep system (bioMérieux, Marcy L'Etoile, France) failed to definitively identify any of the isolates. Applying conventional PCR technique for *ply* gene, a 209-bp fragment was obtained from all isolates (Fig; 1).

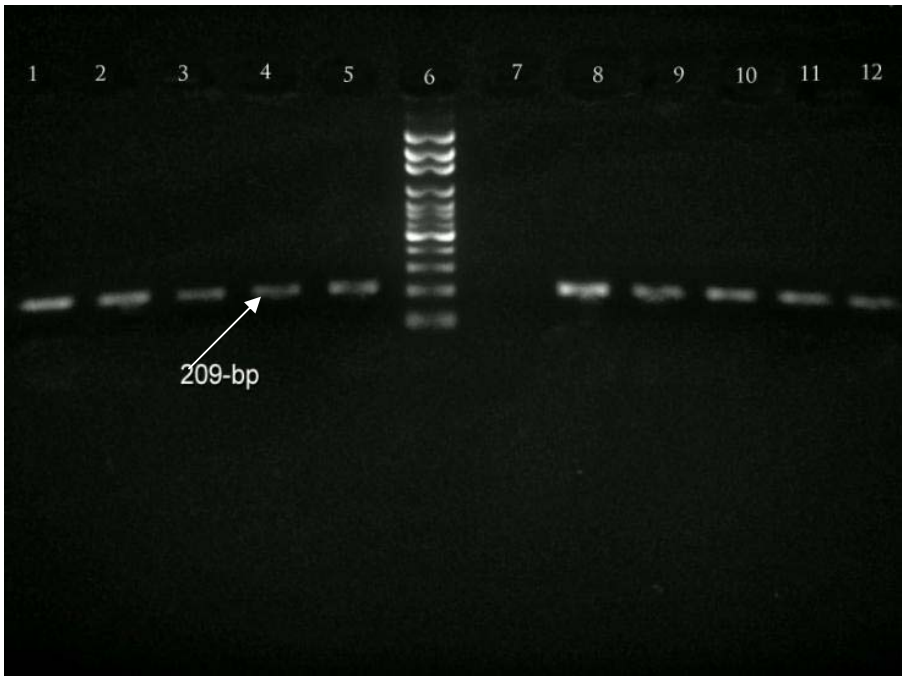

Fig. (1): Agarose gel electrophoresis of PCR-amplified products
Lane 6: Molecular weight marker (Twelve discrete fragments ranging from 100bp to 3000bp);
Lane 7: Negative control; Lanes 1-5, 8- 12: PCR positive

4. Discussion:

The accurate identification of pneumococci isolates has traditionally relied on observations of colony morphology, α-hemolysis on sheep blood agar, optochin susceptibility, and bile solubility tests. Atypical (nontypeable) pneumococci have been previously reported (Kearns *et al*., 2000; Whatmore *et al*., 2000; Obregón *et al*., 2002; Messmer *et al*., 2004). They may produce atypical reactions in one or more of the standard tests, leading to misidentification and thus may influence diagnosis and treatment. PCR for the *ply* gene has been observed to be sensitive and reliable in detecting of pneumococcus. Our result showed that all typical and atypical isolates showed positive band at 209-bp and thus were confirmed to be pneumococci. However, PCR requires special skills and equipment; therefore, at this stage, we suggested that the *ply*-PCR is a basic tool for the identification of "difficult" isolates suspected of being pneumococci.

Bile solubility and optochin sensitivity have shown to have almost complete correlation, but in 10% of cases the interpretation was considered uncertain. In our study, the optochin resistant was observed in 7.31% of isolates that had no inhibition zone. The resistance results from point mutation in the atpC gene, which prevents optochin from disrupting the H^+ transport path, by this way the strains lose their susceptibility to this compound (Pikis *et al*., 2001). However, some studies have presented that the number of colonies and the optochin discs that are used may influence the optochin sensitivity (Wasilauskas & Hampton, 1984; Gardman & Miller, 1998). Kaijalainen *et al.* 2002, reported that the density of colonies has only a small effect on the result of the optochin sensitivity test. However, when heavy inoculums is used, the diameter of the optochin sensitivity test is smaller than when a light inoculums is used, and in borderline cases the result of the optochin sensitivity test should be interpreted as sensitive or the test should be repeated.

On the other hand, the result of the present study suggests that bile solubility test is more sensitive than the optochin sensitivity test as only 4.87% was found to be bile insoluble. This result is consistent with other reported series (Burdash & West, 1982; Wasilauskas & Hampton, 1984; Davis *et al*., 1992; Kellogg *et al*., 2001), on the contrary, Kaijalainen *et al.* 2002 reported that the optochin sensitivity test is still a reliable and practical test for identifying pneumococcus from invasive as well as respiratory infections, and even from nasopharyngeal specimens. A false-positive bile solubility result will occur more often when the test is performed directly

on colonies on the agar surface rather than on those in broth medium (Denys & Carey, 1992).

Biochemical identification of pneumococcus has been proved to be quite difficult. The API 20 STREP system could not identify any of the isolates tested, and in all cases, additional testing was required before identification could be made. Some studies are in agreement with these finding (Fordymacki *et al*., 1998; Verhelst *et al*., 2003; Arbique *et al*., 2004). Other serological tests provide simpler and more rapid serological identification of *Streptococcus pneumonia* from culture (Smith & Washington, 1984; Wasilauskas & Hampton, 1984). These rely on visible detection of an antigen-antibody complex resulting from the reaction between pneumococcal surface antigens and type-specific antibodies. However, pneumococcal strains lacking a polysaccharide capsule cannot be identified by serological tests (Arbique *et al*., 2004).

On the basis of our observations, it is recommended that the genetic test for *ply* could be used to evaluate any isolates giving questionable results by any of the other phenotypic methods. On the other hand, the tube deoxycholate bile solubility test is preferred over the optochin susceptibility assay as a primary means of identification of most routine isolates of *Streptococcus pneumoniae*. Because the latter assay requires overnight incubation and the number of false negative tests were higher.

Acknowledgment

I would like to thank Dr. Ahmed Samir Mohamed, Lecturer of Microbiology, Faculty f Veterinary Medicine, Cairo University, for offering the reference strain (*Streptococcus pneumoniae* ATCC 49619) used in this study.

Relationship between Nursing Procedures and Oxygen Saturation Level of Preterm Infants with Respiratory Distress Syndrome

Randa El-Sayed Mohammed El-Sayed*; Gamalat El-Sayed Mansy; Bahaa Salah El-Din Hamad and Nehad Sabry Basiouny

Pediatric Nursing, Faculty of Nursing, Alexandria University, Alexandria, Egypt
*randa_7373@yahoo.com

Abstract: The present study was conducted to determine the relationship between nursing procedures (Suctioning, change of position, Heel stick) and blood oxygen saturation level, using pulse oximter monitoring. Fifty preterm infants with respiratory distress syndrome were monitored during performing the nursing procedures at the Neonatal Intensive Care Unit, in Maternity University Hospital at EI-Shatby in Alexandria. An assessment sheet was developed for monitoring the oxygen level before, during, and after each of the three nursing procedures. The main results were the preterm neonates with respiratory distress syndrome reacted to nursing care procedures with decrease in oxygen saturation (SPO_2) during different positioning and repositioning, suctioning and heelstick. After the procedures, all preterm neonates returned to pre-procedure average of oxygen saturation except after repositioning from side- lying to supine, from supine to prone position, and after suctioning. The supine position contributed to a slight decrease in oxygenation. Both prone position and suctioning contributed to an increase in oxygenation after the procedures. The main recommendation is that continuous monitoring of oxygen saturation before, during and after performing the nursing procedures is mandatory.

Keywords: Relationship; Nursing; Oxygen Saturation; Preterm Infants; Respiratory Distress Syndrome

1. Introduction:

During pregnancy, the fetus grows in the mother's uterus usually for 37 to 42 weeks. Infants born less than 37 weeks are called preterm or premature infants.(1) Those infants are at increased risk of growth problems, developmental delays and complex medical problems. (2)

According to World Health Organization (WHO)2009 data showed that, worldwide more than one million infants die each year because they are born early (or 28% of total newborn death) .The highest preterm delivery rate in the world are found in Africa (11.9%) , followed by North America (United States and Canada). (3) In the U.S.A, the preterm birth rate has risen steadily from 9.4% in 1981, to 10.4% in 2000, to 10.6% in 2005.(3,4) In Canada, there has been a slight increase in preterm birth for 7.5% in 2000, to 7.7 in 2003, to 7.9% in 2004 % , to 10.6 in 2005.(5-7)

Worldwide, in 2005 the preterm birth rate was estimated as 9.6 %-representing about 12.9 million infants.(3) In Alexandria University Hospital, the rate of preterm admission in El-Shatby Neonatal Intensive Care Unit was 74.7% in 2009. Records show that mortality rate of preterm infants has dramatically improved in the neonatal intensive care unit (NICU) from 75.1% in 2002, to 44.8% in 2004, to 35.7 % in 2009. These, records showed that respiratory distress syndrome was the second main reason for admission to the unit (11.4%) during the year 2009.(8)

The tenuous respiratory status of many preterm infants in the neonatal intensive care units places them at high risk from the potential stress of repetitive diagnostic, nursing and therapeutic procedures. These procedures are associated with alteration in physiological responses, which may result in undetected subclinical episodes of hypoxemia or hyperoxemia. (8) Handling during routine nursing care (i.e., vital signs, changing diaper or position, vein puncture for blood draws or feeding, heelsticks, and suction) can result in increased intracranial pressure, episodes of apnea/bradycardia, agitation, and increased or decreased heart rate and blood pressure. (9 - 11)

The development of oxygen saturation measurement techniques provides a tool with which oxygenation may be continuously and non-invasively monitored during nursing care procedures.(11,12) Care should be taken to include oxygen saturation target in daily practice to avoid prolonged or alternating episodes of hypoxia /hyperoxia in infant breathing supplemental oxygen.(13)

The minimum duration of hypoxia that cause brain damage is not known. Until this critical

period is determined, hypoxia for any length of time should be avoided. If the infant is unable to recover spontaneously, significant hypoxia can end in assisted ventilation and prolonged intubation. To avoid this risk, the arterial oxygen tension of critically ill preterm infants needs to be maintained at 50-70 mmHg. [14]

In the neonatal intensive care unit (NICU), preterm infants often require support of ventilation and oxygenation through endotracheal intubation and invasive positive-pressure ventilation (IPPV). [15] The presence of an endotracheal tube causes soft-tissue irritation and increased secretions. Intubation can lead to thickening of secretions. Increased or thick secretions add to the risks of endotracheal-tube blockage, lobar collapse, and compromised gas exchange. [16]Suctioning the endotracheal tube in infants with RDS is one of the stressful nursing procedures that should be done if there is secretion, and significantly affects gas exchange and should be kept to a minimum. There are many complications associated with endotracheal suctioning which include hypoxemia, bradycardia, tachycardia, pneumonia, fluctuation in blood and intracranial pressure, localized trauma to the airway, infection and tube dislodgement. [17, 18]

Repositioning of preterm infants is a basic nursing care. [19]It includes supine, prone, side lying, and head up tilted position. Several studies demonstrated variable outcomes affected by different positioning of preterm infants .The American Academy of Pediatrics recommended that the prone position is more appropriate for sick preterm infants because oxygenation is better. [20] Therefore, proper positioning may improve oxygenation and reduce the need for supplemental oxygen and mechanical ventilation. Suitable positioning to maintain normal oxygen saturation is a priority in the nursing care.[21] Preterm infants regularly are subjected to a multitude of diagnostic and therapeutic procedures that are painful but medically necessary. The most frequently performed procedure is heelstick.[22-23] Infants undergoing this procedure experience significant pain manifested by crying, facial expressions, body movements and physiologic changes .[24] Physiological indicators of pain are changes in heart rate, respiratory rate, blood pressure, oxygen saturation (SaO_2), vagal tone, palmar sweating, facial expression and intensity of cry.[25] One reason that heelstick blood collection is painful and distressing is the prolonged squeezing of the heel required to complete the sample.[26]

Many events consistently lead to hypoxemia in preterm infants: as drops in transcutaneous oxygenation $TcPo_2$ during the insertion of an intravenous needle, taking vital signs and pharyngeal suctioning.[27] Daily procedures such as feeding, examination, and diaper changes were sometimes associated with hypoxemia.[12] The physiological and behavioral effects of a supposedly beneficial procedure, a sponge bath, on preterm infant may increase heart rate, cardiac oxygen demand, and decreases in oxygen saturation . [28]

From these facts and clinical observation, changes in nursing care of the preterm infant has taken place faster than their evaluation . Meticulous attention must be given to subtle changes in the infant oxygenation status. So, nursing care should be altered and adapted based on specific observations of each infant's response to care giving. When care is structured to support the individual infant's physiologic stability and neurobehavioral organization, stress is reduced for that infant.[29]Certain routine procedures may be more harmful than beneficial to the infant. There are three routine nursing procedures that may be associated with hypoxemia as suctioning, repositioning and performing heelstick. In the present study procedures are selected because of the frequency with which they are performed in the usual management of preterm infants. The effect of nursing care procedures on the fluctuation of the oxygenation level need to be evaluated. [14]

Aim of the study

The aim of the present study was to determine the relationship between nursing procedures (Suctioning, change of position, Heel stick) and blood oxygen saturation level in preterm infants with respiratory distress syndrome.

2. Materials and methods:

Materials:

Research design: It is a descriptive study.

Setting: The study was conducted at the Neonatal Intensive Care Unit, in Maternity University Hospital at EI-Shatby in Alexandria.

Subjects:

A convenient sample of fifty preterm infants with respiratory distress syndrome who had the following criteria:

-Born at 26 -34 weeks of gestation.
- On mechanical ventilator or continuous positive air way pressure (CPAP).
-Free from any congenital malformation.
-Having normal body temperature and hemoglobin level.
-Having normal oxygen tension before nursing procedure (to exclude hyperoxia)

Tool: It comprised three parts:

Part (I):-

Neonate's biodemographic data such as: name, age, sex, birth weight, gestational age and the type of delivery.

Part (II):-

- Physiological indicators as temperature, heart rate and respiratory rate.
- Temperature of incubator.
- Hemoglobin level.
- If the infants had received surfactant or not.
- Method of oxygen administration such as: tracheal CPAP (Continuous Positive Airway Pressure) or mechanical ventilator.
- Continuous Positive Airway Pressure data included:
  * Fraction of Inspired Oxygen (FiO_2) and Positive End Expiratory Pressure (PEEP).
- Ventilator data included:
  * Mode of ventilator, ventilator category: high or low pressure setting,
  * Duration of stay on ventilator, Peak Inspiratory Pressure (PIP), (PEEP),(FIO_2),Inspiratory Time (Ti), Expiratory Time(Te), Mean Airway Pressure (MAP).
- Arterial blood gas less than 2hrs before procedure which included:
  * PH, Partial pressure of oxygen (PaO_2), Partial pressure of carbon dioxide ($PaCO_2$), Oxygen saturation (SpO_2), Bicarbonate (HCO_3).

Part (III):-

- An assessment sheet for monitoring oxygen saturation level before, during, and after each of the three nursing procedures:
- Change of positioning
  From supine to side, from side to supine, and from supine to prone.
- Endotracheal suctioning.
- Heelstick.

Method:

1. An official approval for conducting the study was obtained from the responsible administrative personnel.
2. The tool was developed by the researcher after thorough review of literatures.
3. The developed tool was validated by five experts in the field in nursing and medical field, modification proposed was implemented and the validity was 0.88.
4. Tool reliability was ascertained where the researcher observed five infants using the assessment sheet for two times with an interval period of 48 hours .The reliability of this tool was 0.82 tested by Cronobach alpha test.
5. A pilot study was done on 5 neonates to test the applicability of the tool; these five neonates were excluded from the sample
6. Each infant was observed by the researcher during the morning and afternoon shifts while the nurse was performing endotracheal suctioning, repositioning, and heelstick.
7. Arterial blood gases were obtained from the neonates by the nurse less than 2 hrs before the procedures.
8. Ventilator data were recorded immediately before each of the three procedures.
9. Temperature, heart rate and respiratory rate were measured 10 minutes before the nursing procedures.
10. Heart rate and oxygen saturation were recorded immediately before the procedure.
11. During baseline monitoring, the infants were not disturbed.
12. Oxygen saturation and heart rate were collected while the infant was receiving the nursing care (Change of positioning - suctioning - heelstick)
13. Oxygen saturation level of every procedure was recorded at 30 seconds before starting, during, and 30 seconds after each procedure until reach to average pre-procedure level.
14. The duration of procedures was recorded.
15. The length of time to return to normal O_2 saturation was measured.
16. The observer didn't interfere with the routine care of the infants. The only request made to the nurse performing the procedure was to allow the infants to return to the pre-procedure oxygen saturation average (88%- 95%) before disturbing again .
17. Several parameters were used to determine the relation of nursing procedures and oxygen saturation. These were (a) desaturation: the incidence of oxygen saturation was less than 88%; (b) high oxygen saturation: the incidence of oxygen saturation was 95% or more;(c) bradycardia : heart rate less than 100 b/m ; (d) tachycardia : heart rate more than 160 b/m.
18. Oxygen saturation was measured by pulse oximeter Nelcor-560 made in Korea or Massimo Rad–9 made in U.S.A with Max –N disposable neonatal sensors .A tiny, lighted probe placed on the infant's hand or foot projects a beam of light through the capillary beds in the tissue .The light beam is converted into an electric signal by a photo detector in the probe that is processed within the module and displayed as both a waveform and a digital value for both the oxygen saturation SpO_2 and the heart rate.

19. The three procedures were performed in the following manner consistent with routine practice in NICU:

A-Suctioning:

a. Tracheal suctioning was performed only when there was a clinical need.

b. The following considerations were followed:

- Suction Catheter was selected according to the endotracheal tube size.
- Negative suction pressure was 40-60 mmHg, it was applied intermittently and only during catheter withdrawal while simultaneously rotating the catheter.
- Hyperoxygenation of the neonates was performed before, and after suction through the ventilator by increasing fraction of inspired oxygen (FiO_2) 10-20% above the baseline.
- The endotracheal tube was disconnected at Y piece from the ventilator.
- The suction catheter was inserted into the endotracheal tube for 10-15 seconds and repeated if needed.
- The attending resident did lung recruitment procedure by the ambu bag 3-5 puffs manually.
- The endotracheal tube was reconnected at Y piece to the ventilator, and gradual decrease of FiO_2 to the pre suction level.
- The oxygen saturation level and heart rate was continuously monitored before, during and after the procedure using a pulse oximeter.

B- Changing positioning:

The paediatric nurse picked up the preterm infant during a calm period one continuous motion from back to one side or from one side to back or from back to prone.

First, the supine position was performed by supporting head, feet and body in the midline by using soft rolls around the infant. A roll under the shoulders was placed to support the newborn's airway and allowed slightly forward flexion of the head.

Second, the prone position was performed by putting the newborn's body prone. The arms should be close to the body with the hands symmetrically close up to the mouth. Flexion of the legs can be encouraged with the knees brought up to the chest, raising the hips slightly. This position was maintained by using a rolled blanket to make a boundary. Position device for prone include a small hip roll to assist in maintaining flexion. Use of a rolled cloth placed under the infant (from top of the head to umbilicus) to provide elevation of the body.

Third, the side lying position was performed by ensuring that the head and trunk should be maintained in neutral alignment. The nurse should use a roll along the infant's back (not touching the back of the head as the infant may be stimulated to push back into it). The legs should be flexed and the upper leg supported in neutral position by the use of roll between the legs.

The oxygen saturation level and heart rate were recorded during and after the procedure using a pulse oximeter.

C- Heel stick:

The nurse warmed the heel for one a minute with a warm washcloth, handled the infant's foot, and appliedmild pressure between thumb and fingers to hold ankle in dorsiflexion , cleaned the heel with alcohol swab. The puncture was made at the outer aspect of the heel with micro lancet. One drop of blood was obtained and a dressing was applied to the heel. The oxygen saturation level and heart rate were recoded before, during, and after the procedure using a pulse oximeter.

Data analysis:

Data collected were coded and transferred into specially designed formats to be suitable for computer Feeding: the SPSS version 15.0 statistical program was utilized for results .Descriptive measures included : Percentage, mean, standard deviation , “t” test, F-test ,and Chi-square were used for test of significant. Level of significant was 5% level.

3. Results

Table (1) shows the general characteristics of the study subjects. Male constituted 62.0%. Age ranged from 1-17 days with a mean 4.96 ±2.28 days. Moreover, the gestational age of the neonates ranged between 27-34 weeks with a mean 30.04±2.09 weeks. The highest percentage of preterm neonates (84%) had a gestational age less than 33 weeks.

The weight of the neonates ranged from 600-2020 gms with a mean of 1128.78±261.92 gms. More than half of the sample (54%) had a Very low birth weight (VLBW) i.e weighing 1000 to less than 1500 gms, while 20% of the sample had Extremely low birth weight (ELBW) i.e weighing less than 1000 gms .Concerning the type of delivery, 68.0% were delivered by caesarean section, while 32.0% of the preterm neonates had delivered normaly .

Figure I describes the percent of preterm neonates regarding oxygen saturation when repositioning from supine to side. The present result reveals that 96.0% of neonates had normal oxygen saturation (88-94%) before repositioning. During the procedure, it declined to 68.0%. After the procedure, it increased to 80.0% at half a minute, it was kept the

same at 2.0 minutes, and then it increased to 84.0% at 5.0 minutes. In the rest of neonates, the percent of those who had oxygen saturation ≥ 95% increased. There were statistically significant differences between the percent of neonates before repositioning and their percent during the procedure, and at half a minute, 2 minutes, and 5 minutes after.(p=0.0021, 0.0159, 0.033, 0.048 respectively)

Figure II illustrates the percent of the preterm neonates regarding oxygen saturation when repositioning from side to supine. It demonstrates that before the procedure, the percent of neonates who had normal oxygen saturation (88-94%) were 96.0%. During the procedure, their percent decreased to 54.0%. After repositioning, the percent of neonates declined to 52.0% at half a minute. This decline was apparent in the percent of neonates who had O_2 saturation< 88%. At 2.0 minutes and 5.0 minutes after the procedure, the percent of neonates increased to 74.0%, 84.0% respectively. This difference in the percent of neonates before repositioning and at 5.0 minutes after the procedure shows either increase in the percent of neonates who had O_2 saturation< 88% , or in the percent of neonates whose O_2 saturation ≥ 95% . There was a statistically significant difference between the percent of neonates before repositioning and their percent during, at half a minute, 2 minutes, and 5 minutes later.(p=0.001, 0.001, 0.036, 0.011 respectively)

Figure III illustrates the percent of the preterm neonates regarding oxygen saturation when repositioned from supine to prone. The figure reveals that 98% of the neonates who had normal oxygen saturation between 88-94% before repositioning declined to 44.0% during repositioning. This decline appears in the percent of neonates who had O_2 saturation< 88%. After the procedure, the percent of neonates increased to 88.0% at half a minute, and then kept nearly the same 86.0% at 2.0 minutes, and then it decreased to 52.0% after 5.0 minutes which is parallel by an increase in the percent of neonates who had oxygen saturation ≥ 95%. There was a statistically significant difference between the percent of neonates before repositioning and their percent during, after half, 2.0, and 5.0 minutes.(p=0.001, 0.039, 0.045, 0.001 respectively)

Figure IV shows the percent of preterm neonates regarding oxygen saturation before, during, and after suctioning. It is clear from the figure that before suctioning, all the neonates (100%) had normal oxygen saturation (88%-94%).During the procedure, their percent decreased to 20.0 %. This decline shows an increase in the percent of neonates who had O_2 saturation< 88% .After the procedure, it was observed that, the oxygen saturation of neonates improved when the percent of neonates increased to 74.0%, and 82.0% at half a minute and at 2.0 minutes respectively. At 5.0 minutes, the percent of neonates decreased to 62.0%. The decrease in percent of neonates is apparent in those who had O_2 saturation ≥95%. There were statistically significant differences between the percent of neonates before and their percent at different periods of suctioning except at 2.0 minutes after. (p=0.0001, 0.0013, 0.002 respectively)

Figure V portrays the percent of preterm neonates regarding oxygen saturation before, during, and after heelstick. It is clear that 100% of neonates had normal oxygen saturation (88-94%) before heelstick. During the procedure, the percent of neonates decreased to 72.0% .This decline is apparent in the percent of neonates who had O_2 saturation< 88%. After the procedure, the percent of neonates increased to 80.0% and 88.0% at half a minute and at 2.0 minutes respectively, and then it decreased to 82.0% at 5.0 minutes which is paralleled by an increase in the percent of neonates who had oxygen saturation ≥ 95%. Statistically significant differences between the percent of neonates before heelstick and their percent during the procedure, at half a minute , at 2.0, and at 5.0 minutes after were observed.(p=0.0032, 0.039, 0.0043, 0.045 respectively)

Table II shows the mean values of oxygen saturation of preterm neonates before, during and after the nursing procedures. It is observed that the mean oxygen saturation value was 91.49± 9.25% before repositioning from supine to side, it decreased to 88.32± 8.65% during the procedure, and to 87.86± 9.65% at half a minute after, then it gradually increased to 91.04 ± 9.25% , to 92.68± 10.6 % at 2 .0 minutes and at 5.0 minutes respectively after repositioning. There was statistically significant difference between mean oxygen saturation before the procedure and each of during, and at half a minute after the procedure (p=0.045, and 0.033 respectively). It is clear from the table that the mean value of oxygen saturation was 92.16± 7.89% before repositioning from side to supine, it decreased to 87.44± 7.25% during the procedure, then it gradually increased to 88.9 ±7.65% , to 89.86± 7.65%,and to 90.48±7.98% after the procedure at half a minute , 2.0 minutes , and 5.0 minutes respectively. There was statistically significant difference between mean oxygen saturation before the procedure and each of during, and half a minute after the procedure (p=0.048, and 0.05 respectively).

It is observed also that the mean value of oxygen saturation when repositioning of neonates from supine to prone was 90.34± 6.98% before repositioning, it decreased to 86.84±6.99% during the

procedure, then it increased to 89.38± 8.02%, 92.54 ± 8.06%,and 95.8± 11.3% at half , 2.0, and 5.0 minutes respectively after repositioning. Statistically significant difference was observed between mean value of oxygen saturation before the procedure and each of during the procedure and 5 minutes after repositioning (p=0.047, and 0.021 respectively).

In relation to Endotracheal Tube(ETT) suctioning, the same table shows that the mean value of oxygen saturation was 89.96±7.54% before the procedure, it decreased to 84.86 ± 6.52% during the procedure, then gradually increased to 90.3 ±7.36%, 92.88±7.65%, and 93.62 ±10.6% at half, at 2, and at 5 minutes after suctioning respectively. There was a statistically significant difference between mean value of oxygen saturation before the procedure and each of during the procedure and 5 minutes after repositioning (p=0.041, and 0.048 respectively).

Concerning the heelstick, the mean value of oxygen saturation before the procedure was 92.26±6.98%, it declined to 85.65± 7.41% during the procedure, then it increased to 88.1±5.11%, 92.86±8.04%, and 92.96± 9.65 % at half a minute, 2 minutes and 5 minutes after the procedure. There was a statistically significant difference between mean value of oxygen saturation before the procedure and each of during the procedure and at half a minute after repositioning (p=0.036, and 0.046 respectively).While no statistically significant differences were found between mean oxygen saturation before and during the different nursing procedures.

Table (1): Percent distribution of the preterm neonates according to biodemoographic data.

Biodemographic Characteristics	N	%
Sex		
Male	31	62.0
Female	19	38.0
Age (days)		
• 1-	28	56.0
• 5-	15	30.0
• 9-	5	10.0
• 13-17	2	4.0
Range	1-17 days	
Mean±S.D.	4.96 ±2.28	
Gestational age(weeks)		
• 27-	12	24.0
• 30-	30	60.0
• 33-34	8	16.0
Range	27 – 34 weeks	
Mean±S.D.	30.04±2.09	
Weight (gm)		
• ELBW <1000 -	10	20
• VLBW 1000 -	27	54
• LBW 1500-2020	13	26
Range	600 – 2020 gm	
Mean ± S.D.	1128.78 ±261.92	
Type of delivery		
• Caesarean section	34	68.0
• Normal vaginal delivery	16	32.0
Total	50	100.0

- Extremely low birth weight (ELBW): weighing less than 1000 gms.
- Very low birth weight (VLBW): weighing 1000 to less than 1500 gms.
- Low birth weight LBW: weighing less than 2500 gms

4. Discussion:

The fetus is brought into a world for which he is not physiologically prepared which constitutes an obstacle to normal development. Preterm infants are at high risk for chronic lung disease, intraventricular hemorrhage, retinopathy of prematurity and necrotizing entrocolitis. Moreover, possible insults to the preterm neonates during the time she/he is in the intensive care unit are exposure to stress and pain caused by medical and nursing procedures. [30,31]

In caring for the preterm neonates with respiratory distress syndrome, one of the aims of therapeutic intervention is to maintain optimal oxygenation. Therefore; the fragile preterm infants might need mechanical ventilator support .The appropriate use of oxygen in the preterm infant has been the source of concern and study for more than half a century. Oxygen therapy has been causally linked to adverse neonatal outcomes including retinopathy of prematurity and chronic lung disease due to prolonged exposure to high oxygen tensions.

Lowering oxygen saturation targets in preterm infants in the first few weeks of life has been shown to reduce the incidence of certain complications; however prolonged periods of hypoxemia may result in poor growth, cardiopulmonary complications of chronic lung disease, neurodevelopmental disabilities, or increased mortality. [32]

Preterm infants who require extended mechanical ventilator support are at high risk of the potential stress of repetitive diagnostic, nursing and therapeutic procedures. Routine nursing care (i.e., vital signs, changing diaper or position, vein puncture for blood draws, feeding, heelstick, suction, and physical or neurological examination) may result in unnoticed subclinical episodes of hypoxemia or hyperoxemia. These episodes could be detected by arterial oxygen saturation (SpO_2) monitoring by pulse oximetry. Newborn intensive care unit personnel respond to high / low Spo_2 alarms but any delay of response can prolong exposure to unnecessary high concentration of supplemental oxygen or periods of hypoxemia that may increase the risk for its complications. [10, 33, 34]

As regards positioning of preterm neonates from supine to side-lying, the finding of the present study showed that a statistically significant fall in oxygen saturation was observed during the procedure, then after the procedure there was a gradual slight increase in oxygen saturation that did not reach significance . In accordance to the current finding, Yottiem et al (2004) stated that infants with side lying position had higher mean oxygen saturation than infants with regular position.[32] Furthermore, the neonatology clinical guidelines (2006) recommended that side-lying position can be used to treat unilateral lung disease, with better oxygenation being achieved by positioning the 'good ' lung uppermost. This also supports a better oxygenation. [34]

The present results revealed a significant decrease of oxygen saturation during repositioning from side to supine and short period after the procedure. Within the five minutes observation period the supine position was associated with a slight reduction in oxygen saturation and 6% of infants did not reach the pre-procedure average of oxygen saturation. Such findings raise the doubts about the benefit of supine position .It could be justified that in the supine position the abdominal organs tend to be forced by gravity against the diaphragm. This makes it difficult for the diaphragm to contract and for the newborn to breathe. [35]The present results are supported by Dimitriou et al (2002) and Woragidpoonpol (2001) who reported that the supine position was associated with lower oxygen saturation than the prone**.** [36, 37]

In the current study, although repositioning from supine to prone resulted in a transient fall in oxygen saturation during the procedure, yet the prone position was associated with improvement in oxygen saturation after the procedure.It could be justified that when the infant is placed in the prone, stability of the chest wall is enhanced, particularly during inspiration. This fixation of chest wall allows for an increased thoracic volume when needed without additional work of breathing. This occurs because additional muscles of inspiration are not needed to overcome diaphragmatic contraction. [38,39]

In the same context, Bhat et al (2003) found that oxygenation was better in the prone posture than in the supine posture. The researchers explained that prone placement might contribute to better SpO_2 and lower respiratory resistance, which is attributed to a more stable rib cage. [40]Similarly, Ammari et al (2009) observed an increase in oxygenation when the infants were turned from supine to prone. [41]This is in agreement with Poets et al (2007), Picheansthian and Woragidpoolpol (2003) who reported that infants who are born prematurely exhibit less apnoea and intermittent hypoxia have better thoracoabdominal synchrony, higher lung volumes and better oxygenation when nursed in the prone position. [42, 43]According to Chang et al (2002) the prone position produced fewer episodes of desaturation and lesser levels of activity. [44]

The findings of the present study revealed that the incidence of desaturation increased during repositioning from supine to side, from side to supine, and from supine to prone .It could be

explained that motion results in disruption of the calmed infant when picked up and turned from one position to another. This explanation is in accordance with Claure and Bancalari (2009), Esquer et al (2007), and Bolivar et al (1995) who found that the episodes of hypoxemia have been associated with increased activity of preterm infants.[45-47]The current result is also in agreement with Browne(2000), and Evans(1991) who stated that preterm infants who required assisted ventilation are susceptible to oxygen desaturation because of physiological instability and vulnerability to handling.[48,49] Mourdoch and Darlow (1984) studied handling during neonatal intensive care and mentioned that nursing care like alteration of position was associated with reduction of trascutaneous oxygenation.[50]

The present result revealed no significant difference in mean oxygen saturation between side-lying, supine, and prone position. The findings are congruent with the results of Bozynski et al (1988) who found no significant difference in the median of $TcPaO_2$ value between the lateral positioning and supine position, when examining the effect of side lying versus supine on transcutaneous oxygen saturation $TcPaO_2$ of 18 mechanically ventilated neonates .[51] Crane et al (1990) mentioned that there was no significant difference in oxygen saturation between supine and side-lying position. [52] Elder et al (2005) who also reported that there was no significant difference in oxygen saturation between supine and prone position. [53]The results of the present research are in line with a systemic review done by Balaguer et al (2006) who reported that no evidence concerning whether particular body positions during mechanical ventilation of the neonate are effective in producing sustained and clinically relevant improvements , prone position was found to slightly improve oxygenation.[54]

The practice of endotracheal suctioning (ETT) of ventilated preterm neonates is necessary for removing secretions to prevent obstruction of endotracheal tube.[55,56] The present results show that a statistically significant decrease in oxygen saturation was present in 80% of infants during open endotracheal suctioning .One explanation for the decline in oxygenation during suctioning may be the interruption of the infant's airway by suction catheter as this procedure necessitated the disconnection of the infants from the ventilator and disturbance in oxygen delivery. Another explanation is that, suctioning involved some degree of repositioning of the head and torso, so the effect of the two procedures may have been compounded. [15] Seckel (2008) and Jondgreden et al (2007) added that during open endotracheal suctioning, there was a drop in airway pressure, loss of lung volume and decreased in oxygen saturation. [57,58] In addition, Lindgren (2007) also reported that disconnection of breathing apparatus and negative pressure application during suctioning result in atelectasis, pulmonary shunting and venous return producing hypoxemia and lung compliance change. [59]In addition , Hooser (2002) mentioned that during open suctioning the gas drawn from the lung was replaced by air drawn from the atmosphere through the space left around the catheter which decreases the oxygen saturation .[60]

The finding of the current study are congruent with Hoellering et al (2008), Kalyn et al (2003) and Slevin et al (1998) who mentioned that open ETT suctioning could contribute to disturbance in ventilation, leading to greater degree of hypoxemia. [61-63]After performing of endotracheal suctioning, the present result shows an increase in oxygen saturation up to 5 minutes. This may be due to removal of secretions that partially obstructed the endotracheal tube. It can also be interpreted by the fact that hyperoxygenation before and after ETT suctioning may have a positive effect in increasing oxygen saturation.

Heelstick is one of the most common painful invasive procedures in NICU .It is the conventional method of blood sampling in neonates for screening tests or measurements of serum bilirubin or glucose or blood gas. Sick preterm infants admitted to neonatal intensive care units (NICUs) are exposed to this procedure repeatedly as part of their routine care. Painful procedures are harmful to the infant's physiological stability and ability to self regulate. [64, 65]

The result of current study shows a significant transient decrease of oxygen saturation during squeezing the heel and a short period after the procedure, and then it returned quickly to the baseline oxygen saturation . The result can also be attributed to the fact that decreased oxygen saturation is one of the physiological cues that might indicate pain and distress. The finding is congruent with Newnham et al (2009) who reported that heel prick was associated with hypoxemic episodes. [66]The current study is in agreement with Cong et al (2009) who examined the effect of kangaroo care on heelstick pain. They found that oxygen saturation was lower during heelstick than another phases in kangaroo group and in incubator heel group, supporting evidence that heelstick is a stressful event. [67] Hummel and Van (2006) and Walden & Gibbins (2008) explored that brief, acute noxious stimuli result in decreasing in oxygen saturation during the pain. [68, 69] On the contrary, Herrington et al (2007) found that no significant differences were noted in oxygen saturation in any phases of heelstick procedure. [70] Norris et al (1981) also concluded that transcutaneous

oxygen saturation did not differ significantly during heelstick procedure. (15)

5. Conclusion

Based on the findings of the present study, it is concluded that preterm neonates with respiratory distress syndrome reacted to nursing care procedures with decrease in oxygen saturation (SPO_2) during repositioning from supine to side- lying, from side-lying to supine, and from supine to prone position as well as during suctioning, and during heelstick. After the procedures, all preterm neonates returned to pre-procedure average of oxygen saturation except after repositioning from side- lying to supine, from supine to prone position, and after suctioning. The supine position contributed to a slight decrease in oxygenation. Both prone position and suctioning contributed to an increase in oxygenation after the procedures.

Recommendations

Individual neonates show varied response to nursing intervention especially preterm infants, therefore continuous monitoring of oxygen saturation is mandatory before, during and after performing the nursing procedures because an infant's status can change rapidly.

The need for caution among nurses and other professionals in delivery of care to this vulnerable infant is warranted. In planning care for preterm infant with RDS, the infant's response to procedures should be predicted consideration should be given to the benefits of the procedure in relation to its risk.

Routine intensive care should be altered and adapted based on specific observations of each infant's response to the care given and avoid prolonged exposure to unnecessary high concentration of supplemental oxygen or periods of hypoxemia that may increase the risk for their complications.

Neonatal intensive care units should include updated policies related to oxygen therapy, repositioning, suctioning, heelstick and other nursing care procedures for preterm neonates.

Care protocols for preterm neonates should incorporate a principle of minimizing the number of disruptions in care as much as possible and avoid sudden interruption.

Abstract: Seedlings of the leguminous shrub; *Colutea istria* Mill. were used as explants for the micropropagation of this vulnerable species. Cotyledonary nodes, stem node sections and shoot tips from the *in vitro* germinated seedlings were examined for micropropagation. The *in vitro* establishment of explants was attempted by using various concentrations of 6-benzylaminopurine (BA), Thidiazuron (TDZ) and N6-(2-isopentenyl) adenine (2iP) (0.5, 1, 2 mg/L each) in combination with NAA at 0.1 and 0.2 mg/L incorporated into Murashige and Skoog (MS) and Gamborg's (B5) media, in addition to the MS and B5 media without plant growth regulators (PGRs). The best results were obtained on MS medium supplemented with NAA and BA, in addition to PGRs free MS medium. And the best average number and length of shoots were obtained by using cotyledonary nodes as explants. For multiplication, the explants were cultured on MS medium containing BA at concentrations of 0.25, 0.5 and 1 mg/L either individually or in combination with 2iP at a concentration of 0.5 mg/L. The combination of BA and 2iP is recommended for multiplying the established shoots produced from colyledonary nodes and stem node sections due to the significantly higher average number of shoots/explant comparing to the media containing BA singly. However, BA is better for the multiplication of shoot tip explants. When axillary shoots were subcultured on the same medium, the shoots failed to multiply and began to senesce. The senescence progressed to the entire shoot, and growth ceased. Reducing the duration of the subculture to 3 weeks is necessary to prevent this problem. Explants rooted on MS medium containing 0.5 mg/L of both Indole-3-butyric acid (IBA) and NAA and plantlets with well developed shoots and roots transferred to soil and grew normally without loss of green colour and wilting.

Introduction

The economical and ecological importance of leguminous forest trees necessitated the application of micropropagation technique for their clonal multiplication **(Pradhan *et al,* 1998)**, furthermore, the regeneration rate of leguminous trees in natural habitats is low **(Dewan *et al,* 1992)**. Also, as stated by **Nanda and Rout (2003)**, due to poor germination and death of young seedlings under natural conditions, propagation through seeds, as with most leguminous trees is unreliable. Tissue culture techniques have been used for rapid clonal multiplication of selected genotypes of a number of forest trees including some woody legumes **(Dhawan, 1989 and Trigiano *et al,* 1993)**. During the past few years, a number of woody legumes have been successfully propagated *in vitro* using juvenile as well as mature plant parts **(Pradhan *et al,* 1998)**.

Colutea istria Mill. is a very rare species in Egypt and confined to Sinai which seems to be the westernmost limit of the species distribution. Its Arabic name is Yasser. The genus *Colutea* is belonging to the family Fabaceae (Leguminosae). It is a nano-phanerophyte which grows on crevices of smooth-faced rocky outcrops. Flowering and fruiting of this species is from February to April. *Colutea istria* is a vulnerable shrub. Its vulnerability can be related to its small population size combined with cutting by the natives for the preparation of ropes from the bark fibers. Older branches are used as firewood grazing by domestic livestock leading to the gradual decline of the species. Two populations of *Colutea istria* in Gebel El Rabba (Sant Catherine, South Sinai) and Gebel El Maghara (North Sinai) are being wildlife sanctuaries. Cultivation in botanical gardens as an ornamental is another useful method to protect the species from extinction. The plant is of horticultural value, because of its habit and decorative flowers **(El-Hadidi *et al,* 1991)**. The bark and fibers are used for the preparation of strong ropes **(Danin, 1983)**. It is a highly palatable, has a high nutritive value and is used as a fodder plant.

The seed oils of *Colutea* contained linoleic, oleic and linolenic acids as their major components. Palmitic and stearic acids were the major saturated fatty acids in the seed oils **(Bagci, 2004)**. Sixteen flavonoidal compounds from *Colutea istria* were isolated and identified as: quercetin-3-glucoside; quercetin-3-gentiobioside; quercetin-3,7-diglucoside; isorhamnetin-3-gentiobioside; isorhamnetin-3-rutinoside; kaempferide-3,7-diglucoside; 2',4,4'trihydroxychalcone; 2',4,4',6'tetrahydroxychalcone; formononetin; daidzein; calycosin; cladrin; rhamnocitrin-3-neohesperidoside; rhamnocitrin-3-glucoside; rhamnocitrin-3-galactoside and rhamnocitrin aglycone **(Shabana *et al,* 2005)**. Two new isoflavonoids have been isolated from the aerial parts of *Colutea istria* of Egyptian origin and identified as (3)-7-hydroxy-3',4'-dimethoxyisoflavan-2',5'-quinone and 6,3'-dihydroxy-7,4'-dimethoxyisoflavone **(Radwan, 2008)**.

Hegazi (2005) studied the response of *Colutea istria* Mill. to *in vitro* propagation from nodal segments and shoot tip explants from the mature plants. Explants were cultured on Murashige and Skoog (MS) nutrient medium **(Murashige and Skoog, 1962)** supplemented with different concentrations of 6-benzyladenine (BA) alone or in combination with 0.1 mg/L δ-Naphthalene acetic acid (NAA). In the establishment stage of the nodal segments; MS nutrient medium supplemented with 3 mg/L BA attained the highest average number of axillary shoots/explants. However, MS nutrient medium with 3 mg/L BA and 0.1 mg/L gave the highest value of the average length

of axillary shoots. MS medium supplemented with 4 mg/L BA with or without 0.1 mg/L NAA were the best media for the establishment of shoot tip explants. Nodal segments showed better response to the *in vitro* establishment than shoot tips. The regenerated shoots from both types of explants were multiplied on the best establishment medium. Shoots showed a reduced ability to elongate and became senescent, then abscised. To overcome this problem, different treatments were applied as the elimination of BA from the medium, doubling the amount of Calcium Cloride (CaCl2) in the medium, using the double phase medium, addition of Silver nitrate (AgNO3) to the medium, at different concentrations (1, 2 and 5 mg/L) and reducing the sucrose concentration to 20 g/L. All these treatments did not prevent the yellowing and necrosis of the shoots.

The aim of this study is to develop a micropropagation protocol for *Colutea istria* Miller using seedling explant materials because juvenile explants generally perform better in tissue culture than do mature explants, and to overcome early shoot senescence and obtain complete plantlets of this important endangered plant, to conserve and protect it from extinction. Since, there is no information on the micropropagation of Genus *Colutea* except the previous review.

Materials and Methods

Plant material, media and culture conditions

Seeds of *Colutea istria* Mill. were collected from their natural habitat; Gebel El-Maghara in Wadi El-Arousia. They were washed under running tap water and surface sterilized by immersion into 50% concentration of commercial bleach (active ingredient, 5.25% NaOCl) for 20 min, and then rinsed five times with sterile distilled water.

Seeds were individually planted on MS medium free from plant growth regulators (PGRs). The percentage of survival and seed germination were recorded after three weeks of culture. Cotyledonary nodes, stem node sections and shoot tips from the seedlings were examined for *in vitro* propagation. The *in vitro* establishment of explants was attempted by using various concentrations of BA, TDZ and 2iP (0.5, 1, 2 mg/L each) in combination with NAA at 0.1 or 0.2 mg/L incorporated into MS and Gamborg's (B5) media, in addition to the control media without PGRs, to select the optimum hormonal combination and concentration for shoot development.

All media were supplemented with 100 mg/L myo-inositol, 30 g/L sucrose and gelled with 2.5 g/L phytagel. The pH was set at 5.7-5.8, adjusted with 0.1N NaOH and HCl. Fifteen ml volumes of the media were dispensed into 25×150 mm glass culture tubes for explant establishment and rooting, or 45-50 ml volumes into large jars for seed germination and proliferation of shoots. All containers were closed with autoclavable polypropylene caps and autoclaved for 15 minutes at 121˚C under a pressure of 1.1 Kg/cm². The cultures were incubated at a temperature of 26±2˚C and were exposed to a 16-h photoperiod supplied by a bank of cool-white florescent tubes of 2 K lux light intensity.

For multiplication, the explants were cultured on MS medium containing BA at concentrations of 0.25, 0.5 and 1 mg/L and 2iP at a concentration of 0.5 mg/L – either individually or in combination, to obtain stock materials to be used for the following stages. MS medium without PGRs was also tested.

Thirty replicates were used for each treatment, and each experiment was repeated thrice during 2008-2010. The percentage of explants regenerating axillary growth, the average number of axillary shoots/explant and the average length of axillary shoots (cm) were recorded after 3 weeks of culture.

For root induction, the *in vitro* developed shoots were planted on MS medium supplemented with various concentrations of IBA and NAA (0.1, 0.2, 0.5, 1, 2 mg/L) individually and in combination, as following; 0.1 mg/L IBA+0.1 mg/L NAA, 1 mg/L IBA+0.2 mg/L NAA, 1 mg/L IBA+1 mg/L NAA and IBA at concentrations of 0.5, 1 and 2 in combination with 0.5 mg/L NAA. Explants with well developed roots were placed in pots containing garden soil and peat moss in a ratio of 1:1 and covered with plastic bags to maintain high humidity. The pots were irrigated regularly.

Treatments for overcoming shoot senescence

Treatments tested to overcome shoot senescence and necrosis of the plantlets were 1. Addition of L-glutamine at 100 mg/L – either individually or in combination with thiamine-HCl at 40 mg/L. 2. Reduction of the duration of the subculture from 4-6 weeks as recorded by **Hegazi (2005)** to 3 weeks. 3. Reducing the concentration of BA and addition of 2iP to the medium. 4. Transferring the shoots into growth regulators free medium after each subculture

Analysis of data

Analysis of variance (ANOVA) and Duncan's multiple range test were performed to analyze the obtained data. The differences among means for all treatments were tested for significance at 5% level. Means followed by the same letter are not significantly different at $P \leq 0.05$.

Results and discussion

Seeds germination and establishment stage

The seeds were germinated on MS medium free from PGRs and germination percentage reached 44.2% after 3 weeks of culture (Figure 1A). An experiment was conducted testing the establishment of the three types of explants developed from the germinated seedlings; cotyledonary nodes, stem node sections and shoot tips, cultured on MS and B5 media supplemented with NAA at 0.1 or 0.2 mg/L in addition to three different cytokinins; BA, TDZ and 2iP, at concentrations of 0.5, 1 and 2 mg/L as shown in table 1 (Plate 1B).

Concerning the establishment stage (Figure 1B), table 1 indicates that the use of MS nutrient medium was more effective than B5 medium with respect to the average number and length of axillay shoots for all types of explants. This finding is agreed with **Vengadesan *et al* (2002)** who reported that MS medium was preferred in the micropropagation of many leguminous trees. For shoot tips there was insignificant difference in the average shoot length between MS medium supplemented with 0.1 mg/L NAA+2 mg/L BA and B5 medium supplemented with 0.2 mg/L NAA+0.5 or 1 mg/L BA. And the highest value of the average length of axillary shoots was obtained on MS medium containing 0.1 mg/L NAA+0.5 or 1 mg/L BA. Shoot tips gave the highest percentage of explants regenerated axillary growth (100%) on most of the tested media if compared with the other types of explants. The suitability of shoot tip explants for regeneration and its sensitivity to various hormones is due to the activity of meristematic cells, which are actively dividing and are known to have dense cytoplasm with much more uniform and homogenous composition **(Mathur *et al*, 2002a)**. Also, cotyledonary nodes gave 100% of explants regenerated axillary growth on B5 medium without PGRs and B5 medium+0.2 mg/L NAA+0.5 and 2 mg/L 2iP. However, stem node sections gave the highest percentage of explants regenerated growth (83%) on MS medium supplemented with 0.1 mg/L NAA+1 mg/L BA.

It is noticed that the best medium with respect to the average number of axillary shoots derived from cotyledonary nodes, was MS medium containing 0.1 mg/L NAA+0.5 mg/L BA. However, MS medium without PGRs gave the best average length of axillary shoots (3.6). **Abd Alhady *et al* (2010)** have also recorded similar results on

MS control medium in the establishment of *Periploca angustifolia*. Stem node sections gave the highest number of axillary shoots/explant on MS medium supplemented with 0.1 mg/L NAA+2 mg/L BA, and it significantly decreased with the decrease of BA concentration. The highest average length of axillary shoots was obtained on MS medium supplemented with 0.1 mg/L NAA+0.5 mg/L BA. Shoot tips developed the maximum number of axillary shoots/explant on MS medium containing 0.1 mg/L NAA+0.5 and 1 mg/L BA which decreased significantly with the increase of BA concentration.

Comparing the three tested cytokinins added to B5 medium; differences were observed in the data obtained. It could be noticed that TDZ at 0.5 mg/L followed by 2iP at 2 mg/L gave the highest average number of axillary shoots/explants, and 2iP at concentrations of 1 and 2 mg/L proved to be the best with respect to the average length of axillary shoots developed from cotyledonary nodes. Also, **Scholten (1998)** found that Lilac tree (*Syringa vulgaris*) needed 2iP for elongation and it is used to induce bud growth in many *Acacia* species **(Vengadesan *et al*, 2002)**. Concerning stem node sections; BA and TDZ at concentrations of 1 and 2 mg/L in addition to all the tested concentrations of 2iP (0.5, 1 and 2 mg/L) were insignificantly different in the average number of axillary shoots/explant. Also, the average length of axillary shoots was insignificantly different on all B5 tested media. With respect to shoot tip explants, there were insignificant differences between the three tested cytokinins in the average number of axillary shoots/explants. Although, average length of axillary shoots was significantly the highest on B5 medium containing 0.5, 1 mg/L BA and 2 mg/L TDZ. The B5 control medium without PGRs and B5 medium containing 0.2 mg/L NAA are not recommended for the *in vitro* establishment of *C. istria* plant due to the least or no response of the explants.

In conclusion, the best medium for establishment of all tested explants was MS medium supplemented with NAA and BA, in addition to PGRs free MS medium. This result confirmed by **Al-Wasel (2000)** who obtained multiple shoots from shoot tips of seedlings of *Acacia seyal* when BA and NAA were used together. He found that no clear trend was observed by TDZ. BA in combination with an auxin was also found to be essential for multiple shoot induction in some other leguminous trees as many *Acacia* species **(Shekhawat *et al*, 1993; Bhaskar and Subhash, 1996** and **Vengadesan *et al*, 2002)**. In addition, **Abd Alhady *et al* (2010)** found that the combination of the two cytokinins (BA and 2iP) was more ideal for shoot multiplication than 2iP singly. The best average number and length of axillary shoots were obtained by using cotyledonary nodes as explants. It may contribute to the role of cotyledonary nodes in shoot production from seedling explants as they supply endogenous growth regulators to the cultures as reviewed by **Audiehya (1999)**. Also, cotyledonary nodes were used successfully for the micropropagation of *Acacia mangium* **(Vengadesan *et al*, 2002)**.

Multiplication stage

With respect to the multiplication stage (Figure 1C), data shown in table 2 indicates that cotyledonary nodes gave the maximum average number of axillary shoots/explant on MS medium supplemented with 0.5 mg/L of both BA and 2iP followed by 0.25 mg/L BA which is the best medium in the average length of axillary shoots. The average length of axillary shoots decreased with the increase in BA concentration. Similar observation was reported by **Abd Alhady *et al* (2010)**. There were insignificant differences in the average length of axillary shoots between the MS medium containing 0.5 and 1 mg/L BA and that containing 0.25 and 0.5 mg/L BA+0.5 mg/L 2iP. Concerning stem node sections, MS medium containing 0.25 mg/L BA+0.5 mg/L 2iP induced the highest average number of axillary shoots/explants, followed by MS medium without PGRs and MS+0.5 mg/L of both BA and 2iP which is insignificantly different from the same concentration of BA (0.5 mg/L) without 2iP. Both 0.25 and 0.5 mg/L BA were optimum for the production of the highest average length of axillary shoots, followed by 0.5 mg/L 2iP. Shoot tip explants gave the highest number of axillary shoots/explant on MS medium with 1 mg/L BA and decreased with the decrease of BA concentration or addition of 2iP to the medium. With respect to the average length of axillary shoots, it reached the highest value on MS medium containing 0.25 mg/L BA comparing to the other tested media. BA as a cytokinin proved to be effective *in vitro* with many woody species **(Murashige, 1974; Sharma *et al*, 1981 and Bennett and Davies, 1986)**. Also, it is the most frequently used compound in enhancing the production of proliferated shoots **(Thomas and Blackesly, 1987)**.

In conclusion, the combination of BA and 2iP is recommended for multiplying the established shoots produced from colyledonary nodes and stem node sections due to the significantly higher average number of axillary shoots/explant comparing to the media containing BA singly. However, BA is better for the multiplication of shoot tip explants. It was reported that an excess of synthetic cytokinin like BA is the most effective for the *in vitro* microporopagation of *Acacia mangium* **(Darus, 1993)**.

When axillary shoots were subcultured on the same medium, the shoots failed to multiply and leaves began to senesce. At the same time the leaf senescence progressed to the entire shoot and growth ceased. A similar observation was reported by **Hegazi (2005)** during the multiplication of of *Colutea istria* shoot tips and nodal segments from mature plants, and in other leguminous plants as *Leucaena leucocephala* **(Dhawan and Bhojwani, 1985)**, *Dalbergia latifolia* **(Swamy *et al*, 1992)** and *Dalbergia sissoo* **(Gulati and Jaiwal, 1996)**. For this reason it was important to apply a series of treatments to overcome such a problem.

Treatments for overcoming shoot senescence

Addition of L-glutamine at 100 mg/L either singly or in combination with Thiamine-HCl at 40 mg/L failed to inhibit yellowing and caused complete death of the explants. This result is in contrary with that of **Ranga Rao and Prasad (1991)** who mentioned that the amino acid L-glutamine increases shoot bud regeneration, and **Vengadesan *et al* (2002)** who found that it is ideal for shoot bud induction in *Acacia catechu* and *A. nilotica*. Also, **Mathur *et al* (2002b)** reported that incorporation of additives as glutamine and thiamine HCl was found to be most effective in shoot elongation as well as accelerating multiple shoot proliferation. Glutamine proved to be most effective to stop leaf-fall in multiple shoots, and thiamine is known to be one of the most important vitamin additives. Although green plant parts normally synthesize thiamine, additional amounts to the culture medium appeared to stimulate explants growth and may enhance root growth in the rooting stage.

The reduction of the duration of the subculture from 4-6 weeks as recorded by **Hegazi (2005)** to 3 weeks was very effective in the deterioration of the yellowing of the explants. This observation is supported by **Vengadesan *et al* (2002)** who found that in genus *Acacia*, frequent subculture of explants in constant intervals (25-30 days) make significant improvement in enhancing the number of multiple shoots. Repeated sub-culturing caused activation and conditioning of meristems. Two continuous subcultures excluding the initial culture favoured maximum shoot multiplication in *A. mangium*, *A. nilotica*, *A. sinulata*. Transferring the cultures to fresh

medium after three weeks found to be essential to prevent culture deterioration and sustained shoot growth.

Also, reducing the concentration of BA and addition of 2iP to the medium, gave promising results in the reduction of leaf senescence, since **Hegazi (2005)** used BA at high concentrations reached to 4 mg/L which caused shoot senescence in the multiplication stage. In this experiment the concentrations of BA reduced (0.25, 0.5 and 1 mg/L) and the percentage of explants regenerated growth and survived from yellowing ranged between 40% and 100%. Growth regeneration decreased with the increase of cytokinins concentration or the elimination of BA. It is concluded that BA is very important for the multiplication of shoots but if added with high concentrations it causes yellowing and necrosis of the explants. Also, the regular transferring of the shoots into fresh PGRs free medium after each subculture gave promising results in protecting the shoots. In this respect, **Al-Wasel (2000)** found that shoots of *Acacia seyal* needed to be subcultured into PGRs-free medium to allow and maintain shoot survival and elongation. These results are in harmony with that recorded by **Galiana *et al* (1991)** and **Darus (1993)** who mentioned that high concentrations of BA were observed to stimulate greatly the potential for axillary shoot formation during the first subcultures, but resulted quickly in a noticeable and often irreversible organogenic culture decline. It may rapidly become phytotoxic after a small number of subcultures, as noticed in other species. Also, **Rosu *et al* (1995)** reported that BA appears to have a positive effect only in the initial stage of culture establishment. This effect did not persist because of the leaf senescence which was presumably induced by ethylene. BA has been shown to stimulate ethylene biosynthesis *in vitro* **(Escalettes** and **Dosba, 1993)**.

Rooting and acclimatization

Only two media gave response in root induction; MS medium supplemented with 0.1 mg/L NAA which induced the rooting of 10% of axillary shoots and MS medium containing 0.5 mg/L of both IBA and NAA, on which 40% of explants developed roots (Figure 1D). These results is attributed to the presence of a number of explants that became senescent and caused the yellowing which didn't permit the auxins tested for promoting root formation. Fifty percent of the plantlets with well developed shoots and roots transferred to soil and grew normally without loss of green colour and wilting over 4 weeks observation period (Figure 1E).

Abstract: Amaryl (Glimepiride) is the third generation antidiabetic sulphonylurea known to possess the antioxidant effect in streptozotocin (STZ) induced diabetes. In this study, the antimutagenic activity of amaryl (0.03mg/kg.po daily for 30 days) was evaluated against the cytotoxic effect of alloxan (150mg/kg) on somatic and germinal cells of male and female albino rats . Somatic cells included bone marrow (for chromosome abnormality and micronucleus tests) and liver (for DNA fragmentation test). In germinal cells , sperm shape and count were studied . The present results showed that the glucose levels significantly increased in alloxan diabetic rats compared to those found in the controls. The alloxans diabetes of rats (males or females) had higher frequencies of structural and numerical chromosome aberrations compared to normal control. The diabetic condition in both male and female rats also increased the populations of each of micronucleated erythrocytes and DNA fragmentation. Moreover, the diabetic condition of male rats significantly increased the sperm shape abnormalities besides significant reducing of caudal sperm count. In contrast , the administrations of amaryl (glimepiride) to the alloxan diabetic rats had reduced the blood glucose level, abnormalities of genetic materials (chromosomal aberrations, the population of micronucleated erythrocytes, DNA fragmentation) and sperm shape abnormalities besides enhancing the sperm count. In conclusion, the present findings add that the antioxidant property of amaryl could have contributed for its ability to decrease the alloxan mediated defects in somatic and germinal cells.

1. Introduction

Several studies showed that hyperglycemia and oxidative stress play a central role in diabetic tissue damage (Mastrocola et al., 2005; Somefai. et al., 2006; Kuhad et al., 2008; Rabbani et al., 2009). High level of blood sugar determines overproduction of reactive oxygen species (ROS) by the mitochondria electron transport chain. Also, in diabetic condition, both nitric oxide levels and mitochondrial nitric oxide synthase expressions were found to be increased in brain mitochondria, whereas antioxidant defences, such as glutathione (GSH) peroxidase activity and manganese superoxide dismutase protein content were reduced (Mastrocola et al., 2005; Rabbani et al., 2009). ROS virtually damages all cellular components, leading to DNA and protein modification (Rehman et al., 1999; Rabbani et al., 2009). In consequence, the diabetic patients suffer from an increased risk of oxidative stress-related diseases not only in the present generation but can also transmit the nuclear defects to their progeny (Blasiak et al., 2004).

Induction of diabetes in laboratory animals is a convenient and useful strategy in the understanding and treatment of the disease. An appropriate dose of alloxan was used to induce experimental diabetes. Alloxan (AL) was the first cytotoxic compound reported to cause inhibition of glucose – induced insulin secretion and selective beta-cell damage (Lenzen and Panten, 1988). The cytotoxic activity of this compound seems to be achieved through its penetration into the pancreatic beta-cells, a phenomenon which by itself depends on the expression of the glucose transporter proteins-2 (Schnedl et al., 1994; Bloch et al., 2000). An addition contributor to beta cells sensitivity to alloxan or to various toxins related to their poor antioxidant enzyme defence system (Tiege et al; 1997).

Glimepiride is a sulfonylurea was known to possess antioxidant effect against the oxidative stress induced by streptozotocin –diabetes (Krauss et al., 2003; Rabbani et al., 2009). The mutagenic studies conducted by battery of in vitro and in vivo methods concluded that glimepiride do not have mutagenic potential (Donaubauer and Mayer, 1993; Rabbani et

al., 2009). Since quenching the free radicals generated in the oxidative stress is one of the possible mechanisms to prevent the mutagenic defects in diabetes and there is a need for antidiabetic regimen that also reduce the ROS induced health complications (Johansen et al., 2005; Rabbani et al., 2009), the present study has been planned to evaluate the anti-mutagenic effect of amaryl (glimepiride) in alloxan – induced diabetic rats.

2.Materials and Methods

2.1. Materials

2.1.1. Animals:

Males and females of adult albino rats weighing 150-160 g, bred in the Animal House Lab, National Research Centre, Cairo, Egypt, were used. These animals were maintained under standard laboratory conditions and provided a standard diet and water *ad libitum*.

2.1.2.Drugs:

Alloxan and glucose oxidase peroxidase diagnostic enzyme kit was purchased from Sigma (St. Louis, MO., USA).

Amaryl (Glimepiride tablet) was obtained from local pharmacies, Cairo, Egypt and ground using a mortar. The powder was dissolved in distilled water and orally administrated at dose 0.03 mg / kg b.wt / d 1 for 30 days. This dose equals the dose of acceptable daily intake of amaryl for human (4 mg/ Kg), after modification to suit the small weight of rats. The dose of amaryl was based on previous studies (Sato et al., 1993; Nieszner et al., 2002).

2.2. Methods:

2.2.1. Induction and assessment of diabetes:

A single dose of alloxan monohydrate (150 mg/ kg) was prepared in 10 % saline solution and injected intraperitoneally to induce diabetes (El-Shabrawy and Nada. 1996). Diabetes was confirmed after 72 h of alloxan injection, the blood samples were collected via retro-orbital venous plexus and serum glucose levels were estimated by enzymatic GOD-PAP (glucose oxidase peroxidase) diagnosis kit method (Kuhad et al., 2008 and Rabbani et al., 2009). The rats with serum glucose level above 200 mg / d1 were selected and used for the present study (Kuhad et al., 2008).

Also, blood glucose values were determined just prior to killing the animals at the end of experiment. The animals were fasted for three hours then blood was collected from orbital sinus.

2.2.2. Experimental design:

Male or female rats were randomly selected and divided in three groups of six animals each. First group consisted of non-diabetic control animals, second group was the diabetic control (D), and third group consisted of diabetic animals treated with amaryl (DT).

2.2.3. Chromosome preparations:

For chromosome analysis both treated (D or DT) and control animals were sacrificed by cervical dislocation at the end of experiment. One hour and half or two hours before sacrifice, rats were injected with 4 mg colchicine / kg. b.w. Femurs were removed and the bone marrow cells were aspirated using saline solution. Metaphase spreads were prepared using the method of Preston et al. (1987). Fifty metaphase spreads per animals were analyzed, for scoring the different types of chromosome aberrations.

2.2.4. Micronucleus test:

Bone marrow slides were prepared according to the method described by Krishna and Hayashi (2000). The bone marrow was washed with 1 ml of fetal calf serum and then smeared on clean slides. The slides were left to air dry and then fixed in methanol for 5 minutes, followed by staining in May-Grunwald-Giemsa for 5 minutes then washed in distilled water and mounted. For each animal, 2000 polychromatic erythrocytes (PCEs) were examined for the presence of micronuclei.

2.2.5. DNA fragmentation:

Liver samples were collected immediately after sacrificing the animals. The tissues were lysed in 0.5 ml lysis buffer containing 10mM tris-HCL (PH.8), 1 mM EDTA, 0.2 % triton X-100, centrifuged at 10000 r.p.m. (Eppendorf) for 20 minutes at 4ºC. The pellets were resuspended in 0.5 ml of lysis buffer. To the pellets (P) and supernatants (S), 1.5 ml of 10 % trichloroacetic acid (TCA) was added and incubated at 4ºC for 10 minutes. The samples were centrifuged for 20 minutes at 10000 r.p.m. (Eppendorf) at 4ºC and the pellets were suspended in 750 µl of 5 % TCA, followed by incubation at 100 ºC for 20 minutes. Subsequently, to each sample 2 ml of DPA solution [200 mg DPA in 10 ml glacial acetic acid, 150 µl of sulfuric acid and 60 µl acetaldehyde] was added and incubated at room temperature for 24 hour (Gibb et al., 1997). The proportion of fragmented DNA was calculated from absorbance reading at 600 nm using the formula:

$$\text{DNA fragmentation} = \frac{\text{OD of fragmented DNA (S)}}{\text{OD of fragmented DNA (S)} + \text{OD of intact DNA (P)}} \times 100$$

2.2.6. Sperm analysis:

For sperm-shape analysis, the epididimus excised and minced in about 8 ml of physiological saline, dispersed and filtered to exclude large tissue fragments. Smears were prepared after staining the sperms with Eosin Y (aqueous), according to the

methods of Wyrobek and Bruce (1978) and Farag et al. (2002). At least 3000 sperms per group were assessed for morphological abnormalities. The sperm abnormalities were evaluated according to standard method of Narayana (2008). Epididymal sperm count was also determined by hemocytometer as described by Pant and Srivastava (2003).

2.2.7. Statistical analysis:

Statistical analysis was performed with SPSS software. Data were analyzed using one-way analysis of variance (ANOVA) followed by Duncan's post hoc test for comparison between different treatment in the same sex. However, two-way analysis of variance (ANOVA) followed by Duncan's post hoc test were used in the DNA fragmentation test. Moreover Chi-Square test was used for comparison between male and female rats for inducing micronuclei and chromosome aberrations in diabetic condition and amaryl-treated diabetes. Results were reported as mean ± S.E. and differences were considered as significant when $P<0.05$.

3. Results

3.1. Blood glucose levels:

Blood glucose levels significantly increased in alloxan diabetic rats (Fig. 1, Table 1) compared to those in the normal controls (normal males or normal females). Whereas the blood glucose levels were significantly reduced in alloxan diabetic rats after 30 days of amaryl treated compared to those found in the D groups.

Fig.1:Alloxan - diabetic rats treated with amaryl (4mg/Kg)

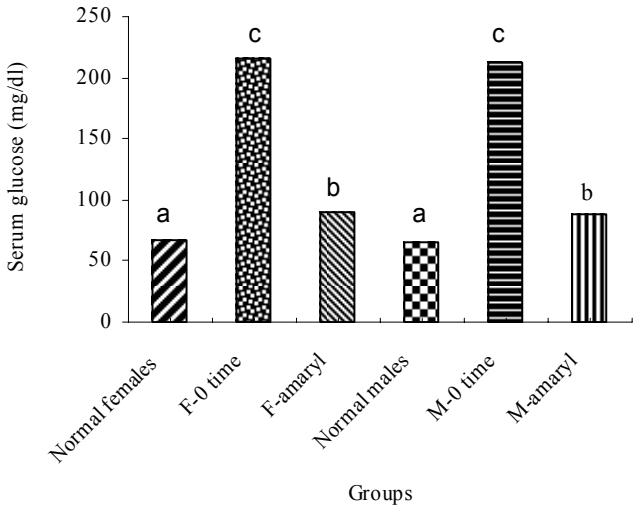

Table (1): Effect of amaryl (4 mg/Kg) on alloxan-induced diabetic female and male rats

Female			Male		
Normal females	F-0 time	F-amaryl	Normal males	M-0 time	M-amaryl
66.33± 1.35 [a]	215.58± 2.46 [c]	89.92 ± 1.36 [b]	66.00 ± 2.24 [a]	212.50 ± 1.86 [c]	88.75 ± 1.86 [b]

Data were expressed as mean ± S.E.

3.2. Chromosome examinations in diabetic male rats:

Chromosome examinations (Table, 2) showed that there were structural and numerical chromosome aberrations. Structural aberrations consisted of chromatic gaps and breaks, deletions, fragments, centromeric attenuation (C.A) and endomitosis. Numerical aberrations were aneuploidy and polyploidy. From the present results it was found that, the diabetic male rats (D group) had higher frequencies of structural and numerical aberrations than control group. Deletions, C.A., endomitosis and aneuploidy were more frequent than other aberrations. Statistical analysis showed that there were significant differences between diabetic and normal rats for the frequencies of total structural aberrations (except fragments) and total numerical aberrations.

On the other hand, the diabetic males treated with amaryl drug (DT group) had decreases in the frequencies of structural and numerical aberrations compared to D group. These decreases were significant ($P< 0.05$) for the frequencies of gaps, C.A, total structural aberrations, aneuploidy and total numerical aberrations.

3.3. Chromosome examinations in diabetic female rats:

Chromosome examinations (Table, 3) showed that the diabetic female rats had higher frequencies of structural and numerical chromosome aberrations compared to normal females. Statistical analysis showed that there were significant differences between diabetic and normal rats for the frequencies of chromatic gaps and breaks, deletions, fragments, C.A, endomitosis, total structural aberrations and polyploidy.

In contrast, the diabetic females treated with amaryl drug (DT) had decreases in the frequencies of structural and numerical chromosome aberrations compared to D group. These decreases were significant for the frequencies of deletions, fragments, C.A and total structural aberrations.

From the present study, it was observed that structural chromosomal aberrations were increased in diabetic females than those found in diabetic males

(Table, 4). These increases were significant ($P < 0.05$). On the other hand, numerical aberrations (especially aneuploidy) were more frequent in diabetic males than those found in diabetic females. However, the statistical analysis showed that the differences for the frequencies of numerical aberrations between the two sexes were not significant.

Moreover, the treatment with amaryl drug led to decrease of the structural and numerical chromosome aberrations in both diabetic sexes. However, the DT females were more response for decreasing of structural aberrations than DT males. Whereas, the frequencies of numerical aberrations were lowered in DT males than those of DT females.

3.4. Micronucleus assay:

In male groups: As shown in table (5), the frequencies of micronuclei were significantly higher ($P < 0.01$) in diabetic males (D group) than those found in the control group. On the other hand, the frequencies of micronuclei significantly decreased ($P < 0.05$) in diabetic males which treated with amaryl drug (DT group) compared with those found in D group.

Table (5): Effect of amaryl on the frequency of micronucleated polychromatic erythrocytes in alloxan-induced diabetic male rats

Treatment	No. of animals	No. of examined cells	Mean values of MNPE
Control	6	12,000	6.50±0.99 [c]
D	6	12,000	16.50±1.78 [a]
DT	6	12,000	11.67±1.05 [b]

Data were expressed as mean ± S.E.
Means with different superscript letters (a, b, c) are significantly different (P<0.05)
D: diabetic condition
DT: diabetic treated with amaryl

In female groups:

Micronuclei results in female groups (Table, 6) were similar with those recorded in male groups.

Moreover, the diabetic females had more frequencies of MNPE than diabetic males. However, statistical analysis showed no differences between the two sexes (Table, 7). On the other hand, the treatment of amaryl drug led to decrease of MNPE in both sexes. However, the DT females were more response for amaryl treatment and had the lowest frequencies of MNPE than DT males.

Table (6): Effect of amaryl on the frequency of micronucleated polychromatic erythrocytes in alloxan-induced diabetic female rats

3.5. DNA fragmentation:

In male groups:

The present results (Table, 8) showed that, the rates of DNA fragmentation were significantly increased ($P < 0.05$) in diabetic males than those in control group. On the other hand, the rates of DNA fragmentation significantly decreased ($P < 0.05$) in diabetic males treated with amaryl drug (DT) compared to D group of males.

In female groups:

The diabetic females had more frequent ($P < 0.01$) of rates of DNA fragmentation. In contrast, the rates of DNA fragmentation significantly decreased ($P<0.05$) in diabetic females treated with amaryl drug (DT) compared to D group of female.

Moreover, diabetic females had higher frequent ($P<0.05$) of DNA fragmentation than diabetic males. On the other hand, the treatment with amaryl drug led to decrease the rates of DNA fragmentation in both diabetic sexes. The DT females were more response for decreasing of DNA fragmentation than DT males. However, statistical analysis showed no differences for the frequencies of DNA fragmentation between two sexes (DT males and DT females).

Table (8): Effect of amaryl treated upon DNA fragmentation of rat livers. The livers were obtained from control, diabetic and amaryl-treated diabetic rats

Sex	Treatment	Rate of DNA fragmentation
Males	**Control**	19.78 ± 0.32 [de]
	D	34.17 ± 1.19 [b]
	DT	23.16 ± 1.38 [cd]
Females	**Control**	19.46 ± 0.22 [e]
	D	41.02 ± 2.08 [a]
	DT	24.68 ± 0.19 [c]

Data were expressed as mean ± S.E. Means with different superscript letters are significantly different (P<0.05)
D: diabetic condition DT: diabetic treated with amaryl

3.6. Sperm-shape analysis:

Sperm examination (Table, 9) showed that the sperm abnormalities (head and tail) were more frequent in diabetic male rats than those of the control. Statistical analysis showed the differences of the frequencies of head abnormalities (such as amorphous, total head abnormalities) and total sperm abnormalities (head and tail) were significant ($P < 0.05$ or $P < 0.01$) between diabetic and normal rats. On the other hand, the sperm abnormalities especially in head decreased in males diabetic treated with amaryl drug (DT) compared to those of the diabetic animals (D group). These decreases were significant ($P < 0.05$) in the frequencies of amorphous, without hock, total head and total sperm abnormalities. Exception to this,

the frequencies of tail abnormalities were few in each of D (0.17) and DT (0.33) groups; these abnormalities non-significant increased in DT group than those found in D group.

Sperm count:

Sperm counts significantly decreased ($P < 0.01$) in diabetic rats than those found in control group. In contrast, sperm counts significantly increased ($P < 0.05$) in diabetic rats treated with amaryl drug (DT) compared to those of the D group.

Table (9): Sperm abnormalities in diabetic condition of male rats and amaryl-treated diabetes

Treatment	Head abnormalities						Tail abnormalities	Total abnormalities	Sperm count
	Amorphous	Without hock	Small shape	Big shape	Banana	Total	Coiled		
Control	0.67± 0.33 [b]	2.33± 0.42 [c]	0.50± 0.34 [a]	0.0± 0.0 [a]	0.17± 0.17 [a]	3.67± 0.84 [c]	0.0± 0.0 [a]	3.67± 0.84 [c]	76.60± 4.06 [a]

D: diabetic condition
DT: diabetic treated with amaryl

4. Discussion

In the present study, the blood glucose levels significantly increased in alloxan diabetic rats compared to those in the normal controls. Our results are in agreement with that reported on observed hyperglycemia in alloxan diabetic mice (Diamond et al., 1989) and rats (El-Shabrawy and Nada, 1996). The observed hyperglycemia may be due to cytotoxic effect of alloxan compound on level of glucose transporter protein-2 (GLUT-2) expression in the pancreatic beta-cells causing inhibition of glucose-induced insulin secretion (Lenzen and Panten, 1988; Schnedl et al., 1994, Bloch et al., 2000). The administration of amaryl for 30 days at dose of 0.03mg/g b.wt. caused a significant reduction of the serum glucose level in alloxan diabetic rats. Similarly, Rabbani et al. (2009) found that the administration of glimepiride to nicotinamide (NA)-streptozotocin (STZ) diabetic rats had reduced the serum glucose level. As known amaryl (glimepiride) belongs to third generation sulphonylureas and chemically it is a carboxamido phenyl pyrroline sulphonylurea. The primary mechanism of action of glimepiride in lowering the blood glucose appears to be dependent on stimulating the release of insulin from functioning pancreatic beta-cells (Kramer et al., 1996; Rabbani et al., 2009). The extra pancreatic glucose reducing effects include inhibition of gluconeogenesis, ketogenesis, stimulation of peripheral glucose transport, glucogen synthase activity and glycerol-3-P-acyltransferase activity (Muller et al., 1995; Rabbani et al., 2009). Also, Kecskemeti et al. (2002) and Yassin and Mwafy (2007) indicated that the main effect of the sulfonylureas is enhancement of insulin secretion and improvement of metabolism both by pancreatic and extra-pancreatic mechanisms.

The present results showed that the alloxan diabetes of rats (males and females) had higher frequencies of structural and numerical chromosome aberrations compared to normal control. The diabetic condition in male and female rats also increased the populations of each of micronucleated erythrocytes and DNA fragmentation. Moreover, the diabetic

condition of male rats significantly increased the sperm shape abnormality besides significant reducing of caudal sperm count. These effects appeared to be mediated through the oxidative stress and inducing of ROS generated due to hyperglycemia (Vikram et al., 2007; Shrilatha and Muralidhara, 2007). The generation of ROS in diabetes was considered to be the major cause for mutagenecity including chromosome aberrations, DNA fragmentation, micronuclei and sperm abnormalities (Chauhan et al., 2000; Otton et al., 2004; Rabbani et al., 2009). Cytogenetic analysis by Tollinger et al.(1974) and Bloch et al. (2000) indicated that the majority of alloxan- induced diabetic rats was composed of hypodiploid cell with a chromosome number of 38 to 41 (2n=42). Also, chromosome abnormalities (aneuploidies and polyploidies) have been reported to be increased frequency in embryos of diabetic mice (Yamamoto et al., 1971). The influence of alloxan diabetes on first meiotic segregation behaviour in female and male mice was studied by Wauben-Penris and Prins (1983) who found in primary spermatocytes higher chiasma frequencies in the translocation multivalent in diabetic males than in controls. Also, the analysis of metaphase -II cells in the females revealed less 3:1 segregation and more adjacent-II segregation in the diabetics. So, they concluded that diabetes influences the meiotic segregation behaviour of chromosomes and that chromosomes showing higher incidence of unbalanced segregation behaviour. Also, alloxan diabetes caused fragmentation of nuclear beta-cell DNA (Okamoto, 1996). The occurrence of DNA fragmentation in lymphocytes obtained from alloxan – induced diabetic rats was found to be 81% compared to 45% of untreated cells from the control (Otton et al., 2004).So, an association between diabetes and both chromosomal abnormalities and DNA fragmentation has been found, and alloxan has been used as a means of studying this association. Despite, the fact that alloxan has been used in chromosomal and DNA fragmentation studies, no information is available concerning alloxan as a cause of micronuclei and sperm abnormalities. However, the increase micronuclei frequency and sperm abnormality has been reported in streptozotocin (STZ) diabetes of rats and mice(Vikram et al., 2007; Shrilatha and Muralidhara, 2007). Also, the results of Rabbani et al. (2009) indicated that STZ diabetes of rats increased the population of micronucleated erythrocytes and sperm shape abnormality besides reducing of caudal sperm count. Several studies reported that suggested mechanism for inducing damage of nuclear component and sperm abnormalities in diabetic condition include the activation of several damaging pathways by the ROS such as accelerated formation of advanced glyccation end production (AGE), polyol pathway, hexosamine pathway, protein kinase (PKC) or increase of lipid peroxidation (LPO) (Piconi et al., 2003; Valko et al., 2007 and Rabbani et al., 2009).

LPO occurs when ROS attacked the poly unsaturated fatty acid residues of phospholipids of cell membrane which is extremely sensitive to the oxidation. Host cell like spermatozoa are highly susceptible to the damage by excess concentrations of ROS due to high content of polyunsaturated fatty acid within their plasma membrane. Increased LPO and altered membrane can affect the sperm function through impaired metabolism, motility, acrosome reaction as well as oxidative damage to sperm DNA leading to increase of morphological changes in sperm and decrease of caudal sperm count (Tramer et al., 1998; Kumar et al., 2002; Sanchez et al., 2006; Rabbani et al., 2009). Also, Sikka (2001) reported that the decrease in sperm count can be attributed to the influence of hyperglycemia on late stages of spermatogenesis, possibly through an increase of reactive oxygen species (ROS). The consequences of such oxidative damage could include loss of motility due to lipid peroxidation. Moreover, Hemachand and Shaba (2003) indicated that the increased hydroperoxide level can affect the spermatogenesis process, since germ cells are more susceptible to peroxidative damage.

In contrast, the administration of amaryl (glimepiride) to the alloxan (AL) diabetic rats in the present study had reduced the abnormalities of genetic materials (chromosomal aberrations, DNA fragmentation, the population of micronucleated erythrocytes) and sperm shape abnormalities besides enhancing the sperm count. These findings indicated that amaryl (glimepiried) inhibited the AL mediated changes in the genetic materials and sperm abnormality and enhanced the antioxidant defence. These observations suggest that the antioxidant property of amaryl could have contributed for its ability to decrease the AL mediated defects in somatic and germinal cells. Similar results were observed by Rabbani et al. (2009) who reported that the administration of glimepiride to the STZ diabetic rats had reduced the population of micronucleated erythrocytes and sperm shape abnormalities besides enhancing the sperm count compared to diabetes control. They also found that this drug has enhanced the serum levels of antioxidant enzymes (CAT, SOD and GPx) and reduced the LPO and hyperglycemia. So they suggested that the increasing levels of CAT, SOD and GPx and reducing the LPO could minimize the cytogenetic damage in somatic and germinal

cells. The same authors indicated that the compound possessing glucose lowering property along with an antioxidant effect play a beneficial role in preventing the ROS mediated DNA damages. Krishnamoorthy et al. (2007) reported that antioxidants limit the nuclear damage by preventing the free radical action.

The antioxidant activity of glimepiride on rats with streptozotocin -induced hyperglycemia was also previously reported by Krauss et al. (2003) who found that the administration of glimepiride had increased the plasma levels of SOD, GPx besides reducing the levels of H2O2 and malondialdehyde. So, they suggested that glimepiride by increasing the level of antioxidant enzymes lead to decrease the ROS mediated damage in the host cells. Kono (1978) and Valko et al. (2007). Rabbani et al. (2009) reported that SOD is an enzyme that catalyses the dismutation of superoxide ion in to oxygen and hydrogen peroxide, thus protecting the cell from the superoxide toxicity. Moreover, Valko et al. (2007) and Rabbani et al. (2009) indicated that the function of GPx is to remove the H2O2 generated by metabolic action or oxidative stress. Another study by Yassin and Mwafy (2007) found in diabetic rats, that serum triglycerides, cholesterol and urea concentration were markedly elevated. However, glimepiride therapy returned such changes towards normal.

In conclusion, the present findings add that the antioxidant property of amaryl could have contributed for its ability to decrease the alloxan mediated defects in somatic and germinal cells.

Abstract: The aim of this study was to evaluate the antimicrobial properties of three calcium hydroxide based endodontic sealers: Apexit sealer (Ivocalr/Vivdent, Schaan and Liechtenstein), CRCS sealer (Coltene-Whaledent, U.S.A) and Sealapex sealer (Kerr Co, Italy) against *Streptococcus α haemolyticus* (facultative anaerobic bacteria). **Materials and Methods**: Three methods were used to evaluate the antibacterial activities of the three root canal sealers against *Streptococcus α haemolyticus* using "Agar diffusion test". The strains were prepared and inoculated into 5ml broth and incubated at 37^{o}C for 24 h. The freshly mixed sealers were placed into the prepared wells of agar plates (inoculated with the test microorganisms). The antimicrobial effect of each sealer was determined by measuring the diameter of zones of inhibition in millimeters at one and three days period. Five plates were prepared for every sealer in each method. **Results** showed that Sealapex gave the highest mean of inhibition zone diameter. This was followed by CRCS and Apexit showed the lowest mean of inhibition zone after one day. While at the three days period, the Sealapex gave the largest inhibition zone diameter and there was no statistically significant difference between CRCS and Apexit groups. The three methods used confirm these results.

Key words: Root canal sealers, *Streptococcus α haemolyticus,* Agar diffusion test

1.Introduction

Among the ideal criteria set up by Grossman in the 1980's, for the selection of root canal sealer; *"It must possess bactericidal properties or at least has bacteriostatic effect"* Fraunhofer and Branstetter (1982).Flora of root canal infections are polymicrobial. While some are asymptomatic, others are associated with serious infections. The seriousness of an infection beyond the apex of a tooth is related to number, virulence, host resistance, and associated anatomic structures. If the infection spread beyond the tooth socket, it may localize or continue to spread through the bone and soft tissues as diffuse abscess or cellulitis, Khemaleelakul et al.,(2002).

Many researchers investigated the composition of the microbiata from acute and chronic endodontic infections. Fox and Isenberg(1967) studied the bacterial populations of 381 positive cultures from root canals and their antibiotic resistance pattern. They found that incidence of *Enterococci* which was second to *Viridans streptococci* in the study, Fox and Isenberg(1967). Ibrahim and Aisa(1973) found that 58.8% (204 out of 381) pure positive cultures taken from infected root canals before treatment were *Streptococci.*Ibrahim and Aisa (1973) . Infective endocarditis caused by the *Viridans* group of organisms is generally a result of their invading into the blood stream during intra oral procedures; tooth extraction, endodontic treatment, or even during tooth brushing,Samaranayake(1996).The *Viridans* group or other species of *Streptococci* typically shows alpha hemolysis on blood agar. Various biological properties of calcium hydroxide are due to its strong alkalinity, (pH 12.5). Thus, several bacterial species commonly found in infected root canals are eliminated after short period when in direct contact with this substance. Most of the endo-pathogens are unable to survive in such highly alkaline environment, Siqueira and Lopes (1999). Mirijana and Branka(2006) evaluated the antimicrobial activity of five root canal sealers: AH26 (a resin based paste);Apexit (calcium hydroxide based paste); Endo-methasone and Tubliseal (zinc oxide eugenol-based materials) and Ketac Endo Aplicap, (glass ionomer based sealer). Antimicrobial activity was tested against *S. mutans* 70C and *L.casei* ATCC 27773 using ADT (agar diffusion inhibitory test) on TYC SB, blood and MRS agars. The results confirmed that epoxy resin and zinc oxide-eugenol based sealers had the greatest antimicrobial effect. Calcium hydroxide and glass ionomer based sealers showed significantly lower antimicrobial activity compared to AH26, Endo-methasone and Tubliseal. The greatest antimicrobial activity was found for epoxy resin based sealer (AH26) for both tested microorganisms. In several studies, the antibacterial activity of calcium hydroxide[$Ca(OH)_2$]containing sealers was tested by 'Agar diffusion test' (Al-Khatib et al.(1990);. Therefore this study aimed to evaluate the antibacterial effect of three $Ca(OH)_2$ based sealers using different cultivating techniques.

2.Materials and methods

2.1.Materials

2.1.1. The root canal

The root canal sealers studied were:

1. Apexit sealer (Ivocalr/Vivdent, Schaan and Liechtenstein).
2. CRCS sealer (Coltene-Whaledent, U.S.A).
3. Sealapex (Kerr, Italy)

All of them were mixed according to the manufacturers' instructions.

2.1.2. Microorganism:

Microorganism used :in this study was *Streptococcus α haemolyticus*.

It is facultative anaerobic bacteria.

2.2.Methods:

Three methods were used to evaluate the antibacterial activities of the three root canal sealers against the *streptococcus α haemolyticus.*

The strains were prepared and inoculated in 5ml broth and incubated at 37^{o}C for 24 h.

2.2.1.Method (1)

1ml of the prepared bacterial suspension was impregnated and mixed by hand shacking with the blood agar while it is still liquid, then poured into sterile Petri dishes. Plates were left for 5 minutes to allow the media to harden. Wells were then punched using sterile disposable micropipette tips of 5mm diameter and 5mm depth in each agar plate and filled with the freshly mixed sealers.

2.2.2.Method (2)

Mueller-Hinton Agar was used instead of blood agar plates. Typical formula of Mueller-Hinton Agar by g/l contains: beef, dehydrated infusion from 300.0, casein hydrolysate 17.5, starch 1.5, agar 17.0, supplemented with yeast extract 0.1% and glucose extract 0.1%. Seeding was done using sterile cotton swabs, by spreading/brushing the bacteria across the surface of the blood agar, vertically and horizontally from the bacterial suspension. Similar to that tube # 3 of the Mc Farland scale. Plates were left for 5 min to allow the absorption of the inoculum.

2.2.3.Method (3)

Petri dishes containing blood agar were prepared .Seeding was done using sterile cotton swabs, by spreading/brushing the bacteria across the surface of the blood agar, vertically and horizontally from the bacterial suspension. Similar to that tube # 3 of the Mc Farland scale. Plates were left for 5 min to allow the absorption of the inoculums. Wells of 5mm diameter and 5mm depth were punched in each agar plate and filled with the freshly mixed sealers.

The agar plates were incubated into anaerobic jars at 37^{0}C for 24 and 72 hrs. The antimicrobial effect of each sealer was determined by measuring the diameter of zones of inhibition in millimeters. Five plates were prepared for every sealer in each method.

3.Results

3.1. Results of Blood agar impregnated with 1 ml of bacterial suspension (Method 1)

(Blood agar impregnated with 1 ml of bacterial suspension-method 1) at one day period showed that there was a statistically significant difference between the three groups (P < 0.001) by ANOVA test.

Duncan's test showed that Sealapex gave the statistically significantly highest mean inhibition zone diameter. This was followed by CRCS. Apexit showed the statistically significantly lowest mean as shown in figures (26, 27, and 28)

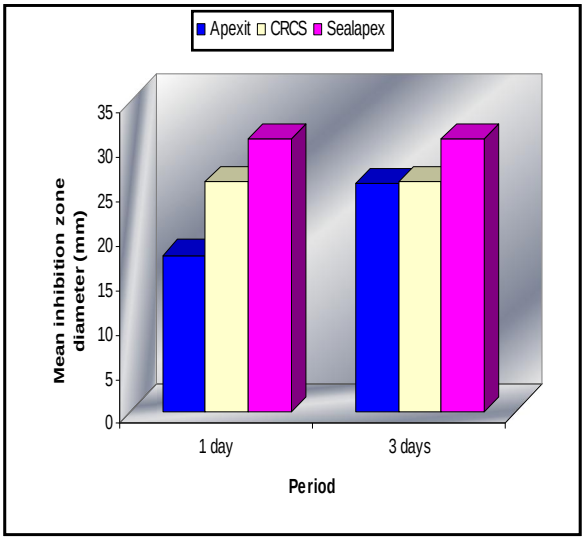
While After 3 days period ANOVA test showed that there was a statistically significant difference between the three groups (P = 0.037).

Duncan's test showed that Sealapex gave the statistically significantly highest mean inhibition zone diameter. There was no statistically significant difference between CRCS and Apexit which showed the statistical significant lowest means of inhibition zones.

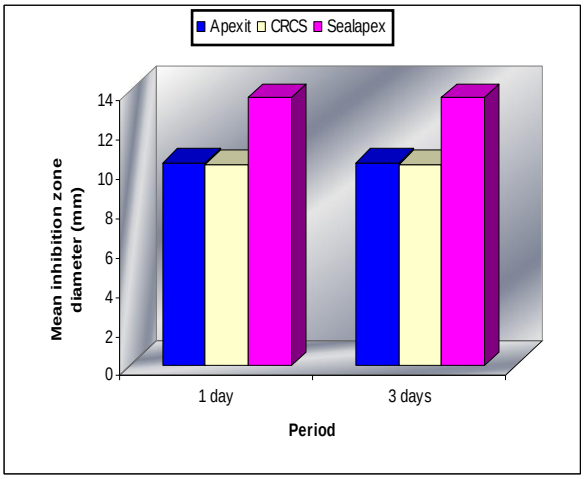
3.2. Results of Meuller Hinton agar (method 2)

After 1 day and 3 days of incubation ,ANOVA test showed that there was a statistically significant difference between the three groups (P < 0.001).

Duncan's test showed that Sealapex gave the statistically significantly highest mean inhibition zone diameter. There was no statistically significant difference between CRCS and Apexit which showed the statistical significant lowest means as shown in figures (1,2,3).



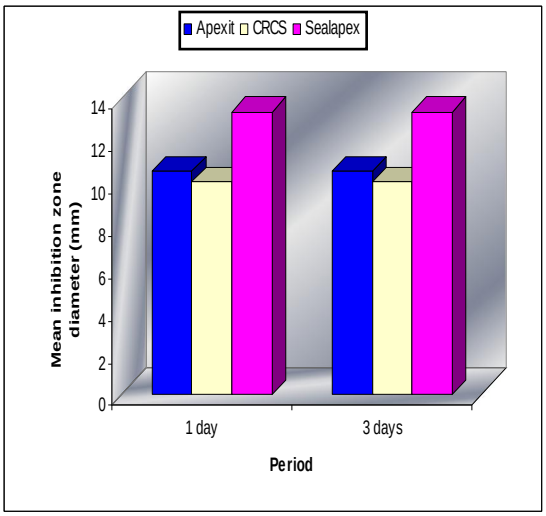
Mean inhibition zone diameter in the three groups (method 1) Fig (1)



Mean inhibition zone diameter in the three groups (method 2) Fig (2)

3.3.Results of Blood agar with bacterial swab (method 3) :

After 1 day and 3 days incubation, ANOVA test showed that there was a statistically significant difference between the three groups ($P = 0.009$). Duncan's test showed that Sealapex gave the statistically significantly highest mean inhibition zone diameter. There was no statistically significant difference between CRCS and Apexit which showed the statistical significant lowest means as shown in fig (3).



Mean inhibition zone diameter in the three groups (method3) Fig (3)

4. Discussion

The endodontic microbiota of untreated teeth was dominated by strict anaerobic bacteria, Siqueira (2000) .However, aerobic and facultative anaerobe microorganisms are usually minor constituents of primary infections, but they have been found in cases in which the treatment had been protracted, in flare-

ups, and associated with endodontic failures. These microorganisms can invade the root canal system during the treatment, survive the treatment procedures, and persist after obturation. Therefore, they cause secondary infections, Waltimo et al.,(1997); Sundqvist et al.,(1998); Siqueira(2000).

So, it is important to evaluate the antimicrobial activity of endodontic materials against aerobic and facultative anaerobic microorganisms.

The microorganism used in this study was *Streptococcus α haemolyticus*. It is facultative anaerobic bacteria. It includes two main groups, which were: *Viridans* group and *Pneumococci* group. The *Viridans* group of *Streptococci* principally lives in oropharynx and the oral cavity. It comprises roughly one-quarter of the total cultivable flora from supra-gingival , gingival plaque, and one-half of the isolates from the tongue and saliva. Thus, they can easily release to the blood stream during dental procedures, and sometimes during tooth brushing. Usually the bacteria released during dental procedures settle on damaged heart valves causing infective endocarditis(60% of the cases are due to this organism),Samaranayake (1996).

Three methods of the agar diffusion test (ADT) were used for antimicrobial evaluation of these tested sealers for the confirmation of the results.

The three methods revealed that after 24 h duration, Sealapex gave the highest mean inhibition zone followed by Apexit and CRCS. Where there was no statistical difference between their means. However, the means of inhibition zones by Apexit were slightly bigger than those of CRCS. This may be due to the high molecular size of CRCS and thus the low diffusion of the antimicrobial component of the sealer. CRCS contains zinc oxide, eugenol, eucalyptol, and small components of calcium hydroxide, Fuss et al.,(1997) .

Its antibacterial effect is probably due to the eugenol content rather than to the calcium hydroxide, Al-Khatib et al.,(1990).

Blood agar impregnated with 1ml of bacterial suspension gave the same results but with higher values in the mean inhibition zone diameters of the three groups in the 24 h period. This is probably due to more inoculum's number. As the microorganisms was totally mixed with the blood agar. Thus the bacteria were available in the whole thickness of the agar, increasing the sealer/ agar contact. Again in the 24h period Sealapex gave the highest statistically significant mean diameter of inhibition zone (30.6 mm), followed by CRCS (25.8mm) and then Apexit (917.6 mm) which showed the lowest mean inhibition zone diameter. At the three days period, the mean inhibition zone diameter of Sealapex and CRCS did not change. However, there was a significant increase in the inhibition zone diameter of Apexit group. This may be due to more diffusion of the material through the agar.

The anti microbial substance must diffuse through the aqueous agar medium and thus only the water soluble agents can be tested, Samaranayake(1996). On the other hand, the results of the media Mueller-Hinton agar (method B) and blood agar (method C) with bacterial swabbing were almost the same in both 24h and 3 days periods.

This confirmed the results that Sealapex had the highest antimicrobial effect against *Streptococcus α haemolyticus*, followed by Apexit and CRCS. These results came in agreement with Estrela et al.(2000) ; Lai et al.,(2001) ; Saleh et al.(2004) and Sipert et al.,(2005).

On the other hand, these results were in consistent with Fuss et al.,(1997) ; Siqueira et al., ,(1997);Mirjana and Branka (2006).

Fuss et al.,(1997) concluded that CRCS had stronger antibacterial effect than Sealapex with fresh samples. They referred their findings to the antibacterial effect of the eugenol content of CRCS rather than the calcium hydroxide content. While, Sealapex is based on polymeric resin and calcium formula. Thus, needs more time for polymerization and the release of hydroxyl ions. Fuss and his colleagues used direct contact test, and recorded their results every 30 min for 15h while in the present study, ADT was used, and the inhibition zones were measured after 1 and 3 days ,Fuss et al.,(1997)

Mirjana and Branka (2006) reported no antimicrobial effect of Apexit against *S. mutans* (*Streptococcus α haemolyticus*) on both types of agar. This is possibly because they measure the inhibition zone exactly after the application of freshly mixed specimens. Also, Apexit is based on resin and calcium hydroxide. Thus time was needed for polymerization of the materials, and accordingly there will be no hydroxyl ions which elevate the pH and having its antimicrobial effect, Mirjana and Branka (2006).

Siqueira et al.(1997) concluded that Sealapex presented low antibacterial activity when exposed to human saliva. This decreased activity might be due to the saliva buffering system, which was provided by proteins and by phosphate and bicarbonate buffering system. Therefore, even if Sealapex released hydroxyl ions which elevated the pH, that might reach to the toxic levels of the bacteria present in saliva. So when these hydroxyl ions were exposed to large volume of saliva, it is likely that the chemical effect of calcium hydroxide be rapidly neutralized by the buffer system, Siqueira et al.(1997)

Conclusions

This study was conducted to compare the antibacterial activity of three calcium hydroxide

based sealers namely: Apexit, CRCS, and Sealapex were three methods were used to evaluate the antibacterial activity of the three sealers. Sealapex had the highest antimicrobial effect. While there was no change in the means of the inhibition zones after three days for the other sealers.

All the calcium hydroxide tested sealers release calcium ions and are able to provide an alkaline medium and thus having antimicrobial property.

The prolonged setting time of Sealapex may render it beneficial for the long-term antimicrobial effect, and thus provide high pH even after complete observation.

Abstract: Inflammatory gingival enlargement is the most common inflammatory gingival disease and is associated with multiple factors including inflammation due to bacterial plaque colonization, as aside-effect of systemic medications, prolonged orthodontic treatment, and other etiological factors. This study investigated the effect of different etiological causes of gingival enlargement; including the treatment with cyclosporine A, the plaque, and the orthodontic treatment; on the angiogenic inflammatory mediators such as vascular endothelial growth factor (VEGF), cycloxygenase-2 (COX-2), 5-lipoxygenase (5-LO), and tumor necrosis factor-α (TNF- α), using histopathological and immune-histochemical analysis. The results of the immune-histochemical analysis of different angiogenic inflammatory mediators in the gingival enlargement samples indicated that in cyclosporine A-induced enlargement neither of VEGF, COX-2, 5-LO, nor TNF-α were affected, while there is a remarkable general over-expression of VEGF, COX-2, and 5-LO in the parakeratinized epithelial surface, the epithelial layer, connective tissue and in the fiber bundles regions of plaque-induced enlargement gingival. Additionally, orthodontic treatment samples indicated that there is a very high expression of VEGF in the epithelial layer of gingival but not in the connective tissue nor in the fiber bundles regions with no change in COX-2, 5-LO, nor TNF-α expression. In conclusion, this report indicated that the expression of different angiogenic and inflammatory mediators in gingival enlargement is influenced by the etiological factor that initially induced this enlargement.

1.Introduction

The inflammatory gingival enlargement is caused by bacterial plaque colonization on tooth surfaces and subsequent invasion of the micro-organisms. Clinically detectable fibrotic overgrowth of gingiva is caused by a variety of etiological factors and is aggravated by local bacterial plaque accumulation. Affected gingival tissues are red, oedematous, soft in consistency, and may bleed when gently probed Clocheret et al.,(2003). In some pathological conditions, gingivitis caused by plaque accumulation can be more severe. Gingival enlargement can be inherited, or is of idiopathic origin, or is sometimes associated with other systemic diseases. The majority of cases, however, occur as a side-effect of systemic medications. There is now general agreement that gingival overgrowth lesions all contain fibrotic or expanded connective tissues with various levels of inflammation and an enlarged gingival epithelium Clocheret et al.,(2003). The degrees of inflammation, fibrosis, and cellularity depend on the duration, dose, and identity of the drug, on the quality of oral hygiene, and on individual susceptibility that stems from genetic factors and environmental influences Trackman and Kantarci (2004).

The clinical presentation of gingival overgrowth varies from a non-inflamed, firm and fibrous condition to an edematous, hemorrhagic appearance with a tendency to spontaneous bleeding. It is usually begins at the interdental papilla in a lobular form, while at later stages it affects the entire gingival and extends coronally, leading to functional, esthetic and phonetic complication, Costa et al.,(2007). A patient history helps establish the inflammatory enlargement as acute or chronic, localized or generalized. Chronic enlargements are generally painless and slow to progress, whereas acute enlargements are characterized by a painful, rapid onset, Lundergan (2003).Chronic inflammatory gingivalenlargements are generally associated with identifiable systemic or

local factors. The primary local factor associated with these enlargements is plaque. Secondary local factors can include calculus, poor dental restorations, prolonged orthodontic treatment, orthodontic braces, caries, tooth crowding or misalignment, open contacts with food impaction, mouth breathing, and removable appliances. A gingival enlargement that is inflammatory and fibrotic can represent an enlargement that was initially fibrotic with secondary inflammation or an enlargement that was initially inflammatory but has become secondarily fibrotic, Lundergan (2003)..

During the past few years, the list of the medications causing a similar gingival overgrowth condition has increased. These medications include the anti-seizure drug phenytoin, the immune suppressor cyclosporin A, and certain anti-hypertensive dihydropyridine calcium-channel-blockers, most notably nifedipine, Trackman and Kantarci (2004).

Cyclosporine A is a lipophilic, hydrophobic, c yclicendecapeptide used to prevent rejection of transplanted organs and to treat various autoimmune diseases, Seymour RA, Jacobs(1992) .A common side effect of cyclosporine is gingival overgrowth which is characterized by epithelial hyperplasia, interstitial fibrosis, changes in blood vessel profile, and focal inflammatory cell infiltrate, Chiu et al.,(2008). A diagnosis of drug induced gingival enlargement can be made if the development of the fibrotic enlargement coincided with the administration of one of these medications. The gingival tissues are enlarged, oedematous, soft, and tender to touch, with a tendency to bleed easily. The gingiva is bluish-red with some pseudo-membrane plaques covering ulcerated surfaces. In some conditions, gingival enlargement can progress rapidly into destructive periodontal diseases, as a result of the altered immune response of the gingiva to the bacterial plaque,Trackman and Kantarci (2004).

Orthodontic treatment may initiate oral clinical manifestations, such as labial desquamation, Lindsten and Kurol (1997) gingival enlargement, Bishara et al.,(1993); Genelhu et al.,(2005); Kouraki et al.,(2005)and multiform erythema, Starkjaer and Menne(1990)gingivitis Shelley (1981).Such manifestations are usually associated with the inflammatory response induced by the corrosion of orthodontic appliances, and major emphasis has been placed on nickel, Eliades et al.,(2003). Inflammatory response to nickel is considered as type IV hypersensitivity and is manifested as nickel allergic contact stomatitis, Holmstrup(1999); Vanarsdall(2000).

Gingival enlargement is a more common sequela of orthodontic treatment than other manifestations, Genelhu et al.,(2005); Genelhu et al.,(2005); Gursoy et al.,(2007). Fibrous gingival enlargements associated with fixed orthodontic appliances seem to be transitory, and it is generally thought that enlargement resolves after orthodontic therapy, Carranza (2006)However, there are also studies reporting that this resolution is not complete Ramadan (2004).Orthodontic treatment-induced gingival overgrowth shows a specific fibrous and thickened gingival appearance, different from fragile gingiva with marginal gingival redness, which is seen in allergic or inflammatory gingival lesions, Ramadan (2004).; Gursoy et al.,(2007) .

This study investigated the effect of different etiological causes of gingival enlargement; including the treatment with cyclosporine A, the plaque, and the orthodontic treatment; on the angiogenic inflammatory mediators such as vascular endothelial growth factor (VEGF), cycloxygenase-2 (COX-2), 5-lipoxygenase (5-LO), and tumor necrosis factor-α (TNF- α), using histopathological and immunohistochemical analysis.

2.Material and methods

2.1.Materials:

2.1.1.Study population

A total of 30 subjects (24 males and 6 females aged 22- 45 years) were submitted to this study. They were attending the Oral Medicine, Periodontology, Oral Diagnosis and Radiology Department, Faculty of Dental Medicine Girls' Al-Azhar University. They included 10 renal transplant patients receiving cyclosporine A therapy for at least 6 months without any other drugs reported to cause drug- induced gingival overgrowth. Ten healthy subjects with teeth plaque and had no systemic disease and none of them had taken medications that could affect their periodontal status for at least 3 months prior to the study. The last 10 subjects were orthodontically treated with fixed orthodontic appliance for a period of 2 years suffering from hyperplastic enlargements covering one third to two thirds of the clinical crown. Smokers, pregnant and post moneposal women were excluded. The patients signed approval consents and samples were collected under the approval of the ethical Committee of the National Research Centre, Cairo, Egypt.

2.2.Methods:

2.2.1.Clinical procedures

Clinical recordings including plaque index O'leary et al.,(1993) gingival index Löe and Silness (1963)and probing depth were performed as shown in table 1. All selected subjects did not have any evidence of clinical attachment loss or bone resorption as diagnosed by radiographs and had not undergone any periodontal therapy. Gingival biopsies were obtained from diseased gingival during gingivictomy for

cyclosporine A treated group as well as in orthodontically treated group as a part of their routine clinical management, which also included intensive plaque control, while the samples were taken during pre-prosthetic crown lengthining procedure for plaque induced gingival enlargement subjects.

2.2.2.Histopathology

The biopsies were immersed in 10% formalin and decalcified in multiple baths of 10% trichloroacetic acid. After decalcification, the blocks were immersed in paraffin, and semi-serial 4 µm histologic sections were stained with haematoxylin and eosin (HE).

2.2.3.Immunohistochemistry

Paraffin sections of the 4 µm of biopsies were collected on Superfrost Plus slides (Menzel-Gläser), the paraffin was removed and the sections were rehydrated again. Before staining, the slides were treated with 0.1 % trypsin 250 (DIFCO Laboratories, Detroit, USA) for 10 minutes and rinsed with PBS. Thereafter, the slides were treated with 3 % H_2O_2 in PBS for 30 minutes to block endogenous peroxidase and rinsed in PBS. All sections were pre-incubated with 5 % bovine serum albumin (PBSA; Sigma Chemical Co., St Louis, Missouri, USA) in PBS buffer. VEGF, COX-2, 5-LO, and TNF-α were detected using their corresponinga rabbit antibodies (Abcam, Cambridge, UK), After being washed, bound antibody was detected using goat anti-rabbit antibody linked to horseradish peroxidase (Cambridge, UK) and bound complexes were detected using O-phenylenediaminedihydrochloride (OPD) (Sigma Aldrich, VA, USA). Representative sections were photographed on a Leitz DMRD Microscope (Leica, Wetzlar, Germany).

3.Results:

3.1. Histopathological examination :

3.1.1.The gingival specimens

Histopathological examination of the gingival specimens in cyclosperin of the treated group revealed a parakeratinized surface epithelium of the attached gingival of variable thickness in different parts of the attached gingival of variable thickness in different parts, connective tissue stroma formed of longitudinal bundles of hyalinized delicate collagen fibrils which showed various distribution, either dense or finely arranged. They were interspersed with a heavy chronic inflammatory infiltrate (mainly lymphocytes and plasma cells) and quit a noticeable number of dilated blood vessels (Fig. 1).

3.1.2.In plaque induced gingival enlargement group:

Histopathological examination in plaque induced gingival enlargement group showed a dense thick band of collagenous fibrous tissue arranged subepithelially demarcating a heavy zone of chronic inflammatory cell infiltrate packed with plasma cells and lymphocytes with fewer dilated blood vessels were found (Fig. 1).

3.2.3. In orthododontic group specimens :

Histopathological examination In orthododontic group specimens showed thinner parakeratinized surface epithelium covering a connective tissue stroma with contentious dense organized collagen bundles with chronic inflammatory infiltrate and a fewer dilated blood vessels were observed (Fig. 1).

3.2.The effect of the immune suppressor drug; cyclosporine A

This effect on the gingival expression of different angigenic inflammatory mediators using immunohistochemical analysis revealed that neither of VEGF (Fig. 2), COX-2 (Fig. 3), 5-LO (Fig.4), nor TNF-α (Fig. 5) were affected (Table 2), as indicated by negatively stained gingival enlargement samples. Despite extensive research, Results from table (1) indicated that there was a remarkable general overexpression of VEGF (Fig. 2), COX-2 (Fig. 3), and 5-LO (Fig. 4) in the parakeratinized epithelial surface, the epithelial layer, connective tissue and in the fiber bundles regions of gingival. Additionally, plaque was found to no influence of the gingival content of TNF-α (Fig. 5).

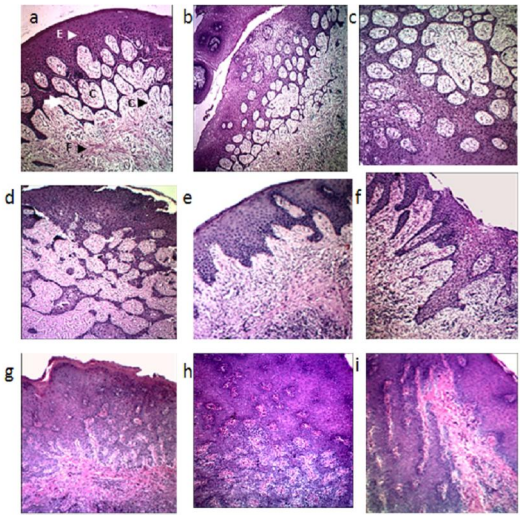

Fig. 1: Histochemical analysis using HE stain of sections represent different gingival enlargement causes including cyclosporine A-induced enlargement (A-C), plaque-induced enlargement (D-F), and the orthodontic treatment-induced enlargement (G-I). The photos labels are E= epithelium, C= connective tissue, F= fibre bundles. Microscopic magnification was X100.

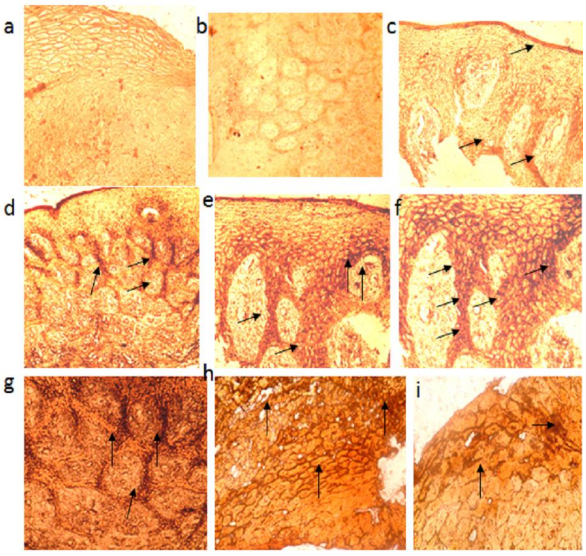

Fig. 2: Immunohistochemical analysis of VEGF expression in sections represent different gingival enlargement causes including cyclosporine A-induced enlargement (A, B), plaque-induced enlargement (C-G), and the orthodontic treatment-induced enlargement (H-I). Microscopic magnification was X100 (A-E) and X400 (F-1)Representative regions of high VEGF expression were marked by black arrows.

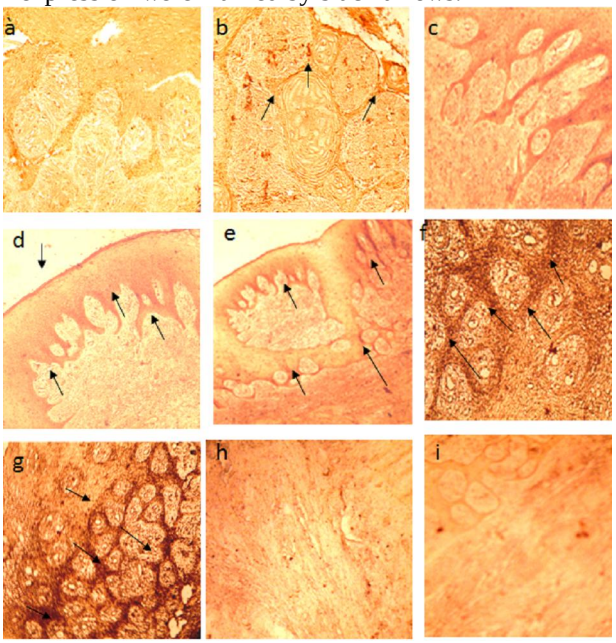

Fig.3:Immunohistochemical analysis of COX-2 expression in sections represent different gingival enlargement causes including cyclosporine A-induced enlargement (A, B), plaque-induced enlargement (C-G), and the orthodontic treatment-induced enlargement (H, I). All microscopic magnification was X100, except in (F, G) it was X400. Representative regions of high COX-2 expression were marked by black arrows.

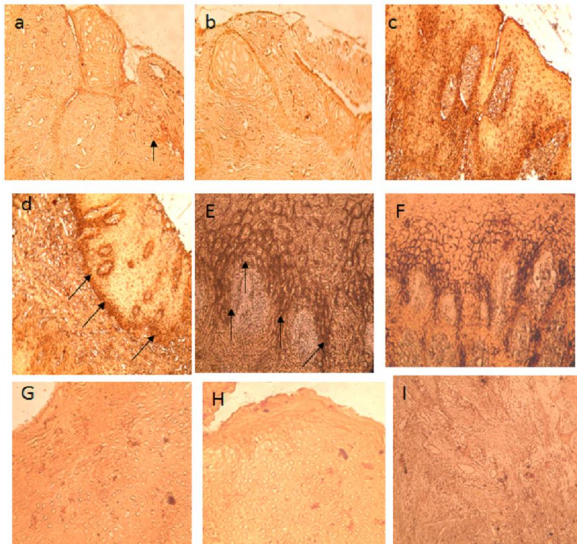

Fig. 4: Immunohistochemical analysis of 5-LO expression in sections represent different gingival enlargement causes including cyclosporine A-induced enlargement (A, B), plaque-induced enlargement (C-F), and the orthodontic treatment-induced enlargement (G- I). All microscopic magnification was X100, except in (E, F) it was X400. Representative regions of high 5-LO expression were marked by black arrows.

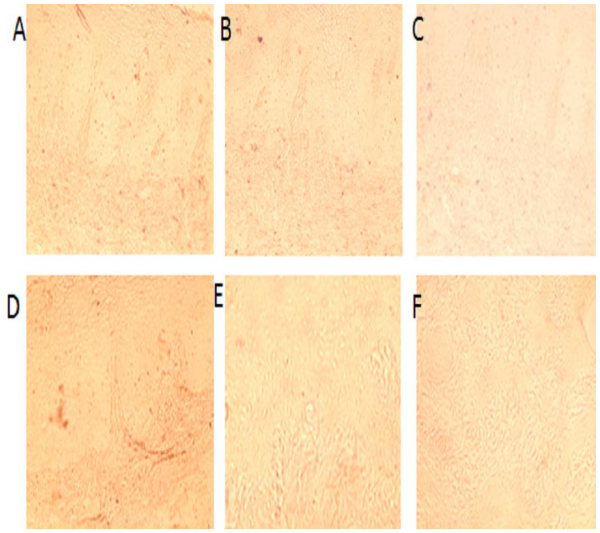

Fig(5):Immunohistochemical analysis of TNF-α expression in sections represent different gingival enlargement causes including cyclosporine A-induced enlargement (A, B), plaque-induced enlargement (C, D), and the orthodontic treatment-induced enlargement (E, F). All microscopic magnification was X100, except in (F) it was X400.

3.3. Immunohistochemical analysis of plaque-induced gingival enlargement

Table 1: Clinical characteristics of the gingival enlargement groups that was induced by different etiological factors including Cyclosporine A treatment (n = 10), Plaque (n = 10), and Orthodontic treatment (n = 10); (mean ± SD).

Marker	Cyclosporine A group	Plaque group	Orthodontic group
VEGF	0/10	10/10	8/10
COX-2	0/10	10/10	2/10
5-LO	0/10	8/10	2/10
TNF- α	0/10	0/10	0/10

Table 2: Number of patients with positively high expression of different angiogenic inflammatory markers, as assayed by immunohistochemical analysis, of the gingival enlargement groups that was induced by different etiological factors including Cyclosporine A treatment (n = 10), Plaque (n = 10), and Orthodontic treatment (n = 10).

	Cyclosporine A group	Plaque group	Orthodontic group
Plaque index	1.45 ± 0.67	1.58 ± 0.64	1.08 ± 0.47
Gingival index	1.24 ± 0.36	1.38 ± 0.29	1.02 ± 0.21
Probing depth	4.17 ± 0.85	3.38 ± 0.47	3.29 ±0.67

Data was represented as: (number of patients with positive high expression) / (total number of patients in the group).

3.**4. Immunohistochemical analysis of gingival enlargement samples from orthodontic treatment** : Patients indicated that there was a very high expression of VEGF in the epithelial layer of gingival but not in the connective tissue nor in the fibre bundles regions. On the other hand, as shown in table 2, orthodontic treatment was found to have no influence of the gingival content of COX-2 (fig 3), 5-LO (fig. 4), nor TNF-α (Fig. 5).

4. Discussion

Gingival tissues are generally in a state of injury and repair that involves repetitive cycles of production of chemotactic factors, angiogenic factors, inflammatory cell recruitment, and tissue resorption, replacement, and remodelling, Clark (1998) . Collagen turnover is unusually high in periodontal tissues, Trackman and Kantarci (2004).

Wound healing and connective tissue turnover are largely controlled by chemokines and cytokines secreted by inflammatory cells such as macrophages and lymphocytes and, to a lesser degree, by fibroblasts. Proliferation and differentiation of connective tissue cells and production of extracellular matrix are controlled by cytokines that initiate signalling cascades mediated by specific receptors, Trackman and Kantarci (2004).

In this regard, the histopathological examination in the present work of the gingival specimens in cyclosperin A treated group revealed a parakeratinized surface epithelium of the attached gingiva of variable thickness in different parts of the attached gingival connective tissue stroma formed of longitudinal bundles of hyalinized delicate collagen fibrils which showed various distribution, either dense or finely arranged. They were interspersed with a heavy chronic inflammatory infiltrate (mainly lymphocytes and plasma cells) and quit a noticeable number of dilated blood vessels. In plaque induced gingival enlargement group a dense thick band of collagenous fibrous tissue arranged subepithelially demarcating a heavy zone of chronic inflammatory cell infiltrate packed with plasma cells and lymphocytes with fewer dilated blood vessels. In orthododontic treated group specimens thinner parakeratinized surface epithelium covering a connective tissue stroma with contentious dense organized collagen bundles with chronic inflammatory infiltrate and a fewer dilated blood vessels were present.

Gingival hyperplasia is a common side-effect of immunosuppression with cyclosporine A. Exploring the effect of the immune suppressor drug; cyclosporine A on the gingival expression of different angigenic inflammatory mediators using immunohistochemical analysis revealed that neither of VEGF, COX-2 ,5-LO, nor TNF-α were affected .Despite extensive research, the mechanism leading to the accumulation of abnormal amounts of gingival tissue in cyclosporine A-induced gingival overgrowth is unclear. Fibroblasts are the main cell type residing in the gingival connective tissue, and are responsible for the formation and turnover of the extracellular matrix. Studies on the effect of cyclosporine A on gingival fibroblast activity have reported conflicting

findings, and it is uncertain if cyclosporine A can induce gingival overgrowth by directly altering the function of fibroblasts Voulgari and Drosos(2002). Recently cyclosporine A was reported to increase both IL-6 and TGF-beta1 levels Chae et al.,(2006)and to inhibit COX-2 Chiang et al.,(2007).

Plaque induced gingival enlargement can progress rapidly into destructive periodontal diseases, as a result of the altered immune response of the gingiva to the bacterial plaque. In present study, the immunohistochemical analysis of plaque-induced gingival enlargement patients indicated that there was a remarkable general over-expression of VEGF ,COX-2, and 5-LO in the parakeratinized epithelial surface, the epithelial layer, connective tissue and in the fiber bundles regions of gingival. Additionally, plaque was found to no influence of the gingival content of TNF-α . Gursoy et al.,(2007).

Nickel, the most common metal used in orthodontic appliances, may activate monocytes and epithelial cells, suppressing or promoting the expression of intracellular adhesion molecule 1 by endothelial cells, mostly depending on its concentration. Nickel ions can also intracellularly accumulate in human oral mucosal cells and human HaCaT keratinocytes, Ermolli et al.,(2001); Faccioni et al.,(2003).

Nickel concentrations, which do not significantly modify oral epithelial cell viability and inflammatory cytokines release (<1.3 mM) can stimulate apoptosis in vitro Trombetta et al.,(2005.)On the contrary, human primary cultured keratinocytes and HaCaT cells also proliferate in response to nickel ions Jia et al.,(1999).Nickel-containing orthodontic wires can reduce cell viability and stimulate apoptosis in three-dimensional cell culture models Vannet et al.,(2005). Even though nickel is related to allergic response seen in orthodontic therapy, Holmstrup (1999); Vanarsdall (2000), its influence of angiogenic inflammatory mediators in gingival overgrowth has not been studied yet.

In the present study, the immunohistochemical analysis of gingival enlargement samples from orthodontic treatment patients indicated that there was a very high expression of VEGF in the epithelial layer of gingival but not in the connective tissue nor in the fibre bundles regions. On the other hand, orthodontic treatment was found to have no influence of the gingival content of COX-2 , 5-LO nor TNF-α . TNF-α was expected to be secreted from the immune cell in the intracellular infiltrate within the inflammatory gingiva, but this was not noticed in all of different gingival enlargement samples. Although there was highly noticed inflammatory cell infiltrate in orthodontic treatment samples, no positively stained TNF-α was noticed. As a positive control, samples of bacterial lipopolysaccharide-treated human macrophages were stained positively for TNF-α.

Nickel has been stated to be corrosive in the oral cavity, Jia et al.,(1999).An average release of 40 µg nickel per day from a stimulated full-mouth fixed appliance has been reported, Park and Shearer (1983) and also nickel accumulation was found to be higher in dental plaque samples of patients receiving orthodontic therapy in comparison with untreated subjects, Fors and Persson(2006). However, it is also suggested that the release of nickel is not necessarily proportional to the nickel content of the alloy, Grimsdottir et al.,(1992).The in vivo and in vitro results of a previous study suggested that low-dose continuing nickel release from orthodontic appliances might be the initiating factor for gingival overgrowth, as it has the capability of increasing epithelial cell proliferation, Gursoy et al.,(2007). Depending on the induced VEGF results of the present study, nickel might be responsible for such induction that may subsequently lead to neo-vascularization, which in turn may support nourishment of overgrown tissue.

In conclusion, the immunohistochemical analysis of different angigenic inflammatory mediators in gingival enlargement samples indicated that in cyclosporine A-induced enlargement neither of VEGF, COX-2, 5-LO, nor TNF-α were affected, while there was a remarkable general over-expression of VEGF, COX-2, and 5-LO in the parakeratinized epithelial surface, the epithelial layer, connective tissue and in the fiber bundles regions of plaque-induced enlargement gingival. Additionally, orthodontic treatment samples indicated that there was a very high expression of VEGF in the epithelial layer of gingival but not in the connective tissue nor in the fiber bundles regions with no change in COX-2, 5-LO, nor TNF-α expression. Taken together, this report indicated that the expression of different angiogenic and inflammatory mediators in gingival enlargement is influenced by the etiological factor that initially induced this enlargement.

Abstract: Power generation business in the United States with approximately 9,733 MW of installed capacity from agricultural waste and non-agricultural sector, the largest source of non-renewable water power in the world has created. The capacity of 9733 MW including 5,886 MW of forest plants and agricultural residues, 3,308 MW power generation capacities of 539 MW waste urban and other materials, such as the gas is obtained from buried waste. Maximum electricity production from biomass to electricity load based on the existing electricity distribution system is used. More than 200 companies from non-wood products and food industries in the United States produce electricity biomass. Four power generation systems using biomass there. Direct fuel, the fuel mixture (with coal), and plants gasify module. Most biomass power plants are direct systems such as traditional fossil fuel power plants often act. Biomass production in North America is 180 million tons of which 43 percent of the amount of agricultural residues in plants using advanced biological anaerobic bacteria and gas production and energy production are a combination of fuel between the available biomass Potential country of Iran 22 million is a system of energy production from residue agriculture often is that this residue in a tank Amplifier as burnt is fuel ash and gas artificial is that gas result can be thermal energy used or by the generator to electrical energy to become today the ability to produce 15 billion cubic meters of gas household artificial residue agriculture there is fuel derived from technologies convert biomass or state gas (Environmental gas) or liquid (methanol, ethanol and biodiesel), which for produce electricity and heat are used. It is estimated that if only 10 percent of farms and forests to provide and providing allocated biomass, annual production of energy from biomass, equivalent to four-fifths of world energy consumption will be present. Developing communities that almost three-quarters of the world's population are included, 35 percent of energy consumption comes from biomass. If the process can be used to power advanced production techniques such as biological America, collecting, etc. in areas such as agriculture in Khuzestan, which remains almost "Between 25-18 percent of products is very high figure is in addition to performing and indigenous on energy production, burning farms and destruction of ecosystems, soil, water, air and will prevent .... Use of biomass resources, one of the best and most economical solutions to provide basic energy needs of people in remote areas, and environmental benefits this type of environment, renewable energy and its development, its application, is reasonable and affordable.

1. Introduction

Where power producers to provide low cost biomass have access to selected conditions using biomass fuels in combination caused their development of market competition is. This especially in the near future for power generation companies will find the truth if their method of electricity generation from biomass with coal combination to select. This method will save on fuel costs. Many active people engaged in the electricity market to offer to purchase electricity generated by the Complies with environmental laws, including electricity from biomass are. This move in response to consumer demand and emergencies is legal As we know, electricity from the most basic needs of life in the new century is considered, such as lighting applications ranging from homes and streets in the use of telephone and television as well as industrial and medical uses, such as metals and machinery and medical instruments ... Shows that this energy unmatched role in the development of human and community needs are. World statistics on the growing world demand shows that about 70 percent of global investment in energy sector development - equivalent to 11 trillion dollars - over the next three decades, is dedicated to providing electricity as compared to three times the equivalent figure last three decades is. International Energy Agency estimates that electricity than any other energy in final energy demand growth rate of 2.8 percent will face. On the other hand the resources scattered in different parts of the world energy supply has caused the country, different methods are used to provide energy. For example, in Norway probe, ninety-nine percent of the country electricity power

plant - water is produced. While in America in less than 10 percent of its electricity this way comes. In a prediction that the next 50 years, 30 percent of plants in the world of fuel coal, 10 percent of gas used, 15 percent of renewable energy sources (water, wind, solar and thermal energy the earth ...), and 15 percent of atomic energy for power plant use, biological plants in this way as fossil fuel power plants with fuel for thermal energy needed to be used. The difference is that the fuel and products of biological organisms (plants, animal waste, crop residues and ...) will be provided. Because this method requires extensive agricultural land is facing many constraints, but with shrinking fossil resources and rising prices, a serious rival for these fuels will be considered.

2. Biological metabolism of plants Fuel biology (biological) Biomass

Means any organic material, known source of renewable energy is considered. Waste sawdust, residues of agricultural products, and organic material from urban and industrial waste can be burned when electricity and liquid fuel directly used in transportation becomes. State Florida, agricultural fuel inventory of about 20% of biomass fuel in this state provide. Agriculture remains a wide variety of compounds are, of course, some for use as fuel are not appropriate. Agricultural residues suitable for fuel in power plants, solid fuel biomass materials are included in the following types:

- Food processing residues such as nuclei, conveyors, and skin
- Destruction of gardens and vineyards
- Pruning of gardens and vineyards
- Straw farm

Cereals and oilseeds major industrial inputs used in production of more ethanol, biodiesel and bio products are used today. Food and feed processing residues and a third residue after the consumer in order to produce a low amount of electricity are used. Of course, this amount of biomass than small agricultural biomass resources currently available, and little of the full potential of agriculture is. With appropriate economic stimulus measures and advanced technologies such as crop plants with increased yield and more efficient harvesting equipment, sufficient amounts of residual agricultural products and food and feed processing residues for the stability can be produced. In addition, the amount of sustainable biomass obtained from agricultural land can be devoted more land to produce wood products and increased herbaceous perennial.

3. Biological metabolism of plants in America

North America produced 180 million tons of biomass is that 43 percent of the amount of agricultural residues that plants using advanced biological anaerobic bacteria and gas production and energy production are a combination of fuel between the available biomass Potential country of Iran 22 million is a system of energy production from residue agriculture often Gasification is that this residue in a tank called Gassy Amplifier as Term chemical burned is Vials fuel ash and gas artificial is that gas result can be thermal energy used or by the generator to electrical energy to become today the ability to produce 15 billion cubic meters of gas household artificial residue agriculture there is fuel derived from technologies convert biomass or state gas (Environmental gas) or liquid (methanol, ethanol and biodiesel), which for produce electricity and heat are used. Large amounts of agricultural crop residue to form straw production that even if outdoors and plowing fields, so that usage can be 30 to 40 percent of these are leftover waste (between and Amos, 2003). This residue can be collected and processed to fuel power plants would. Fuel-based straw are expensive and their low mass density and hardness of some problems in handling their burning creates. Consequently very little material to help fuel sources. Even with the current level of use of biomass fuels leading agricultural areas, enormous amounts of agricultural residues for use as fuel in power plants still open are burned. Fate for most other agricultural residues used for fuel is burned in open space; even a small percentage of these applications in the absence of fuel or plowing are buried. Almost one-third of biomass energy plant in California (as a leading regional) areas Farm state have been constructed to use the residue as fuel in many capital absorbed to compensate for pollution that if some residue biomass in the case of absorption by the plant was not open as it was burned and in these conditions For energy to be used. For example, U.S. agriculture from the beginning to the twentieth century has changed considerably.

Key stimulus for this change in technology and mechanization increased performance fiber in cereal products were the main. Mechanization notably a need for horses, and consequently reduced production of oats (as livestock feed) much reduced. Mechanization, while the same performance per unit area in the period 1915 to 1978 wheat yields per unit area to more than double corn also fulfilled the function of the pan more than tripled its former reach the same performance side shows more product (straw) is equal to two or three. Of course, biotechnology and genetically modified products and high product varieties produced in this way has a role to reward. The point that should be noted here is that many of

the input potential of biomass, like straw, ash problem lies is that software behavior which sedimentation problems are getting.

Researcher's conversion and marine algae befouls and the use of methyl (root univalent hydrocarbon) Gas to convert methane from natural gas components to the remarkable success received. Although ethanol full biological energy known today, but just barely Energy is considered distressed situation. Researchers working to develop the more organic materials such as sugar cane, seaweed, grass, sewage and hospital waste, even for purposes of transportation and power generation to energy with less pollution have become. The current production of biological energy around 643 thousand barrels per day in 2050 that requires about 34 million barrels per day is estimated.

Canals in Venice, one of the important sources of energy known as the green features that can generate electricity at the commercial level will find. A Power 272.6 million dollars in expected electricity production license from biological fuel Canal hast algae. Fuel power plants, algae collected in a canal 26 feet planted biological reactor (with Gas fertilize the plant) and dried and then extracted the juice and add alkaline materials to be converted into befoul. Predicted plant in 2011 could power 40 MW (with the lowest carbon pollution) that production costs in the supply, it provides other types of ships and vessels in the port side should be taken.

After adjustment for maximum boiler power generation with biomass by adding a very small loss in efficiency occurs or no does not make any losses. In these conditions, the energy in biomass with high efficiency (about 33 to 37 percent) coal power plant will become.

Biomass converter system with gas heating biomass in the environment act and there is analysis of solid biomass and flammable gas that is rising. In this way energy than directly burning biomass is superior. Biogas biomass analysis can be cleaned and the spent filters and chemical composition of the device in which it separated. This gas can be more efficient power generation systems that use its combined cycle is called. In this system, gas turbine to generate electricity and steam turbines are combined together. The system efficiency can be increased to 60 percent.

Systems can be converted to gas fuel cell systems for future applications can be combined. Fuel cell using the process (and heat) to hydrogen gas turns it into electricity. Then much of the substance that is water vapor in the air will be rising Iranian researcher with Ohio State University discovered bacteria capable of complex molecules break down cellulose in the cow digestive system for the first time successfully developed microbial fuel cell system capable of generating electricity from waste cellulose was . Innovative Fuel Cell system that also can be a source of renewable energy, clean and efficient electricity supply required for remote control systems and also areas away from electricity transmission network is used, an attractive and promising perspective in making bio-refineries maps in which they discovered by using bacteria, organic waste and waste, electricity, methane and hydrogen is produced. The young Iranian researcher, although already successful researchers and other research groups to design microbial fuel cells systems are available, but mainly from simple ingredients and still qualify for food value, such as simple sugars and starches used for electricity production This is the first time possible to produce electricity from decomposition of complex cellulose molecules that abound in agricultural and industrial waste exist, is provided. Rope Hamid Yazdi, PhD student in Biotechnology Engineering America Ohio State University (2009) who led the investigation is responsible for technology reporter in an interview with Iranian Students News Agency (ISNA) said: The new fuel cell using bacteria that have been discovered in the cow rumen, cellulose from waste paper, wood products, and vegetable waste in the fields after harvesting, parsing, and electricity is produced. He noted: Cellulose is a complex chemical compound that only a few bacteria have the ability to break down the bacteria and the ability to transfer electrons produced from the metabolism of cellulose to have the electrode was not discovered until now. Since the collection of rumen bacteria in ruminants as the best-developed and cellulose. Users can work in anaerobic conditions are therefore used in this way were considered as the result was very good.

Yazdi (2009) rope emphasized: microbial fuel cells a new technology for the production of alternative and sustainable energies in which the use of specific bacteria as catalysts for the production of free electrons from agricultural waste and even sewage electric current is produced. The significance of this lack of technology gases and uses renewable organic sources and thus is infinite. He noted: One of the most important sources of renewable cellulosic waste from agricultural and industrial units that many researchers in the University of Ohio and other universities in America and the world to convert the waste compounds can be used to try, but technically and economically difficulties in the enjoyment of them exists. Our innovative approach lies in the composition of chemical energy directly into electrical energy without combustion and thus produces pollutants and high efficiency electricity is produced. This method, especially in areas that were due to natural disasters or in areas having not

connected to the power grid as well as remote control systems that frequent battery replacement difficult or impossible, they can be used.

In the future we as a bio-refinery oil refinery to create that organic waste (agricultural - industrial) and excretion into the water and electricity, hydrogen and methane, which is outside. According to this scholar, innovative fuel cell system can currently up 3.5 watt per cubic meter volume of the anode, producing electricity with the hope that more progress is research about the result, it can increase efficiency.

Cell Two anode and cathode compartment is composed. The anode compartment anaerobic decomposition of cellulose electrons through electron transport chain to transfer outside the cell is rendered. These electrons are then both directly or by a carrier made of graphite electrode in the anode being transferred and from there through an external circuit to the cathode used. While the hydrogen ions from the bacterial metabolism through a selective membrane to the cathode part is transmitted in this section is that aerobic electrons with input from the anode the hydrogen ions and oxygen in the cathode electrode surface it is made from graphite compound and water are formed. Fuel Cell cycle thus formed. He admitted to the microbial fuel cell that already has been designed, said: This is a very important point in this project have been able for the first time electricity we cellulosic compounds, while other groups of very simple compounds such as sugar and starch that can be used both by humans is their use. Yazdi rope at the end about why use of fuel cells and bacteria in microbial fuel cells to the advantage of fuel cells commonly said: Conventional fuel cells use hydrogen as fuel and purpose platinum catalyst to apply directly, but if compounds organics like cellulose in the cell to produce electricity to use, the catalysts have the ability to break them, so bacteria as biological catalysts will be the best option. Such bacteria also have the ability to break down the complex molecules have such, should be able to directly or indirectly generated electrons are transferred to the electrode.

Technology led to the use of bio fuels for the future will be cleaner but the industry should worry about the supply of food available to solve Washington - The biomass of at least 4000 years ago man first wood burns, simple and reliable source for energy supply have been. Today, the urgent need to reduce dependence on fossil fuels, technological advances had paved the way for the use of biomass in the future. Many believe that bio fuels as an important subset of biomass, clean and renewable alternative to fossil fuels in the transport process considered. Many others say that bio fuels such as ethanol derived from grain, agricultural land and provide food in the world would be dangerous to cast and still being applied materials technology much time remains. Any biomass organic waste material, including sawmills, fruit trees and destroyed the forests, agricultural byproducts, and animal feces and human elements of urban and industrial organic waste and many other refers.

From biomass package organic materials in their manufacturing various products such as plastics, polymers, carpets, textiles, detergent, softener materials and oil and fuel needed for transportation is used. Biomass can be contrary to other sources of renewable energy like solar and wind energy, directly to liquid bio fuels such as ethanol and biodiesel into. This fuels some cases the use of biomass that have the fastest growth. According to the Renewable Fuels Association in Washington, the rate of ethanol production in the world in 2006 was about 51.1 billion liters and the countries to reduce oil imports boost rural economies and help air cleanliness, the amount of ethanol is rising. Also expected to increase concerns about emissions and low world oil resources will also increase the production of ethanol.

Bill, a member of the board of American Council of Renewable Energy, told America.gov: ethanol production is increasing rapidly. United States has the largest production in Brazil is ranked second. Other countries developing their own ethanol industry, China, India and Latin America as well as developing and advancing its bio fuels programs are. Food versus fuel ethanol is an alcohol fuel from sugar in cereals such as sorghum and wheat and skin potatoes, rice, sugar cane and sugar beet is obtained. Tom Fawcett, director of technological applications of biomass renewable energy National Laboratory (NREL) United States Department of Energy, told America.gov: Brazilian ethanol from sugar cane to exclusively produce and the United States almost exclusively from corn ethanol to come. University of Arkansas (UA) in research methods to reduce production costs for bio fuel, alternative fuel from vegetable oil, animal fats or algae, renewable fuel that can replace oil with foundation, they are. Students using three methods of combining sound waves for rapid mixing, factor interplay of solid and chemical conditions close to the explosion at elevated temperatures and pressures to improve production of bio fuels to review.

3. Work in Iran

Study the feasibility for plants with fuel waste city with a capacity of 10 MW in cooperation with consulting and Iranian colleague Germans started that is currently available is an action, he existence of more than 400 million tons of residue

agriculture, forestry and waste of livestock, more than 20 million Tons of waste and more than 5 billion cubic meters of sewage in the human potential of this is based on the feasibility study for construction of urban waste-fueled power plant with a capacity of 10 MW in cooperation with a German colleague of Consulting and began and now Action is in hand. In 2004 about 170 thousand hours of electricity from renewal sources production was ranked second after power plants - water is the primary Reviews shows that in the amount of potential energy potential of biomass resources can be obtained from the equivalent of 6 / 15 million crude oil in 2000 is that the rate of 59 percent share of agriculture and forestry, 11 percent share of urban waste, 28 per cent share of livestock waste, urban sewage and 2 percent share of 5 percent share of food. I attempting to compile the atlas for biomass and municipal waste biomass source 4 includes agricultural residue - forests, livestock waste, and waste human and industrial waste has been. The project to identify suitable sites for energy utilization can be obtained from biomass resources, promotion of culture resources in the production of biomass energy and fuel through the recognition of laws and regulations and provide necessary suggestions, technical and economic studies appropriate extraction technologies biomass energy sources and ways to expand their knowledge and capacities and resources of biomass energy extraction runs.

Optical and mechanical effects of different bleaching regimens on enamel surface

Nagy S *, Zoghbi A M El **, Zaazou MH.*, Abd alsabour K K ***, Taher HA **

*Department of restorative dentistry and dental materials ,national research center; ** Department of operative dentistry, faculty of oral and dental medicine, Cairo University; ***Laser Institute, Cairo university. Corresponding author :mohamedzaazou@yahoo.com

Abstract: Purpose: This study was designed to assess the effect of 3 different bleaching regimens on color and microhardness of enamel. **Materials and Methods**: Ninety bovine upper central incisors were divided into three main groups according to the bleaching regimen used; chemically activated (Viva Style Paint on Plus), photo activated (Zoom 2), and laser activate (Opalescence X-Boost) bleaching agents. Each group was stained with (tea, carbonated beverage or a combination of both tea and carbonated beverage for 1 day or 6 days. Color was assessed using computerized image analysis in terms of grey scale, while Vickers microhardness tester was used to assess change in enamel microhardness. **Results:** Computerized image analysis revealed statistically significant decrease in the mean grey scale value of all teeth immersed in the three staining solutions used. The results also revealed that color change become intense as the immersion time increased. After bleaching with the three bleaching regimens the results revealed increase in the mean grey scale value of all the three bleaching regimens used with statistically significant increase in the mean grey scale value of both photo and laser activated bleaching agents than did chemical activated bleaching agent. Microhardness results revealed that there was statistically significant decrease in enamel microhardness after immersion in the three solutions, where the carbonated beverage group showed the lowest mean microhardness value than did the tea and the combination solutions. After bleaching with the three bleaching regimens enamel revealed a significant decrease in its microhardness. For all groups, no correlation was found between color change of enamel surface and its microhardness. **Conclusion**: Tea and Carbonated beverages have the ability to discolor teeth and alter their microhardness. Different bleaching regimens are lightening the color of discolored teeth but adversely affect enamel microhardnes.

[Nagy S, Zoghbi A M El, Zaazou MH, Abd alsabour KK, Taher HA. **Optical and mechanical effects of different bleaching regimens on enamel surface.** Journal of American Science 2010;6(12):1766-1773]. (ISSN: 1545-1003). http://www.americanscience.org.

Keywords: Optical and mechanical effects of different bleaching regimens on enamel surface

Introduction

Nowadays, esthetic of dentition is of great concern for many individuals seeking dental treatment due to the increase of the patient's awareness of the ability to improve their smile by lightening discolored teeth through few visits to dentists.

Bleaching is considered the most conservative approach to obtain esthetic than aggressive methods such as veneering, crowning or bonding ***(Matis at el, 2000).*** Therefore aesthetic dentistry has turned its attention to develop a series of bleaching techniques and materials to offer the patient a successful pain-free bleaching of both intrinsic and extrinsic stains. These techniques include peroxide based, light-activated, laser-activated or combination therapies. A broad range of peroxide based treatments are currently available including those that are professionally administered (in-office), professionally dispensed (custom-tray based system) and self-directed (over the counter) ***(Zanin et al, 2004).***

Power bleaching is an in-office whitening technique developed to bleach teeth in single office visit with a combination of a whitening agent such as peroxide and an auxiliary light. It has the advantage that all the smile-line teeth are whitened simultaneously ***(Tavares et al, 2003).*** There are several different available types of light sources to accelerate the in office bleaching procedure. The techniques that use coherent or incoherent light sources, have the advantage of being quick and convenient ***(Wetter et al, 2004).***

The mechanism by which teeth are bleached by H2O2 is not completely understood; it is thought that, as the peroxide diffuses into the tooth structure, it may react with organic colored materials found within the tooth structure leading to reduction in color ***(Luk et al, 2004).*** Unfortunately improvement in tooth color may, however, be at the expense of tooth strength.

Thus it was thought that a study aiming at evaluating the effect of different bleaching

regimens on the color change and micro-hardness of enamel surface might be of value.

2. Materials and methods:

2.1. MATERIALS:

2.1.1. TEETH SELECTION AND GROUPING:

Ninety recently extracted sound bovine upper central incisors were selected and stored in isotonic saline (0.2% sodium azide NaN_3) at room temperature until use to avoid bacterial growth and dehydration. The ninety teeth specimens were divided into three main groups of 30 teeth each, according to the bleaching regimen used (B). Where B1 referred to Viva Style paint on plus bleaching agent **(**IvoclarVivadentAG, FL-949schaan/ Liechenstein) B2 referred to photo activated bleaching agent Zoom2 bleaching system (Discus Dental, Inc. Culver City, CA 90232 USA) and B3 referred to Opalescence X-tra Boost + laser activation bleaching gel (Ultradent products, South Jordan, UT, USA).. Each main group was further subdivided into two subgroups, 15 teeth each, according to time of immersion in the staining solutions (T). T1 referred to 1 day and T2 referred to 6 days immersion time in the staining solutions. One day staining was equivalent to one month of three times drinking tea cups or carbonated beverage daily, while six days was equivalent to six month ***(Guler et al, 2005).*** Each subgroup was further subdivided into three classes according to the staining solution (S), where S1 represented tea, S2 represented carbonated beverage and S3 represented a combination of both tea and carbonated beverage one by one respectively.

2.2. Methods:

2.2.1. BLEACHING TREATMENT:

2.2.1.1. Paint on plus bleaching agent 6% hydrogen peroxide (HP):

A thin layer of Viva Style paint on plus bleaching agent was applied to the labial tooth surface using a brush. According to the manufacturer's instructions, this layer was washed out after 10 minutes with water and toothbrush. That procedure was repeated 14 times according to the manufacturer's instructions. Then the specimens were stored in saline till testing.

2.2.1.2. ZOOM 2 photo-activated bleaching agent 25% HP:

The gel was spread on the labial teeth surfaces with the supplied brush for three 15-minutes sessions with the zoom light (short-arc metal halide bulb -wavelength of 365-500 nm). At the end of the treatment the teeth were rinsed with water and each subgroup was stored in a separate bottle filled with normal saline till testing.

2.2.1.3. palescence X-tra Boost 38%HP+laser activation:

The Opalescence X-tra Boost laser activated bleaching agent was applied on the labial surfaces of the teeth for 15 minutes according to the manufactures instructions then the gel was rinsed with water and the teeth was dried with gauze. The bleaching agent was again applied on the labial surface of the teeth and activated with diode laser (wave length 904nm, power 6Wfrequency 500MZ) for 1 minute time exposure. (The diode laser exposure was done in laser technology services center, Cairo University). At the end of laser bleaching the teeth were rinsed with water and each sub-group was stored in a labeled bottle filled with normal saline till testing.

2.2.2. COLOR CHANGE ASSESSMENT:

Each bovine tooth was mounted vertically in a mould of self-cured acrylic resins using Teflon ring with dimension of 2x2cm. Color assessment was made at baseline (control before staining), post-staining and post-bleaching using the grey scale image analyzer software (soft ware image ware, J-13, microsoft, USA). Each tooth was photomicrographed using zoom stereomicroscope (Olympus-SZ-PT,Japan) with charged couple device digital camera(Olympus-DP10,Japan). Four points were randomly selected and measured for each specimen where the mean values of the four points were calculated.

2.2.3. MICRO-HARDNESS MEASUREMENT:

Each bovine tooth was mounted horizontally in a mould of self-cured acrylic resins using Teflon ring with dimension of 3x3cm.The micro-hardness test of enamel surface was made at baseline (control before staining,) after staining and after bleaching. The micro-hardness values of the specimens were determined using a Vickers micro-hardness tester. Three indentations were made with a static load of 200 grams for 20 seconds dwell time. The indentation dimensions were registered. The mean VHN values of the three indentations were calculated.

2.2.4. TATISTICAL ANALYSIS

The recorded data for color change and micro-hardness assessment were collected, tabulated and statistically analyzed using ANOVA and Tukey's tests. Pearson's correlation coefficient was used to determine significant correlation between mean percentage changes in color and microhardness after bleaching with the three different bleaching agents.

3. RESULTS:

3.1. COLOR MEASUREMENTS

3.1.1. Color measurements before (control) and after staining with the staining solutions and after bleaching with the different bleaching gels (Table 1):

Table 1. Mean, standard deviation values, results of ANOVA and Tukey's tests for the effect of the three staining solutions on color and the color change after bleaching with the three bleaching gels:

Bleaching agent	Control		Storage time	Solution / Measurement	Tea		Carbonated beverages		combination		p-value
	Mean	SD			Mean	SD	Mean	SD	Mean	SD	
Paint - on Plus	141.8 [a]	4.5	1 day	After staining	129.5 [b]	1.6	134 [b]	1.9	130.9 [b]	2.3	**<0.001***

SD: Standard Deviation, *: Significant at $P \leq 0.05$, Means with different letters are statistically significantly different according to Tukey's test.

3.1.1.1. For Paint on plus:

-1 day storage:

After staining,

Control group showed the statistically significantly highest mean color measurement.

There was no statistically significant difference between staining with tea, carbonated beverage and combination which showed the statistically significantly lowest means.

After bleaching,

Control group showed the statistically significantly highest mean color measurement.

There was no statistically significant difference between staining with tea, carbonated beverage and combination which showed the statistically significantly lowest means.

3.1.1.2. For Zoom2 bleaching:

-1 day storage:

After staining, Control group showed the statistically significantly highest mean color measurement. There was no statistically significant difference between staining with carbonated beverage and combination which showed lower mean values.

Staining with tea showed the statistically significantly lowest mean.

After bleaching, there was no statistically significant difference between the four groups.

-6 days storage:

After staining,

Control group showed the statistically significantly highest mean color measurement.

There was no statistically significant difference between staining with carbonated beverage and combination which showed lower mean values.

Staining with tea showed the statistically significantly lowest mean. After bleaching, there was no statistically significant difference between the four groups.

3.1.1.3. For opalesence extra-boost+ laser-activation bleaching:

-1 day storage:

After staining,

Control group showed the statistically significantly highest mean color measurement.

There was no statistically significant difference between staining with carbonated beverage and combination which showed lower mean values.

Staining with tea showed the statistically significantly lowest mean. After bleaching, there was no statistically significant difference between the four groups.

-6 days storage:

After staining,

Control groupshowed the statistically significantly highest mean color measurement. There was no statistically significant difference between staining with carbonated beverage and combination which showed lower mean values.

Staining with tea showed the statistically significantly lowest mean. After bleaching, there was no statistically significant difference between the four groups.

3.2. MICROHARDNESS RESULTS:

3.2.1. Microhardness measurements before (control) and after staining with the three staining solutions and after bleaching with the three different bleaching gels (Table 2):

Table 2. Mean, standard deviation values, results of ANOVA and Tukey's tests for the microhardness measurments.

bleaching agent	Control		Storage ti	Solution / Measurement	Tea		Carbonated beverages		combination		p-value

SD: Standard Deviation, *: Significant at P ≤ 0.05, Means with different letters are statistically significantly different according to Tukey's test.

3.2.1.1.Paint on plus:

1 day storage:

After staining, the highest mean microhardness both tea group (132.2) and combination group (130.6) which showed no statistically significantly difference between them which showed lower mean. The lowest mean microhardness was for carbonated beverage group (124). **After bleaching**, the highest mean microhardness was the control group (135), followed by the other 3 groups, tea group (115.8), carbonated beverage group (111.2) and combination group (108.6) which showed no statistically significantly difference between them which showed lower mean.

6 days storage:

After staining, the highest mean microhardness was the control group (135), followed by both tea group (131.6) and combination group (128.7) which showed no statistically significantly difference between them which showed lower mean. The lowest mean microhardness was for carbonated beverage group (121.4). **After bleaching,** the highest mean microhardness was the control group (135), followed by both tea group (118.4) and combination group (109.7) which showed no statistically significantly difference between them. The lowest mean was for carbonated beverage group (111.6).

3.2.1.2.Zoom2 gel+ photo activation.

1 day storage:

After staining, the highest mean microhardness was the control (135), tea group (133.1) and combination group (132.3) which showed no statistically significantly difference between them. The lowest mean value was for carbonated beverage group (126).

After bleaching,the highest mean microhardness was the control group (135), followed by both tea group (116.6) and combination group (110.6) which showed no statistically significantly difference between them which showed lower mean. The lowest mean microhardness was for carbonated beverage group (89.6).

6 days storage:

After staining, the highest mean microhardness was the control group (135), followed by both tea group (131.2) and

combination group (131) which showed no statistically significantly difference between them The lowest mean was for carbonated beverage group (125.1). **After bleaching**, the highest mean microhardness was the control group (135), followed by both tea group (117.4) and combination group (111.4) which showed no statistically significantly difference between them which showed lower mean. The lowest mean microhardness was for carbonated beverage group (104.2).

3.2.1.3.Alesencextra-boost+Laser activation.

1 day storage:

After staining, the highest mean microhardness was the control group (135), followed by both tea group (133.9) and combination group (131) which showed no statistically significantly difference between them The lowest mean was for carbonated beverage group (122.6).

After bleaching, the highest mean microhardness was the control group (135), followed by tea group (120). Both carbonated beverage (112.8) and combination groups (105.1) showed the lowest mean with no statistically significant difference between them.

6 days storage:

After staining, the highest mean microhardness was the control group (135), tea group (133.5) and combination group (130.4) which showed no statistically significantly difference between them. The lowest mean was for carbonated beverage group (120.4).

After bleaching, the highest mean microhardness was the control group (135), followed by tea group (119). Both carbonated beverage (111.7) and combination groups (108.2) showed the lowest mean with no statistically significant difference between them.

4. DISCUSION

Since the last decade, methods to improve the esthetics of the dentition by tooth whitening were of interest to dentists, their patients and the public. Thus, dental bleaching has become an alternative to change the color of discolored teeth.

In the current study bovine teeth were used as it was practical and suitable because of its large labial surface area and its validity in a sound, non carious form. Bovine teeth were also used in previous studies according to **Adeyemi et al, 2006; Al Salehi et al, 2007**. The results and observations in studies by **Titley et al, 1991 & 1993** utilized human teeth generally support the results and observations recorded for bovine teeth.

In this study, the effects of tea and carbonated beverages on enamel surface were investigated, as they are the most commonly used by the population. Moreover carbonated beverage was chosen as it continues to replace milk and other nutrient-dense foods and beverages in which patients consider it harmless, **Jain et al, 2007; Owens and Kitchens, 2007.**

Three peroxide based bleaching regimens were used in this study. As peroxide based products are effective in achieving a wide range of shade enhancement and are available by professional application in-office or through professional dispensing for daily use (Custem-tray based system) and self-directed (over the counter)**; Bernie et al, 2003; Zanin et al, 2004.**

In this study, chemical activated bleaching agent was tested as it is the most commonly used and available bleaching regimen, **Sulieman et al, 2006; Luo et al, 2007.** In addition photo and laser activated bleaching agents were also tested to accelerate lightening of discolored teeth during chair side treatments, where immediate whitening occurs. This was in accordance with previous studies by **Wetter et al in 2004 and Buchalla and Attin in 2007;** who used Light and laser for the activation of the bleaching agents. In the current study color change and microhardness were measured to assess the effect of the three bleaching regimens used on enamel surface.

Color changes could be assessed visually using shade guide systems and digital photographic means or digitally using colorimeter, spectrophotometer and digital analysis; **Sulieman et al, 2006; Braun et al, 2007; Luo et al, 2007.** However each system has its own limitation. In this study Color change was assessed using computerized image analysis in term of grey scale (ranging from 0= black and 255= white) as it is one of the objective measuring procedure that eliminates the potential for human variability. Microhardness was assessed using Vickers hardness tester as it was used in previous studies by **Unlu et al in 2004 and Al-Salehi et al in 2007**.

Results of computerized image analysis revealed statistically significant decrease in the mean grey scale value of all the teeth immersed in the three solutions used. As the normal color of the teeth is determined by the blue, green and pink tints of the enamel and is reinforced by the yellow through to brown shades of dentine beneath. Direct staining has multifactorial etiology with chromogens derived from dietary sources or habitually placed in the mouth. These organic chromogens are taken up by the enamel pellicle and color imparted is determined by the natural color of the chromogen as stated by

Watts and Addy in 2001. Moreover the chromogens diffuse rapidly into the dentine to saturate binding sites. The diffusion occurs mainly through the dentinal tubule system, although diffusion through inter-tubular dentine is possible and must occur to produce staining in the body of the dentine which is the main cause of showing the translucent enamel discolored. Teeth immersed in tea showed the lowest mean grey scale value this result was in agreement with **Sulieman et al in 2003 and 2005** where they revealed considerable colour changes in all L*a*b* values with the most marked value change in L* indicating tooth darkening. The change in a* and b* were of interest since these moved in the direction of red and yellow, this could be attributed to the polyphenolic chromogens found in tea namely, the theorubigins and theoflavins, which are red and yellow, respectively. As well as results revealed that as the immersion time increased the color change become intense.

After bleaching with the three bleaching regimens results revealed increase in the mean grey scale value of all the three bleaching regimens used. This result is in agreement with **Bartlett, 2001; Reinhard et al, 1993; Matis et al, 2002 & 2003; Zekonis et al, 2003; Joiner et al, 2004; Duschner et al, 2006 and Sulieman et al 2006.** This could be attributed to the fact that when hydrogen peroxide interacts with a tooth, it decomposes into hydroxyl radicals or into water and oxygen molecules, depending on the mechanism of hydrogen peroxide decomposition. The free radicals released are unstable and immediately seek an available target with which they may react. The reaction may decompose organic materials, including stains on enamel, from larger-chained, darker-colored molecules into smaller, shorter-chained, light- colored molecules. In the course of decomposition, a color change occurs on the enamel surface and the decomposed organic materials are dissolved in the hydrogen peroxide solution.

Moreover results of computerized image analysis revealed statistically significant increase in the mean grey scale value of both photo and laser activated bleaching agents than did chemical activated bleaching agent.

This could be attributed to the difference in hydrogen peroxide concentrations between the bleaching agents used where the chemical activated bleaching agent has 6% H2O2 while the photo and laser activated bleaching agents have 25% and 38% H2O2 respectively. These results indicate that bleaching efficiency might be concentration dependant. This result is in agreement with the results of **Matis et al in 2000 and Braun et al in 2007.**

Moreover this may be also attributed to under photo-chemically initiated reactions using light or laser, the formation of hydroxyl radicals from hydrogen peroxide has been shown to increase, by a rise in temperature according to the following equation: H2O2+211 KJ/mol----2HO. This is in accordance with increase in speed of decomposition of a factor of 2.2 for each temperature rise of 10ºc. Due to the increased release of hydroxyl-radicals (thermocatalysis), an increase in efficacy is conceivable. If light is projected onto a bleaching gel a small fraction is absorbed and its energy is converted into heat. Most likely,

this is the main mechanism of action of all light activated bleaching procedures. Moreover the bleaching process is a chemical reaction composed of different factors that determine the rate of the chemical reaction and the increase of the temperature. Concentration of the reactants and intensity of light in a photo-chemical reaction are all proportional to the rate of chemical reaction of the tooth whitening. Similar results have been suggested by **Sun et al in 2000; Luk et al in 2004; Perdigo et al in 2004 and Buchalla et al, 2007.**

However the results suggested by **Zekonis et al in 2003 and Sulieman et al in 2006** were contradicting. This might be to significant variations in the bleaching agents, time of application and color assessment methods used.

Microhardness results revealed that there was statistically significant decrease in enamel microhardness after immersion in the three solutions, where the carbonated beverage group showed the lowest mean microhardness value than did the tea and the combination solutions. This is in agreement with the results of previous studies by **Kim et al in 2001; Willershausen and Dobrick in 2004; Jain et al in 2007; Owens and Kitchens in 2007.** This may be due to the acidic nature of the carbonated beverages that may result in enamel erosion. In addition, there are many other factors affecting the rate of enamel erosion and dissolution, which are the total exposure time that would depend on the actual amount of beverage consumed, the frequency of consumption (that is, if small sips are taken at frequent intervals or the entire can/bottle is consumed quickly), if the consumer uses a straw to drink these beverages (reducing the enamel's exposure as a result), and so forth. This explanation matches that of **Willershausen and Dobrick in 2004; Joiner et al in 2004 and Jain et al in 2007.**

Moreover, microhardness results after bleaching with the three bleaching regimens revealed a significant decrease in enamel microhardness. This is with agreement with

Park et al, 2004; Pinto et al, 2004; Unlu et al, 2004; Junior et al, 1996; Rotstein et al, 1996. This may be attributed to surface degradation, resulting from the complicated oxidation process of free radicals. Since the organic materials (proteins, lipids or dental staining substance) are distributed mainly in the inter-zone of inorganic structures, the removal of such organic materials makes the surface uneven. Hydrogen peroxide can also interact with inorganic materials and dissolves the enamel surface gradually by removing the mineral elements. As the main building block of enamel is hydroxy-apitite crystal that is composed of calcium and phosphorus. Therefore changes in ca/p ratio indicate alteration in the microhardness, since microhardness directly related to the mineral content of enamel.

However, the results suggested by **Joiner et al in 2004; Duschner et al in 2006 and Ferreira et al in 2006;** were contradicting. This can be due to variations in the methodology applied, such as time of exposure, pH of the immersion solution, type of teeth and mainly the storage environment. When the specimens are stored in artificial saliva or exposed to oral environment in situ, no change in the superficial hardness of enamel is observed, considering that saliva presents a large remineralization potential. The enamel contact with the bleaching solution slightly below the critical pH for a short period followed by the contact for a longer period with a hypermineralized solution of artificial saliva seems to be unable to result in demineralization.

For all groups, no correlation was found between color change of enamel surface and its microhardness. This is in agreement with **Basting et al, 2003 and Joiner et al, 2004**. However, other study by **Rodrigues et al in 2005** have shown that the increase in the concentration, duration and frequency of exposure of tooth structure to hydrogen peroxide is directly proportional to the increase in the bleaching action and the associated sequelae such as effect on enamel microhardness.

Nevertheless, in vitro procedures are not necessarily representative of the in vivo situation. By the lack of the positive outward pressure along the dentinal tubules, which in vivo might retard the penetration of any bleaching agent clinically with vital teeth. The use of extracted teeth that were devoid of dentinal fluid also probably allowed the agent to penetrate the tooth more quickly than would be the case clinically as stated by **Sulieman et al, 2003.**

Conclusion:

Tea and carbonated beveraves have the ability to discolor teeth and alter their microhardness. Different bleaching regimens are lightening the color of discolored teeth but adversely affect enamel microhardness.

Enamel microhardness is directly proportional with hydrogen peroxide concentratin in the bleaching agent**.**

Abstract: Studies of maxillary overdentures supported by conventional implants often show a high implant failure rate. It was believed that maxillary implants should be splinted to retain a removable maxillary overdenture in order to maintain osseointegration. **Materials and Methods:** The present study evaluated the clinical performance of new generation of OsteoCare's Midi self-tapping self-drilling one-piece (ball type) implants for the support of maxillary overdentures. Seventy five implants were placed in the anterior maxillary region of 14 patients. A transmucosal flapless procedure was used to place four to six implants for each patient and followed by immediate delivery of an overdenture. The patients were evaluated at 6-month intervals for a follow-up period of 18 months. The clinical criteria to be checked were survival rate, Periotest values, radiographic crestal bone level and patient satisfaction. The **results** showed that 73 implants had successfully osseointegrated as indicated by the clinical and radiographic examinations. Implant survival rate of 97.3% was attested. The accumulated mean marginal bone loss was 0.88mm at the end of the follow-up period. Patients showed a very high degree of satisfaction of the treatment outcome due to the highly improved retention with partial palatal coverage using horse shoe designed maxillary over-dentures. This procedure has many advantages which include implant placement with minimally invasive transmucosal flapless surgery, decreased postoperative pain and a decreased cost of treatment. Single-stage one-piece implant placement, immediate loading, and transmucosal flapless surgery can result in high success rates when proper techniques are utilized with appropriate patient selection. In **conclusion**, the use of the Osteocare's Midi one-piece (ball type) implants is a valid unique simple treatment modality to support maxillary overdentures.

Keywords: Midi one-piece implants, immediate loading, maxillary overdentures.

1- Introduction

Implants supported overdentures appear to be highly successful in the edentulous mandible, Burns et al (1995); Feine et al (2002); Chiapasco and Gatti (2003); Zahran (2008). In contrast, treatment outcome with maxillary overdentures seems to be less predictable in comparison to other prosthetic indications with conventional implants. To this date, maxillary overdentures have not been adequately addressed in the literature. Over viewing of the few available maxillary over denture case presentations and studies, reveals a low implant survival rate , Jemt and Lekholm (1992); Jemt (1993); Mericske et al (2002).

With the conventional implant designs and the traditional surgical techniques, maxillary implants appear to cause more problems than mandibular implants supporting overdentures in patients with poor bone quality and severely resorbed maxillae , Misch et al (2004).

In some cases, the retention of the upper dentures is difficult while some patients suffer from the big size of the maxillary denture with full palatal coverage that restricts their tongue movements. The placement of implants to support a maxillary overdenture allows for optimal results which include retention, function, phonetics and patient satisfaction ,Cleave (2000).

The traditional original Brånemark's 2-stage protocol initially calls for the submerging of the implants, which remain load-free for a healing period of 3-6 months to ensure successful osseointegration , Branemark et al (1977); Adell et al (1981). The actual need for healing periods of such duration has been greatly questioned because they were determined on empirical basis, De Vasconsellos et al (2006). Many clinicians, however, are unaware that the concept of immediate loading of implants actually began more than 30 years ago , Hahn (2005). For a long period

of time, the success documented for Brånemark's protocol convinced clinicians that this was the only acceptable protocol. On the other hand, earlier results with immediately loaded implants were often unpredictable , Gapski et al (2003).

Recently, the evolution of the science of Dental Implantology yielded technological breakthroughs of the macro- and the micro-design of the dental implants, including improved implant shape, thread patterns and surface treatments that have demonstrably fostered greater primary stability and faster osseointegration , Stanford (2002); Jones and Cochran (2006); Sakoh et al (2006). These modern implants were designed for the immediate loading procedures and were applied to rehabilitate the edentulous mandible with high predictability. In parallel with the recent technical advances of the implant designs, the better understanding of biology had led to shifting towards the minimally invasive or the a traumatic flapless surgical procedures , Al-Ansari and Morris (1998); Hahn (2000); Kan et al (2000); Becker et al (2005); Zahran and Gauld (2007); Zahran (2008). Appropriate patient selection, single-stage surgery, immediate loading, and flapless site preparation are dependable treatment approaches that offer favorable long-term prognosis, Fortin et al (2006).

Nowadays, many clinical studies validate the immediate loading protocols as a viable therapeutic alternative to the original Brånemark's protocol in its appropriate conditions , Misch et al (2004). The ultimate goal of an immediate loading protocol is to reduce the number of surgical interventions and shorten the time frame between surgery and prosthesis delivery, all without compromising the success rate of the procedure , Fortin et al.; (2006).

The use of the Midi one-piece (ball type) implants is a unique simple treatment modality which have been specially designed to support over dentures. They are considered an alternative to the conventional implantation regimen and are ideal for immediate loading in varying bone qualities as well as thin atrophic ridges. They allow minimally invasive trans-mucosal flapless placement and limit the requirement for hard tissue grafting procedures. The conical macro-design of the Midi implants, the special buttress thread pattern and the undersized drilling using one drill result in compression or condensation of the bone with the increase of the initial stability of the implants , Zahran and Gauld (2007); Zahran (2008); Zahran (2008 a).

The aim of the present study was to evaluate the clinical performance of the new generation of self-tapping Midi one-piece (ball type) implants for supporting of maxillary overdentures.

2-Materials and Methods

2.1. Materials:

2.1.1. Subjects:

A total of 14 patients, including 8 males and 6 females, were consecutively included in this study. The average age at the time of implant placement was 60.42 years (range 52-72 years). Six patients were completely edentulous. The other patients had partially edentulous mandibles. All patients were completely edentulous in the maxilla except one patient who has 2 second molars. All the implants were placed well spaced, in the anterior part of the maxilla between the left and right second premolars area to avoid the maxillary sinus.

Table (1): Overview of clinical data of patients and number of implants included in the study.

Patient	Age	Sex	Number of implants	Opposing arch	Comments
1	63	♂	6	Implant supported overdenture	
2	58	♂	6	Partially edentulous	
3	72	♀	6	Implant supported overdenture	
4	52	♂	4	Partially edentulous	
5	54	♀	4	Implant supported overdenture	
6	60	♂	4	Implant supported overdenture	
7	57	♀	6	Implant supported overdenture	1 failed implant
8	62	♂	6	Implant supported overdenture

All patients had at least 5mm of ridge width for the placement of implants. The ridge width of each patient is evaluated by ridge mapping or by using bone callipers. The patients received Midi implants with diameters of 3.3mm, 3.8mm and 4.3mm and length of 13mm. The patients were thoroughly informed of the immediate loading protocol and of all the risks associated with this type of procedure. They all gave their full informed consent. Clinical evaluation included the ridge

width and shape, the opposite jaw (being partially or completely edentulous with an overdenture) and the occlusal forces. The selected patients were systemically healthy and not heavy smokers.

2.1.2. Implants

The treatment plan for the patients in this study included placement of 4-6 Midi implants in the anterior maxillary area and the premolar region of the alveolus bilaterally. Eight patients received six implants, one patient received five implants and five patients received four implants. The implants were placed in healed bony sites with bone types (D1 to D3). The 75 implants used in the study were OsteoCare's Midi one-piece (ball type) implants (OsteoCare™ Implant System, London, United Kingdom). Midi implants have range of diameters (3.30, 3.80 and 4.30mm) and lengths (10, 13, and 16 mm). The implants have blasted and acid etched surface, and a high load "buttress" thread that has the advantage of allowing maximum bone-to-implant contact. This results in achieving high initial stability in even poor quality bone. The conical macro-design of the Midi implants has the advantage of allowing for the compression and expansion of the site.

Table (2): Implant number, diameter (mm) and length (mm).

Size of implants	Number	Failed Implants
3.3x 13 mm	4	1
3.8x 13 mm	65	1
4.3x13mm	6	0
Total	75	2

2.2. Methods:

2.2.1. Pre-surgery evaluation:

Pre-surgical radiographic evaluation was carried out with panoramic radiographs, periapical radiographs and cone beam volumetric tomography (CBVT) whenever indicated.

The ridge width was evaluated through the diagnostic casts, ridge mapping or directly in the patients' mouth using callipers.

Before surgery, final impressions of the arches were made, and working models were casted. The models were mounted in an articulator after bite registration on occlusal rims for establishing the centric relation. Tooth settings try-in were made and confirmed by the patients.

2.2.2. Surgical Protocol and implant placement (using Flapless trans-mucosal technique):

2.2.2.1.Marking of the drilling sites:

Using a skin marker, marks were made directly onto the patient's dried mucosa covering the alveolar ridge, to determine the drilling positions of the implants as planned from the diagnostic casts and the panoramic radiograph.

2.2.2.2. Site preparation:

The implant surgical procedures were performed under local anesthesia and without sedation. Only one perforation profile drill (1.3mm diameter) was used for site preparation to give needlepoint accuracy for position, angle and depth. The use of saline was paramount when making the perforation. When the drill passed through the mucosa (trans-mucosal), it reached firstly the cortical bone then the cancellous bone. Confirmation of reaching the cancellous bone was achieved via the physical feel; the drilling was harder through the tough cortical plate and became far easier when engaging the softer cancellous bone. Preparation of the osteotomy was shorter than the implant length as Midi implants have a strong self-tapping self-drilling property.

2.2.2.3. Implant Placement:

The implant was removed from its protective pouch and offered to the site. The implant was manually placed after the trans-mucosal site preparation and was rotated clockwise for approximately three revolutions or until the plastic carrier could no longer rotate the implant manually. Then the over-hex driver with the ratchet wrench was used to complete the seating of the implants.

2.2.2.4.Immediate Loading (Same day of implant placement):

The Initial stability (primary fixation) of the Midi implants was carefully checked by the torque wrench to confirm that the initial primary fixation was exceeding 30N/cm which was crucial to start loading.

2.2.2.5.Relief of Denture to Accommodate the Housings:

Holes were made in the denture at the pre-marked locations by using a laboratory bur. The polycarbonate housings were placed on the implants, and were checked to make sure that they were securely seated with full passivity. Try in of the denture was made to check full seating without binding on the housings.

2.2.2.6.Pick-up of the Housing (chair-side pick-up procedures)

Once the spaces for the housings had been relieved, they were filled with self-cured acrylic resin and the denture was placed over the housings. The patient was allowed to bite in centric occlusion.

After setting of the self-cured acrylic resin, all the excess was removed and the denture was trimmed and polished.

2.2.3. Post-operative care:

After the implants placement and delivery of the overdenture, the patients were instructed to consume easily chewable food for 2 months. No preoperative or postoperative antibiotics were prescribed. Analgesics were used when needed.

2.2.4 Post operative follow-ups and evaluation

The patients were evaluated at 6-month intervals for 18 months. The clinical criteria to be checked were survival rate, Periotest values and radiographic crestal bone level.

The following criteria were applied to evaluate implant success:

(1) Absence of clinically detectable mobility when tested with opposing instrument pressure.

(2) No evidence of peri-implant radiolucency on periapical radiographs.

(3) Absence of recurrent or persistent peri-implant infection.

(4) No complaint of pain at the site of treatment.

(5) No complaint of neuropathies or paraesthesia,

(6) Crestal bone loss not exceeding 1.5 mm by the end of first year of functional loading and less than 0.2 mm/year in the ensuing years (according to the criteria proposed by Albrektsson et al.; (1986) up to the 18 months of the follow-up period.

Panoramic and periapical radiographs were obtained at implant insertion and subsequently at 6-month intervals up to 18 months postoperatively to evaluate crestal bone loss. The linear measurement obtained by means of conventional radiographs and indirect digital images evaluated by the Digora software for Windows, version 1.5 (Soredex, Helsinki - Finland), Kawauchi et al (2004).

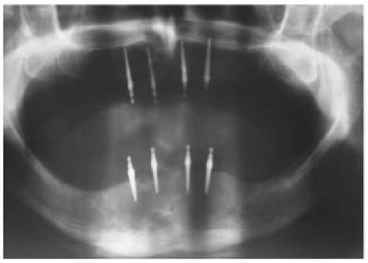

Figure 1f: Panoramic radiograph at 18 months

Figure 1g: Clinical aspect at 18 months

Figure 1h: Placement of the polycarbonate housings on the implants

Figure 1i: The finished overdenture with the housings

The Periotest M (Medizintechnik Gulden, Bensheim, Germany) was used to evaluate the clinical stability. Periotest values (PT) of (-8 to 0) were considered the ideal values that denote successful osseointegration.

For the evaluation of the patient satisfaction, questionnaires were filled by the patients at the 6 months follow-up visit. The questions were based on the questionnaire proposed by Brånemark et al (1999).

3. Results:

3.1. Complete soft tissue healing was generally uneventful in all patients within the first 2 weeks after implants placement. The patients reported minimal postoperative swelling or pain experiences with no occurrence of hematoma and minimal need for analgesics. Most patients returned to their normal lives the day following surgery.

3.2. The number of implants placed, status of the opposing arch and the implant diameter and length are summarized in table (1) and (2). All patients demonstrated bone type D2 or D3 as determined by tactile perception during the time of osteotomy preparation and implant placement.

Figure 2b: Placement of the polycarbonate housings on he implants

Figure 2c: The finished overdenture with the housings

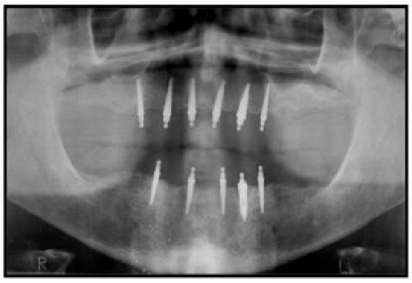

Figure 2d: Panoramic radiograph at 18 months

Figure 2e: Immediate delivery of the overdenture

3.3. During the 18 months postoperative follow-up period, all patients showed no postoperative inconveniences. Seventy three Midi implants were successfully osseointegrated as revealed by clinical and radiographic examinations. Implant survival rate of 97.3% was attested.

3.4. The mean marginal bone loss was 0.72mm at 12 months, while it was 0.88mm at 18 months. The mean values of linear radiographic measurements were recorded using digital programs.

3.5. The Periotest values (PT) during the 18 months follow-up period never exceeded a maximum of (PT= 0) and the minimum value was (PT= -5) for all the successfully osseointegrated implants.

3.6. Reviewing of the patient satisfaction questionnaires showed subjective answers that demonstrated a very high degree of satisfaction of the treatment outcome. All patients have verbally indicated their comfort with the horse shoe denture design due to their partial palatal coverage. It

provides them with more room for their tongue and exposes more palatal tissues and improves the feeling of the texture of their food.

4. Discussion

Immediate loading of dental implants is becoming a widespread therapeutic procedure for the rehabilitation of patients with edentulous jaws. In general, patients with completely edentulous maxillary jaws are restored with an implant supported overdenture. They are at the highest risk of occlusal overload for immediate loading protocols when conventional implants are used to support a maxillary overdenture , Jemt and Lekholm (1992); Jemt (1993); Mericske et al (2002).

The high failure rate of the maxillary over dentures supported by conventional implants is related to the inadequate bone volume and the low bone density of the completely edentulous maxilla. Generally, the bone is less dense in the anterior maxilla than the anterior mandible. The maxilla presents very thin porous cortical labial bone and the trabecular bone is usually very fine, Cleave (2000); Misch et al (2004).

Several factors may influence the results of immediate implant loading. These could be divided into the following categories: surgery, host, implant, and occlusion-related factors. Surgical factors consist of primary implant stability and surgical technique. Host factors comprise the quality and quantity of bone, and wound healing. Implant factors include the macro and the micro designs, surface textures, and dimensions of the implant. Occlusal factors involve the quality and quantity of force and prosthetic design ,Gapski (2003).

The 97.3% successful results of the present study illustrated that the new generation of OsteoCare's Midi dental implants present the opportunity to provide patients with a minimally invasive, less costly, less complicated, and less surgically intensive treatment in a high percentage of cases that would be difficult to treat with the current inventory of conventional root-form implants for supporting of maxillary overdentures.

The OsteoCare's Midi one-piece dental implants have a number of unique points that set them apart from their conventional counterparts. There is no similarity between the OsteoCare Midi implants that were placed in this study and the other commercially available conventional implants.

All the 75 Midi implants reached high initial stability over 30 N/cm due to their conical design, buttress threads and the roughened surface (grit blasted and acid etched). Also, the under dimensioned drilling and the bone condensing property of the Midi implants have been used to increase initial stability as well as to improve the bone quality , Zahran and Gauld (2007); Zahran (2008); Zahran (a) 2008).

It was reported that conical implant design in combination with the use of an undersized form drill could lead to higher initial stability than conventional implants, O'Sullivan et al (2000); Sakon et al (2006). Also experimental and clinical studies proved that the implant surface roughness and the thread design are major factors in achieving success with immediate loading Stanford (2002).

The trans-mucosal flapless procedure for placement of the Midi implants resulted in minimal swelling and pain with no occurence of hematoma.

The patients required minimal postoperative medication. The flapless procedure resulted in a very high increase of the patient acceptance and satisfaction of this treatment modality. It was reported that flapless surgery also admits a maintained better blood supply to the marginal bone, thus reducing the likelihood of bone resorption ,Al-Ansari and Morris (1998); Hahn (2000); Kan et al (2000).

Although flapless implant placement is considered a blind surgical procedure, there is a learning curve with every surgical procedure, after which it becomes routine. There are many advantages for the patient as well as for the surgeon, since the procedure is less time consuming, bleeding is minimal, implant placement is expedited, and there is no need to place and remove sutures ,Becker et al (2005).

The one-piece implant design eliminates the need for placing healing collars and makes it possible to avoid manipulation of the soft tissue portion after initial healing. The implant-abutment junction in a two-piece implant design constitutes a structural weakness that may complicate the procedures, Hahn (2005).

The polycarbonate housings with rubber O-rings were successfully used for retention of the overdentures. O-rings possess a number of advantages, including ease of use and maintenance and low cost. The patients were pleased with the function and esthetics of the overdenture O-ring prosthesis. Clinical comparisons of ball and bar designs for mandibular over-dentures revealed a significantly higher number of complications and/or repairs for the bar group, Trakas et al (2006).

Implant retained over-dentures could be considered the treatment of choice for most patients of advanced age who are already denture wearers, Romanos (2004). They have an increased probability of having medical problems such as diabetes mellitus or using anticoagulant therapy, so they need a simple a traumatic surgical protocol as offered by the use of the Mini and Midi implants. Advantages of this procedure include implant placement without any bone augmentation surgery, minimally invasive surgery resulting in virtually no

bleeding, decreased pain and a decreased cost of treatment. Another important advantage is the possibility of removal of the palatal part of the maxillary overdenture that results in having smaller horse shoe designed denture that gives bigger space for the patient's tongue. This will result in improvement of phonetics, taste sensation as well as patient's self confidence.

Conclusion

The use of four to six Midi one-piece (ball type) implants in the maxilla is a feasible treatment option to support maxillary overdentures. These implants have a number of distinct features that set them apart from their conventional counterparts. They allow minimally invasive flapless trans-mucosal placement. Immediate loading is also possible and they are ideal for most types of bone qualities, quantities and for atrophic ridges. They are reliable and cost effective implants that bring secure dentures within the reach of many patients, who are medically or financially compromised. This technique can contribute to a higher degree of implant treatment acceptance due to less discomfort and generally shorter treatment times.

The Journal of American Science

ISSN: 1545-1003

The international academic journal, "***The Journal of American Science*"** (ISSN: 1545-1003)**,** is registered in the United States, and invites you to publish your papers.

Any valuable papers that describe natural phenomena and existence or any reports that convey scientific research and pursuit are welcome, including both natural and social sciences. Papers submitted could be reviews, objective descriptions, research reports, opinions/debates, news, letters, and other types of writings that are nature and science related. All the manuscripts will be processed in a professional peer review. After the peer review, the journal will make the best efforts to publish all the valuable works as soon as possible.

Here is a new avenue to publish your outstanding reports and ideas. Please also help spread this to your colleagues and friends and invite them to contribute papers to the journal. Let's work together to disseminate our research results and our opinions.

Papers in all fields are welcome, including articles of natural science and social science.

Please send your manuscript to editor@americanscience.org;
sciencepub@gmail.com;
americansciencej@gmail.com
