The observed improvement in glucose, insulin profile, triacylglycerol and HDL-C confirm the potent biological action of green, roasted and decaffeinated coffee and suggest that chlorogenic acid (a component in coffee) might have an antagonistic effect on glucose transport. Suggesting a novel function of coffee on lowering the risk factors of diabetes and delaying the progress of diabetes complications as well.

Abstract: To estimate plasma gelsolin levels in multiple trauma patients and its predictability for their outcome in relation to clinical data. The study included 70 multiple trauma patients and 20 healthy adult controls for blood donation as control group for the plasma level of gelsolin. All patients underwent history taking, time elapsed since trauma inflection and amount of external bleeding if present. Clinical evaluation included both Acute Physiology and Chronic Health Evaluation II (APACHE II) and Injury Severity Scores (ISS). Patients were evaluated daily throughout their ICU or hospital stay for the development of secondary morbidities and/or mortality. Venous blood samples were obtained at 12 hours after ICU admission for ELISA estimation of plasma gelsolin level. During hospital stay, 20 patients (28.6%) developed secondary morbidities and 8 patients (11.4%) died. Mean plasma gelsolin levels were significantly lower in patients compared to control levels with significantly lower levels in non-survivors compared to controls and survivors. Development of secondary morbidities showed a positive significant correlation with at admission ISS score and a negative significant correlation with plasma gelsolin. Survival rate showed positive significant correlation with plasma gelsolin level and negative significant correlation with both time since trauma inflection and ISS score. ROC curve analysis, defined prolonged time since trauma inflection as the significant sensitive predictor for both morbidity and mortality, while plasma gelsolin level was significant specific predictor for development of secondary morbidity and combined with ISS score were significant specific predictors for mortality. Conclusion: At admission plasma gelsolin level is a specific independent marker for prediction of the development of secondary morbidities that may progress to endanger patients' life and time since trauma inflection was found to be significant sensitive parameter for the patients' survival irrespective of development of these morbidities.

[Adel F. Al-Kholy, Mosad M Odah, Jehan Sabry, Ehab El-Shahat, Ehab Said**. Combined at-admission estimation of plasma gelsolin and injury severity score could predict the outcome of multiple trauma patients**. Journal of American Science 2010;6(12):442-447]. (ISSN: 1545-1003).

Keywords: Gelsolin, Trauma, Sepsis, Morbidity, Mortality

1. Introduction

Most patients with severe traumatic injury have a prolonged stay in the intensive care unit, the outcome being a long-term disability or death, with a minority of patients achieving a functionally independent outcome and despite the therapeutic advances; certain patients remain at high risk of infection and the attendant morbidity and mortality. Several clinical studies, (Somasundar et al., 2004 and Jeremitsky et al., 2005) tried to identify certain prognostic factors that may influence outcome; however within certain limitations. Moreover, the development of adverse secondary events including development of adult respiratory distress, systemic inflammatory response syndrome, or multiple organ dysfunction syndromes may mislead the clinician during scoring and disturb the primary score and its predictability (Calfee et al., 2007).

This diagnostic dilemma pointed to the need for an early predictor for these secondary events prior to its commencement; Aslar et al., (2006) found APACHE II score and the arterial lactate level are the most important determinants of clinical outcome in critically injured patients and a correlation exits between lactate and APACHE II and between lactate and base deficit. Cunningham et al., (2006) found the admission lipopoly-saccharide-binding protein (LBP) concentration was significantly greater in non-survivors than in survivors, but after controlling for age and ISS, the admission LBP concentration did not predict death. Meisner et al., (2006) found that in patients with multiple trauma, procalcitonin level provides more information than the C-reactive protein level since only moderate amounts of procalcitonin is induced, and higher concentrations correlate with more severe trauma and a higher frequency of

various complications, including sepsis and infection.

Gelsolin is a protein found in both the cytosol and the plasma that has been reported to function primarily as a part of the actin-scavenging system with Gc globulin (vitamin D-binding protein) (Sun et al., 1999). Cellular disruption or necrosis releases cellular actin, both globular and filamentous fractions, into the circulation which results in capillary plug formation with subsequent tissue ischemia. The plasma actin scavenging system functions to cleave the filaments, cap the ends, preventing repolymerization and assist in the plasma clearance of filamentous actin. Additionally, gelsolin is known for its ability to bind lipids such as lipopolysaccharide, lysophosphatidic acid and phosphotidylinositol (Goetzl et al., 2000 and Karliner et al., 2001) and may modulate the inflammatory system. Experimentally, animals subjected to 40% total body-surface area burns demonstrated attenuated acute lung injury with the infusion of recombinant gelsolin to normal plasma levels (Rothenbach et al., 2004). Therefore, the present study aimed to estimate plasma gelsolin levels in multiple trauma patients and its predictability for their outcome in relation to clinical data.

2. Patients and Methods

The present study was conducted since Jan 2006 till June 2009 at Departments of Anesthesia & ICU and Clinical Pathology, Benha University Hospital in conjunction with Medical Biochemistry Department, Faculty of Medicine, Benha University. After approval of the study protocol by the Local Ethical Committee, the study was designed to include 70 trauma patients, irrespective of the anatomical site of trauma, required management and admission to surgical ICU. All patients arrived to the emergency unit dying or gasping was excluded of the study. The study was also designed to enroll 20 healthy adult controls for blood donation as control group for the plasma level of gelsolin.

All patients underwent full history taking with special regard time elapsed since trauma inflection, loss of consciousness and time elapsed till its regaining, amount of external bleeding if present. Clinical evaluation included both Acute Physiology and Chronic Health Evaluation II (APACHE II), (Rowan et al., 1993) and Injury Severity Scores (ISS), (Copes et al., 1988) determination.

All patients received first aid management at emergency unit, and when indicated surgical interference was carried upon, patients were admitted to ICU either immediately for conservative treatment or for postoperative follow-up for either discharge from the ICU or the development of additional morbidity or mortality.

Patients were evaluated daily for the development of septic morbidities including systemic inflammatory response syndrome (SIRS), sepsis, severe sepsis or septic shock. The frequency of development and outcome of these complications was recorded either at ICU or at ward after discharge from ICU.

Venous blood samples were obtained at 12 hours after hospital admission and were collected in EDTA containing tube to prevent clotting and plasma was separated by centrifugation and then separated and stored at -80^{o}C till ELISA (Uscn Life Science Inc. Wuhan, USA) estimation of plasma gelsolin level, (Smith et al., 1987).

Obtained data were presented as mean±SD, ranges, numbers and ratios. Results were analyzed using Chi-square test and Wilcoxon Signed Ranks Test. Sensitivity & specificity of evaluated parameters as predictors for patients' outcome were evaluated using the receiver operating characteristic (ROC) curve analysis judged by the area under the curve (AUC) and Logestic Regression analysis (Stepwise Method). Statistical analysis was conducted using the SPSS (Version 10, 2002) for Windows statistical package. P value <0.05 was considered statistically significant.

3. Results

The study included 70 patients who had successful resuscitation so as to be fully examined and managed and all were immediately admitted to the surgical ICU. During hospital stay, 11 patients (15.7%) developed adult respiratory distress syndrome (ARDS), 5 patients (7.1%) had sepsis and 4 patients (5.7%) had multiple organ failure (MOF) with a total secondary morbidity rate of 28.6%. At end of one month follow-up, 62 patients (88.6%) were survivors and 8 patients died with a total mortality rate of 11.4%. Three of non-survivors developed septic shock that could not respond to conservative treatment; 4 patients with MOF could not withstand and one patient with ARDS developed acute respiratory failure and died 3-days later. Detailed baseline characteristics and clinical data of the study

population, stratified as survivors or non-survivors, are presented in Table 1 and showed non-significant difference between survivors and non-survivors concerning these data apart from a significantly higher ISS, (Z=2.524, p=0.012) and APACHE II (Z=2.035, p=0.042) scores in non-survivor compared to survivors.

Table (1): Patients' characteristics and clinical data determined at admission

		Survivors	Non-survivors
Number		62 (88.6%)	8 (11.4%)
Age (years)		33.7±9	38±13.4
Gender; M:F		50:12	5:3
Time since trauma (min)		52.5±21.3 (20-100)	77.5±19.3 (45-100)
Scene external bleeding		18 (29%)	5 (62.5%)
Loss of Conscious-ness	Number	10 (16.2%)	3 (27.5%)
	Duration	6±3.5 (4-10)	4.7±2.5 (1-9)
ISS score data		20.3±9.2 (11-59)	45±13.9 (29-66)*
APACHE II score		11.3±4.5 (7-15)	13.9±1.7 (8-19)*

Data are presented as mean±SD, ratios & numbers; ranges & percentages are in parenthesis
ISS score: injury severity score
*: significant versus survivors

Figure 1 shows that mean plasma gelsolin levels were significantly lower (Z=3.576, p<0.001) in patients (127.7±34; range: 45.6-192.4 ng/ml) compared to control levels, (196.4±27.6; range: 134.5-246.5 ng/ml) and were significantly lower in patients categorized according to survival compared to control levels with significantly lower (Z=2.521, p=0.012) levels in non-survivors (84.4±32.2; range: 45.6-145.2 ng/ml) compared to survivors (133.3±30.2; range: 59-192.4 ng/ml).

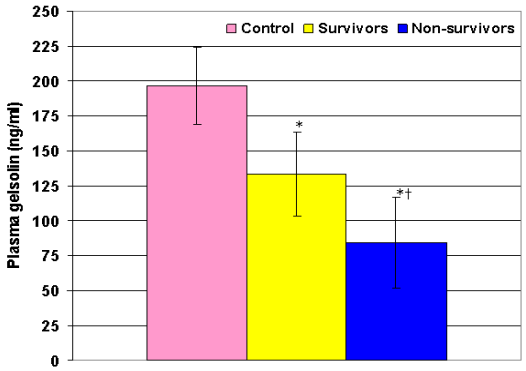

Figure 1: Mean (±SD) plasma gelsolin levels estimated in patients categorized according to the survival compared to control levels
*: significant versus control †: significant versus survivors

Patients developed secondary morbidities showed a significantly higher (Z=2.576, p=0.01) ISS score with a significantly (Z=3.246, p=0.001) lower plasma gelsolin levels and were presented after significantly (Z=2.577, p=0.01) longer time since trauma inflection compared to those passed smoothly without development of secondary morbidities. Patients' age and body mass index showed non-significant difference between both patients' groups, (Table 2).

Table (2): Levels of evaluated parameters in studied patients categorized according to the development of secondary morbidities

	Secondary Morbidities	
	No (n=50)	Present (n=20)
Age	33.3±8.8	36.5±11.2
BMI	28.9±3.9	29.7±3.6
ISS score	19.1±7.3	33.2±16.8*
[a]Time	50.9±20.4	66.5±23.8*
P. Gelsolin	136.4±29.2	106.2±36.3*

Data are presented as mean±SD
Time since trauma affliction (minutes)
P. Gelsolin: plasma gelsolin levels
*: significant versus no secondary morbidities

Regression analysis defined at admission decreased plasma gelsolin as a significant (p<0.001) predictor for the development of secondary morbidities, while long time since trauma inflection and at admission high ISS score were the significant predictors for mortality, (p<0.001 & =0.011, respectively). Using ROC curve analysis, as shown in figures 2 and 3, defined prolonged time since trauma inflection as the significant sensitive predictor for both morbidity, (AUC=0.338, p=0.035) and mortality,

(AUC=0.075, p<0.001), while at admission plasma gelsolin levels were the most significant specific predictor for development of secondary morbidity, (AUC=0.506, p<0.001). On the other hand, at admission, ISS score and plasma gelsolin were the significant specific predictors for mortality, (AUC=0.787 & 0.871, p=0.009 & 0.001, respectively).

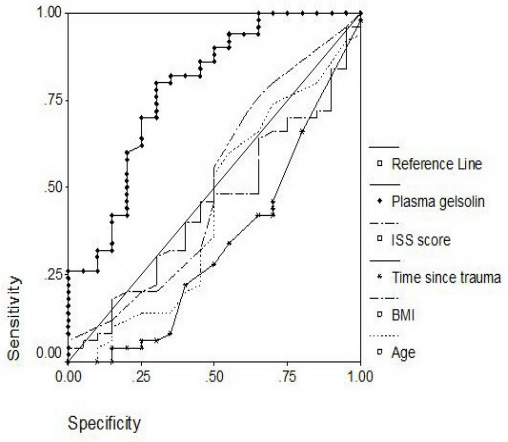

Figure (2): Specificity of evaluated parameters for prediction of secondary morbidities development

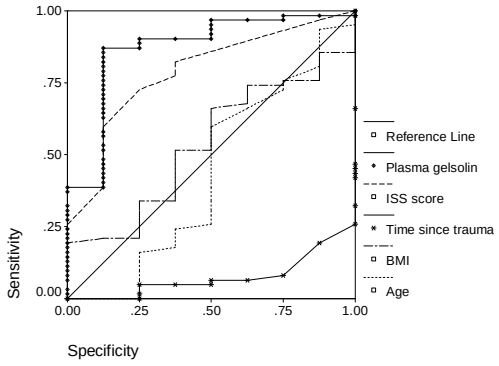

4. Discussion

Prediction of outcome, either as regards morbidity or mortality, of multiple trauma patients still a diagnostic dilemma. Twenty of the studied 70 multiple trauma patients developed secondary morbidities with a frequency of 28.6% and 8 patients could not withstand and died with a mortality rate of 11.4%. There was a non-significant difference between survivors and non-survivors as regard the constitutional parameters, and the number had external bleeding. However, non-survivors had significantly higher APACHE II and ISS scores with significantly longer time since trauma inflection.

These data illustrate a fact that trauma itself and its sequalae, and body systems and regions affected impose a high effect on the outcome, in support of this assumption there was a positive significant correlation between the determined ISS score and the survival of trauma patients and the frequency of development of secondary morbidities, however, the correlation was stronger with survival and this was assured using ROC curve analysis that defined ISS score as one of specific predictors of survival not for development of secondary morbidities.

Prolonged time since inflection of trauma till patient arrival to the hospital was found to be a highly sensitive predictor for both mortality and development of secondary morbidities; such parameter indicated bad transport systems for trauma patients, lack of road ambulance first aid facilities and experiences of health care providers, and lack of general knowledge about first aid till arrival of ambulance among population.

Considering survival is a first target for multiple trauma patients, post-traumatic mortalities could not be a secondary to trauma itself but to development of secondary mortalities. Eight patients died among this series all of them had secondary mortalities; 4 had MOF, 3 developed septic complications progressed to septic shock and one had ARDS progressed to acute respiratory failure and patient died. These findings point to the necessity for early prediction of such morbidities; plasma gelsolin, the plasma parameter evaluated through the present study, was found significantly depleted in non-survivors compared to both controls and survivors and in survivors compared to control. These findings illustrate the impact of trauma itself on plasma gelsolin level, irrespective of the outcome and its depletion is a bad finding that predicts the development of secondary morbidities and the possibility of its progression to endanger patients' survival. In support of this assumption, there was a negative significant correlation between plasma gelsolin levels and both morbidities and mortality and regression analysis defined it as a significantly specific predictor for morbidities; a result that assured using ROC curve analysis.

These findings supported that previously documented in literature, Dahl et al., (1999) found gelsolin level on admission was

reduced significantly in the trauma patients compared with normal controls, but they found no correlation between admission levels of gelsolin and ISS or survival. Thereafter, Lee et al., (2006) found low plasma gelsolin levels were associated with increased risk of death occurring in the ICU and could predicted longer ICU stay, prolonged ventilator dependence, and increased overall in-hospital mortality. Also, Wang et al., (2008) found the admission gelsolin levels were significantly decreased in severe sepsis compared with non-septic critically ill patients and healthy control individuals and survivors of severe sepsis exhibited substantial recovery of their depressed plasma gelsolin levels, whereas gelsolin levels in non-survivors remained at or below their depleted admission levels and concluded that plasma gelsolin may be a valuable marker for severe sepsis and recovery of depleted plasma gelsolin levels correlated with clinical improvement.

Gelsolin is one of actin-scavenging proteins that counteract the pathophysiological consequences of actin leaked into the circulation from dying cells, but the capacity of this defense system can be overwhelmed by massive tissue injury. Various studies tried to explore the pathogenesis of gelsolin depletion after trauma Löfberg et al., (1998) measured the serum gelsolin levels in five patients after rhabdomyolysis and observed a tendency of serum gelsolin to increase during the study period of 11 days with no intracellular gelsolin found in the serum, although it is abundant in muscle, and the destruction was severe as judged by other parameters and concluded that serum gelsolin thus behaves differently in rhabdomyolysis than after acute tissue damage in other organs, such as liver necrosis and adult respiratory distress syndrome.

Mounzer et al., (1999) failed to attribute gelsolin depletion to generalized protein loss due to trauma as they reported no correlation between post-traumatic hemoglobin values and plasma gelsolin concentrations but found plasma levels of albumin correlated with plasma gelsolin, however, the extent of plasma gelsolin depletion was much greater than that of albumin and concluded that plasma gelsolin depletion was specific and not a result of generalized plasma protein loss. On contrary, Lee et al., (2006) found plasma albumin depletion of no prognostic value but documented the predictability of depleted gelsolin for development of secondary morbidities, despite the absence of correlation with the development of ARDS, a contradictory finding to both Mounzer et al., (1999) and the current study.

These data point to a fact that depletion of plasma gelsolin is independent of extent of body protein loss, hemoglobin loss, or sole muscle injury but is dependent on injury severity of other organs and tissues especially in patients liable to secondary morbidities. It could be concluded that at admission estimation of plasma gelsolin is a specific independent marker for prediction of the development of secondary morbidities that may progress to endanger patients' life and time since trauma inflection was found to be significant sensitive parameter for the patients' survival irrespective of development of these morbidities. However, wider scale studies were advocated to correlate the predictability of estimation of plasma gelsolin versus inflammatory markers.

Abstract: To investigate the relationship between clinical parameters of pre-eclampsia (PE) and serum levels of Retinol binding protein4 (RBP4) and Placental growth factor (PlGF). Patients and Methods: The study included 90 pregnant women categorized as Group I: Control group (n= 20), included pregnant women who continued their pregnancy without development of PE manifestations, Group II: included patients had Mild PE (n=56) and group III included patients had Severe PE (n=14). After clinical evaluation and ultrasonographic examination, samples of maternal peripheral blood were obtained either at time of diagnosis of PE in groups II and III or at time of delivery in control group for ELISA estimation of serum RBP4 and PlGF. Results: PE patients had significantly lower serum PlGF, but significantly higher serum RBP4 levels when compared to the corresponding levels of the control group. Serum levels of PlGF showed negative correlation with systolic and diastolic blood pressures (SBP and DBP) and extent of proteinuria, but showed positive significant correlation with birth weight, while serum levels of RBP4 showed positive significant correlation with DBP, extent of proteinuria and patients' body weight measures. Conclusions: RBP4 and PlGF were associated with the development and severity of PE.

Keywords: Pre-eclampsia, Placental growth factor, Retinol-binding protein

1. Introduction

Pregnancy is a physiological situation where major changes in energy homeostasis occur to meet the nutrient demands of fetal growth. The energy needs are met by increased food intake and/or mobilization of stored fuels and decreased sensitivity of maternal tissues to insulin. This change in insulin sensitivity allows for decreased glucose utilization and a shift to fat metabolism by maternal peripheral tissues and increased availability to the feto-placental unit. The pregnant state parallels the insulin-resistant states of obesity and type-2 diabetes, which are also characterized by insulin resistance, and can become manifested as gestational diabetes in humans (Herrera, 2000, Di Cianni et al., 2003).

Pre-eclampsia is the major cause of maternal and fetal morbidity and mortality, involving 15% to 20% of pregnancies in developed countries and even more in less developed parts of the world. Superficial placentation driven by immune maladaptation, with subsequently reduced concentrations of angiogenic growth factors and increased placental debris in the maternal circulation, are likely responsible (Dechend and Luft, 2008).

Retinol (vitamin A) bound to its specific transport protein, retinol-binding protein (RBP), is the predominant (95% or more) retinoid form in the fasting circulation. Postprandially, retinyl ester packaged in chylomicrons and chylomicron remnants can constitute a large percentage of the total retinoid present in the circulation. As RBP is the sole specific transport protein for retinol, it has been proposed to play an important role in the delivery of retinoid from mother to fetus. However, the mechanisms and the physiology of maternal-fetal vitamin A transfer are not fully understood (Soprano and Blaner, 1994, Sapin et al., 1998).

Dysregulation of maternal circulating adipokines has been implicated in several "great obstetrical syndromes" including pre-eclampsia, small-for-gestational age, neonate and fetal death. It has been suggested that adipokines provide a molecular link between metabolic derangements and inflammatory response in complicated pregnancies. Retinol binding protein 4, a novel adipokine, plays a role in obesity-related disorders, as well as in the regulation of the immune response (Vaisbuch et al., 2009). Solini et al., (2009) determined serum RBP4,

leptin, adiponectin, and resistin levels in hypertensive and normotensive lean non-pregnant women with normal glucose tolerance and found serum RBP4 levels are increased in naive hypertensive women and correlated with the degree of intima-media thickness

Placental growth factor is a pregnancy-specific hormone that has been proposed to play a role in trophoblast invasion and fetal growth, as well as maternal adaptation to pregnancy (Lacroix et al., 2005). PlGF demonstrates somatotrophic, lactogenic and lipolytic properties similar to pituitary growth hormone, although its growth-promoting activity surpasses its other functions. Syncytiotrophoblast and extravillous cytotrophoblast express PlGF mRNA and protein. This hormone is secreted in a non-pulsatile fashion and can be detected in maternal blood at as early as 5 weeks of gestation (Chellakooty et al., 2004) and increases throughout pregnancy until term (Chellakooty et al., 2002), at which time PlGF concentration has been observed to either plateau or slightly decrease (Chellakooty et al., 2004).

Central to the pathogenesis of PE is shallow placentation with abnormal maternal-placental vascular development. Shallow placentation causes release of endothelial deranging factors to the maternal circulation. Among these placenta-derived factors are the antiangiogenic proteins such as soluble fms-like tyrosine kinase receptor (sFlt1) which binds and reduces the free circulating levels of the proangiogenic factors such as vascular endothelial growth factor (VEGF) and placental growth factor (PlGF). sFlt thereby blunts the beneficial effects of these proangiogenic factors on maternal endothelium, with consequent maternal hypertension and proteinuria (Redman and Sargent, 2005, Maynard et al., 2003, Troisi et al., 2008).

The aim of the present study is to evaluate the association between the levels of serum RBP4 and PIGF and the development of PIH or its severity.

2. Patients and Methods

Pre-eclampsia was diagnosed by the presence of gestational hypertension beginning after the 20th week of pregnancy with an absolute blood pressure ≥140 mmHg systolic and/or 90 mmHg diastolic on at least two occasions, 4 hours apart, and proteinuria (one dipstick measurement ≥2+ on a voided random urine sample). Severe PE was defined as severe hypertension (diastolic blood pressure ≥ 110 mmHg) plus mild proteinuria (2+ protein by dipstick measurement) or mild hypertension plus severe proteinuria (≥ 3+ protein by dipstick measurement). Mild PE was defined as mild hypertension with diastolic blood pressure <110 mmHg plus mild proteinuria (≥ 2+ protein by dipstick measurement). Patients with eclampsia were also classified in the severe pre-eclampsia category (Gifford et al., 2000).

This study was conducted at Benha University hospital in conjunction with Medical Biochemistry Department, Benha Faculty of Medicine and included 90 pregnant women, signed a fully informed written consent and categorized as Group I: Control group (n= 20), included pregnant women who continued their pregnancy without development of PE manifestations, group II: included patients had Mild PE (n=56) and group III included patients had Severe PE (n=14). Exclusion criteria included multiple gestation and preexisting medical conditions such as diabetes, chronic hypertension, and renal diseases.

At time of enrollment in the study, all women underwent full history taking, general and abdominal examination to determine a baseline arterial blood pressure and body mass index (BMI). Ultrasonographic examination was conducted to confirm the gestational age, and to exclude the presence of fetal congenital abnormalities. Body mass index was calculated according to the equation: BMI = [(Weight)/ (Height) ^{2}]. A person with a BMI of ≥30 are considered obese and morbidity rise sharply when the BMI is >30 kg/m^{2} (Vella et al., 2003).

Throughout the period since baseline data collection, all women were examined weekly for the progress of pregnancy and fetal wellbeing, the extent of hypertension and occurrence of other complications. Urine analysis was performed for the presence of urinary tract infection and the degree of proteinuria.

Samples of maternal peripheral blood were obtained either at time of diagnosis of pre-eclampsia in hypertensive group or at time of delivery in control group. Collected maternal blood samples were allowed to clot then serum was separated by centrifugation at 2000 rpm for 10 min. Serum was removed, placed in pyrogen-free Eppendorf tubes and stored at -80°C until ELISA assayed (within one month) for estimation of serum RBP4 (AdipoGen Inc., Seoul, Korea), (Lewis et al., 2007) and PlGF (RayBiotech, USA) concentrations, (Nemzek et al., 2001).

Statistical analysis: obtained data were presented as mean±SD, ranges, numbers and ratios. Results were analyzed using one-way ANOVA test and Chi-square test. Statistical analysis was conducted using the SPSS (Version 10, 2002) for Windows statistical package. P value <0.05 was considered statistically significant.

.

3. Results

The study was extended till enrollment of 70 PE pregnant women; Table (1) shows that mean age of enrolled PE patients was 27.9±3; range with a mean BMI of 31.2±1.8 kg/m^2. At time of diagnosis, mean SBP was 150.3±5.9 mmHg and mean DBP was 100.6±6.4 mmHg. All patients were proteinuric with a mean level of 1.8±0.7; range by dipstick measurement. Mean gestational age at time of enrollment was 30.9±3.8 weeks. The study also included a control group consisted of 20 pregnant women of cross-matched age and gestational age.

Table (1): Characteristics of the entire study population at time of enrollment

		Control group (n=20)	PE group (n=70)
Age (years)		28.3±2.4 (25-33)	27.9±3 (22-33)
Weight (Kg)		80.5±2.9 (75-85)	82.9±2.9 (79-90)
Height (cm)		164.7±4.9 (158-172)	163±3.5 (156-173)
BMI (kg/m^2)		29.7±2.1 (27.3-33.6)	31.2±1.8 (27.4-36.1)
Nulli:multipara		13:7	43:27
Gestational age (wk) at time of enrollment		29.7±3.6 (24-36)	30.9±3.8 (23-37)
Blood pressure	SBP	122±4.7 (115-130)	150.3±5.9 (140-165)*
	DBP	79.3±5.2 (70-85)	100.6±6.4 (90-118)*
‡Level of protein in urine		0.7±0.5 (0 to +1)	1.8±0.7 (+1 to +4)*

Data are presented as mean±SD, ranges are in parenthesis
BMI: Body mass index
SBP: systolic blood pressure
DBP: diastolic blood pressure
*: significant difference versus control group
‡: Level of protein in urine as judged by dipstick measurement and expressed as number of + marks

Table (2) shows that 14 women had severe pre-eclampsia with a mean SBP and DBP of 154.8±8.5 mmHg and 107.9±7.4 mmHg, respectively and the mean proteinuria level of 2.7±0.8 by dipstick measurement. While the other 56 women had mild pre-eclampsia with a mean SBP and DBP of 149.2±4.4 mmHg and 98.8±4.7 mmHg, respectively and mean proteinuria level of 1.6±0.5 by dipstick measurement. Patients developed severe PE had significantly higher mean blood pressure measures and significantly higher level of protein in urine compared to those had mild PE. However, other evaluated parameters showed non-significant difference between severe and mild PE patients.

Table (2): Clinical characteristics of pre-eclamptic patients

		Mild PE (n=56)	Severe PE (n=14)
Age (years)		27.8±3.2 (23-33)	27.9±3 (22-33)
Weight (Kg		82.9±3.2 (79-87)	82.8±2.8 (79-90)
Height (cm)		164±2.8 (159-169)	162.7±3.7 (156-172)
BMI (kg/m^2)		30.9±1.3 (29-33.2)	31.3±1.9 (27.4-36.1)
Nulli: multipara		35:21	8:6
Gestational age (wk) at time of enrollment		30.7±4.2 (24-36)	30.9±3.8 (23-37)
Blood pressure	SBP	149.2±4.4 (140-155)	154.8±8.5 (142-165)*
	DBP	98.8±4.7 (90-106)	107.9±7.4 (95-118)*
‡Level of protein in urine		1.6±0.5 (+1 to +2)	2.7±0.8 (+2 to+4)*

Data are presented as mean±SD, ranges are in parenthesis
BMI: Body mass index
SBP: systolic blood pressure
DBP: diastolic blood pressure
*: significant difference versus control group
‡: Level of protein in urine as judged by dipstick measurement and expressed as number of + marks

Table (3) shows that among the studied 90 women, 56 women (62.2%) had vaginal delivery, while 34 women (37.8%) had cesarean section (CS). Women developed PE had significantly higher, (X^2=3.853, p<0.05) frequency of CS compared to control group (41.4% versus 25%, respectively) and women developed severe PE had significantly higher, (X^2=4.962, p<0.01) frequency of CS compared to control group (57.1% versus 25%, respectively). Gestational age at time of delivery was significantly shorter in PE group compared to control group and in those developed severe PE compared to those had mild PE. Moreover,

birth weight was significantly (P<0.01) lower in PE group compared to control group and in those developed severe PE compared to those had mild PE.

Table (3): Delivery data of the study population

		Control (n=20)	Mild PE (n=56)	Severe PE (n=14)
‡GA (weeks)		39.7±1.3 (38-42)	35.4±1.3 (34-38)	33.3±1.1† (32-35)
Gestational weight (gm)		3.31±0.5 (2.5-4.2)	2.8±0.62 (1.6-3.9)	2.44±0.55† (1.6-3.35)
Delivery mode	CS	5 (25%)	21 (37.5%)	8 (57.1%)
	Vaginal	15 (75%)	35 (62.5%)	6 (42.9%)

Data are presented as mean±SD & numbers, ranges & percentages are in parenthesis

†: significant difference versus mild PE

Table (4) shows significantly lower PlGF and higher RBP4 serum levels in PE women compared to control women and in women had severe PE compared to both controls and those had mild PE with significant difference between mild pre-eclamptic and controls.

Table (4): Mean (±SD) levels of serum PlGF and RBP4 in control and PE groups

		Serum PlGF (µg/ml)	Serum RBP4 (ng/ml)
Control group (n=20)		346.7±113.6 (221.5-578.6)	20.7±8.6 (9-45)
PE group	Mild (n=56)	242.3±84.3* (103.7-395.4)	60.1±18.4* (29-105)
	Severe (n=14)	183±42.1*† (122.4-250.4)	104.9±17*† (72-127)
	Total (n=70)	230.4±81* (103.7-395.4)	69.1±25.5* (29-127)

Data are presented as mean±SD, ranges are in parenthesis
*: significant difference versus control
†: significant difference versus mild pre-eclampsia

Figure (1) shows a significantly lower PlGF serum levels in PE women compared to control women, with significantly lower levels in women had severe PE compared to controls and those had mild PE and between patients had mild PE and controls. On contrary, figure (2) shows a significantly higher RBP4 serum levels in PE women compared to control women with significantly higher levels in women had severe PE compared to controls and those had mild PE and between patients had mild PE and controls.

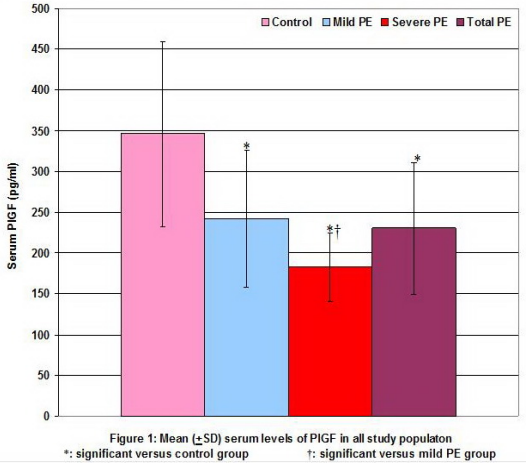

Figure 1: Mean (±SD) serum levels of PlGF in all study populaton
*: significant versus control group †: significant versus mild PE group

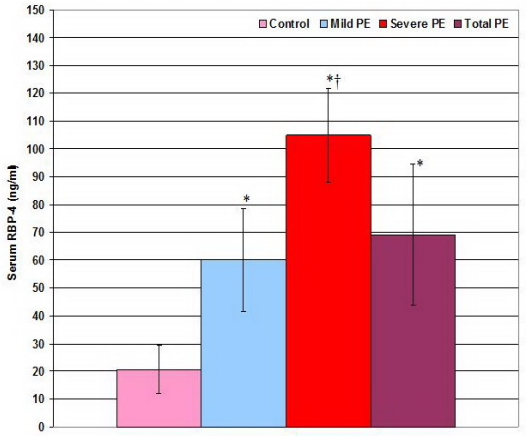

Figure 2: Mean (±SD) serum levels of RBP-4 in all study populaton
*: significant versus control group †: significant versus mild PE group

Serum levels of PlGF showed negative significant correlation with the severity of PE manifested as SBP (-0.429, p<0.001), DBP (-0.276, p=0.021) and the extent of proteinuria (-0.236, p<0.001), while serum levels of RBP4 showed positive significant correlation with as DBP (0.509, p<0.001) and extent of proteinuria (0.417, p<0.001). Serum levels of PlGF showed positive significant correlation with birth weight (0.312, p=0.009). On contrary, such correlation was non-significant with serum RBP4 that showed positive significant correlation with body weight (0.246, p=0.040) and mass index (0.318, p=0.007). Moreover, there was a

negative non-significant correlation between serum levels of PlGF and RBP-4.

4. Discussion

Depending on both DBP and extent of proteinuria, 14 cases had developed severe PE and 56 cases had mild PE. All cases developed PE, irrespective of its severity, showed significantly higher serum levels of RBP4 and lower PlGF compared to levels estimated in control group and in patients who had developed severe PE compared to those had mild PE. These findings pointed to an association between both RBP4 and PIGF serum levels and the development of PE. In support of such assumption, there was a significant correlation between serum levels of both parameters and estimated DBP and extent of proteinuria defined at time of inclusion in the study.

As regards serum RBP4, the obtained results go hand in hand with Inoue et al., (2009) who found that serum RBP4 levels were increased in pregnant women with PIH compared with normal pregnancies. However, Stepan et al., (2009) found that the mean maternal serum RBP4 concentrations were not significantly different in PE as compared with controls. This discrepancy could be attributed to small sized sample of PE women (n=16) studied by Stepan et al., (2009). In support our results, Vaisbuch et al., (2009) found that the maternal plasma RBP4 concentration was higher among patients with PE than in those with a normal pregnancy, and in patients with preterm PE (<37 weeks) than those with either term PE or normal pregnancy.

The obtained data suggested a participation of RBP4; an adipocytokine; in the pathogenesis and/or modulation of the PIH process and pointed to a role exerted by the adipose tissue as an endocrine organ. In support of such assumption, the current study reported a positive significant correlation between serum RBP4 and body weight and body mass index which coincided with that reported by Broch et al. (2009) who found that circulating RBP4 levels positively correlate with waist circumference, one of the obesity-related parameters.

The role played by RBP4 in pathogenesis and/or modulation of PIH could be attributed to concomitant insulin resistance that occurs during pregnancy and several previous studies documented such attribution between RBP4 and insulin resistance; Yang et al. (2005) demonstrated that adipose tissue-specific (Glut4)knockout mice have increased serum levels of RBP4 and downregulation of GLUT4 in adipose tissue is an important feature of insulin resistance. Clinical studies also reported that RBP4 is positively related to insulin resistance especially in obese (Graham et al., 2006) patients with impaired glucose tolerance (Cho et al., 2006) and type-2 diabetics (Cheng et al., 2009).

Insulin has important endothelial-dependent vasodilator actions mediated by nitric oxide (NO) via phosphatidylinositol 3-kinase (PI 3-kinase)–dependent activation of endothelial NO synthase (Zeng et al., 2000), but interestingly, insulin also has vasoconstrictor actions mediated by mitogen-activated protein kinase (MAPK)-dependent endothelial secretion of endothelin-1 (ET-1) (Cardillo et al., 1999). Insulin resistance is characterized by selective impairment in PI 3-kinase–dependent signaling pathways regulating metabolic actions of insulin in skeletal muscle with intact MAPK signaling pathways (Cusi et al., 2000) and is accompanied by compensatory hyperinsulinemia that serves to overcome impairment in PI 3-kinase signaling to maintain euglycemia. However, this hyperinsulinemia is predicted to overdrive unaffected MAPK signaling that may promote pathological actions of insulin, including increased secretion of ET-1, increased expression of vascular adhesion molecules, proliferation of vascular smooth muscle, increased expression of proinflammatory cytokines and activation of cation pumps (Potenza et al., 2005). These factors may shift the balance between vasodilator and vasoconstrictor actions of insulin and result in predisposition to hypertension in insulin-resistant states (Sowers, 2004).

As another explanation for association between RBP4 and PIH, Cabré et al., (2007) found that plasma RBP4 concentration might be a biomarker of nephropathy and cardiovascular disease in type 2 diabetic subjects and Frey et al., (2009) also demonstrated that there is a strong correlation between kidney function and RBP4 isoforms; thus serum RBP4 may reflect the degree of renal affection in these pre-eclamptic women and in support of this, the our study reported a positive significant correlation between serum RBP4 and extent of proteinuria.

Our results also showed that serum PlGF levels were significantly lower in PE group especially patients who had severe PE, a fact indicating abnormal placentation process as PlGF; an angiogentic factor; is physiologically essential for embryogenesis and development.

Such decrease of serum PlGF levels was manifested as increased frequency of small-for-gestational age (SGA) newborns with a negative significant correlation between serum PlGF and birth weight. These findings go hand in hand with multiple previous studies which reported significantly lower serum PlGF in association with low birth weight in pre-eclamptic patients in comparison to control group (Shibata et al., 2005, Espinoza et al., 2007, Romero et al., 2008).

Osol et al., (2008) experimentally reported that PlGF is a potent vasodilator of several vessel types in both humans and rats. Its potency and mechanism vary with physiological state and vessel location and are mediated solely by the vascular endothelial growth factor receptor-1 (VEGFR-1) subtype and gestational changes in the uterine circulation. The authors added that this might suggest that PIGF may play a role in modulating uterine vascular remodeling and blood flow during the pregnant state.

Erez et al., (2008) documented that changes in the maternal plasma concentrations of soluble form of endoglin (s-Eng), sVEGFR-1, PlGF or their ratios between the first and second trimesters of pregnancy confer an increased risk to deliver an SGA neonate and/or develop PE. Thus the effect imposed by decreased serum PlGF and development or maintenance of PE could be attributed to the loss of the vasodilator effect of PlGF. In support of this attribution, the current study reported a negative significant correlation between serum PlGF and both SBP and DBP.

In conclusion: both RBP4 and PlGF were strongly associated with the development and/or severity of PE. However, such association might need wider scale studies to be confirmed.

solomonadejoro@yahoo.com

ABSTRACT: The work investigated the effects of combined application of oilpalm bunch ash (OPBA) with NPK fertilizer (NPK) on soil and plant nutrient content and maize performance at two sites in southern Nigeria. Six treatments: control, OPBA at 4 t/ha, NPK (15-15-15) at 300 kg/ha, 75% NPK + 25% OPBA, 50% NPK + 50% OPBA, 25% NPK + 75% OPBA were applied to maize at Nigeria Institute for Oilpalm Research (NIFOR) Benin and Ekiadolor in rainforest zone of Nigeria. Relative to control, other treatments increased soil organic matter (OM), N, P, K, Ca, Mg and pH, and plant nutrients content, growth and cob yield. The effects were generally significant except in case of OPBA alone. The NPK, 75% NPK + 25% OPBA and 50% NPK + 50% OPBA gave significantly high and similar values of the parameters. The treatments increased cob yield by 20 – 22%, OPBA most increased soil pH and K.

Key words: oilpalm bunch ash; nutrient; maize

INTRODUCTION

Maize is staple food for an estimated fifty percent of human population in Subsahara Africa (SSA) being a source of carbohydrates, protein, iron, vitamin B and minerals. However its production is hampered by inadequate soil fertility, high cost and scarcity of the recommended NPK fertilizer. Hence the area devoted to maize continues to reduce and maize farmers shifted to more resistant crops like sorghum and millet. In Nigeria output per hectare of maize grain stand at 1.31, which is 25 percent of world total output (RMRDC, 2004), use of N fertilizers and declining soil fertility are problems for maize production in SSA. Also the present high recommended rates of NPK fertilizer (NPK) are unaffordable and do not give corresponding high yields (Uyovbisere *et al*, 2000). Therefore, there is renewed interest in the use of organic wastes as source of nutrients. Those wastes that have been found useful include animal wastes, plant wastes, ash, and agro-industrial wastes. They were found to improve soil fertility, reduce soil acidity and improve crop yield. Types of ash derived from plants also produce similar effects on maize (Nottidge *et al*, 2005a, 2005b, 2006, 2007; Ayeni *et al*, 2008; Ayeni *et al*, 2009). The wastes can be used alone or fortified with inorganic fertilizers.

The oilpalm bunch ash (OPBA) has not received adequate research attention in maize production, although study by Ojeniyi *et al* (2006) found that OPBA supplied organic matter (OM) N, P, Ca and Mg to soil and maize and increased its yield by 26% when used at 4 t/ha. It was also found to increase nutrient supply to cassava and its yield significantly (Ezekiek *et al*, 2009a, 2009b,). The OPBA results from incineration of oilpalm bunch waste. The bunch waste is generated at about 850 kg/ha on yearly basis in oilpalm plantations in Nigeria. According to Omoti *et al* (1989) there is great potential of reducing fertilizers bills by recycling empty oilpalm bunch waste. Particularly combined application of OPBA and NPK fertilizer in maize production has not received research attention. In the tropics integrated application of organic and inorganic wastes is the sustainable method of maintaining soil fertility and productivity. Hence the objective of this work is to find suitable rates for combined application of OPBA and NPK fertilizer in maize production. The effect on soil and crop nutrient content, growth and yield of maize will also be determined in relation to sole use of fertilizer and OPBA

MATERIALS AND METHODS

Field Experiment

Two trials were conducted at Nigerian Institute for Oilpalm Research (NIFOR) Benin (06^o 33' N, 05^o 37' E) and Ekiadolor (06^o 34' N, 05^o 38' E) in rainforest zone of Southern Nigeria. The sites were manually cleared. Ridges were made at 1 m interval and maize seedlings planted at 40 cm interval on ridges were thinned to one plant per stand.

There were six treatments applied to maize. They were: (1) control, (2) 100% oilpalm bunch ash (OPBA) at 4 t/ha, (3) 100% NPK (15-15-15) fertilizer (NPK) at 300 kg/ha, (4) 75% NPK + 25% OPBA, (5)

50% NPK + 50% OPBA, and (6) 25% NPK + 75% OPBA. Treatments were replicated three times using a randomized complete block design, and were applied three weeks after planting in ring form. NPK and OPBA were mixed. There were 75 plants per each of 15 plots in each site. Weeding was done once.

Ten plants were selected per plot. Ear leaf length and width were determined 9 weeks after treatment, and leaf area was calculated by multiplying the product of the two parameters by 0.65 (Saxena and Suigh, 1965). Plant height and stem growth (at 10 cm height) were determined. At 80 days after treatment, harvest was done and cob weight was determined.

Leaf Analysis

Ear leaf samples collected per plot were oven-dried at 90 ^{o}C 24 hr, milled and ashed for 6 hr. at 500 ^{o}C. Nutrients were extracted using nitric perchloric acid mixture (Tel, 1984) and N was determined by microkjeldahl approach. The P in extract was determined using molybdenum blue colorimetry and read on spectrophotometer. The K was determined on flame photometer, and Ca and Mg by EDTA titration.

Soil Analysis

Composite soil samples collected after land clearing and soil samples collected at harvest from treatment plots were air-dried, ground and sieved using 2 mm sieve mesh. They were chemically analysed as described by Tel (1984). Organic matter was determined by wet oxidation method through chromic acid digestion. Nitrogen was determined by microkjeldahl approach; P was extracted by Bray-P1 solution and determined using the spectrophotometric method. Exchangeable K, Ca and Mg were extracted using ammonium acetate; K was determined using flame photometer, and Ca and Mg by EDTA titration method. Soil pH in ratio 1:2 water suspension was determined using a glass electrode.

Statistical analysis was performed using analysis of variance, and means separated using Fischer's least significance test at 5% level of probability.

RESULTS AND DISCUSSION

Data on soil properties at NIFOR and Ekiadolor sites are shown in Table 1. The soils are sandy, slightly acidic, low in organic matter (OM), total N, available P, exchangeable K and Ca.

Table 1: Soil properties at NIFOR and Ekiadolor

Properties	NIFOR	Ekiadolor
Sand %	92.3	93.8
Silt %	3.7	2.1
Clay %	4.0	4.1
pH (water)	5.3	5.5
Organic matter %	1.40	1.52
Total N %	0.04	0.07
Available P mg/kg	8.6	7.1
Exchangeable K c mol/kg	0.13	0.10
Exchangeable Ca c mol/kg	0.95	1.02
Exchangeable Mg c mol/kg	0.60	0.72

OPBA, NPK and their combined use at reduced levels increased soil OM, N, P, K, Ca and Mg at both sites (Tables 2 and 3). The increases were significant in case of NPK and its combined use with OPBA. However, OPBA gave highest values of soil pH and K, and had significant effect on these parameters. NPK gave highest values of soil N, P at NIFOR and P, Ca and Mg at Ekiadolor. The increases in soil nutrients due to NPK and OPBA can be adduced to increased soil OM which might be due to enhanced microbial activity. The OM is a natural source of nutrients and cation exchange. The OPBA due to its composition is also able to release macronutrients thereby increasing soil fertility and crop nutrient uptake. Analysis of OPBA as given by Ojeniyi *et al* (2006) was 1.60% OM, 0.19% N, 0.13% P, 29.8% K, 7.95% Ca and 3.2% Mg. Hence because of its high content of cations (K, Ca, Mg), OPBA was able to give highest soil pH and K. Therefore, OPBA had liming effect, and it is an effective source of K. In Ghana cocoa pod ash was used as source of K for maize (Adu-Dapach *et al*, 1994).

Increases in plant nutrient contents given by OPBA were not significant (Tables 4 and 5). Infact tissue N was reduced relative to control by OPBA at Ekiadolor. Combined application of OPBA and NPK and NPK alone significantly increased tissue N, P, K, Ca and Mg (Tables 3 and 4). The treatments generally gave higher tissue N, P, K, Mg and Ca. Treatments 75% NPK + 25% OPBA, 50% NPK + 50% OPBA and NPK had similar values of plant N, P, K, Ca and Mg. Among the combined treatments, 25% NPK + 75% OPBA generally had least plant nutrients content. This might be due to its highest OPBA concentration. However, it gave higher nutrients content than the control and OPBA alone. It is suggested that addition of NPK to OPBA enhanced nutrients availability. This is attributable to enhanced mineralization of nutrients in OPBA.

Increased availability of nutrients in soil and maize crop led to enhanced growth and cob yield (Table 6). This affirms the importance of N, P, K, Ca and Mg to maize performance. Generally OPBA, NPK and their combinations at reduced levels significantly increased plant height, leaf area and cob weight. Treatments NPK, 75% NPK + 25% OPBA and 50% NPK + 50% OPBA with similar and highest values of soil and plant nutrients content also had highest and similar values of growth and yield parameters. OPBA which had least values of soil and plant nutrients compared with NPK and its combined applications with

LSD (0.05)	0.09	NS	0.08	0.17	0.02

NS = Not significant

OPBA had least values of growth and yield parameters which were not significantly different from that of control. Therefore, OPBA is less suitable for maize production compared with its combination with NPK fertilizer. Compared with control, OPBA, NPK, 75% NPK + 25% OPBA, 50% NPK + 50% OPBA, and 25% NPK + 75% OPBA increased cob weight by 11, 22, 20, 22 and 16% respectively. Therefore NPK, 75% NPK + 25% OPBA, and 50% NPK + 50% OPBA are equally suitable for maize production. Instead of the recommended 300 kg/ha NPK fertilizer, OPBA could be combined with NPK fertilizer as 215 kg NPK/ha + 1t/ha OPBA, or 150 kg NPK/ha + 2 t/ha OPBA for maize production without loss of yield, soil and plant nutrient content.

Table 6: Growth and yield of maize as influenced by oilpalm bunch ash (OPBA) and NPK fertilizer (NPK)

Treatment	Plant height (cm)		Leaf area (cm^2)		Cob weight (g)	
	Site 1	Site 2	Site 1	Site 2	Site 1	Site 2

LSD (0.05)	4.1	5.1	25.8	41.9	35.8	18.9

Site 1 = NIFOR, Site 2 = Ekiadolor

The findings from this work align with the observation of Ezekiel et al, (2009a, 2009b) who noted that sole and amended forms of OPBA had beneficial effects on soil chemical properties. Ojeniyi *et al* (2006, 2009), Ezekiel *et al* (2009a, 2009b) also found that OPBA used alone increased nutrient availability, controlled soil acidity and increased yield of maize and cassava.

CONCLUSION

Oilpalm bunch ash (OPBA) is suitable for reducing soil acidity and supplying macronutrients

especially potassium. It could be combined with NPK fertilizer at 25% + 75% or 50% + 50% OPBA + NPK in order to reduce expenditure on NPK and reduce soil acidity without loss in soil fertility, nutrient availability and maize yield.

Abstract: The objective of the present study was to explore modification in toxico-pathological responses of rats toward aflatoxins (AF) in the presence of white ginseng. The dietary supplementation with white ginseng (WG) at levels of of 0.0, 1 and 2 % (W/W) of the composition of daily rations, on the performance and toxicity of female Albino rats received aflatoxins-contaminated diets (1.011 mg/kg ration, of dry matter basis), were successively examined for six weeks, as attempt to prevent or minimize the negative probabilities due to ingesting aflatoxin(s) contaminated food. Thirty native apparently healthy female Albino rats with average weight of 100± 3.4 gm., were put under observation for two weeks, then they were divided into five equal groups of six rats each according to their live body weight for performing feeding trials. An exposure study extended for two different stages was conducted using female Albino rats. The 1st stage (pre-treatment) was suggested to compare the performance of animal groupings under the normal conditions before receiving any treatment, either level of contamination(s) or dosage(s) of additive, such stage extended for 2 weeks. The 2nd stage (treatment), the animals received different levels of aflatoxin(s) and the food additive (white ginseng), such stage extended for 4 weeks. Rats treated with AF-contaminated diet alone showed depression, decrease in feed intake, body weight and loose feces. The activities of serum ALT, AST enzymes, which are reflecting liver function, were obviously affected during exposure to aflatoxins, but such levels came back to normal as the level of the WG in the ration increased. Serum urea and creatinine concentrations had also severed and such severe effects came back to moderate when receiving the proposed additive. Livers exhibited fatty change, necrosis and newly formed bile ducts. Lesions in kidney included tubular necrosis and pink homogeneous tubular casts. Rats fed white ginseng only had no significant differences compared to the negative control group (fed on a sole diet without any additives). A concurrent treatment of AF with white ginseng indicated a potentiation of the animal performance reflected by decreased severity of clinical signs and inccreased body weight gains. The studied food additive minimized and reduced significantly the deterioratsion of such performance which obviously observed in animal grouping received AF-contaminated diet. Female rats were responding to contaminated diets and to the food additive as well. Thus, our data strongly suggested that deleterious effects of AF could be overcome or, at least, significantly were diminished by WG. Moreover, this plant by itself did not show any toxic effects.
[Abdel- Fattah, Sh. M.; Sanad, M.I; Safaa,M.A and Ragaa F. F.Ghanem. **The Protective Effect of White Ginseng against Biochemical and Pathological Changes Induced by Aflatoxins in Rats**. Journal of American Science 2010;6(12):461-472]. (ISSN: 1545-1003).

Keywords: Ginseng; Aflatoxins; Histopathological changes; Food additives.

1. Introduction:

Both human and animal health has been dramatically affected in outbreaks of acute mycotoxicosis, but these tragic events may be only a part of the cost to society in terms of impaired health and productivity from the ingestion of sub-clinical levels of aflatoxins (WHO, 1981; Saad, 1993 and Moos, 2002). Aflatoxins B1, B2, G1 and G2 were occurred on different foodstuffs when exposed to certain strains of Aspergillus flavus and Aspergillus parasiticus (Wogan, 1977 and Casado et al., 2001). AFB_1 is the most abundant and toxic form of all naturally occurring aflatoxins. AFB_1 represents 75% of all aflatoxins found in contaminated food and feeds. Many reports stated the harmful effects of aflatoxins on wide variety of animals and human; depression of growth and production (Saad, 1993), immunosuppression (yeong–Hsiang, 2001), liver disorders (Guerre, et al., 1996 and Anong and Suparats, 2006), abnormalities of enzyme picture (Patrick et al., 2002 and Tulayakul et al., 2005). However, such harmful effects seem to be difficult to overcome since aflatoxicosis gave no reaction response for any available treatment of drugs and / or antibiotics (Abdelhamid, 1990 and saad, 1993). The metabolisms of aflatoxins are due mainly to sex and specie differences besides the mitochondrial enzymatic reaction. AFB1 is first metabolized mainly by the cytochrome P-450 enzyme (CYP450) system found in the microsome. This metabolism will produce a variety of metabolites such as AFB_1-epoxide and hydroxylated metabolites (AFM1, AFP1, AFQ1, AFB 2α and aflatoxicol). (Tylayakul et al., 2005 and Anong 2006). The rate of metabolism, the repeativeness of exposure, the dosage and type of

mycotoxin(s) were reported as limiting factors affect the type of toxic action of mycotoxicosis (Saad, 1994; Jia-Sheng and John, 1999; Hussein and Jeffrey, 2001).

Natural substances that can prevent AFB1 toxicity would be helpful to human and animal health with minimal cost in foods and feed. Traditional medicinal plants were used by some authors for their antifungal, anti-aflatoxiGEnic and antioxidant activity (Joseph et al., 2005; Kumar et al., 2007).

Ginseng, a traditional medicinal herb in Asia, has become internationally popular in recent years. The traditional source of ginseng root has been Asian ginseng (Panax ginseng C.A. Meyer) but American ginseng (Panax quinquefolium L.), a plant native to North America, is now also cultivated and used in many countries. While the full pharmaceutical activity of ginseng is due to a ranGE of compounds, the triterpene saponins, known as ginsenosides, are widely considered to be the most important components contributing to the multiple medicinal properties of both Asian and American ginseng. The importance of the saponins in Asian ginseng has been known for about 100 years and, with the advent of modern chromatographic techniques, about 30 triterpene saponin glycosides, designated as neutral ginsenosides, have been identified (Sticher, 1998). The presence of neutral ginsenosides in American ginseng was first demonstrated by Ando et al., (1971) with later studies confirming that a range of neutral ginsenosides exists in this species similar to the previously studied Asian ginseng (Panax ginseng). The two major groups of ginsenosides are the Rb and Rg groups, which have 20 (S) protopanaxadiol and 20 (S) protopanaxatriol, respectively, as the sapogenines. Rb group includes the ginsenosides Rb1, Rb2, Rc and Rd, while Rg group includes the Re, Rf and Rg1 ones as the main compounds. Among all these ginsenosides, Rb1 and Rg1 are the most effective compounds (Tanaka and Kasai, 1984).

In previous works, we reported that Korean Panax ginseng has a protective role against many toxicants (Mannaa et al., 2006; Khalil et al., 2008; El-Kady et al., 2006). However, the components of ginseng that might bring about the decreased cancer risk remain unknown.

The aim of the present work is to investigate the effects of AF on lethality, on some haematological and biochemical parameter changes and on histological damages in the absence or presence of ginseng in order to appreciate the potential protective effects of this medicinal plant against AF- toxicities. The effects of this herb alone were also evaluated.

2. Materials and methods

2.1- Experimental design.

Depending on our previous results (Abdel-Fattah, 2002; Abdel-Fattah and Abdel-Salam, 2004 and Abu-Seif, *et al.,* 2009), concerning the antimicrobial effects of herbs and medicinal plants, this study was achieved. Sixty female Albino rats were used in this study. Animals were divided into six groups as shown in Table (1). All groups were exposed to the main two stages of the experiment period as follows, the first 2 weeks were the pre-treatment period, followed by 4 weeks of treatment. Both the 1st and 2nd groups were fed on sound rations, free from aflatoxins, but the 1st one had no additive to act as “negative control”, while the 2nd group fed on the same sound ration plus the studied additive at concentration equivalent to 0.2 % (w/w). The other three groups ingested aflatoxin(s) contaminated diets containing 225 mg B1, 30 mg B2, 70 mg G1 and 10 mg G2 /kg . The 3rd group exposed to contaminated diets only without any addition, but the 4th and 5th groups fed on aflatoxin(s) contaminated diets, plus the proposed additive (WG) at 1 and 2 % w/w. Feed intake and body weight gain were recorded daily. At the end of the treatment period all animals were fasted for 12 h, then blood samples were collected from the retroorbital venous plexus under diethyl ether anesthesia. Sera were separated using cooling centrifugation and stored at - 20 oC until analysis. After the collection of blood samples, animals were killed and samples of the liver and kidny of each animal were dissected.

Quantitative measurement of serum biochemical parameters included ALT, AST, urea and creatinine, were determined using a commercial kits.

2.2. Experimental animals

One-month old Female white Albino rats weighting 100–110 g (purchased from animal house of National Research Centre, Cairo, Egypt) were maintained on standard lab diet (protein: 160.4; fat: 36.3; fibre: 41 g/kg and metabolizable energy 12.08 MJ), and housed in a room free from any source of chemical contamination, artificially illuminated and thermally controlled, at the Animal House Lab., National Research Centre, Dokki, Cairo, Egypt. After an acclimatization period of 2 weeks, the animals were divided into five groups (6 rats/group) and housed in filter-top polycarbonate cages. All animals were received humane care in compliance with the guidelines of the Animal Care and Use Committee of the National Research Centre, Dokki, Cairo, Egypt.

2.3- Organisms. *Aspergillus parasiticus* (*A.parasiticus*) NRRL 2999 was obtained as lyophilized preparation from the Mycotoxin lab. National Research Center, Dokki, Giza, Egypt.

2.4- Plant material:

American white ginseng was purchased from an Egyptian local market (Harraz Co., Cairo, Egypt).

2.5- Aflatoxins standards and chemicals:

All standards of Aflatoxins (B1, B1, G1,G2, and B2 α) were purchased from sigma company, USA. All Chemicals and solvents used were of ACS grade. Thin layer TLC aluminum plates recoated with 0.25 mm silicagel 60 (Merk).

2.6- Preparation of aflatoxin(s)- artificially contaminated ingredient.

A balanced ration of growing rats with 14 % crude protein and 3100 kg calorie were purchased and artificially infected (in vitro) with a certain strain of *Aspergillus parasiticus* (NRRL-2999) which identified as an aflatoxin(s) producing strain. The inoculated substrates were incubated at 28 °c for 18 days (Shotwell et al., 1966). Qualitative and quantitative assay for the presence of aflatoxins in the contaminated substrate has been caried out using HPLC (Agilent Technologies, Waldbronn, Germany) as recommended by AOAC (1990). The AFs within the contaminated material consisted of 225 mg B1, 30 mg B2, 70 mg G1 and 10 mg G2 /kg. The contaminated material was incorporated into the basal diet in the ratio 15.55. % of the daily ration, to provide the desired level of 1.011 mg of total AFs or 0.7 mg AFB1/Kg diet.

2.7- Sampling

2.7.1- Blood samples:

Blood samples were taken weekly from the jugular vein prior to the morning feeding, at the following times: 0, 6, 13, 20 and 27 days of treatment period. Blood samples were placed on ice, allowed to clot and after centrifugation, serum was separated and frozen at -20 °C until it was analyzed for AFB 1, AFB2α and aflatoxicol.

2.7.2- Sampling of feces and urine

During the 3rd wk of the experiment, total feces and urine of animals were collected twice daily over a 7-days period. Urine was collected from an indwelling cyatic catheter, which was also placed 1-day before the toxin administration. Feces were collected in fecal bags. Following the collection period, total samples of urine and feces from each animal were homogenized, and aliquot samples were stored at -20°C until further analysis. Sampling and methods of analyses were adopted as recommended by (AOAC, 1990).

2.8- Histological study:

At the end the treatment stage, all animals were slaughtered, liver and kidney were dissected out, Organs were fixed in 10% neutral buffer formalin and processed for histopathological examination using routine paraffin embedding technique. Sections of 5 mm thickness stained with hematoxylin and eosin (H&E) were examined for morphological alterations and morphometric measurements. The slides were examined under 400 imagnification using an optical microscope (Carl Zeiss, Germany) as reported by Pearse (1979) and Sheehan and Harapcbak (1980).

2.9- Analytical methods:

2.9.1- Aflatoxins analysis:

Analysis of aflatoxins.

Aflatoxin(s) in feed and feces samples were extracted by B.F. method as described in AOAC (2000). The AFB1, its metabolites B2α and aflatoxicol were analyzed in urine, and serum samples according to method of Richarda and Lyona (1986).

Visualization and quantitation of aflatoxin B1, aflatoxicol and aflatoxin B2α.

AFB_1, aflatoxicol and AFB2α, were located by UV exposure. Extracts were dissolved in soul chloform and vortex, 20µl aliquot and 10µ of the standards were stopped on TLC plates and developed in dark room with chloroform : actone (90:10). After drying the spots were examined with U.V at a wave length of 365 nm. For the quantitative determination of the compounds, the silica plates were developed in solvent system (chloroform: actone, 90:10) and scanned in a Vitatron LTD 100 densitometer equipped with a mercury lamp (excitation at 366 nm and emission at 460 mm). The recorded areas of the spots were compared with standards of the respective compounds.

2.9.2- Serum biochemical parameters determination:

Blood was collected from the jugular vein of rats anesthetized with ether vapors on the days, 0, 14 and 28 of treatment period. Serum separated from clotted blood was stored at -20 ^{o}C for estimation of different biochemical parameters which included, total aflatoxins (AOAC method, 1990), ALT (Randox UK, catalogue no. AL 484), AST (Randox UK, Catalogue no. TR 1697) creatinine (Randox UK, catalogue no. CR 523), and urea (Randox UK, catalogue no. CH 280).

2.10- Statistical analysis

The data was subjected to the analysis of variance test. Different group means were compared by Duncan's multiple range test using a computer statistical package ($p \leq 0.05$) (Duncan, 1955).

3. Results and Discussion:

(1) Effects of ingesting aflatoxins and the WG additive on the performance of treated animals:

The selected doses of aflatoxin were literature based (Gelderblom et al., 2002) however; the selected

dose of WG was based on previous work (Abdel-Wahhab and Ahmed, 2004, Saad and Abdel-Fattah, 2008). The levels of aflatoxin B_1 selected in the present study were derived from the reported LD50 of both substances. Aflatoxin B_1 LD50 through oral route for rats has been reported as 5 mg/kg b. wt. (Betina, 1984). To produce a clinical aflatoxicosis, 1/10 LD50 (1 mg/kg b. wt.) was selected for daily doses.

In the current study, we evaluated the protective effects of WG against AFB_1 initiated and promoted hepatic carcinogenesis in rat model. The effect of different treatments on body weight gain of rats is depicted in Table (1). During the pre-treatment stage the average of body weight and body weight gain of both five groups show almostly similar values and ranges.

Rats fed with AF at level 1mg/kg diet in the present study exhibited a significant decrease in feed intake and body weights, the negative and positive control groups showed almostly the same values obtained from groups 4 and 5 which fed on high level of contamination simultaneously with the additive (WG) at concentrations of 1 and 2%.. Reduced weight gains have been observed in rats following an exposure of AF-contaminated diets (Saad and Abdel-Fattah, 2008).

Our results indicated that ingestion aflatoxin-contaminated diets resulted in a significant decrease in food intake and consequently the body weight gain was also reduced. Similar decrease in food consumption and body weight was reported in rats fed AFB_1-contaminated diet (Mayura et al., 1998, Abdel-Wahhab and Aly, 2003;, El-Nekeety et al., 2007, Saad and Abdel-Fattah, 2008). The reduced feed intake may indicate protein catabolism, thereby contributing to the observed kidney injury and causing impaired glomerular filtration (Tessari et al., 2006). On the other hand, the decrease in body weight in the animals treated with the aflatoxins alone may be due to the effects of these aflatoxins on the balance between orexigenic and anorexigenic circuits that regulate the homeostatic loop of body weight regulation, leading to cachexia (Rastog et al., 2001). In this regards, Abdel-Wahhab et al. (2006) reported that rats treated with AFB_1 showed a significant decrease in leptin. Low leptin concentration is usually associated with the high levels of cortisol and IL-6 which toGEther act to influence the feeding response, causing weight loss in patients with pancreatic cancer (Barber et al., 2004). This correlation may explain the recorded decrease in body weight inanimals inGEsted AFB1 and FB. Since leptin and its receptor are the key players in the regulation of energy balance and body weight control (Yuan et al., 2004; Abdel-Wahhab et al., 2006). Moreover, food intake was improved when the combined treatments of toxin plus WG was applied. Whereas, significant differences were still found between the control or WG alone groups and the other treatment groups.

Mnay authors stated that ingesting aflatoxin(s) contaminated food leads to negative effects on both animal and human performance (WHO, 1981, Park, 1983 and Saad, 1993; Abdel-Fattah, et al., 2006; Saad and Abdel-Fattah, 2008). It's worthy to mention that the group 2 which ingested the studied additive WG and sound diets showed non significant ($P<0.5$) effects compared with the negative control and the groups 4 and 5 which ingested the high level of contamination and the food additive at 1 and 2%. These findings are in agreement with those reported by Casado *et al.,* (2001) on rats and Biing-Hui *et al.,* (2002) working on swine.

Table 1. Means ± SE and comparison of body weight changes in all groups during experiment period (6 weeks).

Groups	Means ± SE

N.B.: 1- The same capital litters in columns denotes no significant difference between treatments in the same period at ($p \leq 0.05$) and vise versa. But the differences in small litters in raws denotes significant difference between periods in the same treatment at ($p \leq 0.05$) and vise versa. Day (0): Beginning of the experiment. Day (42): End of the experiment

2- Some biochemical analysis of rat serum (liver and kidney function tests) as affected by dietary aflatoxin and / or WG treatment.

Data for selected serum constituents are presented, from the beginning and the end of the treatment period, in Table (2). There is no a consistent pattern shown in the metabolic indicators as influenced by the AF and / or the WG food additive additive. The average(s) of the transaminases (ALT and AST) level and both urea

and creatinine concentrations showed the normal picture during the pre-treatment stage with no differences between groups (Table 2). During the treatment stage, the groups 1 and 2 showed constant level of both ALT and AST enzymes activities, while serum activities of ALT and AST of animals fed dietary AF only (group 3) had elevated ($p \leq 0.05$) compared with those fed sound rations with or without WG additive. Similarly, urea and creatinine concentrations were higher ($p \leq 0.05$) at the end of the treatment period for group which fed AF-contaminated diet only. On the other hand, the level(s) of both ALT and AST activities were not significantly affected during treatment in the 4th and the 5th groups, leading to suggest the positive effect of studied additive on the liver function when the animals exposed to high level of aflatoxin(s) contamination.

Tracing the level(s) of transaminase ALT and AST in both animals of the 2nd group which received the additive only without any level of contamination, it could be easily noted that no changes were obtained during the two successive stages of the study. The obtained data were in accordance with those reported by Yeong-Hsiang *et al*. (2001), working on ducklings, Biing-Hui *et al*. (2002) on swine and Anong and Suparats (2006) on broilers.

High serum levels of AST and ALT are usually indicative of liver damage in animals (Lind et al. 1989) and humans (Gil et al. 1988; Hassal et al. 1990; Rati et al., 1991). It is of interest to mention that in animals fed diets contaminated with toxicants, the serum levels of these enzymes increased after liver damage because of increased membrane permeability or because of liver cell necrosis and cytosol leakage into the serum (Abdel-Wahhab, *et al.,* 2002 ; Saad and Abdel-Fattah, 2008 and Ozer *et al.,* 2008).

The intermediary metabolites produced during biotransformation of aflatoxins are held responsible for hepatotoxicity and the increase of serum activities of liver enzymes. They may cause cellular damage by covalent binding to cellular components such as enzymes, nucleic acids and proteins or by another mechanism. Damage of cellular components may play an important role in death of liver cells (Lind et al. 1989; and Teppema et al. 2002), hence, ALT and AST may be released to serum levels of these enzymes would increase.

Serum enzyme activities of AST and ALT are generally elevated in aflatoxicosis and are indicative for changes in the hepatic tissues and biliary system (Abdel-Wahhab et al., 2002), whereas increased levels of urea and creatinine may indicate protein catabolism and/or renal dysfunction (Abdel-Wahhab and Aly, 2003, 2005). Moreover, El-Nekeety et al. (2007) and Abdel-Wahhab et al. (2002) reported that rats fed FB-contaminated diet showed a significant increase in serum transaminases which indicated a necrosis in the liver tissue. These results clearly indicated that AFB_1 have stressful effects on the hepatic and renal tissues, consistent with those reported in the literature of mycotoxicosis (Sherif et al., 2009).

The results of our study (Table 2) are in agreement with the reports of another studies performed using antioxidants and hepatotoxic substances (). Alterations in different serum biochemical parameters observed in the present study are in agreement with the previous reports (Durak et al. 1996; Huang et al. 1996; Naziroglu 1999; Manna et al., 2004; Abdel-Wahhab and Aly, 2003, 2005). Adding of WG during aflatoxins treatment succeeded to improve ALT, AST, activities and a significant improvement was also found in urea and creatinine concentrations.

Several studies on the mechanisms of aflatoxins induced liver injury have demonstrated that glutathione plays an important role in the detoxification of the reactive and toxic metabolites of these aflatoxins, and the liver necrosis begins when the glutathione stores are almost exhausted (Dilkin et al., (2003); Abdel-Wahhab and Aly, 2003, 2005). In the same regards, Kim et al., (1997) reported that ginseng has a potent protective action against CCL4-induced toxicity and it showed inhibitory effect on cytochrome P450-associated monoxygenase activities. Therefore, it is suggested that the protective effect of WG is attributed to its free radical scavenging activity (Abdel-Wahhab and Ahmed, 2004; Mannaa et al., 2006). Generally, these results indicated that WG have protective effects against liver injury induced by aflatoxins and it plays a role in increasing the antioxidant status as well as lowering the oxidative damage of nucleic acids in the body (Abdel-Wahhab and Ahmed, 2004; Mannaa et al., 2006). Furthermore, Yun et al. (1987) reported that prolonged administration of Korean red ginseng (KRG) extract resulted in substantial suppression of pulmonary tumorigenesis induced by such chemical carcinogens as aflatoxin B_1. It was reported that the non-saponin components of red ginseng (RG) suppressed the harmful effects of free oxygen radicals (O2, H2O2, and OH2), which exercise an important role in tissue degeneration (Kim et al., 1997). Moreover, Zhang et al., (1996) showed that hydroxyl radical formed by the Fenton reaction were completely inhibited by ginseng extract. This antioxidant effect of ginseng may be responsible for its wide pharmacological actions in clinical practice by a free radical reaction-inhibition mechanism.

Therefore, the protective effects of WG may be related to the antioxidant properties consequently decreased risk for most cancers including carcinomas of the esophagus, stomach, colon, pancreas, lung and liver (Matsuda et al., 1986; Jeong et al., 1997; Dayan and Paine, 2001). Recently, Li et al., (2008) postulated that Ginsenoside Rg1, cinnamic acid, and tanshinone IIA isolated from ginseng could serve as protective agents in cancer prevention and treatment.

Treatment of the intoxicated rats with WG resulted in significant improvement in kidney function as indicated by the marked decrease in serum urea and creatinine levels. These results were in conformity with those reported by Yokozawa et al., (1994) who demonstrated that WG and its active component, saponin, could significantly reduce the blood urea nitrogen and creatinine levels in the blood of nephrectomized rats. Other studies asserted the nephroprotective effect of Korean ginseng saponin against cisplatin-nephrotoxicity (Liu and Zhou 2000; Abdel-Wahhab and Ahmed, 2004). These authors suggested that Korean ginseng saponin reduced cisplatin-induced cytosolic free [Ca2+] ions overload and formation of DNA interstrand cross-link and DNA–protein cross-link.

Furthermore, Yokozawa and Liu (2000) demonstrated that ginsenoside could decrease the severity of renal injury induced by cisplatin. These authors suggested that decreased level of urea in serum in rats given WG reflected the protective action of ginsenoside against the renal dysfunction.

Our results may lead us to suggest that there is a significant liver and kidny dysfunction in the AF-treated groups, 1.011mg of AF/kg diet was sufficient to impair performance and cause liver and kidny damage in female Albino rats, adding of WG during the mycotxins treatment (groups 4 and 5) resulted in a significant improvement in ALT and AST activity as well as urea and creatinine concentrations. It was suggested that WG displays a pronounced hepatoprotective effect, assessed through the transaminases (ALT, AST) activities following hepatotoxicity in rats treated with AF-contaminated diets.

Table 2. Means ± SE and comparison of enzymes levels and biochemical parameters in all groups during the AF and WG treatments for 4 weeks.

Day (0): Beginning of the experiment Day (28): End of the experiment

(3) The histopathological changes in different studied groups:

The biochemical results reported in the current study were confirmed by the histopathological study of the liver and kidny.

Liver: The results obtained from studies with slices prepared from the livers of AF-treated rats indicate that there is some disturbance in protein synthesis throughout the course of the poisoning. One may speculate whether such an inhibition could play a role in the cellular necrosis. Rats of control groups (Groups 1, 2) did not show any histopathological alteration in liver tissue (Fig. 1). In groups fed AF-contaminated diets, hepatocytes were swollen and had cytoplasmic vacuoles at the end of experiment. In group 3, vacuolar degeneration of some hepatocytes and local areas of necrotic hepatocytes was found and hepatocytes had small roughly rounded multiple vacuoles in the cytoplasm. These changes became more intense and extensive accompanied by cellular swelling and disorganized hepatic cord pattern. A portal areas showed newly formed bile ducts and foci of cellular necrosis in the parenchyma. Aggregates of cells having round to oval vesicular nuclei and indistinct cytoplasm were

present in the parenchyma. Rats of groups 4 and 5, in which animals treated with WG at levels 1 and 2%, respictively, showed microscopic lesions slight to those of group 3. However, lesions in group 4 given the low level of WG were more severe than those of group fed AF and 1 % WG.

The present results revealed that WG had no harmful effects on liver tissues. However, the liver of the animals in the aflatoxins-treated groups showed severe histopathological changes typical to those reported in the literature. In this concern, Gelderblom et al. (2002), Abdel-Wahhab et al. (2002) and El-Nekeety et al. (2007) stated that treatment with FB_1 resulted in hepatotoxicity, apoptosis and inhibitory effect on cell proliferation, interferes with normal growth related processes and hence the disruption of normal liver homeostasis. Moreover, AFB_1 treatment induced a severe cytotoxicity and inhibition of hepatocytes cell proliferation (Neal and Cabral, 1980; Mayura et al., 1998; Abdel- Wahhab et al., 1998, 2002, 2007).

In the current study, the sequential treatment with AFB_1 resulted in cirrhotic livers with numerous regenerative and dysplastic nodules encircled extensively by ballooning and fatty degeneration cells. Therefore, the sequential treatment of AFB_1 extensively enhance the susceptibility of the liver to the toxicity and the induction of dysplastic nodules.

Kidneys: Kidneys of the groups given WG and AF together also showed changes not similar to those observed in groups given AF alone (Fig. 2). In group 3, there were severe and diffuse degenerative changes of the renal tubular cells, haemorrhage and congested blood vessels and pyknotic nuclei of epithelium of proximal and distal convoluted tubules were observed. Distal tubules had coagulated material in their lumens. Degeneration and necrosis of tubular epithelial cells those of collecting ducts were present. Histopathological lesions induced by AF in liver and kidneys of rats in the present study were similar to those reported by other workers (Hussain et al., 2009; Saad and Abdel-Fattah, 2008; Abdel-Wahab et al., 2007).

Our results suggested that a potentiation of the toxic response was evident by increased severity of clinical signs, increased activities of some liver enzymes, decreased body weights of rats administered AF. Alterations in serum biochemical and pathological parameters employed in the present study could detect some modification in toxic responses of rats administrated the two agents (AF plus WG) concurrently suggesting that these parameters were compromised by concurrent exposure to AF and WG. Since both the levels of AF in the present study produced toxic changes as evident by all the parameters used, it is possible that the modulation of the toxic response by AF might have been masked by the alterations induced by WG dose levels.

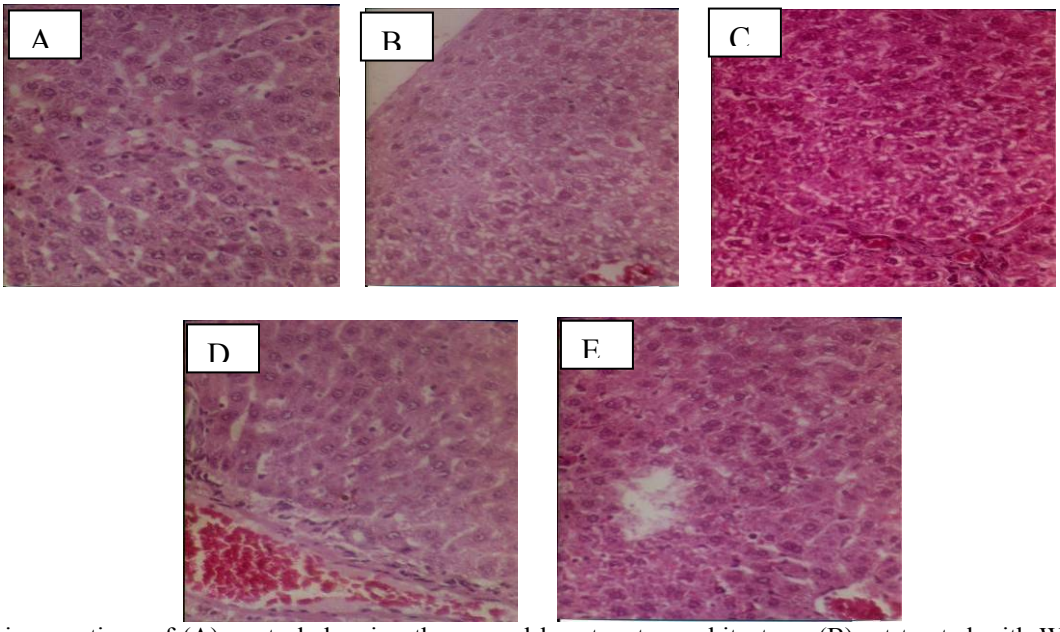

Fig. 1. Liver sections of (A) control showing the normal hepatocytes architecture, (B) rat treated with WG alone showing normal hepatocytes architecture, (C) rat liver treated with AF alone showing vacuolar degeneration of some hepatocytes and local areas of necrotic hepatocytes, (D) rat treated with WG at level of 1 % of daily ration (W/W) during AF treatment, showing congestion of blood vessels with degenerative changes of hepatocytes; (E) rat treated with WG at level of 2 % of daily ration (W/W) during AF treatment, showing slight vacuolar and other

degenerative changes of the hepatocytes with local necrotic area, marked decrease in damaged area and the hepatocytes restoring their normal structure (H&E) (X400).

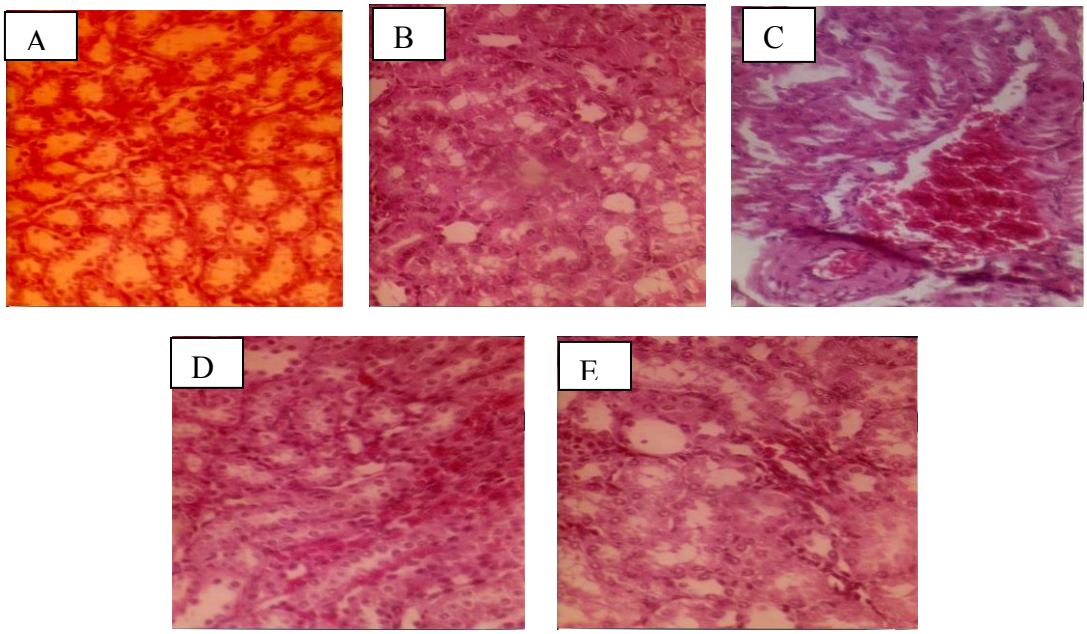

Fig. 2. Kidney sections of (A) control showing the normal renal tubules; (B) rat treated with WG alone showing normal normal renal tubules; (C) rat liver treated with AF alone illustrating severe and diffuse degenerative changes of the renal tubular cells, haemorrhage and congested blood vessels; (D) rat treated with WG at level of 1 % of daily ration (W/W) during AF treatment demonstrating severe and diffuse necrotic changes of the renal tubules; (E) rat treated with WG at level of 2 % of daily ration (W/W) during AF treatment demonstrating diffuse areas of necrosis of the renal tubules, vacuolar degeneration of some renal tubular cells (H&E) (X400).

4- Proportional urinary and fecal excretion of aflatoxib B_1, and its corresponding metabolites ($AFB_{2\alpha}$, aflatoxicol), for rats fed AFs-contaminated diets with or without WG.

Data in Table (3) represent the proportional excretions of AFB_1 and its metabolites ($AFB_{2\alpha}$ and aflatoxicol) via feces and urine. AFB_1 and $AFB_{2\alpha}$ concentrations in feces and urine varied according to dietary treatment. The cumulative excretion of $AFB_{2\alpha}$ is expressed in terms of AFB_1 equivalents. Results shown in Table (3) clearly indicate that treatment with WG in groups treated with dietary aflatoxin, had affected the route of AF excretion and metabolism where major the most of the excreted AFB_1 was found as the metabolite $AFB_{2\alpha}$ in the urine (41.13 to 59.35%), whereas approximately 5.11 to 8.53% was found as $AFB_{2\alpha}$ in feces. In contrast, fecal and urinary excretion of $AFB_{2\alpha}$ in the group fed dietary aflatoxin only was very low (6.17 and 8.19%, respectively). No aflatoxicol amount was detected neither in feces nor urine samples tested. These results indicate that the major excretory route was found to be the urine (accounting for 15.22% to 67.49% of the tatal AFs-excretion forms, whereas less than 10% of these forms were excreted in the feces. Treatment with WG improved the AF excretion via feces and urine in identifiable forms, mainly $AFB_{2\alpha}$ and unchanged AFB_1 without any detectable amount of aflatoxicol. In this respect, our results were in contrast with those observed by Richarda and Lyona (1986) in pigs.

Fecal excretion of $AFB_{2\alpha}$ reduced significantly by the WG-treated groups, this might be explained by a more pronounced renal elimination, which in turn might result in lower biliary secretion of $AFB_{2\alpha}$ in these groups. Our reslts were in the same trend with those observed by (Bennett *et al.,* 1981), who found that the lower toxicities of AFB_1 and $AFB_{2\alpha}$ in mammals are mainly as a result of a faster rate of clearance via urine and feces compared with that of AFB_1. Our results indicated that AFB_1 metabolites are cleared at a much faster rate than AFB_1. Hence, the rate of AFB_1 biotransformation represents the main mechanism through which detoxification occurs.

It's worthy to report that data obtained from the analysed samples of excreta (faces + urine) of the different studied groups showed no traces of aflatoxicol. This finding might be due to the

biotransformation of the ingested contaminants, aflatoxin B1, B2, G1 and G2 to other metabolites and /or the uncompetitiveness of Table (3).

Table (3) Proportional urinary (ng/mL) and fecal excretions (ng/gm) of aflatoxin B_1, and its corresponding metabolites ($AFB_{2\alpha}$, aflatoxicol), of female Albino rats fed aflatoxin (s)-contaminated diets with or without WG for 4 weeks.

N.B: 1- The same capital litters in columns denotes no significant difference between treatments in the same raw at ($p \leq 0.05$) and vice versa.

2- Excretion of $AFB_{2\alpha}$ expressed in terms of AFB_1 equivalents as calculated from the molecular weight of AFB_1 /molecular weight of $AFB_{2\alpha}$ (412/430) x mg of $AFB_{2\alpha}$.

In conclusion, we determined that aflatoxin could increase the liver enzyme levels and affect some hematological parameters. Increase in these parameters may occur due to peroxidation reactions, arising in aflatoxin biotransformation, and these reactions may inflict oxidative injury to cellular components. Administration of WG to rats received AFB_1-contaminated diet, resulted in a significant improvement in all biochemical parameters as well as improvement histopathological picture of the liver and kidny in different experimental groups.. In the light of these results, WG was found to induce the potent protective action in rats may play a role in the prevention of hepatic cellular injury produced by aflatoxins.

Abstract: This article seeks to understand the mentality of Akhond Khorasani, the leader of the Iranian constitutional revolution (1905-1911) regarding the political and social concepts such as freedom and justice. In the Iranian society, concepts such as freedom and justice were always affected by various kinds of understanding and comprehension. These concepts were never interpreted based on their original and true meanings which are essentially the principles of democracy. In other words, the Iranian society was faced some problems and difficulties in absorbing these concepts and it seems even nowadays these concepts do not possess their true meaning in the political social culture of Iran and everybody explain them based on their own personal assumptions and subjectivity. It is for this reason that Iran has not had much of a practical experience from the existence of these concepts and achieving such and experience needs more time. Understanding the opinions of Akhond Khorasani (the revolution's leader) vis-à-vis these concepts can be an indication of the formation of democracy's pillar in Iran and also an indication of how the clergy faced these concepts, understand them and what practical ways they used to realize them. The theoretical framework of this article is based on the modernity theory. In essence, modernity comprises the theoretical aspects of the entire social, political, economical and cultural issues and guide human societies through the passageway of tradition to the modern world. The methodology used in this study is the unobtrusive research methodology, since this is a qualitative and historical research. The content analysis method which is one of the methods used in qualitative and historical researchers has also been implemented in this research.

[Alireza Soroush, Sarvinder Kaur Sandhu, Hamed Alaei. Akhond Khorasani's Viewpoints Towards Modern Concepts such as Freedom and Justice. Journal of American Science 2010;6(12):473-479]. (ISSN: 1545-1003).

Keywords: Iran; politics; modernity; freedom; justice; democracy

1. Introduction

One of the most prominent transitions in political history of Iran was the Constitutional Revolution *(Mashruteh)* which changed the political and social structures of Iran. Modern and traditional attitudes, social and political philosophy of thinkers and theologians (as subjective conditions), livelihood and economical conditions, social classes (as objective conditions) as well as a kind of exercising of authority by governors were the most important reasons which resulted in Constitution Revolution and the consequent social and political changes.

2. Freedom

Freedom is very general concept and has been defined in a number of ways. An absolute definition of freedom is impossible because of the relative character of the concept. The word freedom does not have any clear or definite meaning. The encyclopedia Britannica defines it *"As a state of freedom, especially opposed to political subjection, imprisonment or slavery"* (Jahanbakhsh, 1997)

Freedom has been regarded as a negative concept in the sense that its existence requires the absence of something that might be considered as restraint, limit or compulsion. The possession of freedom is indispensable for any individual. It gives a sense of identity and character to a person. Moreover, it is freedom that allows and individual to be present in a society and think of him\herself as part of it. A free human being is someone who is aware of all his\her rights and receives them accordingly and in order to be aware of those rights he\she is educated.

On the other side, the society does not spoil those rights and gives to every individual his\her entitled rights.

Furthermore a free human being is someone who has the right to choose and is able to, along with civil freedoms, possess a suitable carrier and in accordance to it, have sufficient income and live a satisfied life. He\she can receive education so that by which his\her practical and theoretical abilities are ameliorated. The individual can also complain if his\her rights are not respected and can be sure that complain will be paid attention to justly. In a free society individuals have the option to freely participate in among all others political, religious, cultural, and artistic activities or not participate all together. Moreover they can have any religion and any political tendency and not be accountable because of them. They are allowed to have freedom of speech and state their religious and political believes freely and not have any constraint.In order to further clarify the subject matter, it should be mentioned that human beings are not free to commit any actions they want and do not always have the right to do as they wish. If it was so, there would be little difference between humans and animals. (Zargarinejad, 2008)

Freedom should not be mistaken with being self will. Freedom only makes sense when the individual does not hurt him\herself or others and it is law that constraints freedom in such away. In other words the individuals are free when they can benefit from all of their abilities in order to reach their entitled rights in a society and at the same time not inflict any hurt or harm to their fellow human beings.. The limitations imposed on freedom can be different in any country. And thus every society shapes these limitations are the laws of a country. It is the law that specifies how freedoms are given and how individuals can benefit from them. Each individual must be educated with law in order to benefit from true freedom. It is law that defines how individuals should conduct themselves in a society. (Zargarinejad, 2008)

Laws are usually written by governments which intend to ratify them in a way as to limit freedom. Nonetheless people have the right to protest against rules and laws and to modify them this symbolizes the prevalent of freedom over law.

3. Freedom in Iran during the constitution revolution

The concept of freedom preoccupied the writings and concerns of many constitutionalists during this period. What was freedom and when and how could it restricted and contained, was perhaps the most debatable issue during the first phase of the constitutional movement (1906-1908) (Minuchehr, 1998).

In spite of all the debates and discussions, not all constitutionalists could provide a single, homogenous understanding of this term, which could mean that freedom, actually represented multiple meanings for every distinct group. The sudden opening up of public sphere, perhaps accounts for the plurality of visions and ideas during this period, which included the multiple understanding of the term freedom. As the public sphere emerged as a social, cultural and political sphere for the open expression of ideas, with the publication of various newspapers and formation of numerous associations, the limits of freedom became a main issue for the government and the individuals. Specially, the sudden unrestricted freedom to express anti governmental sentiments started to make the shah and his people quite uncomfortable, creating a "freedom crisis." In recognition of this unbridled stage of freedom, Fereydoun Adamiyat, the renowned qajar historian, named his book, "the First parliament and the crisis of Freedom." This point to the fact that the public sphere of 1906-1908 encountered a major crisis with regard to freedom. (Minuchehr, 1998)

It was in such an unrestricted atmosphere that intellectuals and constitutionalists began to define the meaning of freedom.

4. Justice

Justice is a beautiful concept which has always been sought by the humankind. The sense of seeking justice is one of the prominent and clear characteristic of any human being and many of the historical evolution and social changes were formed with the motivation of implementing justice. The account of justice is described by john Rawles as fairness. The principals of justice formed in order to characterize the moral foundation up on which a political government is constructed are defined. The hypothetical model of human nature theorized by Rawles. He supports his model by using his theory of justice. These principals state that humans are in need of freedom and liberty so that their interests are pursued provided that others are not harmed by them. Contentment is realized by the people when they are able to freely follow their interests in a society that is supportive. Rawles argues that "every citizen deserves the same opportunities to succeed as every other citizen", because of this argument Rawles is

considered to be a liberal political philosophy. (Choptiany, 1973)

Justice is a political concept it can be defined as the connection between politics and ethnics, i.e. it is true justice that politics become ethical. Both politics and ethnics are governed by the concept of justice which is itself a complex subject. Justice means the balance between rights and obligation. The concept of justice as a balance corresponds with the conception of justice being on rights, when we speak of rights, we speak of obligations. A person is considered to be just when that person is someone who forms a balance between rights and obligations through the fulfillment of both in a justified manner. (Soroush, 2007)

According to Plato, justice is defined as *"every citizen performing one social service in the state for which his nature is best adopted." (Soroush, 2007)*

The principals of religious faith in addition to law and politics seem to be the roots of social justice values. The aforementioned themes are all inter linked in various ways and in different culture they play out in different ways. By examining writings from the mean branches of Christianity, Judaism and Islam references to social justice and its values can be found, all stating that before God every person is equal to the other and that all the people must behave respectfully towards each other. (Mayer, 2007)

5. Justice at the time of the Iranian constitutional revolution

Up until the constitutional revolution in Iran, the concept of justice had no meaning. The country was administered and managed based on self – wellness and there did not exist a place where judges can judge between the people so that the oppressors and the oppressed are differentiated. According to Kasravi's opinion at that time, in Iran, there was no department of justice (Adliye) where judgment takes place justly between the able and disables the rich and the poor. (Kasravi, 2006)

However, Kasravi continues by saying that people at that time were not greatly in need of a justice the parliament, since they were less inclined to oppress or commit crime against each other and if there was a case it would had been resolved by the clergies or the elders but then again sometimes the people and their properties were violated by the countries and or those people close to power and it was then that the need for a courthouse that did not exist in Iran was felt. (Kasravi, 2006)

In the early days of the revolution when the leaders of the clergy took refuge in Shah Abdolazim (in Shahreray, a city in south of Tehran), as a sign of protest they proclaimed their request to the Shah. One of the most important of those requests was the establishment of a house of justice (such as the justice department today).

Shah (Mozaffaredin Shah) accepted all the demands of the clergies through a letter to his prime minister (Ainoddoleh) and wrote a separate letter regarding the establishment of a house of justice as the clergies important request and in that letter he emphasized on it. An abstract of that letter had presented below to his Excellency, the Prime Minister (Atabak Azam), as we said several times establishing a governmental house of justice for implementing the laws of the Shariah and the well – being of the people is more essential than any other important goal. We clearly determine that for the execution of Islamic laws in the whole of the nation, the house of justice must be soon established and there must not be any discrimination between different strata of the people, and to take sides any pay heed to somebody in appropriately is absolutely forbidden. (Kasravi, 2006)

The discussion about the existence of justice in the society and a democratic modern courthouse that can be accessible for complaining against the oppressor had started exactly before the writing of this letter by Mozaffaredin Shah. Kasravi writes that the government was forced to make a law to accommodate to request of the clergy regarding the establishment of a house of justice and this was the first step towards the presence of law in the country and thus constitutionalism. He continues by saying that the clergies return to the city (Tehran) with pride and honor and then they were not satisfied with only a house of justice and thus made their next request apparent which was the establishment of a parliament. (Kasravi, 2006)

What is certain is that a despotic way of thought is against law and parliament. With this kind of thinking, Ainoddoleh (prime minister) disregarded the demands of the clergy and even the Shah's letter and resisted against the idea of establishing the house of justice. Ayatollah Tabatabaei, one of Tehran's prominent clergies, made speech after the letter of the Shah was not paid attention to for four mounts. He said:

"there is a cure for every malady and the cure for self – wellness is council. Whether it takes a year or ten years we want justice and the place for

realizing it. We want a parliament where the Shah and the beggar are treated equally." (Kasravi, 2006)

6. Freedom in the view of Akhond

Reaching freedom is a constant struggle and an effort by social movements pursuing it as a holy objective. The concept of freedom does not mean unrestraint, libertinage and having a laissez – fair and unbound society. In its modern sense, freedom is limitable and it is the law of each country that indicates those limitations. In reality when social – political freedom receives its reason for existence from law and it is determined what situations and conditions encompass freedom, it is then that democracy is formed. Freedom is more inclined towards democracy rather than despotism, however it is the constitution law that determents the measure and degree of this inclination. As Habermas pointed out that all citizens must be free and equal with respect to constitutional law, it is these freedoms equality that guarantees a government's legitimacy.

Akhond Khorasani views freedom as being the opposite of despotism. He considers nation as free when the government respects the rights of the people and does not transform them in to obedient slaves by oppression and tyranny. This is how he describes freedom:

"the freedom of each nation which is based on constitution consists of the government not dominating by means of intractable and self – willed orders, in addition to a lack of obstacles in the way of realizing the legitimate right of the nation. In other words, the will of a nation does not lack any capability any in comparison to the will of the government. The reality of the freedom is the government and the nation not violating laws that are in accordance with religion. These are the laws that preserve the interests of Muslims and establish order in the society and are barriers against enemies of the nation." (kadivar, 2006)

The Akhond considers freedom as a divine blessing and a right of all humans, and further states that where there is no freedom, there is bondage. He indicates that the nation must make the effort of liberating itself from the self – willed decision of the government and not obeying oppressive officials. (kadivar, 2006)

The Akhond reminds the modern and lawful definition of freedom to associations and the media and tells them to respect each other and make their efforts towards the accomplishment of their scientific and practical matters, in addition to accepting all of the parliament's decisions and not interfering in any of them moreover, he states that newspapers are free to educate the people regarding the fundamentals of religiousness and civilization. Also he expects the newspapers to be active in growing the cultural civility and the morality of the nation. However, he reminds them that shirking this duty means violating the limits of the Sharia and the laws of the nation. (kadivar, 2006). Freedom is a concept not given to the people by dictator governments, thus for the people to experience freedom with such governments there must be struggle and conflict. Akhond Khorasani believes one of the constitutional government's objectives to be gaining the experience of freedom. He requested intellectuals residing to spend time make the necessary effort for the realization of freedom in Iran so that Iranians also could experience and understand freedom and progress in an announcement directed at the French people, he subtly reminds them of their struggle in attaining freedom and requests that they help Iran to realizing it as well.

"I request the noble French to remember the golden pages of their history when they fought for freedom and assist Iran in reaching freedom from lawlessness and tyranny." (kadivar, 2006)

Habermas fundamentally believes in freedom for a society, in such a way that he considers a society to be ideal when it encompasses freedom and justice. Such a society will be able to achieve social – moral amelioration for which modern science and knowledge are effective and modernity lays the groundwork for the establishment of such condition, in other words, it is through modernity that freedom is realized. Moreover, he believes that freedom, especially religious freedom, controls the level of confliction a society and prevents imbalance between the powerful and powerless groups, therefore, freedom is essential for a civil society.

Habermas is placed exactly on the same path where Akhond Khorasani is on for achieving freedom and as the Akhond believes individuals to be free to the extent defined by constitutional law prepares the conditions for such freedom to happen. The important issue that both are sensitive to is that the government gains legitimacy through freedom supported by law and conferring it to social group, the press and political parties. Otherwise a tyranny will take place. As Habermas considers all parties to be free, the Akhond too believes all social groups are free to elect parliament representatives as well. The Akhond does agree with freedom on the basis of law and the Islamic faith and considers it essential for the society. Moreover he believes it to be the cause of a

government's legitimacy and considers it the opposition to a despotic government in addition to being the necessary precedent to a constitutionalist government.

It is clear that freedom leading to anarchy and disorder and a situation where everybody does as he or she wishes in a society is not anybody's intention of freedom. Nonetheless those freedoms specified on the bases of a country's laws and according to be respected and possess a democratically form, where by the press can be published in such a way that they are allowed to criticize the establishment without any fear and moreover political parties can be active with the objective of creating awareness for the people and no belief, whether it be political or religious, is not imposed and finally can be their own decision makers, in their private lives individuals and followers of the law in their social lives.

Constitutionalism sought to establish freedom of thought, equality of individual's rights, and the governance of people on the people so that it leaves the destiny of the land and the nation to the hands in the people themselves and that the nation be placed in a situation where it is free to pass laws based on morality and the society's interests. (Malekzadeh, 1984)

7. Justice in Akhond's viewpoint

The ultimate goal of any society is attaining justice for the purpose of living a better life. The justice mentioned by Plato in his utopian society where every citizen serves it on the basis of his or her on specialty, and the justice defined by Habermas as the people's participation in the public sphere where its constitution leads to preservation of justice and freedom in the society, and finally the statement by Akhond Khorasani that says in order to diffuse justice both the government and the nation must act on the basis of laws that are according to Islam and they must not violate each other's rights, all three viewpoint consider justice as the ultimate goal and believes that all social – social political activities are only justify when they are in the path of reaching justice, otherwise the society will progress in the wrong direction caused by injustice.

In Akhond's eyes, justice is the objective of constitutionalism and he considers its reality based on which the constitutionalist movement was formed. The point he emphasize on is that we demand constitutionalism for the establishment of justice and progress and the renewal of the history of civilization. (kadivar, 2006)

In a letter to Ahmad Shah, he writes:

"struggle for the expansion of true justice and equality in such a way that the Shah himself is equal to the weakest individuals of the nation in terms of rights. Whenever the Shah is resolute and determined on this path and makes the necessary efforts for the implementation of this duty, undoubtedly the enemies will be in despair and the foundation of justice will strengthen." (Kafaei, 1980)

Justice was a true cause of Akhond Khorasani and equality of all people of his purpose, in such a way that in his view even the clergy are equal to the people and they all should benefit from equal rights. For instance some clergies demanded that he issues order an appointing five of Tehran's clergies to lifetime parliamental seats and that this becomes one of the constitutions laws. Hearing this, the Akhond became enraged and said:

"What a futile statement this is, the dignity and honor of this parliament is in equality. Nobody is to be preferred over somebody else otherwise this will lead to conflict and destruction." (Kafaei, 1980)

The Akhond furthermore considers the action of taking refuge to the Shah Abdolazim Shrine (a city in south of Tehran) by some of Tehrani's clergy, a movement on the path to justice and requests that the people accompany them who raised the banner of seeking justice for the purpose of its diffusion and the removal of oppression and took refuge in the cold winter. (kadivar, 2006)

Habermas believes that all the laws and decrease of the courts must be equal for all citizens; otherwise, equality will only be a verbal concept. In a similar manner, Akhond Khorasani writes to Ahmad Shah emphasizing that one must be determined in implementing justice and is realization must not be only the subject of conversations but must put to action. Akhond Khorasani held a modern an at the same time practical view of achieving justice in the society by means of the formation and existence of a parliament. In responding to a question posed regarding parliament, he said:

"During the two – year period since the formation of the parliament, not even one tenth of the oppression imposed on the people during the time of despotism took place, and if it did, take place it was on behalf of ill – wishers not the parliament." (kadivar, 2006)

He did not sanction offending any individual, be it Muslim or non-Muslim, so that in

this way the grate civilization of Iran is known to other countries. Likewise, similar to the Akhond, habermas considers all citizens to have equal share of citizenship rights from which they can benefit without the government pressuring the due to the political – religious standpoint. In conclusion governing essentially means taking actions in direction of justice. Both Akhond Khorasani and Habermas emphasize governing justly, which is to say governing without violating others' rights and the equality of all people in a society in front of the law can guaranty the legitimacy of a government; otherwise, it will not take long for it to collapse.

An economical justice that has a practical aspect to it and is not only rhetoric was one of the Akhond's plans for reforming Iran. He found training of the work force and acquiring knowledge in a variety of specialized technological and industrial fields to be crucial. A skilled and professional work force, in his opinion, can locally produce the needed goods and thus reduce the level of Iran's dependence on other countries and moreover is a propellant for eradicating poverty and expanding economical justice among the people. To emphasize his views, in a letter to Ahmad Shah, Khorasani brought up Japan and its emperor Mikado as examples, stating that *"the emperor of Japan knew that the key and the way to the nations progress is the people not needing foreign imported goods and it is due to this policy that Japan attained remarkable levels of progress and development. To whatever extent you choose such an admirable path and cause the nations progress, you will reach a society where poverty is a radiated and its people are self – sufficient. This principle causes the nations advancement and true independence and eventually the expansion of justice."* (kadivar, 2006)

Furthermore, he requests from the Shah for the ground work of learning and diffusing modern sciences and industries to be laid and he believe that the pinnacle of the countries glory depends of acquiring them and that Iranians have always had the necessary talent and potential in the fields of sciences and industry. He proclaimed that these abilities have been that manifested trough out history and that the poverty and backwardness of the Iranian society at the time are due to neglecting this very historical fact and not pursuing the learning of modern industries and sciences. Utilizing this two important factors (modern sciences and industry), he believes, results in the revitalization and rejuvenation of Iran. Not paying attention to these two important issues consequently results in higher dependence on foreign goods and with it more poverty and destitution becomes apparent among the people.

The emphasize of the Akhond on the accordance of ratified parliament laws on the Islamic laws manifests itself when he claimed that when the social laws passed by the parliament are not in contradiction with the Islamic Shariah laws, these two together give the Islamic nation the benefit of increased justice. Islamic is a form of rule that insist on justice and thus is a suitable framework for the parliament's representatives to notify social and political laws and regulations inside it. So, that all the citizenship rights for both Muslims and non Muslims of the society are respected and nobody endues operation and disrespect. Moreover, if the case arias where, and individual's rights are violated, in accordance to laws obtain from the Islamic Shariah and the parliament, that individual would be able to complain to a court of justice and redeem his or her rights.

In Akhond's view Islam is like a container from which social laws are taken by the parliament representatives. Although these laws do not represent absolute justice but they are so very near it. It is for this reason that politics gets situated next to religion and the conformity of these two has the benefits of revealing the function of religion while deepening the behavior of politics for the people and making it more acceptable by them.

8. Conclusion

Iran is a religious country and the effect of religion has penetrated all the country's social and political structures. Today, Iran has been named an Islamic republic meaning a totally religious form of government administered and managed by the clergy. The mentality of Akhond Khorasani is essentially the same mentality of those clergy who today believe in the governmental and political principals on the basis of Islamic principles and also similar to the Akhond believe that not only Islam does not contradict modern political concepts if placed next to each other, the ability of establishing a free and equal society based on constitutional law can be attained. However, today this stratum of the clergy is not able to directory be involved in the society's administration and the opposite way of thinking that is currently in power believes in the contradiction between Islam and modern concepts and the impossibility of the accordance of democracy and Islam. Thus in reality the lack of mutual understanding regarding freedom, justice, is still ongoing.

Chemical Composition and Potential Application of *Spirulina platensis* Biomass

Aly, M. S[*1] and Amber. S., Gad[2]♀

[1]Agriculture microbiology Dept, [2]Chemistry of Natural and Microbial products Dept., NRC, Cairo, Egypt.
[*]mohamed_saad_1@hotmail.com

Abstract: Submerged batch cultures, Semi -pilot scale cultivations and Outdoor biomass production were performed to increase *Spirulina platensis* biomass which is naturally grown in El Khadra lake water body. Comparing *Chlorella vulgaris* and *Spirulina platensis* showed higher protein contents of *Spirulina* as it reached 64 % (w/w) so, it may be used in agriculture as a nitrogen biofertilizer and as an animal and fish growth promoter. Bio-chemical analysis of *Spirulina* biomass showed presence of 17 amino acids, 10% (w/w) carbohydrates, 8 %(w/w) fibers and 8 %(w/w) lipids. *The biomass of Spirulina* contained 0.04 ppm Mg, 0.3 ppm Ca, 0.16 ppm Mn, .0.8 ppm Fe, 0.16 ppm Zn, 11.3 ppm Na, 0.003 ppm Se and 5.6 ppm K. It also contained 1 ppm Cu, 0.04 ppm Hg, 0.03 ppm Ni, 0.9 ppm Cr, 0.1 ppm Cd, and 0.6 ppm Co.

Key words: *Spirulina platensi,,* El Khadra lake, biofertilizer..

1. Introduction:

The mixotrophic culture might be used as an alternative to conventional photoautotrophic mass culture systems for production of high value pharmaceuticals by *Spirulina platensis*. Chen (1996) satisfactorily cultured *S. platensis* in a mixotrophic mode by using a mix of different sources of energy and carbon ; glucose at high cell biomass densities 10.24 (g/ L) for the production of phycocyanin. Under mixotrophic conditions, some microalgae are known to grow rapidly and to have a higher growth rate than under photoautotrophic conditions, Samejima and Myers (1958). The algae usually not only contain nearly every required vitamin and mineral, but also have the effect of increasing oxygen while reducing nitrogen and carbon. Lee *et al.* (1996) cultured *Chlorella sorokiniana* mixotrophically in an outdoor enclosed tubular photobioreactor reaching an optimum biomass productivity of 10.2 (g /L/ d) during the day and 5.9(g /L/ d)during the night using an initial glucose concentration of 0.1 M. The daily volumetric productivity of photosynthetic *Chlorella* cultures in a similar tubular photobioreactor was about 3 times lower, Lee and Low (1992). These values are the highest reported for outdoor conditions, Ogbonna *et al*. (1997). Chen and Zhang (1997) stated that growing *S. platensi* under mixotrophic conditions reported a productivity 2.4-fold higher than of photoautotrophic cultures. Mixotrophic cultivation is an alternative to photoautotrophic production of biomass. The growth rates and biomass concentrations increase, apparently due to a synergistic effect of light and the organic substrate, Cid *et al.* (1992). Mixotrophic cultivation is a dual limiting process in which low light intensities or low organic carbon substrate concentrations may limit cell growth; while high light intensities or high carbon substrate concentrations may inhibit cell growth, Chen (1996). The cellular concentrations of the photosynthetic products depend on the relative heterotrophic and photoautotrophic growth rates. At high cell concentrations, light becomes limiting and the contribution of the photoautotrophic growth to the overall growth rate is very low. Under this condition, both the protein and the chlorophyll contents of the cells are much lower than of those of the autotrophic cultures, Ogbonna *et al.* (1997).Heterotrophic growth of microalgae could eliminate the requirements for light, and thus may offer the possibility of greatly increasing the algal cell concentration and productivity on a large-scale; however, only a few industrial heterotrophic processes have been attempted to date**,** Chen and Johns (1995). This is probably because limited number of available heterotrophic algal species; increased potential of contamination by bacteria; inhibition of growth by organic substrates at low concentrations; and the inability to produce some light-induced products, such as pigments ,Chen (1996). Photosynthetic microorganisms are able to synthesis organic C, N, and P which allow treating wastewater and simultaneously producing useful biomass when intensive algal culture is employed in outdoor ponds as tertiary for the removal of waste residual compounds, Kim**,** *et.al* (2000). *S.platensis* cultivation is usually preformed in open ponds so that the solar energy is used to fix inorganic carbon. Since heterotrophic metabolism is faster than autotrophic, simple carbon source is used to sustain growth. However, heterotrophic metabolism tends to suppress

the photosynthetic activity, therefore a mixed heterotrophic and autotrophic (mixotrophic) culture could be preferable, Lee *et al*. (1992 and 1996).

The high content protein indicates relatively good amino acid profile and low metal content enabled the use of algal biomass as feed supplement. The use of micro- algae in industry encourage the development of better cultivation system in order to optimize the production of algae rich in active substances such as vitamins protein, amino acids,fatty acids and trace elements . This study aimed to evaluate the amino acid composition of corkscrew-shaped filament *S. platensis* microalgae grown in El Khafra lake water. This seaweed is also characterized by fast growth, (dividing three times a day) , Furthermore, the *Spirulina* has advantages over other seaweeds by having the pleasant taste and thus it is used in the preparations of *Spirulina* capsules or in foods such as beverages and pastes. *Spirulina* causes no problems for digestion and no toxicity to humans, in contrary to occur to other seaweeds such as *Chlorella* and *Scenedesmus*. *Spirulina* is also known for its antioxidant and hypocholesterolemic actions**;**Parikh *et al*. (2001); Mao *et al*.(2005) **;** Colla,. *et al. (* 2008)and Muthuraman *et al.* (2009*).*

2. Materials and Methods:

Micro-organisms:

Spirulina platensis and *Chlorella vulgaris* isolates used in this study were obtained from El-Khadra lake at Wadi El Natroun, Egypt, characterized by extreme conditions of pH 10.5 and salt concentration of 0.55 M,,(Aly ,2000).

Maintenance stock media:

Zarrouk's synthetic solid medium (Zarrouk, 1966), amended with 2% (w/v) agar was used for maintaining *S.platensis* N-8 medium; Vonshak(1986)used to maintain the unicellular green algae *Chlorella vulgaris.*

Inoculums preparation:

Spirulina stock cultures were propagated in 50 ml Zarrouk's synthetic broth medium at 30±2 °C under continuous illumination with fluorescent lights for seven days in 500 mL Erlenmeyer flasks; Colla *et al.* (2004). The inocula concentrations were determined by spectrophotometer using a standard curve. a calibrated at 560 nm ;Volkman(2008). Inoculation conditions of *C.vulgaris* were performed according to Mandalam and Polsson and (1998).

Batch culture condition.

The *S. platensis* batch culture was incubated_at agitation of 160 rpm, temperature, 30ºC and luminosity 5000 lux in 250 mL Erlenmeyer flasks containing 50 ml of both basal Zarrouk medium, Zarrouk, (1966), and El Khadra lake water. Fermentations media were sterilized at 120°C for 20 min. The stock cultures were transferred to outdoors 130-L photobioreactor earlier 24 hours after inoculation. Cultivation conditions of *C. vulgaris* were performed according to Mandalam and Polsson and (1998).

Semi -pilot scale condition:

The bioreactor was inoculated by the previously prepared locally isolated *S.platensis* and *C. vulgaris* with initial biomass concentration of 0.16 g/l, These cyanophytes were used to inoculate Zarrouk's synthetic media ,Zarrouk, (1966) ; N-8 medium ,Vonshak (1986) and El Khadra water respectively. Cultures were incubated at 30°C with 5000 lux/cm^2 and pH 10.5 for 7 days . Zarrouk's medium contained (g/L):$NaHCO_3$, 16.8; K_2HPO_4, 0.5; $NaNO_3$, 2.5; K_2SO_4, 1.0; NaCl, 1.0; $MgSO_4 \cdot 7H2O$, 0.2; $CaCl_2$, 0.04; $FeSO4 \cdot 7H_2O$, 0.01; EDTA, 0.08; H_3BO_3, 2.86 mg/L; $MnCl_2 \cdot 4H_2O$, 1.81 mg/L; $ZnSO_4 \cdot 7H_2O$, 220 µg/L; $CuSO_4 \cdot 5H_2O$, 79 µg/L; MoO_3 , 15 µg/L; and Na_2MoO_4, 21 µg/L; Cases *et al*. (2001)). All the reagents used were of analytical grade, obtained from Merck Chemical Co. (Darmstadt, Germany). Aeration was conducted using air pump according to Costa *et al.*, (2002), and was incubated for 7 days at 30°C under illumination with fluorescent lamps (5000 lux) with 12h light /dark photoperiod according to Vonshak *et al.,* (1982).

It was supplied with flow rate of 0.03% CO_2. (100ml /min) in a 3L batch fermentor of 2.5L working volume with air. Cultivation conditions of *C.vulgaris* were performed according to Mandalam and Polsson and (1998) .After seven days , the biomass was filtered through a 20-µm membrane, thoroughly washed with distilled water, and stored after freeze drying.

Outdoor *Spirulina* biomass production*:*

2 L Erlenmeyer flasks, containing 1.8 L of Zarrouk's nutritive medium (Zarrouk, 1966) were used as starter inocula. *S. platensis* were grown in water outdoor mass culture 130 L photobioreactor, Colla *et al*. (2004).

Harvesting the biomass

At the end of seven days, the algal biomass was aseptically filtered and washed with distilled water to remove the salts from the algal surface then, lyophilized and stored at 4-5◦C °until need according to ,Colla *et al*.(2004) or dried at 50° C. The dried *S.*

platensis was powdered and stored in plastic container till used.

Preparation of *Spirulina* aquous extract (SAE):

The air dried *S.platensis* cells (5 g) was mixed under cooling conditions with sterile dist. water. The slurry was filtered through 50 mesh polyester rope and centrifuged at 5000 rpm for 10min. The clear supernatant was taken and made up to 100 ml then, sterilized through Millipore membrane 0.25µ.This sterilized *Spirulina* aqueous extract (SAE) represents the stock sources used for chemical analysis.

Analytical procedures.

pH of El Khadra lake was determined directly in the field with scan 2 pH meter .

Determination of the protein content of the cultivated material according to Lowry *et al.* (1951).

Determination of amino acids The amino acid profile was analyzed in algal protein precipitate after HCl hydrolysis using LC3000 amino acid analyzer with a flow rate , 0.2 ml/min , pressure for buffer, 0-50 bar, pressure for reagent ninhydrin 0-150 bar, column temp. 50°C.

Total carbohydrates were determined as glucose according to Dubois *et al*. (1956).

Fibers contents of *S. platensis* were determined according to the standard method of A.O.A.C. (1980).

Lipids were determined according to Folsh *et al.* (1975) method using extraction mixture of methanol – chloroform mixture (1:1,v/v) at 28ºC for 24 hrs in darkness followed by filtration. The extract was mixed thoroughly with half volume of 0.9% NaCl solution and the organic phase containing fatty acids was separated. The solvent was evaporated under nitrogen and the lipid content was gravimetrically estimated.

Heavy metals and minerals were analyzed by atomic absorption spectrophotometer varian A220, NRC, Cairo.

Spirulina semi-pilot scale production studies:

100 mg axenic culture prepared from powder of the local *S.platensis*; 15 mg PVP (polyvinylpyrrolidone) ; 10mg magnesium stearate and 300 mg avicel .For all formulations with (5-20,w/w) PVP the mixture was compressed using single punch tablet machine , hardness tester, disintegration apparatus and Roche Frabilator Erweka (GmbH. Frankfurt) in the machine setting were adjusted to produce *S.platensis* pellets having approximately the same hardness and weight .

3. Results and Discussion:

Protein content of *S. platensis* and *C.vulgaris* grown in El Khadra Lake and on basal synthetic media.

Fig(1) shows that the bluish-green seaweed *Spirulina* is characterized by its high protein content (64.0,and 58,0)% on dry weight basis when grown in Zarrouks, and El Khadra lake water ,respectively compared to *C. vulgaris* grown in N-8 medium Vonshak (1986)and El Khadra lake water .So, further studies will be focused on *Spirulina* .As a cyanobacterium, *S. platensis* does not contain a heterocyst necessary for nitrogen fixation. Thus, it must absorb nitrate from the media, and cultivation requires substantial inputs of soluble nitrogen. Exclusive use of sodium nitrate is essential for biomass production. *S. platensis* grown on basal medium because of its high solubile nitrate.

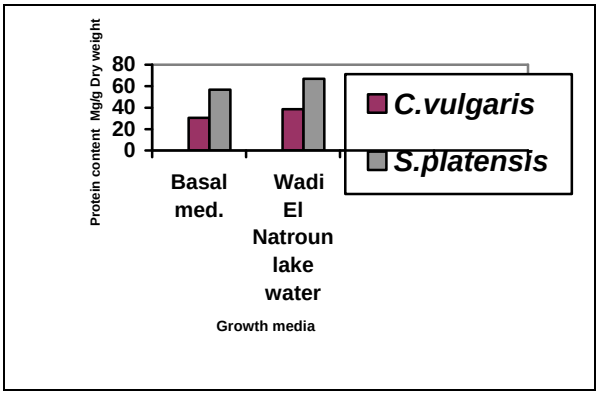

Fig.(1)Protein content of *Chlorella* and *Spirulina* grown in basal media and Waadi El Natroun Khadra lake body water.

The Biochemical analysis of *S.platensis*

Nitrate assimilation involves its uptake and sequential reduction by nitrate reductase (NR) and nitrite reductase (NiR) into ammonium ions, which are then incorporated into amino acids mainly by the glutamine synthetase/glutamate synthase (GS/GOGAT) pathway. In higher plants, these enzymes are induced by nitrate and regulated by light, hormones, sugars and carbon and nitrogen metabolites, Raghuram *et al,* (2006). The genes involved in these reactions have been cloned from many plants and mutants and transgenic lines are also available,Lochab *et al.* (2007). *Spirulina* contains at least 10-fold higher protein than rice, indicating a correspondingly high capacity for nitrate utilization,(Goto *et al.* 1998,;Kronzucker *et al.* 2000;Ali *et al.*(2007). However, its biochemical basis is not known ,Vonshak (1997), except nitrate induction by NR and its inhibition by nitrite and

ammonium ions ,Jha *et al*., (2007), Characterization of NiR (Yabuki *et al*., 1985; Ali *et al.* 2008), and regulation of nitrate assimilation by calcium and phosphate were reported ,Singh and Singh (2000). Wong and Chan (1980) found that the protein content of sewage grown *Spirulina* was 45.6 %and fat was 14.7% of the total dry weight

Results obtained in table (1) revealed the *Spirulina* high crude protein content which amounted 64.00(% w/w) on Zarrouk medium. Crude fat was 8% (w/w); 10%(w/w) total carbohydrate content;8%(w/w) fiber .Wong and Chan(1990)revealed that *C.vulgaris* and *S.bijuga* have a fiber content of 5-8%(w/w)and 10%(w/w) minerals. The protein malnutrition is a public health problem that has affected a large proportion of the world population for many years, especially in the developing countries indicates tremendous importance of this alga in nutritional, industrial and environmental biotechnology, Vonshak (1997). However, it is not clear how the organism steers its nitrogen metabolism to produce so much protein. This alga is a nitrate-utilizing, non-nitrogen fixing and photosynthetic organism. The nitrate-utilizing ability of *Spirulina* has been exploited in the decontamination of nitrate-polluted waters and effluents (Kim *et a*l., 2000; Lodi *et al*., 2003).

Amino acid profile of *S. platensis*

Seventeen amino acids were detected in *S. platensis* grown on Zarrouks growth media as table (2) shows that *S. platensis* contains wide spectrum of amino acids . Glutamic acid was the most common amino acid of the dry matter of *S. platensis* followed by aspartic acid. Isoleucine was the most abundant essential amino acid as indicated in table (2).The phenyl aalanine is also present in comparatively high doses, therefore, people with phenylketonuria should avoid *Spirulina*.

The high protein and amino acid content of the algae grown on agriculture drainage water could be attributed to the availability of essential elements in quite high amounts as well as the tendency of algae for bioaccumulation and incorporation of these element into their macromolecules .El Adel *et al*. (2003) reported that salinity ,inorganic N and P of agriculture drainage water resulted in higher protein content in *Spirulina* especially due to the lack of organelles and intracellular transport constraints. The contents of proline and sulfur containing amino acid :methionine and cystine of the algae is low remarkably. The results reported that amino acids aspartic, serine, alanine, leucine, and glycine collectively amounted 50% of the detected amino acid content while methionine, cystine, tyrosine, and histidine collectively amounted less than 20 %.

The amino acid profile of *S. platensis* biomass is a presented in Fig (2).

Table(1). The Biochemical analysis El Khada lake of *S. platensis* biomass grown in Zarrouks basal medium.

Component	Concentration (%w/w)
Crude protein	64.00
Fat (lipids)	8.00
Total carbohydrate	10.00
Fiber	8.00
Minerals	10.00

Minerals in *S. platensis*

Table (3) shows that, *Spirulina* might concentrate ions found in its environment. The natural El khadra lake waters *Spirulina* are so saturated with minerals originating from ancient soils and mountains while *Spirulina* favors to live in this aquatic environment no other plants can live there. Because *Spirulina* prefer to thrives in such alkaline waters, it incorporates and synthesizes many minerals and derivative compounds into their cells. The absorbed minerals are transformed into natural organic forms by *Spirulina.* Minerals become chelated with amino acids and are become more easily assimilated by the body .The biomass of *S. platensis* contained 0.04 ppm Mg, 0.3ppm Ca, 0.16 ppm Mn,0.8 ppm Fe,0.16 ppm Zn,11.3 ppm Na,0.003pppse,and 5.6pppK. Potassium is a crucial mineral that regulates body electrolyte balance, Beck (2000). Its deficiency can cause heart arrest, hypertension, adrenal exhaustion and muscular collapse. Calcium is especially important to bone and dental health and also in neural transmissions to the muscles; Aloia, *et al.(*1996). Zinc is the pivot point of over thirty vital enzymatic reactions, with profound effects on mental health, skin tone, prostate function and healing capacity**, Gonzalez**(2009). Magnesium deficiency can lead to spasmodic muscle disorders, including cardiac irregularities. This element helps in assimilation of C, B vitamins and proteins; Sawka and Montain(2000). Manganese at concentration of 0.16 (ppm) activates enzyme systems, along with zinc. It promotes the activity of neurotransmitter acetylcholine, and helps stabilize blood sugar ,Takeda(2003). Selenium was originally believed to be a toxic heavy metal, but now known to be necessary for health. It retards aging, harmful oxidation and free radical formation, reduces and improves cardiac efficiency. Selenium is an essential trace mineral that functions as an antioxidant and promotes a healthy immune system; Cases *et al.* (2001), and Tsavachidou *et al*. (2009). Iron is required in remarkably small amounts .It promotes formation of hemoglobin, the oxygen-carrying blood pigment found in healthy red blood cells. Iron deficiency is most common among women in their reproductive years, Steinberg (2001).

Table (3). The minerals content of *S. Platensis* .

Mineral	Conc. (ppm)	Mineral	Conc. (ppm)
Mg^{+2}	0.04	Zn^{+2}	0.16
Ca^{+2}	9.3	Na^{+}	11.3
Mn^{+2}	0.16	Se^{+4}	0.003
Fe^{+2}	0.8	K^{+}	5.9

Heavy metals *in S. platensis:*

The UN-FAO recognizes *Spirulina* as a potential weapon against malnutrition for the third world and has sponsored safety studies since the early 1980. Table (4) shows the heavy metals content of *Spirulina*. Phytoremediation potential of *S. platensis:* resemble *Chlorella* which known to bind to the heavy metals .Biosorption and toxicity probably most concern is *Spirulina's* ability to absorb and concentrate heavy metals such as lead and mercury if they are present in its environment The biomass of *S. platensis* contained 1.00 ppm Cu, 0.04 ppm Hg, 0.03 ppm Ni,0.90 ppm Cr,0.10 ppm Cd,and 0.6 ppm Co.. However, *Spirulina*-associated hepatotoxicity and reactions from heavy metal contamination are possible. *Spirulina* is considered nontoxic to humans at usual levels of consumption .This justify the use of alga biomass in nutrition if necessary; however, information is limited as insufficient clinical data to guide dosing of *Spirulina* for therapeutic effect.

Table (4).The Heavy metal content of *S. Platensis*

Heavy metal	Conc. (ppm)	Heavy metal	Conc. (ppm)	Heavy meta	Conc (ppm)
Cu^{+2}	1.00	Hg^{+2}	0.04	Ni^{+3}	0.03
Cr^{+2}	0.901	Cd^{+2}	0.10	Co^{+3}	0.60

Therapeutic *Spirulina* pellets:

Because of the high cost of extraction of polyunsaturated fatty acids and other constituents from *Spirulina* ,it seems that the best way is to use *Spirulina* by direct consumption as a nutritional supplement,Kapoor and Mehta (1993), *Spirulina* can be used either as a food supplement or taken in capsule form.Capsules appeare to be the preferred form at present, Colla *et al*. (2004).

Table (5) shows that 5 % (w/w) poly vinyl pyrrylidone (PVP) is the most suitable for capsules formation. *Spirulina* is sold as a feed additive for aquaculture and as a dietary supplement It has a long history of use as food and it is the nature's richest and most complete source of organic nutrition. The concentrated nutritional profile of *Spirulina* occurs naturally, so it is ideal for those preferring a whole food supplement to artificial nutrient sources. *Spirulina* has a unique blend of nutrients that no single source can provide. It has been labeled as a powerful food, rich in proteins, carbohydrates, polyunsaturated fatty acids, sterols and some more vital elements like calcium, iron, zinc, magnesium, manganese and selenium. It is a natural source of vitamin B12, vitamin E, ascorbic acid, tocopherols and whole spectrum of natural mixed carotene and xanthophylls phyto-pigments (Chamorro *et al*., 1996; Pinero Estrada *et al* .2001; Chamorro *et al.,* 2002, Islk *et al.,* 2006, and Al Attat 2010).*Spirulina* is also used as a feed ingredient for pigmentation of ornamental fish, especially gold fish and fancy red carp. *The spirulina* is reported as a potent anti-cancer (Ismail *et al.,* 2009), hypocholesterolemic and hypolipidemic (Colla *et al.,* 2008), antidiabetic (Muthuraman *et al.*, 2009) as well as for health improvement (Annapurna *et al.,* 1991; Cingi *et al.* 2008, and Al Attar, 2010).

Despite considerable progress in medical therapy, there is no satisfactory drug to treat kidney stones. So, capsules could be used for antilithiatic activity of *Spirulina* . In addition, the incidence of kidney stones has been increased in most societies in the last five decades, especially in association with economic development. In spite of tremendous advances in the field of medicine, there is no truly satisfactory drug for the treatment of nephrolithiasis. Recently, there is increasing evidence that many healthy natural food and medicinal herbal and supplements have the potential to become valuable complementary therapy in the treatment of various renal disorders and in the protection against iatrogenic nephrotoxicity. The administration of *Spirulina* solution to rats with ethylene glycol induced nephrolithiasis reduced and prevented the growth of kidney stones, renal and hepatic impairment can be concluded that the food supplementation with *Spirulina* has a beneficial effect on nephrolithiasis induced by ethylene glycol, Al-Attar(2010). The *Spirulina* components which are responsible for these therapeutic properties are thought to be compounds with antioxidant abilities such as polyunsaturated fatty acids, phycocyanin and phenolics ,Colla *et al*. (2004),and Islk *et al.(*2006).

Table (5).Physical characteristics of *S. platensis* pellets formulation.

PVP conc.(%)	Weight mg(±CV)	Thickness(±SD)	Friability(%)	Hardness(kg)	Disintegration time(min)
5	300±1.70	0.321±0.80	1.05	6.43	0.22
10	338±1.90	0.351±0.80	0.99	5.92	1.73
15	278±0.50	0.333±1.21	0.06	5.77	2.76
20	302±1.75	0.322±1.53	0.05	6.99	6.28

Abstract: Occurrence and survival of some classical bacterial indicators, (salmonellae group, total staphylococci and *Pseudomonas spp.)* in water samples at surface and one meter depth of El-Khadra lake have been studied as well as, cyanobacteria and fish lagoons were included for comparison. The results showed that, fecal streptococci and *Pseudomonas spp.* are not present in surface and deep lake water samples respectively, while other bacteria tested are presented. Similarly, salmonellae group and fecal coliform were absent in all water samples from the fish lagoon and the deep lake samples. In addition, the high and low log average counts of total viable bacteria incubated at 37 ºC for 24 hours were 7.5 and 3.4 /100m in cyanobacteria lagoon and surface lake water samples respectively. On the other hand, the high log average counts of total viable bacterial incubated at 22 ºC for 48 hours was 7.3 /100m in cyanobacteria lagoon, while the low recorded 3.67 /100m in surface water samples. The statistical analysis (log average) showed that, some factors such as human activity, sun ray and sedimentation as well as biological activity play role on the bacterial distribution in all water samples tested.
[Ali, M. S. and Osman, G. A. **Microbial load as Pollution Indicator in Water of El-Khadra Lake at Wadi El-Natroun, Egypt**. Journal of American Science 2010;6(12):489-496]. (ISSN: 1545-1003).

Key words: Lake water, Classical bacterial indicators, Salmonellae group, Total staphylococci and *Pseudomonas spp.*

1. Introduction:

Water must be safe and free of risk factors. Risk factors related to water pollution, can be divided into two basic categories: chemical and biological pollutants. Both categories derive from human activity which inevitably tends to modify water composition, with respect to its original state in nature (Grabow, 1996 and Payment *et al*, 1997). The lake water sources must be protected from contamination by human and animal wastes which contains a variety of bacterial, viral, protozoan pathogens and helminthes parasites.

The heterotrophic plate count (HPC), gives a valuable indication of general microbiological quality of water. The test is widely used to monitor the water pollution, as well as the deterioration of water quality during storage and distribution (Reasoner *et al*, 1989; Grabow, 1996 and WHO, 2001).

Generally, the European Union regulation require that the HPC be assessed at two recovery temperatures: 22 ºC for 72 hrs and 37 ºC for 24 hrs. The 37 ºC plate count was believed to give an indication of fast-growing bacteria more likely to be related to pathogenic types and 22 ºC. Plate count was used for enumeration of characteristic water bacteria that tend to develop slowly (Ramalho *et al,* 2001).

Coliform group that have a wide distribution in the environment and are not specific to faecal material. *Enterobacter* (*Aerobacter*) *aerogenes* and *Enterobacter cloacae* are frequently found on various types of vegetation in soil and in polluted water. All of these coliforms group, may be found in sewage and in polluted water environment (Edeberg *et al,* 1990). The value of selected indicators for assessment of faecal pollution as well as the distinction of faecal pollution of human and animal origin has been investigated (Jagals *et al,* 1995).

Several Studies for the survival of faecal coliforms are numerous (Dawe & Penrose, 1978 and LaBelle *et al*, 1980). Most investigations have involved either soil or marine environments and have concentrated only on reduction in bacterial numbers over time. Studies in recent years have frequently revealed much higher numbers of indicator and pathogenic bacteria in sediments than in overlying waters. Apparently, higher concentrations of indicator and pathogenic bacteria in the sediments are due to a combination of sedimentation, sorption (which provides protection from bacteriophage and microbial toxicants (Weiss, 1951 and Roper& Marshall, 1978), and the phenomenon of extended survival in sediments (Goyal and Adams, 1984). The water quality testing criteria in use at present do not take into account sediments as a potential reservoir of pathogens. The higher numbers of pathogens occurring in sediments, along with increasing usage of recreational waters, creates a potential health hazard from resuspension and subsequent ingestion (Matson *et al*, 1978 and Grimes, 1980). Thus, there is a need to obtain additional information on the survival of indicator and pathogenic bacteria in sediments and the factors which contribute to their survival.

Enterococci have also been related to human disease becoming firmly established as major nosocomial pathogens (McDonald *et al*, 1997). In addition, *Enterococcus* and *Streptococcus* have been proposed as indicators of faecal contamination in water because of their high abundance in feces and their long survival in the environment. Although the ratio of faecal coliforms to faecal streptococci have been ruled out as indicator (Pourcher *et al*, 1991 & Olajide, 2010). With respect to the relative proportions of faecal coliforms and faecal streptococci, faecal streptococci species profiles whether these characteristics can be used to distinguish between human and animal effluent (Sinton and Donnison, 1994).

The presence of *Pseudomonas aeruginosa* in water indicates that the source has become polluted either by organic material or contamination. De Victorica and Galvan (2001) reported that *Pseudomonas aeruginosa* is used as indicator of health risk association with drinking water.

Pseudomonas aeruginosa is considered as opportunistic bacteria expresses virulence factors which are related to serious infections in human especially in immuno-compromised individuals and special precautions may be required to limit the exposure of these susceptible populations (Warburton 2000). It is also, widespread in natural and industrial environments and is able to grow in water (Leclerc and Da Costa, 1998).

Staphylococci have been recently investigated as possible indicator for pollution of swimming pool waters and other aquatic environment (De Araujo *et al*, 1990 and WHO, 2003). Because the staphylococci had a higher resistance to the chlorine level in pool waters than coliforms and streptococci, they were isolated when coliforms and streptococci were absent (Favero *et al*, 1964 and Antai, 1987).

The enumeration of either total staphylococci or specific *Staphylococcus aureus* appears to provide a useful index for the water quality level of the aquatic sources. Staphylococci are salt tolerant which survive in the marine environment (Gabutti *et al*, 2000 and Kamel, 2005).

Salmonellae grow at temperatures ranging from 7 to 48°C, at pH 4–8, and at water activities above 0.93 (Baird-Parker 1990). Salmonellae are capable of prolonged survival in faecal materials, in slurry, or on pasture (Wray & Sotka, 1977). The fact that salmonellae are able to survive and readily multiply in the environment is an important factor in the transmission and spread of salmonellosis. Examples quoted by Williams (1984) illustrate this: salmonellae will live for 28 months in naturally infected avian faeces; *S. heidelberg* was recovered from contaminated poultry litter, grit, feed, and dust held for extended periods at room temperature (the poultry litter was positive at 7 months); *S. thompson* survived 4–5 weeks in old poultry litter and 8–20 weeks in new litter; and *S. typhimurium* survived in urban garden soil in England for at least 280 days (WHO, 2003).

The specific objectives of this study are to describe the relative association of classical bacterial indicators as well as some pathogenic bacteria in Lake water samples during winter 2010 at Wadi El-Natron, Egypt and in lagoons for growing cyanobacteria and fish.

2. Materials and methods

Sample collection. Lake water samples were collected monthly during winter season 2010, from El-Khadra lake at Wadi El-Natron, Egypt. Water samples were collected in 1 liter sterile glass bottles and then transferred from the sites to the lab in ice box. Water sampling was taken at 0, 30 and 100 cm deep from El-Khadra lake. Water samples were taken also from cyanobacteria lagoon and fish lagoon to assess the pollution load.

Microbial load of water samples

Collected water samples were analyzed for total viable microbial count and total count of different bacterial indicators using the poured plates and the most probable number (MPN) technique, respectively.

Poured plates technique (APHA, 2005).

Method for decimal dilution of water samples was used for determination of total bacterial load, on nutrient agar (APHA, 2005). The plates were incubated for 1-2 days for fast growing bacteria at 37°C and 2-3 days at 22°C for characteristic water bacteria (APHA, 2005).

The most probable number technique [MPN] (APHA, 2005).

The most probable number technique was carried out for estimation of some microbial indicators in the tested water samples using special presumptive and confirmed tests for each indicator. During presumptive test, 5ml of each appropriate three decimal dilutions of raw water samples were used to inoculate five tubes (20 x 1.5cm^2) each containing 5ml of proper medium (single strength), and the tubes were incubated at 37°C for 48 hours. The positive presumptive tubes were used to inoculate the confirmed test which detected the bacterial indicators as following:-

- Total coliform; Lauryl tryptose broth medium was used for presumptive test. The positive tubes which showed gas and acid were used to inoculate brilliant

green lactose bile broth medium (BGB), as a confirmed test. The production of gas and acid was recorded as positive confirmed test for total coliforms (APHA, 2005).

- Faecal coliform estimation was carried out by inoculation in the EC broth tubes from positive BGB broth medium tubes, then incubated at 44.5°C for 24 hours (APHA, 2005). The positive tubes containing gas production were used to detect the count per 100 ml sample (MPN index / 100ml) and streak the eosin methylen blue agar medium (EMB) plates, then incubated at 37°C for 24 hours. Metallic sheen colonies considered as a positive confirmed results for *E. coli* presence (APHA 2005).
- Faecal streptococci; Azide dextrose broth was used as presumptive test without fermentation tubes. The positive tubes were turbid, (APHA, 2005), then used to inoculate ethyl violt azide broth medium, (EVA) as a confirmed test. The positive results were turbid after incubation at 37°C for 48 hours (Gerhardt, *et al*, 1981). The positive tubes were used for the confirmed test which detected by streaking on m-Enterococci medium (APHA, 2005).

Salmonellae groups was counted from inoculated buffer peptone water (British Standard Institute, 2002) tubes (incubated at 37°C for 24 hours) which used as MPN technique (Morinigo *et al*, 1992). One loop from these tubes were streaked on the plates of bismuth sulphate agar as a confirmed test. After incubation at 37°C for 48 hours, typical black colonies with or without metallic sheen and blackening extended beyond the colonies considered as confirmed positive results for the presence of salmonellae.

Staphylococcus sp was determined by streaking one loop from buffer peptone water tubes on the surface of mannitol salt agar plates, then incubated at 37°C for 24 hours. The growing colonies had yellow zones, flat and 1.2 mm diameters (APHA, 2005).

Pseudomonas sp. was detected in the lake water samples using asparagine broth medium as a presumptive test. The positive tubes produced a greenish fluorescent color after exposing to long-wave ultraviolet light were used to streak the surface of acetamide agar slants as confirmed test. a positive confirmed tubes with the purple color indicated high pH value after incubation at 37°C for 24 hours (APHA,2005).

3. Results and Discussion

The bacteriological quality of the collected water samples was evaluated by monitoring of the total bacterial counts, fecal bacterial indicators and some pathogenic bacteria in five different water body sites at Wadi El-Natron, Egypt.

The results in table (1) show that; generally the high log average counts of total viable bacterial counts were increased at 37°C and 22°C in water samples taken at 100 cm depth of the lake than that at 0 and 30 cm depth. Whereas, the high log average counts recorded 6.47 cfu at 22°C the low log average was 2.9 cfu at 37°C / 100ml in the water samples taken at 100 cm. These results agree with Mansour and Sidky, (2003) where they found total viable bacterial counts in Qarun lake water samples and Rayan lake water $5.8x10^6$ and $8.1x10^5$ respectively. Also Ali, *et. al.* (2008) counted average of the total bacteria at 37°C and they found that the counts reached 2.1 x 10^6/ 100ml in lake water sample. This may be due to the effect the sunlight (UV ray), organic substances, biological activity and sedimentation (Olayemi, 1993). Phillip *et al*, (1988) suggest that the decline in lake water of bacteria that are resistant to starvation may be a result of protozoan grazing and that the extent of growth of introduced species may be limited by the supply of available carbon and sometimes of nitrogen and phosphorus, and by predation by indigenous protozoa. In addition, Olayemi (1993) found that sun light was shown to cause sublethel injury to some bacteria from10^5 to 10 for *St. bovis* and 10^6 to10^5 for *E.coli* 1n 14 days. On the other hand, he noticed more decrease in the counts of these bacteria with exposure to UV irradiation from 10^5 to 10^2 and from 10^4 to not detected for *St. bovis* and *E.coli* respectively.

In 100 cm deep water samples of this lake the faecal streptococci were recorded log average 1.43 cfu / 100ml, while it was absent in the surface (0 cm) and sub-surface (30 cm) water samples. On the other hand, total coliforms were detected, with the high and low log average count 1.57 and 1.3 cfu / 100ml respectively. Moreover, faecal coliforms was present in surface and sub-surface water samples while they were absent in the bottom water samples. The average log numbers of fecal coliforms was 0.43 cfu / 100ml, these results conflicted with U.S. Environmental Protection Agency (2003). Ola et al, (2006) confirmed our investigation where they found that *E. coli* levels in three sites out of studied 11 sites of Michigan lake shore was less than the recommended U.S. Environmental Protection Agency (2003) limits, 235 cfu/100 ml while the others ranging from 0 to 6,900 cfu/100 ml. in addition, the authors suggested that *E. coli* and enterococci survival and growth in the direct sun light. Moreover, the ability of *E. coli* to survive for several days in aquatic sediment in situ suggests that faecal coliforms in water may not always indicate recent faecal contamination of that water but rather reuses pension

of viable sediment-bound bacteria Lalibertet and Grimes, (1982).

Table (2) shows the counts of all types of bacteria tested and it shows that the bacteria were excesses in water samples which collected from cyanobacteria and fish lagoons than lake in water samples. The bacterial count log average in water samples from cyanobacteria lagoon at 22°C, 37°C showed that total coliforms, fecal coliforms and fecal streptococci were 7.37, 7.5, 3.3, 2.13 and 2.13 / 100ml respectively. With regarded to the water samples collected from fish lagoon recorded 4.47, 4.3, 1.97, 1.13 and 1.43 cfu / 100ml for total bacterial counts at 22°C, 37°C, total coliforms, fecal coliforms and fecal streptococci respectively.

Table (1): The average log of the viable count of the total bacterial load as well as classical bacterial indicators in the tested water samples during winter season of 2010 at El-Khadra Lake, Wadi El-Natron, Egypt.

**Site of water samples	Date	Samples number	Log number of colony forming unit (cfu) / 100 ml				
			Total bacterial count at:-		Bacterial indicators *(MPN-index)

Note:
* TC: Total coliforms FC: Faecal coliforms FS: Faecal streptococci

Table (2): The average log off the viable count of the total bacterial load in water of El-Khadra Lake at Wadi El-Natroun, Egypt used in growing cyanobacteria and fish outside the water body of the lagoon.

Site of water samples	Date	Samples number	Log number of colony forming unit (cfu) / 100 ml				
			Total bacterial count at:-		Bacterial indicators (MPN-index)		
			22 °C	37 °C	TC	FC	FS
Cyanobacteria lagoon	12/1/2010	1	7.1	7.5	3.5	2.2	2.1
	9/2/2010	2	7.4	7.3	3.2	2.1	2.2
	9/3/2010	3	7.6	7.7	3.2	2.1	2.1
		Average	7.37	7.5	3.3	2.13	2.13
Fish lagoon	12/1/2010	1	4.3	4.7	1.7	0	1.3
	9/2/2010	2	4.5	4.8	2.1	1.7	1.3
	9/3/2010	3	4.6	4.5	2.1	1.7	1.7
		Average	4.47	4.3	1.97	1.13	1.43

This phenomenon may be due to the nutrients availability for growth of the bacteria. Niemi and Niemi (1991) and Putheti & Leburu (2009) reported that domestic and industrial wastewater, agriculture waste environment are sources of faecal bacterial to rivers. In these lagoons the water was found to be contaminated with pathogenic microorganisms, some of which originate

from animal wastes (Ho & Tam, 1998). Contamination of water sources by wastewater can pose a health risk due to the presence of pathogenic microorganism agents in water used for recreation, drinking and fishing Olajide, (2010). In Uruguay (Laguna de Rocha) piccini (2006) found that bacterial counts (4.3 x 10^5cfu / ml) were higher average three times in the brackish southern part of the lagoon than the freshwater, in addition they suggested that this may be a consequence of better growth conditions. Moreover, they reported that the lagoon receives domestic waste from a small town through its main tributary

Table (3) demonstrates the occurrence of some pathogenic bacteria (Salmonellae groups, *Staphylococcus sp.* and *Pseudomonas sp.*) in lake water samples [except at 100 cm depth of the lake for *Pseudomonas sp* and Salmonellae groups in fish lagoon water samples (table 4)]. The water samples from the lake water showed that Salmonellae groups were decreased and the log average count recorded 2.37, 2.17 and 1.57 cfu / 100ml for the surface, the surface, sub-surface and the bottom respectively.

Table (4) shows the occurrence of the same pathogenic group in the lake water transported to special tanks to grow cyanobacteria and fish. Nearly the log counts of Salmonellae groups were stable in all water samples collected from cyanobacteria lagoon while absent in fish lagoon. The log average counts of *Staphylococcus sp* were 1.7 / 100ml in cyanobacteria lagoon. Pe´rez *et al,* (2004) reported that protozoa can be grazing bacteria where they found to reduce the survival of another pathogenic bacterium, *Vibrio cholerae*, in brackish waters (Christoffersen, 2004).

Table (3): The log average viable count of some pathogenic bacteria in lake water samples during winter 2010 at Wadi El-Natron, Egypt.

* Site of water samples	Samples number	Date	Number of cell forming unit (cfu) / 100 ml		
			Salmonellae group	Total staphylococci	*Psudomonas spp.*
Surface lake	1	12/1/2010	2.3	4.4	2.4
	2	9/2/2010	2.6	4.1	1.9
	3	9/3/2010	2.2	4.6	2.6
	Average		2.37	4.37	2.3
Sub-surface lake (30 cm)	1	12/1/2010	2.1	4.6	1.3
	2	9/2/2010	2.2	4.5	1.7
	3	9/3/2010	2.2	4.4	1.3
	Average		2.17	4.5	1.43
One meter depth	1	12/1/2010	1.3	4.5	0
	2	9/2/2010	1.7	4.5	0
	3	9/3/2010	1.7	5.1	0
	Average		1.57	4.7	0

The results show that *Pseudomonas sp.* were absent in one meter deep of lake water samples while detected in others. This may be due to the competition between the microbes in aquatic environmente. Schallenberg *et al,* (2005) demonstrated that *Daphnia carinata* (40 cell /liter) were grazing type bacteria (*Campylobacter jejuni*) where it declined 2 orders (from 10^7 to 10^5/ ml) of magnitude in day.

The log counts of Salmonellae groups were stable in all water samples collected from cyanobacteria lagoon while decline in fish lagoon. These results conflict those of Khatun1, et al 2007, who found the Salmonellae groups (in the average of 3.3 x 10^6 cfu / 100ml.) in swamp water sample used in growing the fish during November 2001 to October 2002. On the other hand, these results agree with those of Sangu, et al (1985) who reported that the total population of bacterial species specially *Escherichia coli, Aerobacter aerogenes, Staphylococcus aureus*, *Pseudomonas sp.* and *Micrococcus sp*. were considerably high in Keetham Lake (India) water sample.

In this investigation, the count log average of *Pseudomonas* sp. Recorded high values being 3.6/100ml in water samples collected from fish lagoon (table 4). On the other hand, the results show the log counts of *Staphylococcus* sp. were from 1.7 to 4.7/100ml which detected in water samples from cyanobacteria lagoon and one meter deep of the lake (table 3&4).

The *Pseudomonas sp.* Were absent in one meter deep of lake water samples while detected in others (table 3). These results agree with Ahmed and Naim, (2006) where they found that *Flavobacterium* sp., *Micrococcus* sp., *Streptococcus* sp., *Burkholderia*

glumae and *Pasteurella* sp. were present in some seasons of the year as well as *Pseudomonas fluorescens* and *Salmonella* sp. were present only in winter, whereas *Pasteurella pneumotropica* was found only in summer. In addition, results agree with Naim and Ahmed, (2004) where they found that. *Flavobacterium* sp. and *Pseudomonas* spp. were dominant only in the winter. This may be due to ambient seasonal temperature variation could account for some of the bacterial population variation.

The counts and the type of bacteria in the fish lagoon indicated special variation which might be due to the intestinal flora of fish is characterized by both the day-to-day and individual-to-individual variations (Sugita, 1990).

It is necessary to assess the microbial pollution load which is likely related to the chemical composition of the water in lake throughout the seasonal variations to which the lake water is exposed. This particularly important when the lake water is used for production of special biomaterials for potential commercial uses.

Table (4): The log average viable count of some pathogenic bacteria in water of El-Khadra Lake at Wadi El-Natron, Egypt used in growing cyanobacteria and fish outside the water body of the lagoon.

Site of water samples	Samples number	Date	Number of cell forming unit (cfu) / 100 ml		
			Salmonellae group	Salmonellae group	Salmonellae group
Cyanobacteria lagoon	1	12/1/2010	1.3	1.7	3.1
	2	9/2/2010	1.3	1.3	1.9
	3	9/3/2010	1.3	2.1	2.2
	Average		1.3	1.7	2.4
Fish lagoon	1	12/1/2010	0	4.1	3.2
	2	9/2/2010	0	4.2	3.5
	3	9/3/2010	0	4.4	4.1
	Average		0	4.23	3.6

Effect of Different Rates of Cobalt on some Macro-Micronutrients and Heavy Metals Contents in Lettuce under Different Types of Recently Reclamation Soils

Abdel Fattah. M. S and Khaled. S.M.

Plant Nutrition Dept. National Research centre-Cairo, Egypt.

Abstract: The main objective of this research work is to assess the influence of cobalt element addition on the uptake of some macronutrients (N, P and K) and some heavy metals (Cd, Ni and pb) in two different reclaimed soils. The first soil was sandy from (Abu- Rwash) region, the second soil was calcareous from (El Noboria) region. Cobalt was added with different rates (10, 15 and 20) ppm after plantation stage. Nitrogen was added by rate 100 ppm N at form amonium nitrate NH_4NO_3. Moreover, Dihydrogen potassium phosphate H_2KPO_4 at rate 200 ppm as source of phosphours and potassium was added at the same time. Lettuce plant of class (lactuca sativa var capitata). The obtained results can be summarized as follows: In sandy soil a positive connection between rates of cobalt and (N,P,K) contents, negative contact was found between cobalt concentrations and heavy metals contents (Cd, Ni, pb). Dry weight gave a positive contact with cobalt treatments, all differences were significantly to each of chlorophyll concentration and all trace elements contents except Mn were a positive relationship with cobalt treatments. All differences between treatments were significantly. In calcareous soil negative contact was found between rates of cobalt and nitrogen, while potassium a positive contact was found with phosphorus, concerning the heavy metals (Cd, Ni, pb) contents, positive contact was found with rates of cobalt. All this connections were significantly. Dry weight gave a negative connection with cobalt treatments but not significantly. Chlorophyll concentration and trace elements contents were in a positive relationship with cobalt treatments. All differences between treatments were significantly. Dry weight gave a negative connection with cobalt treatments but notsignificantly. Chlorophyll concentration and trace elements contents were in a positive relationship with cobalt treatments. All differences between treatments were significantly.

Key words: Cobalt – lettuce plant – Sandy- Calcareous soil- Macronutrients – Heavy metals – Trace elements - Chlorophyll- Dry weight.

1. Introduction:

The need to determine the best practices for land use in regions with rigorous climates makes it necessary to recognize that any type of human use of land involves a chang in the natural ecosystems or their replacement by different artifical biological systems. The basis of decision making with respect to land use should be to maintain control of the anticipated transformation and to apply ecologicl principles so that the adverse effects on the environment will be minimum despite of introduction of permanent human use of the land resource.

The modern ecological term "ecosystem" describe show the biological community, functions as unit with extremely complex interactions. When crop growing and livestock raising are introduced and developed into highly specialized forms of land use, biological systems are created which differ greatly from natural ecosystems.

Nutrient availability in the soil differs in many aspects. Factors of major importance for the mineral nutrition of plants are root induced changes in rhizosphere, pH and amount and composition of root exudates (Uren and Reiseauer, 1988). The proximity, extent, and pattern of contact between soil and root are important factors in the absorption of heavy metals which are tightly bound to the soil colloids (Merckx et al., 1986). Many investigators reported a relationship between solubility of heavy metals in soil and soil pH. It is well established that concentration of most of heavy metals increases to various degree with the decrease in soil pH (smis, 1986 and förstner, 1988). Root – induced changes in the rhizosphere are important factors for the metal dynamics in this zone. However, little attention has been paid to the extent to which plant roots effect the ability and distribution of heavy metals (CO) in the vicinity of the roots.

In this work, it was found that applied Co at a different rate on some mineral and heavy metals contents in lettuce plant in different reclamation soils (sandy and calcareous).

2. Materials and methods

A pot experiment was conducted to study the availability of some macronutrients namely, nitrogen, phosphorus and potassium and some heavy metals as cadmium, nickel and lead contents in lettuce plants of class (lactuca sativa var capitata) as affected by the addition of cobalt element at different rates (10, 15 and 20) Ug/g soil and two different types of reclamation soils, sandy soil of (Abu-Rawash region) and calcareous soil (El Nobaria region). Table (1) indicat to some physical and chemical properties. Pot contents as 5 kg soil. Nitrogen was added at form ammonium nitrate NH_4No_3 at a rate 100ppm nitrogen, dihydrogen potassium phosphate H_2Kpo_4 as sources potassium and phosphours by rate 200 ppm was added.

All the fertilizers were added at one dose after plantation stage.

Three levels of cobalt were added as $CoSo_4.7H_2O$ at (10,15 and 20) ppm, urifornly mixed with soil. The moisture content of the pot was maintained at 80% of the water holding capacity along tim of the experiment. Plants were harvested on 50 day.

Plant samples were reweighed and dried to constant weight at 80°C in a ventilated oven. Dried samples material were analysed for total nitrogen a chieved determined by distillation using microkjeldahel distillation (Jackson 1985). Phosphours, potassium, heavy metals (Cd, Ni, pb) and tracelements as according (Jackson 1985) .

Chlorophyll concentration in the fresh leaf was determined according to (licheloem and weil burn, 1983).

Table (1): Som physcial and chemical properties of the studied soils

Site	Texture	pH 1:2.5	EC Dsm⁻¹ 1:5	Cations meq/L				Ppm	Anions meq/l			%	Heavy metalsmg μ g/g	Cations meq/L

3. Results and Discussion

Sandy Soil:

The data presented in table (2) reveal that some macronutrients (N,p and k) contents in lettuce plant in different types of reclamation soils as affected by different rates of cobalt (10,15 and 20) ppm. N,P and K percentages contents in sandy soil was in positive relations with rates of cabalt as cobalt concentration increasing follow up (N,P,K) percentages contents in lettuce plant increased. Head values of (N,P,K) registered with rate of cobalt 20 ppm while among value came with rate of cobalt 15 ppm, the least values of (N,P,K) with cobalt concentration 10 ppm. Cobalt maybe enhance to rise representation of nutrients to plant as it important role in constitution of Co-enzymes and some hormons. (Youssef 1997).

It has been reported that cobalt increased the total dry matter and yield of pigeon pea and peanut (shehata 1989) found that cobalt significantly increased the percentage of stomatal closure and increase dramatically ABA which play a central role in some hormon of iso plant. (Anter and nadia 1999). Revealed that cobalt applicat ion[reduced transpi-ration rate and leaf water potential specially at low cobalt concentrations Abscisic Acid in contrary to both Auxine and Gibberelins was promotively affected by cobolt application. Root xylem and phloem were beneficially affected by cobalt specially at water deficit condition. Of what previously mention show that cobalt stimulate to the nutrients plant uptake.

Table (2): Macronutrients contents as percentage (%) in lettuce plant as affected by different rates of cobalt and soil types.

Cobalt treatment (ppm)	Sandy soil		
	N	P	K
Control	2.52	0.79	0.16
10	2.11	0.31	0.18
15	2.80	0.46	0.19
20	3.64	0.65	0.21
L.S.D 0.05	0.23	0.028	0.017
Calcareous soil			
Control	2.24	0.69	0.22
10	4.85	0.79	0.22
15	4.09	0.91	0.14
20	2.67	1.19	0.11
L.S.D 0.05	0.32	0.062	0.013

Calcareous soil:

Table (2) Concerning calcareous soil as lettuce plant uptake some macronutrients (N, P and K) as affected by different rates of cobalt show that a negative relation between (N,K) uptake and cobalt concentrations as increasing of cobalt rates decrease of (N, K) content in lettuce plant.

Head values of nitrogen and potassium (N and K) uptake were with cobalt rate 10 ppm and among values with 15 ppm, the least values of (N and K) content with 20ppm of cobalt rate, may be due to some properties of the studied calcareous soil such as rising of calcium carbonate rate thus rising rate of sodium cations and soil pH this is to lead to little of exchangeable sites. All differences between the treatments were significantly.

Phasphorus contents was in a positive relation with cobalt rates as it increasing phosphorus contents increase. Head value of P contents with 20 ppm of cobalt rate, among value with 15 ppm and the least value of P contents with 10 ppm of cobalt rate, it seems that the cobalt element stimulation to phosphorus uptake despite the phosphorus problems in calcareous soils such as the fixation it to make at form unavailable. All differences between the treatments were significantly (youssef et al 2001) show that cobalt addition by rate 40 ppm to cause decreasing soil pH almost 2 units in the rhizosphere compared to that of bulk soil, due to soluble and available phosphours increased in calcareous soil.

Date in table (3) showed that some heavy metals content (Cd, Ni and pb) in lettuce plant as affected by different rates addition of cobalt (10, 15 and 20) ppm and soil types (sandy and calcareous).

Sandy soil:

The data presented in table (3) reveal that entity negative relation between cobalt rates and (Cd, Ni and pb) content , head values of heavy metals were with rate of cobalt 10 then 15 ppm differences between them were slightly can be negligible.

The least values of heavy metals content with 20 ppm of cobalt rate. That's meaning , cobalt inhibition effect on heavy metals content especially with the rising of cobalt rates in sandy soil.

(Zhang, M; and zixia, ke 2009) showed that in the polluted soils by heavy metals may be enhance entity of cobalt element with the fertilization in the little levels of heavy metals contents.

Calcareous soil:

Head values of some heavy metals (Cd, Ni, pb) were with 20 ppm of cobalt rate, among values with 15 ppm of cobalt concentration, the least values was with 10 ppm of cobalt rate.

This results meaning entity positive contact between cobalt rates and heavy metals content in lettuce plant. May be due to properties of calcareous soils such rise of soil pH, calcium carbonate highly rate and sodium cations rising concentration in soil studied. All the differences between the treatments were significantly.

Table (3): Heavy metals contents in lettuce plant (ppm) as affected by different rates of cobalt and soil type.

Sandy soil:

Data in table (4) shows that a positive contact between for each iron, manganese zinc and cobalt in lettuce plant uptake and dry weight (gm) where as its increased with increasing of this micronutrients with increasing of cobalt treatments in a sandy soil where Fe uptake with a rate comparison with control (48, 106 and 153) % with cobalt treatments increasing respectively. May be cobalt nutrient stimulate Fe, zin and co.

Behavior Mn was in contrary relation with dry weight to lettuce plant. May be Mn at form unavailable for uptake in sandy soil or it competition with Fe on granulars surface in sandy soil where, as a little surface specific specially.

Chlorophylle concentration to be have same of relationships with cobalt treatments and it gave similar results with (Fe, Mn, Zn and Co) contents in lettuce plant. My be that find a positive effect between dry weight and chlorophylle concentration in lettuce plant.

Calcareous soil:

It was found opposite contact between cobalt treatments and dry weight but the differences were negligible may be cause soil pH rising which due to limited hinder to cobalt available. Positive contact between cobalt treatments and all nutrients conten in lettuce plant under study (Fe, Mn, Zn and Co, all the differences between nutrients content and cobalt tseatments were significantly, where that (Fe) absorption percentage comparison control (82, 78, 123) % respectively.

Chlorophyll concentration in lettuce plant was at a positive contact with cobalt treatments where as percentage comparison control (103, 194, 278) respectively.May be due to increasing of (Fe) in plant.

(Perez, et al, 2008) revealed that cobalt remarkably increased fresh and dry weight, of shoots and roots. The amounts of dry matter of tomato plants were the highest when Co was spotted in 1mm compartment compared with that of other soil compartments. The influence of Co placements on plant growth was most pronounced in roots than shoots. It has been reported that low concentration of Co had favorable effect on plant growth.(Takahashi and satio, 2007) found that the trace elements were increased under cobalt treatments wich to follow increasing chlorophyll concentration in tomato plant (Sposito, 2003) got a general conclusion that activities of the micromutrients in solution rather than concentrations per shops would be more meaning ful.

In this study.

The reduction in trace elements extractability was accompanied by Co placements.

4. Summary and Conclusion:

In sandy soil cobalt treatments gave a positive effect with most of the previously results at all cobalt concentrations, therefore were recommended to using it with example this soils.

In Calcareous soil cobalt element gave a negative effect with high concentrations, while it gave a positive effect with low concentrations, therefore were recommended to using it where not more cobalt concentration of (10 ppm) in example this soils.

Abstract: Stability analysis was carried out for six traits in snakecucumber by growing 5 genotypes (1,2,3,4,5) collected from different regions of Egypt (Assiut,Ismialia, El-kalyoubia, Domiat and Fayoom) respectively, in 3 years at El-kassaseen region, Ismailia. Genotypes × environment interaction was significant for all studied traits; the linear component of genotype × environment interaction was significant for number of fruits plant, yield / Fadden and fruit shape index. Environments (linear) were significant for yield / plant, yield / Fadden, fruit diameter and fruit shape index . The linear regression on environmental means (bi) close to unite with significant for genotypes (2,3,5,) for number of fruits / plant and (3,4,5,) for fruit diameter . Broad sense heritability was high for number of fruits / plant, yield / plant, fruit length and fruit shape index, but it was moderate for yield / Fadden and fruit diameter. The figure genotypes showed different patterns in presence of bands, the maximum number of band (6) in genotype (2) and the minimum number (3) was present in genotype (6), there are non resemblance between any genotypes, each genotype was characterized by a unique Finger print, except genotype (2) was monomorphic .

Keywords: Phenotypic Stability; Analysis; Heritability; Protein; snake; Cucumber; Genotype

1. Introduction:

Snakecucumber (Cucumis melo var.flexuosus Naud.) belongs to cucurbits family, preferred to the consumer, it is rich in A, B and C vitamins and contents of iron, calcium, phosphors and zink elements, moreover, it has medical benefits. In spite of, it does not exist on the agriculture map of Ismailia, as other members of its family (melon, squash, watermelon, cucumber). Snakecucumber can be a replacing option for cucumber; its cultivation has been reduced significantly in the late summer season and has been planted under plastic tunnels in the November month or under a greenhouse. The study aimed at the introduction of snakecucumber variety grown in Ismailia, with choice of the most suitable ways to improving of the important snakecucumber genetic traits under conditions of the region. Rare researches on snakecucumber breeding were done if compared with melon. Stability parameters for yield components were described by Gill and Kumar (1989) on watermelon, Yhia (1999) evaluated some of snakecucumber ecotypes for three years under Assiut conditions. Parmer and Lal (2005) and Singh and Lal (2005) studied the genetic variability and heritability for yield traits on muskmelon.

2. Materials and methods

Five genotypes of snake cucumber were collected from different regions of Egypt (Table.1).

Table 1: Serial number of genotypes and its sources

Sources	Serial number of genotypes
Assiut	**1**
Ismailia	**2**
Kalyoubia	**3**
Domiat	**4**
Fayoom	**5**

The genotypes were tested at El –Kasaseen research station, Ismailia, during summer seasons of 2005, 2006 and 2007 using a complete randomized block design with 3 replications . Each experimental plot was 15 m long, 150 cm wide and 50 cm a part between hills, all agricultural practices were carried out, by equal and optimum quantities to each plant. Observations were recorded for number of fruits / plant, yield / plant, yield /Fadden, fruit length, fruit diameter and fruit shape index. Stability analysis was carried out following Eberhart and Russell (1966). Heritability in the broad sense was estimated for the former traits, as illustrated by Collins et.al. (1987) according to the following formula,

$H\% = \delta^2 g / (\delta^2 g + \delta^2 m) \times 100$

Coefficient of variability values were estimated depends on phenotypic (P.C.V) and genotypic (G.C.V) variances using the next equations:

$$P.C.V = \sqrt{Vph / \bar{x}} \times 100$$

$$G.C.V = \sqrt{Vg / \bar{x}} \times 100$$

Whereas $\sqrt{Vph}$ = Phenotypic standard deviation.

$\sqrt{Vg}$ = Genotypic standard deviation.

$\bar{x}$ = Genotypes means.

Electrophoresis studies:

Protein electrophoresis

This investigation was carried out at the laboratory of Genetic Department, National Research center. Sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE) was performed according the method of Leammli (1970). After being modified by Studier (1973) the youngest fully expanded leaf samples were taken from each of the four genotypes, (2) Ismailia, (3) Kalyoubia, (4) Domiat and (5) Fayoom. Samples of 0.5 gram of each genotype with 5 ml. of buffer was homogenized, then they centrifuged for 15 minutes at 15000 rpm. Supernatants containing water soluble protein to eppindorf tubes. Incubation and agitation were carried out at room temperature until bands appeared in clear background then the gel was washed with distilled water then gel was photographed Yamamato *et.al* (1982) .

3. Results and Discussion

Differences among genotypes were significant for all the traits, except fruit diameter, indicating the presence of considerable genotypic variation in the germplasm material for these traits (Table 1). The significant mean squares due to environment (years) for all traits suggested that environment (years) considerably influenced on the genotypic performance. The interactions between genotypes and environments for all traits were significant indicating that genotypes behaved differently under different years, this result was in accordance with Gill and Kumar (1989), with respect to yield/plant and number of fruits/plant. Significant mean square due to environments (linear) for yield/plant, yield/Fadden, fruit diameter and fruit shape index indicating the differences between 3 years (environment) and their considerable influence on these traits. The higher linear component of G × E than non-linear component for number of fruits/plant indicates the possibility of production of genotypes in different environments, the mean square due to environment +(G × E)was significant for number of fruits/plant, fruit diameter and fruit shape index. It shows that there was considerable interaction of genotypes with environmental condition in different years. The regression analysis (Table 3)shows that genotypes (2,3,5) had high mean performance for number of fruits/plant with significant regression close to unity (b=1.2,1.4,1.4 respectively), indicating their suitability for all environments. The relatively high values of regression coefficients in genotype 2 (b=3.7) and genotype 4 (b=4.04) with high mean performance for yield/Fadden, reflected the suitability of these genotypes to favorable conditions, like high fertility, timely sowing and good management practices. The S2di values were significant for all genotypes classifying them as unstable for yield/plant, genotype 5 has highest yield/Fadden (8.0 tones) and its bi value is less than 1.0 (b=0.59), revealing its adaptability to unfavorable or poor environmental and management condition. The crooking of snakecucumber fruits that is caused by their excessive length is causing marketing problems. Consequently, that gives importance to the studding of fruit length, diameter and shape index traits. All genotypes under studying were selected on the basis of moderate length. The genotype 4 gives a regularity performance for fruit length, diameter and shape index traits with regression close to unity (b=1.05, 1.1 and 0.99 respectively) and least deviation from regression S2di. The genotypes 2 and 4 could be considered most stable for yield/Fadden; also these genotypes have high yield/Fadden (7.9 and 7.5 tones, respectively). As reported by Perkins and Jinks (1968) and Finlay (1971) the stability like any other character is a heritable trait, thus these two genotypes can be judiciously used in snakecucumber breeding programs as a source of genes for stability and high productivity.

The values of genotypic, phenotypic and error variance, heritability, genotypic (G.C.V) and phenotypic (P.C.V) coefficients of variation are presented in Table (4). For all the studied traits, the genotypic and phenotypic estimated variance appeared large, in comparison with the estimated values of error variance, such a result seemed to indicate that the number of replicates used in the evaluation experiment of these genotypes were adequate to give a better estimation for the error variance. Heritability percentage in the broad sense was found moderate values for number of fruits/plant, yield/Fadden and fruit diameter as appears in Table (3). Accordingly, it might be stated that phenotypic selection for these traits would be reasonably effective. The higher estimated heritability values for yield/plant, fruit length and fruit shape index indicating that phenotypic selection for these traits could be highly efficient. These results were in harmony with those obtained by Parmar and Lal (2005) and Singh and Lal (2005).

The estimations of genotypic (G.C.V) and phenotypic (P.C.V) coefficients of variation exhibited small differences between genotypic and phenotypic coefficient of variation for yield/plant, fruit length and fruit shape index, revealing that environmental effects

were not great importance on these traits. These results were assured by heritability values

Protein electrophoresis:

The four genotypes showed different patterns in presence of bands (Fig 1 and Table 5), the maximum number of band (6) in(Ismailia 2) and the minimum number (3) was present in (Fayoom5)and (Kalyoubia). However, there are non resemblance between any genotypes each genotype was characterized by a unique fingerprint except for genotype (Ismailia2) was monomorphic. At the same time there was a marker band (5) for some genotypes such as band 2 at 49 KD for genotype (Fayoom 5), band 5 at M.W 39 KD for genotype (Domiat4). These results were in agreement with Jurgen and Helmut (1978) who confirmed that SDS- protein page was a highly successful technique in genotype identification Staub *et al*. (1983) reported that electrophresis employed as enzymatic for studying breeding material in the genus and taxonomy of cucumber.In relation to number and intensity of bands, genotypes (Ismailia 2) and (Domiat4) had the same number groups of bands with more intensity than other genotypes (Kalyoubia 3 and Fayoom 5).From the previous results, it could be deduced that the variation in banding patterns between four genotypes; showed different behavior for genotypes under Ismailia conditions, whereas genotypes (Ismailia 2 and Domiat 4) were more adaptation, and confirm that these four genotypes are genotipically and evolutionary different.

Bio-removal of nitrogen from wastewaters-A review

Gaber Z. Breisha[1], Josef Winter[2]

[1.] Department of Agricultural Microbiology, Faculty of Agriculture, Minia University, Minia, Egypt
[2.] Institut für Ingenieurbiologie und Biotechnologie des Abwasser, Universität Karlsruhe, Germany
gaberbresha@yahoo.com, Josef.Winter@iba.uka.de

Abstract: If the present large volumes of nitrogen-containing wastewater of domestic and industrial origin are discharged into the environment without proper treatment, they lead to extensive soil and water pollution. Proper elimination of pollutants from these effluents is essential in industrialized countries and is becoming increasingly important from an environmental and human health point of view in developing and emerging countries. Beside the conventional nitrogen removal process (lithoautotrophic nitrification and denitrification), novel and cost-effective biological nitrogen elimination processes have been developed, including simultaneous nitrification and denitrification, anaerobic ammonium oxidation (Anammox), and its combined system (completely autotrophic nitrogen removal over nitrite, Canon). This review summarizes the recent studies dealing with agricultural, domestic and industrial wastewaters regarding their nitrogen content. Traditional and novel biological nitrogen elimination technologies are reviewed. Furthermore, recent studies dealing with temperature, dissolved oxygen, nitrate concentration, salinity, pH or the free ammonia concentration as factors affecting the nitrogen removal efficiency have also been incorporated.

Keywords: wastewaters; nitrogen removal; salinity; free ammonia; temperature; dissolved oxygen

1. Introduction

Although access to safe drinking water has improved steadily and substantially over the last decades in almost every part of the world [1, 2], in the developing countries 90% of all wastewater still goes untreated into local rivers and streams [3] and thus limits safe fresh water supply. Some 50 countries, with roughly a third of the world's population, also suffer from medium or high water stress, at least during the rain season and 17 of these extract more water annually than is recharged through their natural water cycles [4]**.** The increasing water demand not only affects surface freshwater bodies like rivers and lakes, but it also degrades groundwater resources. Due to more groundwater extraction than recharge it is expected that for instance the soil surface of Jakarta/Indonesia will settle 0.4-0.6 m until 2020 [The Jakarta Post, 25. 08.2009] and periodic flooding of many city parts during the rain season will be the consequence. Eutrophication**,** associated with discharge of nitrogen compounds or nitrogen compounds-containing wastewater into freshwater has become a severe water pollution problem in many countries [5]. The water quality is deteriorated and potential hazards to human or animal health e.g. by toxic algal blooms are consequences. The presence of excess nitrogen in the environment has caused serious alterations of the natural nutrient cycle between the living world and the soil, water, and atmosphere [6]. Excess discharge of nitrate as a fertilizer but also as one the most common water and groundwater pollutants causes serious problems including cancer, blue-baby disease in new-born infants and methaemoglobinaemia [7]. However there are many other pollutants in water such as e.g. antibiotics, X-ray contrasting agents, health care residues or sugar derivatives in industrial wastes or wastewater that are also potential toxicants. In recent years, a number of studies have focused on carbon, nitrogen and phosphate removal from domestic, agricultural and industrial wastewaters. The objectives of this review are a) to identify nitrogen pollutants concentrations in domestic, agricultural and industrial wastewaters, b) to compile the latest achievements of technologies developed for the removal of nitrogen from these wastewaters and c) to clarify the effect of temperature, dissolved oxygen, nitrate concentration, salinity, pH and free ammonia concentrations as factors that influence the nitrogen removal efficiency.

2. Nitrogen -containing wastewaters

2.1. Nitrogen in agricultural wastewater

In recent years, several papers have addressed the recovery of nitrogen compounds from agricultural manures. The concentration of nitrogen compounds varies according to the origin of the respective manure. Poultry manure in a farm near Istanbul, Turkey, for instance, contained 1580 mg l^{-1}

total Kjeldahl nitrogen and 1318 mg l^{-1} NH_4^+-N [8]. Livestock species, their type and age, the nature of their feed and how it is fed, whether or not the livestock are housed, weather and climate, all contribute to wastewater composition, volume and its rate of production [9]. The variation of ammonium-N concentrations (mg l^{-1}) in livestock wastewaters in south County Waterford, Ireland, was measured for almost a decade (Table 1). There were high annual variations of ammonia and even higher variations within single years [10].

Table 1. Ammonium concentration (mg l^{-1}) in livestock wastewater includes discharges from eight cattle/dairy farmyard and one sheep yard [10].

Year	Mean	SD[1]	N	SEM	%CV	Min	Max
2001	41.30	74.29	46	10.95	179.89	179.89	480.00
2002	85.95	193.28	6	78.91	224.87	5.88	470.00

2008	47.05	48.25	62	6.13	102.57	0.00	262.12
2009	43.86	43.38	14	11.59	98.91	4.85	152.27

[1]SD = standard deviation; N= sample size (l); SEM = standard error of the mean; %CV = coefficient of variation; Min. = minimum; Max. = maximum.

Excessive amounts of chemical nitrogen fertilizers are applied in agriculture in many parts of the world under a broad spectrum of climatic conditions. Humid weather conditions may cause nitrate leaching, leading to pollution of surface and ground water resources. The consequences are eutrophication of surface waters and contamination of groundwater with nitrate. Such raw water sources should no longer be used as sources of potable water without treatment [11-13]. The horizontal subsurface drainage system, in addition to controlling water table and leaching out harmful dissolved salts from the drained soil profile, may also cause losses of various forms of nitrogen through the drainage effluent [14]. Such nitrogen losses, besides wasting a part of the applied fertilizer, are also likely to cause environmental degradation that will be detrimental to aquatic life, plants, and animals. Nitrogen leaching through subsurface drainage systems has been studied under different irrigation and fertilizer management regimes for semi-arid, arid and humid climates [15-17]. Gheysari et al. [18] studied NO_3-N leaching from a soil depth of 30 cm under different nitrogen fertilizer levels and different irrigation systems. The estimated leached NO_3-N ranged from 3.1 kg ha^{-1} at no N application and deficit irrigation to 40.8 Kg ha^{-1} at fertilization level of 142 kg N ha^{-1} and full irrigation, which would be the minimum annual N-requirement for corn in European countries.

2.2. Nitrogen in domestic wastewater

Effluent of domestic wastewater treatment plants contains high concentrations of inorganic nitrogen that may lead to eutrophication of the receiving water bodies [19, 20]. In Rajasthan, India the raw sewage received at the activated sludge plant has a BOD of 600–800 mg l^{-1} and a NH_4^+-N concentration of 80–110 mg l^{-1} during summer when water shortage was acute [21]. Ammonia and eventually nitrate in the effluent caused eutrophication. The disposal of domestic wastewater in areas not served by sewer systems is almost exclusively by use of septic tanks and seepage fields. Effluents from septic tanks generally contain high concentrations of ammonia. Zeng et al. [22] found that the ammonia concentration in real domestic wastewater from one septic tank in China was 54-74 mg l^{-1}. A similar finding was reported by Guo et al. [23]. The effluent of septic tanks is usually discharged to aerobic seepage fields, where ammonia and organic nitrogen are transformed to nitrate, which may be trickling into the groundwater [24]. Table (2) summarizes the values of total Kjeldahl nitrogen (TKN) and ammonia nitrogen (AN) found in domestic wastewaters in different locations during the recent years.

2.3. Nitrogen in agro-industrial and industrial wastewaters

The concentration of nitrogen compounds in some industrial wastewaters is tremendously higher than what is found in agricultural and domestic wastewater. Ammonia and nitrate are the most

problematic nitrogen compounds in this sort of wastewater. Ammonia in industrial wastewater is normally eliminated by nitrification which is achieved by the complete oxidation of ammonia. Thus, nitrate removal from these types of industrial wastewater is an inevitable step in treatment. Different industrial and agro-industrial wastewaters are reported to contain more than 200 mg l^{-1} NO_3^--N [25, 26] and some contain even higher nitrate levels. For instance, the wastewater from glasshouses contained 325 mg l^{-1} NO_3^--N [27]. Several other industries generate wastewater with varying amounts of nitrate, being 222 mg l^{-1} in a tannery wastewater of Pisa. Italy, [28], 2320 mg l^{-1} in wastewater from the cochineal insects processing to produce natural carmine used principally as a coloring agent in cosmetics, beverages and products with low pH [29], 3600 mg l^{-1} generated from an initiating explosive factory in China [30] and 4000-6000 mg l^{-1} produced during the frosting process of bottles in a winery [31]. In Egypt the El-Nasr Pharmaceutical and Chemical Company, South-East of Cairo, discharges both industrial (6000 m^3 d^{-1}) and municipal wastewater (128 m^3 d^{-1}) into a nearby evaporation pond without any treatment. The generated raw wastewater is characterized by high values of ammonium (about 300 mg l^{-1}) [32].

Table 2. Concentrations of TKN and AN in different domestic wastewaters.

Location	Description	TKN (mg l^{-1})	AN (mg l^{-1})	Reference
Belgium	Collected domestic wastewater samples for a period of 450 days.	40	24 ±11	[183]
Australia	Weekly collected domestic wastewater samples after on-site primary edimentation and predenitrification treating.	43	-	[184]
China	Domestic wastewater derived mainly from restaurants and dormitories.	70	40	[185]
Nigeria	Samples collected from a septic tank.	17	13	[186]
China	Samples collected from a septic tank.	85	79	[187]

TKN = total Kjeldahl nitrogen.
AN = ammonia nitrogen.

3. Processes for N-removal

3.1. Nitrification/denitrification

Biological autotrophic nitrification followed by heterotrophic denitrification has long been applied in municipal wastewater treatment. For application of nitrification-denitrification in industrial wastewater treatment, however, things become more complicated because the characteristics of wastewaters vary case by case and sometimes even day by day. Wastewater from antibiotics production, for instance, usually contains large amounts of fermentation products, some residual antibiotic activity, and a high concentration of ammonia. These wastewaters and some fermentation byproducts may not be easily utilized by denitrifiers as electron donors, and the residual antibiotics have a toxic effect on microorganisms [33].

Under strict aerobic conditions, complete nitrification is carried out in two sequential oxidative stages: ammonia is first converted to nitrite by ammonia-oxidizing bacteria:

$$NH_4^+ + 1.5O_2 \rightarrow NO_2^- + H_2O + 2H^+ \quad (1)$$

Then the nitrite is further converted to nitrate by nitrite-oxidizing bacteria:

$$NO_2^- + 0.5O_2 \rightarrow NO3^- \quad (2)$$

Each oxidative stage is performed by different bacterial genera which use ammonia or nitrite as an energy sources and molecular oxygen as electron acceptor, while carbon dioxide is used as a carbon source. The most commonly recognized genus of bacteria that carries out ammonia oxidation is *Nitrosomonas.* However, *Nitrosococcus*, *Nitrosopira*, *Nitrosovibrio* and *Nitrosolobus* are also able to oxidize ammonium to nitrite. These ammonia oxidizers are genetically diverse, but related to each other, and can be found in the beta subdivision of the *Proteobacteria*. For nitrite oxidation several genera such as *Nitrospira*, *Nitrospina*, *Nitrococcus*, and *Nitrocystis* are known to be involved. However, the most famous nitrite oxidizing genus is *Nitrobacter*,

which genetically is closely related within the alpha subdivision of the *Proteobacteria* [34]. The complete nitrification, as seen during wastewater treatment can be expressed as follow:

$$NH_4^+ + 2O_2 \rightarrow NO_3^- + H_2O + 2H^+ \quad (3)$$

In a subsequent process denitrification is generally performed by heterotrophic denitrifyers under anoxic conditions. The oxidized nitrogen compounds (NO_2^- and NO_3^-) are reduced to gaseous nitrogen by heterotrophic microorganisms that use nitrite and/or nitrate instead of oxygen as electron acceptors and organic matter as a carbon and energy source. Denitrifiers are common among the Gram-negative bacteria such as *Pseudomonas*, *Alcaligenes*, *Paracoccus*, and *Thiobacillus*. Some Gram-positive bacteria (such as *Bacillus*) and a few halophilic archaeal microorganisms (e.g. *Haloferax denitrificans*) are able to denitrify [35, 36]. Unlike some contaminants which are in need for a certain microbe to be treated, denitrifying bacteria are ubiquitous in nature [37] and numerous researchers cultivated them using mixed cultures taken from wastewater treatment plants as seeds. There has been a huge interest towards microbial removal of nitrate as the most environmentally friendly and cost-effective method, although biological denitrification may be slow, particularly for industrial wastewaters that contain high concentrations of nitrate [38]. The process of heterotrophic denitrification in environmental biotechnology is accomplished with a variety of electron donors and carbon sources. Both liquid and solid forms of organic carbon sources are conventionally used although the aqueous type is more common for treatment of water and wastewater. Among liquid carbon sources, the most common ones are methanol, ethanol [39, 40] and acetic acid which have been used for wastewater denitrification as well as in full-scale plants of drinking water treatment [41]. A combined carbon source using methanol and acetic acid was found to be superior in nitrogen removal and additional benefits of this mixed carbon source included the excellent sludge settling properties compared to the use of methanol or acetic acid alone [42]. Park et al. [43] treated waste plant material either physically or biologically to produce several organic carbon rich liquors for use in denitrification experiments. The choice of substrate depends on a number of considerations such as costs, capacity and configuration of reactors and on the post-treatment process of the denitrified water. The theoretical methanol requirement for nitrate is 2.47 mg CH_3OH per mg NO_3-N as indicated in equation (4) [44].

$$NO_3^- + 1.08CH_3OH + 0.24H_2CO_3 \rightarrow 0.056C_5H_7O_2N + 0.47N_2 + 1.68H_2O + HCO_3^- \quad (4)$$

Later studies tried to speed up biological denitrification by applying different process strategies through which a better contact of the nitrate in the water with microorganisms was maintained, such as packed beds [45], rotating biological contactors [46] and fiber-based biofilm reactor [47]. Efforts are still ongoing and some novelties in combination of biological and other methods, such as membrane biofilm reactors (MBR), were manifested [48].

3.2. Simultaneous nitrification and denitrification (SND)

The SND process starts with a partial nitrification of NH_4^+ to nitrite and subsequently continues with a direct reduction of nitrite to N_2 gas [49, 50]. In SND nitrification and denitrification occur concurrently in the same reactor vessel under identical operating condition. If successful, this process could reduce the relatively large reactor volumes and energy costs for recirculation that are required for a separated aerobic and anoxic system. Several types of treatment units have been proposed in which SND can be realized [51]. Zhang et al. [52] introduced a flexible biofilm reactor having adjustable aerobic, buffer and anoxic zones with liquid circulation being dependent on the aeration flow rate. Both studies were successful in proving the possibility of nitrification and denitrification in one reactor. Successful SND experiments were also carried out by Walters et al. [53] who used a biofilm airlift suspension reactor with biodegradable carrier material. Investigation of Fux et al. [54] of the shortened nitrogen removal pathway via nitrite revealed a high reduction of the COD demand for denitrification, a high rate of denitrification, low biomass yield during anaerobic growth and no apparent nitrite toxicity effects for the microorganisms in the reactor. SND is also effective in maintaining a neutral pH level in the reactor, without the addition of an acid or base. This is important since the optimal pH for the nitrifying and denitrifying bacteria lies between 7 and 8.5 [55]. Further, Ma et al. [56] constructed a bench-scale continuous flow system, consisting to remove nitrogen and carbon simultaneously from terramycin crystallization mother solution (TCMS). Approximately 82% of the chemical oxygen demand (COD) and 81% total nitrogen were removed by the system when tap water diluted TCMS was continuously fed (dilution ratio, 1:4). Sulfide which was produced during anaerobic hydrolysis was used as part of electron donors for denitrification in the anoxic reactor.

Polymeric beads, in which a nitrifier and a denitrifier were co-immobilized, were used to remove

nitrogen in a single step. Uemoto and Saiki [57] investigated a novel immobilized-cell bioreactor containing packed gel envelopes capable of simultaneous nitrification and denitrification. The packed gel envelopes consisted of two polymeric gel plates with an internal space between them for injecting the electron donor for denitrification. An ammonia oxidizer, namely, *Nitrosomonas europaea*, and a denitrifier, namely, *Paracoccus denitrificans*, were coimmobilized in the plate gel. The immobilized *N. europaea* oxidized ammonia to nitrite on the outer surface of the plate that was in aerobic contact with the wastewater containing ammonia; the immobilized *P. denitrificans* reduced nitrite to nitrogen gas on the inside of the plate that was in anaerobic contact with the electron donor. This system did not require an additional aerobic step because the electron donors were not supplied to the wastewater directly but to the internal space of the gel plate. This resulted in an increase of the utilization efficiency of the electron donor for the denitrification process and a decrease in the quantity of surplus sludge. In another attempt, a bioreactor system with 30 packed gel envelopes was installed in a thermal power plant for the removal of nitrogen from ammonia-containing desulfurization wastewater. Each envelope consisted of double-sided plate gels containing *Nitrosomonas europaea* and *Paracoccus denitrificans* cells with an internal space in between for injecting an electron donor. The envelope could remove ammonia from wastewater in a single step. During continuous wastewater treatment with the bioreactor system 95.0% removal of the total nitrogen was obtained. The total nitrogen concentration in the outlet was below 9 mg l^{-1}. Since the bioreactor system could use the electron donor effectively, it was not necessary to use an additional aerobic tank to remove the electron donor and a settling tank to segregate the surplus sludge containing bacteria from wastewater [58].

3.3. Autotrophic denitrification

The heterotrophic denitrification rate was strongly dependent on the type of carbon source, the concentration of the carbon source and the C/N ratio [59]. This could vary for different microorganisms, water streams, and environmental conditions [60]. In contrast, autotrophic denitrifiers utilized inorganic carbon substrates (carbon dioxide or bicarbonate) as a sole source of carbon. Some advantages of autotrophic over heterotrophic denitrification are; evasion of the poisoning effect of some organic carbon, low biomass build-up and less sludge production which results in reduction of reactor clogging and easier post-treatment [61]. Since some wastewaters have a very low concentration of biodegradable organic materials, autotrophic denitrification, which utilizes CO_2 from water as carbon source requires addition of an electron donor substrate. Extensive studies have been carried out on elemental sulfur [62-66] and H_2 [67-69] as electron donors for autotrophic denitrification systems. Under typical aquifer conditions, iron sulphide (pyrite) is typically expected to be the electron donor [70] for denitrification assisted by *Thiobacillus denitrificans*:

$$5\ FeS_2 + 14\ NO_3^- + 4\ H^+ \rightarrow 7\ N_2 + 10\ SO_4^{2-} + 5\ Fe^{2+} + 2\ H_2O \quad (5)$$

In the sulfur-limestone autotrophic denitrification (SLAD) process element sulfur is used as electron donor and limestone is used to adjust the pH, but an increase of the sulfate concentration and hardness limits its application. Hydrogen gas would be an ideal electron donor for biological autotrophic denitrification. It has, however, a poor solubility in water. A biofilm-electrode reactor as a combined electrochemical and biological reactor was developed by Sakakibara et al. [71] and improved by Prosnansky et al. [72] to solve these problems. In this system, autotrophic denitrifying microorganisms are immobilized on the surface of the cathode and hydrogen gas as an electron donor is produced by electrolysis of water. Combining this bioelectrochemical and sulfur autotrophic denitrification system for water denitrification was proposed by Wang and Qu [73] and applied at large scale by Wan et al. [66]. In such a process, sulfur and hydrogen autotrophic bacteria were integrated for the following reasons: the H^+ generated during denitrification with sulfur could be consumed by the bioelectrochemical denitrification with hydrogen to achieve neutralization, thus the limestone added into the SLAD system could be left away and the hardness increase could be avoided; the sulfate concentration of the effluent could be controlled by the nitrogen load of the autotrophic sulfur denitrification process, and would be lower than in the SLAD process. In general *Thiobacillus denitrificans* and *Thiomicrospira denitrificans* are the two most commonly reported autotrophic denitrifiers [74]. Because in nature these bacteria are likely to encounter autotrophic and heterotrophic conditions, it is of considerable interest that their nitrate removal characteristics under mixotrophic conditions are determined.

3.4. Anaerobic ammonium oxidation (Anammox) process

Anaerobic ammonium oxidation (anammox) has received special attention since its discovery, because it is an efficient biological alternative to conventional nitrogen removal from wastewaters. Under anaerobic conditions, ammonium is oxidized

to nitrogen gas with nitrite as the electron acceptor (Eq. 6) and carbon dioxide is used for growth of the anammox microorganisms involved. In comparison to traditional nitrification–denitrification process, this autotrophic process consumes 100% less biodegradable organic carbon and at least 50% less oxygen [75] and has, therefore, lower operating cost.

$$NH_4^+ + NO_2^- \rightarrow N_2 + 2\,H_2O \quad (6)$$

Anammox needs ammonium and nitrite in a ratio of roughly one to one. For sludge digester effluents, this ratio can be achieved without control, because these effluents contain bicarbonate as the counter ion for ammonium. When half of the ammonium is converted, the alkalinity of the water is depleted leading to a drop in pH and preventing further nitrification (Equation Eq. (7) [76]:

$$NH_4^+ + HCO_3^- + 0.75\,O_2 \rightarrow 0.5\,NH_4^+ + 0.5\,NO_2^- + CO_2 + 1.5\,H_2O \quad (7)$$

If the Anammox process is combined with a preceding nitrification step, only part of the ammonium needs to be nitrified to nitrite, while the Anammox process combines the remaining ammonium with the nitrite to yield dinitrogen gas. This will reduce the oxygen demand in the nitrification reactor and reduce costs. The biomass yield is very low, and consequently, little sludge is produced. This is another factor that contributes to substantially lower operation costs of Anammox compared to the conventional denitrification process. However, the low biomass yield also necessitates an efficient system for sludge retention, and long start-up times are required to obtain a sufficient biomass concentration [77].

The possible metabolic pathways for anaerobic ammonium oxidation are shown in Fig. 1 [78]. Using ^{15}N-labelling the experiments showed that the electron acceptor nitrite is reduced to hydroxylamine and that hydroxylamine somehow reacts with the electron donor ammonium, leading to the ultimate production of dinitrogen gas. In batch experiments with excess hydroxylamine and ammonium, a transient accumulation of hydrazine was observed, indicating that hydrazine is the intermediate of this final step. Jetten et al. [77] postulated that the oxidation of hydrazine to dinitrogen gas generates the electrons for the initial reduction of nitrite to hydroxylamine. It is well known that occurrence of free hydrazine in microbial nitrogen metabolism is rare, if not unique [79].

The anaerobic ammonium oxidizing bacteria (AnAOB) are autotrophic members of the *Brocadiales*, belonging to the phylum *Planctomycetes*, which is one of the major distinct divisions of the bacteria. Currently, five genera of AnAOB have been reported: *Candidatus brocadia*, *Candidatus kuenenia*, *Candidatus scalindua*, *Candidatus anammoxoglobus*, and *Candidatus jettenia*. However the most common AnAOB are "*Brocadia anammoxidans*" [80] and "*Kuenenia stuttgartiensis*" [81]. These two bacteria are very similar. They have the same overall structure and also produce hydrazine from exogenously supplied hydroxylamine. The high Anammox activity is detectable for both bacteria in a pH range between 6.4 and 8.3 and a temperature between 20 °C and 43 °C [82]. The optimum pH and temperature of the two organisms are very similar. These bacteria have a highly unusual physiology, in that they live by consuming ammonia in the absence of oxygen. Furthermore, these metabolically versatile bacteria are, for example, capable of oxidizing short chain fatty acids with nitrate [83], co-oxidizing propionate and ammonium in the presence of nitrite and nitrate [84], and performing dissimilatory nitrate reduction to ammonium [85]. Anammox is highly exergonic and linked to the energy metabolism of the organisms involved. In addition, Anammox bacteria were recently shown to be able to tolerate higher O_2 concentrations than originally established by Strous et al. [86] being metabolically active at oxygen concentrations of up to ~13 µmol O_2 l^{-1} [87]. Altogether, these results have important ecological and biogeochemical implications, since they extend the metabolic and environmental spectra of these bacteria.

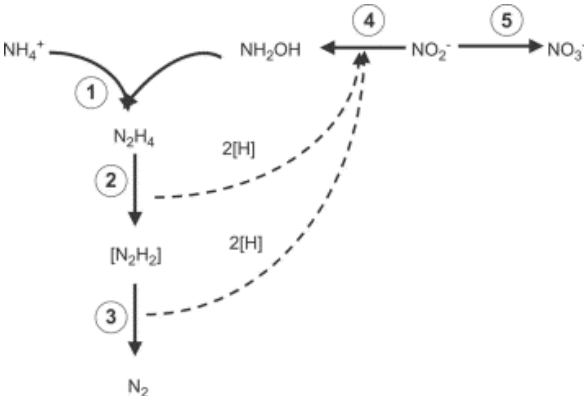

Figure 1. Metabolic pathways for anaerobic ammonium oxidation

The Anammox process is suitable for wastewater with low C:N ratios. At C:N ratios above 1, the Anammox bacteria are no longer able to compete with heterotrophic denitrifying bacteria . The organic loading rate was found to affect the Anammox process performance, but the exact inhibitory levels still remain unclear [88, 89]. An organic matter concentration above 300 mg COD l^{-1} was found to inactivate Anammox communities in a

UASB reactor fed with fat milk as organic matter source [90]. Concentrations of 50 mM of acetate resulted in 70% inhibition of the Anammox process [91]. Therefore it is necessary to clearly establish the COD levels inhibiting the Anammox process.

The Anammox process has also been maintained easily in a gas lift reactor achieving nitrogen removal rates of up to 8.9 kg $N/m^3 \cdot day$. This removal rate was 20 times higher compared to the removal rates previously achieved in the laboratory [92]. Ammonia removal via Anammox has been developed for the treatment of many different wastewaters with low organic matter content (below 1700 mg COD l^{-1}), such as water from the secondary clarifier of a municipal wastewater treatment plant in a down flow biofilter [93], nitrous organic wastewater in ASBR reactors and landfill leachate in a continuous reactor [94]. Only a few studies have investigated the possibility of using the Anammox process for ammonia removal from animal waste treatment water, which is indeed a residue with high organic matter and nitrogen content [95]. However, there is still a big gap regarding the effect of different pre-treatments (reducing organic and ammonia loads) of the wastewater streams on Anammox process performance. Up to 98.5 ± 0.8% of ammonia was removed from a diluted partially oxidized pig manure effluent (121 mg COD l^{-1}) using the Anammox process under different organic loadings in a semi-continuous UASB reactor. Mass balance clearly showed that an increase in organic loading (from 121 mg COD l^{-1} to 290 mg COD l^{-1} negatively affected the Anammox process and facilitated heterotrophic denitrification [5].

3.5. Partial nitrification/Anammox

The increases in the operating costs of wastewater treatment systems is challenged by a novel microbial process, combining the Anammox reaction with partial nitrification in one reactor, entitled CANON (completely autotrophic nitrogen removal over nitrite) [96]. This combination of the preceding partial nitrification and the subsequent anaerobic ammonium oxidation is regarded as a promising new method of removing nitrogen from wastewater with a low C/N ratio and a large quantity of ammonium [97]. Compared to the conventional nitrification and denitrification process, more than 50% [98] or 62.5% [99] less oxygen demand and the non-requirement of organic carbon addition, in the combined partial nitrification/Anammox process offer considerable cost savings. The combination of partial nitrification and Anammox is based on the fact that nitrite is an intermediary compound in both. Therefore, it will be convenient and economical to achieve 50% partial nitrification up to a condition wherein one-half of ammonia is converted to nitrite and the other half is not, followed by the anammox to ensure total nitrogen removal throughout an autotrophic process. [100, 101]. In the CANON systems, *Nitrosomonas*-like aerobic ammonium-oxidizing bacteria and *Planctomycete*-like Anammox bacteria perform two sequential reactions simultaneously under oxygen limited conditions [102, 103]. The nitrifiers oxidize ammonium to nitrite, consume oxygen and so create anoxic conditions needed by the Anammox bacteria. The produced nitrite is utilized with the remainder of the ammonium by Anammox bacteria and converted into dinitrogen gas [104]. Equations number (8), (9) and (10) represent these reactions:

$$2NO_3^- + 12H^+ + 10\ e^- = N_2 + 6H_2O \quad (8)$$

$$NH_4^+ + 1.32\ NO_2^- + 0.066\ HCO_3^- + 0.13H^+ \rightarrow 0.066\ CH_2O_{0.5}\ N_{0.15} + 1.02\ N_2 + 0.26\ NO_3^- + 2.03\ H_2O \quad (9)$$

$$NH_4^+ + 0.85\ O_2 \rightarrow 0.44\ N_2 + 0.11\ NO_3^- + 1.43\ H_2O + 0.14\ H^+ \quad (10)$$

Typically in the CANON process the *Nitrosomonas*-like ammonium-oxidizing bacteria are active in the outer aerobic region of both biofilm and aggregates, while Anammox bacteria are active in the inner anoxic region. This way the Anammox bacteria are protected from oxygen, which is consumed in the outer aerobic region. Oxygen would inhibit the Anammox activity [86]. The cooperation of these two groups of ammonium-oxidizing bacteria results in completely autotrophic nitrogen removal under oxygen limited conditions in one single reactor.

The CANON process has quite sensitive operational characteristics for dissolved oxygen, the nitrogen-surface load, biofilm thickness and temperature, etc. [105]. The oxygen-mass transfer efficiency from gas to the liquid phase and effective biomass retention are considered two key rate-limited factors for the operation of a CANON system [92]. Moreover, the growth rate of autotrophic ammonium oxidizing bacteria is lower than that of heterotrophic bacteria, with which they have to compete for oxygen. Without long retention times the suspended nitrifiers will be easily washed out of the reactor. The biomass concentration is increased by recirculation of the sludge after sedimentation, but limited by the efficiency of the sedimentation vessel. Besides, the ammonia oxidation rate is strongly influenced by the nature of nitrifying cultures and a variety of environmental factors, including substrate concentration, dissolved oxygen, temperature and pH. To overcome these problems and to promote the oxygen-mass transfer in a high biomass retention reactor configuration, immobilization techniques can

be used. This is an important challenge in order to scale up CANON systems from laboratory to industrial application [106, 107]. Immobilization is an efficient method to prevent biomass from being washed out and allows hyperconcentrated cultures. This can lead to relatively small reactors and provide some protection from adverse temperatures and toxic shocks, which would help in maintaining year-round treatment [108]. Immobilized biomass can be divided into "naturally" attached biomass (biofilm) and "artificially" immobilized biomass. Biofilms have been widely applied in wastewater treatment. However, some particles can become anaerobic in the centre and settle to the reactor floor. Membrane-aerated biofilm reactor (MABR) represent a new technology for aerobic wastewater treatment, in which hydrophobic, gas-permeable membranes are used for bubbleless oxygen transfer [109, 110]. Membrane aeration is advantageous because gas transfer efficiencies are much higher than conventional bubble diffusers. In an MABR, the microporous membranes play two roles: the oxygen gas supplemental material and the carrier for bacterial immobilization [111]. The oxygen on the lumen side of the membrane is transported through the pores of the membrane wall without the formation of bubbles and utilized by microorganisms in the membrane attached biofilm. Extremely high oxygen-mass transfer efficiency can be achieved [112, 113]. Recent research has demonstrated that thick membrane-aerated biofilms can simultaneously provide favorable conditions for both nitrification (near the membrane) and denitrification (near the biofilm-liquid boundary) within a single biofilm [114]. Gong et al. [107] developed a novel MABR, equipped with non-woven fabrics support around the microporous carbon tube membrane, and investigated its feasibility and process performance of the CANON-type single-stage autotrophic nitrogen removal to treat the synthetic ammonium-rich wastewater like anaerobic sludge liquids. This reactor allowed air to be supplied through the microporous carbon tube wall to the biofilm that was supported by non-woven fabrics. The partial nitrification and consumption of dissolved oxygen occurred in the inner layer and Anammox in the anoxic outer layer of the non-woven fabrics, thus realizing autotrophic nitrogen removal in a single reactor. This study demonstrated that MABR was a very suitable experimental set-up for the operation of the single-stage autotrophic nitrogen removal process.

One of the most common techniques for artificially immobilization is gel entrapment. Both natural and synthetic polymers can be used as the immobilization support, but it must fulfill various requirements, such as photo-transparency, non-toxicity, retention of cellular viability, and stability in the culture medium. This immobilization technique is commonly used to immobilize a pure strain of bacteria because the mechanisms of pure strains are more easy to understand [115, 116]. Nevertheless, the immobilization of activated sludge has also been reported [117, 118]. Compared to pure strains of bacteria, immobilization of activated sludge could remove multiple pollutants due to the biodiversity of the activated sludge. Yan et al. [106] studied the characteristics of the partial nitrification and degradation of organics with an immobilized biomass in treating ammonium-rich organic wastewater. It serves as a first step in the Anammox process with partial denitrification via nitrite. They used four materials, i.e. sodium carboxymethylcellulose, sodium alginate, polyvinyl alcohol and sodium alginate, and chitosan for entrapping the biomass. Sodium alginate was selected as the best entrapment support after comparing partial nitrification rates and the adsorption efficiency.

4. Factors affecting nitrogen removal efficiency

4.1. Effect of temperature

The temperature range of 22–37 °C gave best results in terms of maximum nitrogen and carbon removal from a shrimp aquaculture wastewater [119], but denitrification processes will normally occur in the range 2–50 °C [120] and possibly beyond, where bacteria have evolved to cope with specific environmental conditions. Groundwater temperatures are typically around 10 °C (in northern Europe), with the exception of shallow groundwaters impacted by extreme surface temperatures. Reaction rates are typically assumed to double for every 10 °C increase in temperature (i.e. Arrhenius rate law). Elefsiniotis and Li [121] investigated the role of temperature within the range of 10–30 °C on biological denitrification using synthetically produced volatile fatty acids as carbon sources. Their results confirmed that a temperature change from 10 to 20 °C exerted a greater effect on both the specific denitrification and carbon consumption rates than a further temperature increase from 20 to 30 °C, which was also evident in the corresponding temperature coefficient values. At a given temperature, the specific denitrification rate appeared to depend on the initial nitrogen concentration, while the specific carbon consumption rate was a function of the initial carbon content. The nitrogen removal capabilities of the denitrification process, when treating sanitary landfill leachate containing an ammonia concentration of over 2200 mg N/l^{-1}, were investigated at operating temperatures down to 10°C. When the operating temperature was decreased from 20 to 17°C, an approximate 15%

decrease in denitrification was immediately experienced, with no noticeable effect on nitrification. With the temperature of 14°C, aerobic wasting was also stopped and methanol (carbon source for denitrification) loading was progressively decreased to match actual denitrification requirements. At 10°C, the system suffered major nitrification and denitrification inhibition. Changes in operating parameters, such as a decrease in influent ammonia and methanol loading, as well as an increase in ambient temperatures, from 10 to 15°C, did not significantly improve the overall system performance, within a reasonable time frame. Changes in the rate of denitrification with seasonal temperature variations may be masked by variations in the rate of organic carbon flux. For example, freeze–thaw cycles increase the flux of carbon to the unsaturated zone and can create anaerobic micro-environments in which denitrification can be established [122].

Present reports show that high temperature of 28–38 °C is favorable for nitrogen removal via nitrite due to the fact that the specific growth rate of AOB is higher than that of NOB [123]. The reports about the effect of temperature on nitritation can be grouped into two classes: (1) achievement and maintenance of nitritation at high temperatures of 28–35 °C [124], and (2) start-up of nitritation at high temperatures and a gradually decline of the temperatures. Nitritation was maintained at room or low temperatures [125]. Some researches also proved that nitritation start-up could be promoted and accelerated at high temperatures [126]. However, the temperatures of real domestic wastewater (usually at 10–25 °C), especially in winter, cannot reach the optimal temperature of 30 °C for nitrogen removal via nitrite. In the temperature range of 10–20 °C, a high nitrite accumulation rate can hardly be maintained due to the fact that the specific growth rate of NOB is higher than that of AOB [127]. Therefore, a relatively low wastewater temperature such as in domestic wastewater is the major obstacle for achievement and full-scale application of nitrogen removal via nitrite. However Zeng et al. [22] achieved nitritation at a temperature of 19 ± 1 °C by controlling the dissolved oxygen (DO) concentration and pH. The dominance of ammonia oxidizing bacteria (AOB) was enhanced through the combination of a low DO concentrations (<1.0 mg/l) and a preset short-cycle control of the aeration time. Nitritation was successfully established with a NO_2^--N/NO_x^--N ratio over 95%.

Several authors [128,129] found that the optimum temperature for the operation of the Anammox process was around 30–40 °C. Perhaps for this reason, most of the works where this process was applied were carried out at temperature values higher than 30 °C [130]. Recently, Cema et al. [131] proved that a rotating biological contactor (RBC) with an established Anammox process could be successfully operated at temperatures around 20 °C. Similar results were reported by other workers [132, 133] who operated an anaerobic biological filtrate reactor (ABF) which treated 8.1 g N $(l\ d)^{-1}$. Moreover, several works done with marine Anammox samples reported measurable activities at low temperatures. Rysgaard et al. [134] working with sediments of the east and west coasts of Greenland, observed Anammox activity between −2 and 30 °C, the optimum temperature being 12 °C. Similar results were found by Dalsgaard and Thamdrup [135] working with marine sediments from the Skagerrak (Baltic-North Sea). These results indicate that the application of the Anammox process must not be restricted to effluents with temperatures around 30 °C. Therefore, Dosta et al. [136] evaluated the effects of moderately low temperatures on the stability of this process. First, the short-term effects of temperature on the Anammox biomass were studied using batch tests and the maximum activity was found at 35–40 °C. Activity tests done at 45 °C showed an irreversible loss of the activity due to biomass lysis. Temperatures from 30 to 15 °C were used to determine long-term effects. The system was successfully operated at 18 °C but when the temperature was decreased to 15 °C, nitrite started to accumulate and the system lost its stability. On the other hand, some authors reported that the denitrification rate showed only a rather weak dependence on the temperature, the rate at 3°C being approximately 55% of that at 15°C. The maximum denitrification rate obtained at 15°C was 2.7 g NO_x^--N m^{-2} carrier d^{-1}. The maximum denitrification rate at 3°C during an 8-day period was found to be constant [137].

4.2. Effect of dissolved oxygen

Denitrifiers are facultative bacteria that energetically prefer oxygen over nitrate as the terminal electron acceptor. Denitrifying bacteria use nitrogen oxides as terminal electron acceptors most rapidly in the absence of oxygen. Thus, the dissolved oxygen (DO) concentration has an important influence on the success of the nitrogen removal process. A high DO plays a crucial role in nitrification and has a negative influence on biological denitrification. DO can inhibit denitrification because oxygen functions as the electron acceptor for microorganisms over nitrate and aerobic conditions repress enzymes involved in denitrification [138]. Although high DO concentrations are necessary to enhance the activity

of nitrifying bacteria in the biofilm reactor, denitrification is inhibited by oxygen. Lowering the aeration rate i.e. operating the wastewater treatment at low DO concentrations is a possible measure to control the inhibitory effect of DO on denitrification [139]. The negative effects of high DO concentrations on the denitrification process depended on the carbon source. Denitrification with alcohols such as ethanol and methanol was less affected by DO than with sucrose. The development of a biofilm was also influenced by the DO concentration as excess O_2 caused reduced biofilm growth. Biofilms that developed in presence of oxygen revealed a smaller bacterial density and a smaller atio of denitrifying versus nitrate reducing bacteria, which led to an unfavorable inorganic nitrogen removal and the presence of nitrite in the treated water. All these effects were more pronounced when sucrose was used as carbon source [140].

Until now, a significant amount of research has focused on the partial nitrification and SND achieved by low DO [141]. Using low DO, Blackburne et al. [142] achieved partial nitrification to nitrite in a lab-scale continuous-flow reactor treating synthetic wastewater containing ammonium as the sole energy source. Ma et al. [143] showed a clear correlation between nitrite accumulation and low DO levels in a continuously run pilot plant. For nitrogen removal via nitrite with real wastewater the nitrite pathway in a continuous-flow system has not been fully demonstrated previously [144]. However, Ma et al. [145] established the nitrite pathway in a pilot-scale continuous pre-denitrification plant (V = 300 L) treating domestic wastewater by controlling the DO concentration at 0.4–0.7 mg/l. It was demonstrated that the nitrite pathway could be repeatedly and reliably achieved, with over 95% of the oxidized nitrogen compounds at the end of the aerobic zone being nitrite. The nitrite pathway improved the total nitrogen removal by about 20% in comparison to the nitrate pathway, and also reduced aeration costs by 24%. Moreover, the short-term effect of DO on biological nitrogen removal has been discussed in many studies using batch test [146, 147]. With the exception of the report of Guo et al. [148], limited reports are available on comparisons of partial nitrification performance under different DO for long-term operation. It is still doubtful whether high a DO level would destroy the stable and high nitrite accumulation ratio built by low DO or other operational factors. It is also not very clear whether high DO would cause the recovery of NOB after long time operation. Guo et al. [148] found that the average efficiencies of SND in a high DO (above 3 mg/l on average) and a low DO (0.4–0.8 mg/l) reactor were 7.7% and 44.9%, and the specific SND rates were 0.20 and 0.83 mg N/(mg MLSS h), respectively. Low DO did not produce sludge with poorer settling properties but attained lower turbidities of the effluent than high DO. AOB were the dominant nitrifying bacteria and NOB did not be recovered in spite of exposing nitrifying sludge to high DO.

4.3. Effect of nitrate concentration

Excess nitrate concentrations affect the denitrification process by inhibiting the formation of N_2 gas and causing the denitrification process to terminate with the formation of N_2O [149]. A small number of research studies has been published to date on the denitrification of wastewater containing nitrate at concentrations higher than 600 mg NO_3-N l^{-1} [150]. Biological denitrification of high nitrate concentration in wastewater is a slow process. To increase the rate of denitrification, parameters such as pH, temperature, COD/NO_3^--N and biomass concentration of the process must be optimized. Acclimatization of sludge to nitrate wastewater is one of the methods used to develop the suitable consortium to treat high strength nitrate wastewater. Sludge, generally consists of different types of bacteria, broadly divided into two categories viz; nitrate tolerant and nitrate intolerant bacteria. Nitrate tolerant bacteria include nitrate respirators (capable of reducing nitrate to nitrite) and true denitrifiers (capable of reducing nitrate to nitrogen). The growth rate of nitrate tolerant and nitrate intolerant bacteria varies depending upon nitrate concentrations. At high nitrate concentration, the population of nitrate tolerant bacteria multiplies faster than that of nitrate intolerant bacteria. Thus, acclimatization is essentially a process of manipulating differential growth rates of two types of bacteria to obtain a desired population balance by subjecting them at controlled nitrate concentration. To acclimatize the sludge for treating high nitrate wastewater, it is subjected to high nitrate concentrations in which nitrate tolerant bacteria outgrow nitrate intolerant bacteria [153].

4.4. Effect of salinity

The effect of high salt concentration on nitrification and denitrification has been previously investigated [154, 155]. Seawater has been used as an alternative water source for toilet flushing in some arid areas such as Hong Kong and some other coastal cities, resulting in a high salt content in the sewage [156, 157]. Salinity levels have a definite impact on the microbial community structure in the wastewater and may affect the nitrification and denitrification process [158] and ultimately the performance of

wastewater treatment systems. High salt concentrations in wastewater induce salt stress to the microbial flora, resulting in the inhibition of many enzymes, decreasing cell activity and eventually leading to plasmolysis [159]. It was reported in these studies that nitrification and denitrification activities were sustained by gradual acclimatization of freshwater sludge to high salt conditions. Halophilic denitrifying bacteria were isolated from the long-term acclimated sludge, and higher denitrification performances were demonstrated when the long-term acclimated sludge was used as inoculums [160]. Furthermore, Furukawa et al. [161] reported that nitrifying sludge taken from a night soil treatment plant employing a sea-water dilution in the summer season could adapt more smoothly to high salt condition than sludge from freshwater.

Rene et al. [162] investigated the effect of different COD/N ratio (3–6) and salt concentrations (up to 3.2%) on organics and nitrogen removal efficiencies in fish market wastewater under different operating schedules. Different combinations of the COD/N ratio and salinity showed a negligible effect on organics removal, while they affected nitrification and denitrification efficiency to a larger extent. However, salt inhibition can be reduced significantly after long time acclimatization of the biomass. The treatment showed high COD (>80%) and nitrogen (>40%) removal efficiencies despite of high loading rates and COD/N fluctuations, which is due to the acclimatization of the biomass within the SBR. Using a sequencing batch reactor for the treatment of shrimp aquaculture wastewater, the results of Fontenot et al. [107] indicated that the salinity of 28–40 parts per thousand, produced best results in terms of maximum nitrogen and carbon removal from the wastewater.

Since the partial nitritation–Anammox process was successfully applied to the treatment of sewage sludge digester liquor, it opened doors for application to many kinds of wastewater treatment such as industrial wastewater, livestock wastewater, and landfill leachate. However, these wastewaters contain high concentrations of salts which have been considered as an inhibition factor in the biological nitrogen removal process [163]. However, marine Anammox bacteria belonging to the genus *Scalindua* have been detected in natural surroundings [164] and recently Nakajima et al. [165] enriched them from an enclosed coastal sea in Japan using a continuous culture system. These results suggested that Anammox bacteria, inherently preferring high concentration of salts and living in the high salt habitats, would be enriched in the cultivations and would be available for industrial application. On the other hand, there is an inconsistent experiment. Kartal et al. [166] adapted *Candidatus Kuenenia stuttgartiensis* and *Candidatus Scalindua wagneri* to a salt concentration of 30 g l^{-1}. Although this would be the culture conditions suitable for growth of *Candidatus scalindua*, they reported that the major Anammox bacteria after the acclimation were *Candidatus kuenenia stuttgartiensis* enriched from freshwater. Because Kartal et al. [166] used the seed sludge containing marine Anammox bacteria besides a freshwater Anammox bacterium, the result that major Anammox bacteria at high salt conditions were freshwater Anammox species is an open question. In addition, Kartal et al. [166] focused on only the population of Anammox bacteria species without the evaluation of the coexistent bacteria community. The effect of high salt concentration on the Anammox treatment was investigated by Liu et al. [167] to establish an acclimation strategy under high salt concentration conditions. An Anammox fixed-bed reactor with non-woven biomass carrier was used and the salt concentration was gradually increased from 2.5 g l^{-1} to 33 g l^{-1}. The Anammox reactor revealed a stable nitrogen removal rate (NRR) of 1.7 kg-N m^3 d^{-1} for 65 days under a salt concentration of 30 g L^{-1}. However, the NRR sharply declined at a salt concentration of greater than 30 g l^{-1}.

4.5. Effect of pH

The pH range preferred by heterotrophic denitrifiers is between 5.95 and 7.9 [168], although the optimal pH level in an anoxic/oxic membrane bioreactor with over 99.9% of nitrate removal and without accumulation of nitrite was 7.5-8.5 [30]. The pH values outside this range may hinder the denitrification process, but the optimal pH is site-specific because of the effects of acclimation and adaptation to the microbial ecosystem. Strongly acidic environments (pH < 5) inhibit denitrification and tend to arrest the denitrification chain with the formation of nitrite or N_2O [120]. In well-buffered calcareous aquifers, such acidification is unlikely [169]. *Halomonas campisalis* (ATCC 700597) however was shown to completely reduce nitrate at 125 g/L NaCl and pH 9 in brine produced from regeneration of ion exchange resins with NaCl, containing a high concentration of nitrate that was difficult to remove using standard biological, physical, or chemical technologies [26]. On the other hand, experiments of nitrate removal from high salinity wastewater are usually carried out without controlling the pH because denitrification from high salinity wastewater favors high pH levels [170]. Heterotrophic denitrification itself can increase the pH because it causes a release of hydroxyl ions and raises alkalinity. Each mg of nitrate-N reduced to N_2

causes an alkalinity increase of 3.57 mg $CaCO_3$ according to the following stoichiometry:

$2NO_3^- + 12\ H^+ + 10\ e^- = N_2 + 6\ H_2O$ [171]

Contrary to heterotrophic denitrification, autotrophic denitrification consumes alkalinity and, in addition, generates high concentrations of sulfate. High sulfate concentrations do not pose an undue problem in coastal areas, where treated wastewater can be discharged directly to the sea, which has a natural sulfate concentration of 2.7 g l^{-1}. Alkalinity of 3.91 g (as $CaCO_3$) will be consumed for reducing 1 g of NO_3^--N to nitrogen gas. Previous research showed that the optimum pH for growth of *Thiobacillus denitrificans* (*T. denitrificans*) cultures was between 6.8 and 8.2, approaching zero at pH 5.5 [172] and with a maximum efficiency at 8.4. Increasing the pH above 8.6 caused a significant decrease in the nitrate removal rate and a dramatic increase in nitrite accumulation [173]. Therefore, alkalinity may have to be supplied to the autotrophic denitrification system to control the pH. The most effective and commonly used alkalinity source in research is $NaHCO_3$. For wastewater of low alkalinity, large amounts of $NaHCO_3$ are required to maintain the autotrophic denitrification process. An alternative and cheaper alkalinity source in conjunction with elemental sulfur particles is granular limestone. If the initial alkalinity of the wastewater is insufficient for complete denitrification, limestone can supply effective buffering capacity [174]. Furthermore Jha and Bose [175] evaluated the suitability of pyrite (FeS_2) as an in situ buffering agent for arresting pH increase during metallic iron assisted hydrogenotrophic denitrification by microorganisms that reduce nitrate to nitrogen gas by utilizing hydrogen as energy source. Pyrite is considered promising for this purpose because it is a mineral which is unstable under moderately reducing, i.e., anoxic conditions, where such denitrification takes place, and therefore is expected to consume hydroxide ions produced due to hydrogenotrophic denitrification reactions and get oxidized to ferrous hydroxide $Fe(OH)_2$. Experimental evaluation of the buffering efficiency of pyrite showed that it was effective in arresting a pH increase associated with denitrification in both, batch systems and during flow through reactive porous media. Furthermore, addition of pyrite had no demonstrable toxic effect on the denitrifying microorganisms, though elevated sulfate concentration was seen in the effluent after denitrification.

4.6. Effect of free ammonia concentration

Traditionally, accumulation of nitrite resulting from higher activities of AOB than NOB is considered undesirable in biological wastewater treatment systems. Factors such as pH, temperature, and the concentrations of DO, CO_2 and heavy metals were all found to influence the nitrite build-up [30]. However, one of the main causes is believed to be the inhibitory effects of free ammonia (FA) [176]. Anthonisen et al. [177] observed that both ammonium and nitrite oxidations are inhibited by FA; inhibition of nitrite oxidation by *Nitrobacter* began at a concentration of 0.1–1.0 mg FA/l, while ammonium oxidation by *Nitrosomonas* became inhibited at 10–150 mg FA l^{-1}, allowing selective inhibition of nitrite oxidation at a range of FA concentrations of 1.0–10 mg/l. Supporting this observation, Bae et al. [178] reported that nitrite accumulation occurred at an initial FA concentration of around 4.7 mg/l, giving a high NO_2/NO_X ratio (up to 77%) in a batch reactor. Chung et al. [179] accomplished a long-term accumulation of nitrite in a continuous-flow reactor by maintaining the FA concentration in the reactor around 20 mg/l. Chung et al. [180], however, found that a FA concentration of 5–10 mg/l was most efficient in inhibiting nitrite oxidation without slowing down the rate of ammonium oxidation. To have appropriate kinetic expressions for both ammonium oxidation and nitrite oxidation under inhibition, Park and Bae [181] studied inhibition of ammonium oxidation and nitrite oxidation by FA using three different sludges. An uncompetitive inhibition model fitted the experimental data well when the reactions were under FA inhibition. The estimates of the inhibition constant (K_I) were 46 μM for nitrite oxidation and 290–1600 μM for ammonium oxidation. The much smaller values of K_I for nitrite oxidation reflected the susceptibility of that reaction to inhibition by FA, which could lead to accumulation of nitrite during nitrification. Such studies revealed the impact of FA on the respiration of NOB. Little information was gained with regard to the impact of FA on the growth of NOB. However Vadivelu et al. [182] indicated that FA has a limited inhibitory effect on the respiratory capability of *Nitrobacter*. While the real mechanisms remain to be identified, the study of Vadivelu et al. [182] indicates that the FA inhibition of *Nitrobacter* is likely much more serious than suggested by previous studies where the presence of inorganic carbon (or the equivalent nitrite oxidation rate) was used as the sole measure of the inhibitory effects.

Comparison of Electrostatic and Spinning-discs Spray Nozzles on Wheat Weeds Control

Ali Esehaghbeygi[1], Ali Tadayyon[2], Shahin Besharati[2]

[1]Department of Agricultural Engineering, [2]Department of Agronomy and Plant Breeding
College of Agriculture, Shahrekord University, Shahrekord, Iran, 115
esehaghbeygi@cc.iut.ac.ir

Abstract: Electrostatic spraying is the method that is noted for improving the spraying efficiency and droplet deposition. The efficacy of electrostatic charge and spinning-discs spraying were assessed for the application of 2, 4-D to control weeds in irrigated wheat. Sprayer nozzle performance was evaluated in terms of wheat grain yield (*Ghods* variety), weed shoot biomass, and wheat residual (straw) at the research farm of Shahrekord University in 2007 and 2008. The results indicated that electrostatic spraying gave better weed control. Spray penetration through dense weeds enhanced with electrostatic charging. The spinning disc nozzle decreased water use and so was cheaper to operate, but it did not significantly improve herbicide efficacy, especially in dense canopies compared with the electrostatic charge.

[Ali Esehaghbeygi, Ali Tadayyon, Shahin Besharati. **Comparison of Electrostatic and Spinning-discs Spray Nozzles on Wheat Weeds Control.** Journal of American Science 2010;6(12):529-533]. (ISSN: 1545-1003). http://www.americanscience.org

Keywords: electrostatic, spinning disc, wheat, weed

1. Introduction

As summarized in the foregoing review, there have been significant advances in the research and development of electrostatic-spraying technology for beneficial agricultural and biological applications throughout the 20th century (Law, 2001). Hislop (1987) concluded that different application methods and droplet size spectra produced by hydraulic nozzles make relatively little difference in spray partitioning between different parts of the canopy and that canopy density or growth stage is of much greater importance. Coarser sprays are recommended to enhance canopy penetration, although optimum spray quality for penetration is probably specific to the canopy architecture (Spillman, 1984). When spraying into a no-till canopy, droplet interception by the stubble should be minimized and capture by the target weed maximized. These two goals may not be reconcilable because sedimentation and impact on stubble and weeds may be governed by the same criteria. Additionally, because canopies differ in texture, morphology, orientation, and depth, generalization is difficult (Bache and Johnstone, 1992). Grain yield losses due to weed competition in the wheat crop are estimated to be 25% (Montazeri *et al.*, 2005). The importance of better herbicide application equipment has been reported by Shaw (1982) for integrated weed control management. Such equipment could decrease chemical and water application per unit area. A spinning disc nozzle is suggested as a tool to reach such objectives. Uremis *et al.* (2004) stated that spinning disc nozzles with a reduced spray volume did not improve weed control and gave inadequate weed control with reduced dosage of herbicide. Spinning disc nozzles are recommended for both weed and insect control to meet the goals of integrated pest management systems. Although integrated weed management has been used for over a decade, weed management practices still need to be improved to achieve its goals. Based on Sikkema *et al.* (2008) study, the optimum nozzle type, water carrier volume, and spray pressure is herbicide and weed species-specific.

Diverse crop rotations, competitive cultivars, higher crop seed rates, reduced row spacing, specific fertilizer placement, and cover crops have been identified as integral components of competitive cropping systems (Blackshaw *et al.*, 2006). Electrostatic charging of agricultural sprays has several demonstrated advantages over conventional application methods, the most significant being more spray deposition on the target plants and less deposition on the ground (Bailey, 1988). Physical characteristics of charged sprays, such as their predisposition to deposit in the upper regions of the crop canopy (Morton, 1982), contribute to erratic pest control and have required that canopy penetration are an important part of the evaluation of such technology. Because most electrostatic charging has been done on naturally sedimenting sprays, the use of hydraulic pressure or air assistance has been suggested as a means of

enhancing the penetration characteristics of such sprays (Hislop, 1988). The combination of 45 kV electrostatic charge and 50 cm nozzle spacing produced maximum spray deposition on weeds and increase in deposition compared to the uncharged controls (Wolf *et al.,* 2000). Use of electrostatic sprayers has been studied for agricultural spraying (Kirk *et al.,* 2001, Kang *et al.,* 2004). Deposition of charged sprays on leaf abaxial (underside) and adaxial (upper) surfaces as influenced by the spray charging voltage, application speed, target height, and orientation parameters was studied in the laboratory by Maski and Durairaj (2010). Results showed that electrostatically charged spray improved the underside (abaxial) and overall deposition. Electrostatic spraying of pesticides was not successfully commercialized because of the higher cost of equipment and the relatively small coverage, especially on cereals. The latter was due to less penetration in to the crop canopy although the charge on small droplets was effective, which increased deposition and reduced downwind drift (Allen *et al.,* 1983; Lake and Marchant, 1984). The aim of this study was to investigate the effectiveness of different herbicide application methods of electrostatic charge and spinning-discs under natural weed flora in the irrigated wheat field of Shahrekord University region, Iran.

2. Materials and Methods

An air-assisted electrostatic induction spray charging system for water-based liquids designed at the Agricultural Research Engineering of Jehade-Isfahan, Iran was used (Fig. 1). That required a high velocity air flow (30 m s^{-1}) within the spraying head assembly to keep the charging electrode (8 kV) from accumulating water and then earthing the electrode. Earthed electrodes close to the spray had absorbent tubes along their lower edges and a suction system to recover spray liquid attracted to the electrodes.

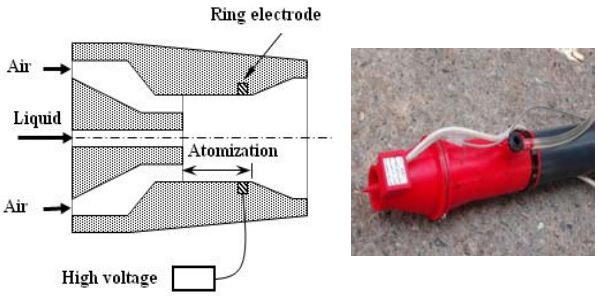

Figure 1. Electrostatic induction spray head

The charging nozzle consisted of a circular electrode and fluid jets. The high-voltage generator supplied high electric potential to the nozzle's electrode. The discharge rate of spray liquid was constant. A regulated quantity of spray liquid to the nozzle's individual fluid jets was supplied via spray liquid distributor. Two field experiments were carried out on irrigated wheat (*Triticum aestivum* L.) at the research farm of Shahrekord University in 2007 and 2008 to investigate the efficiency of different sprayer's nozzles on weed control in wheat grain yield, *Ghods* variety. A low volume spinning disc with the disc speed of 2000 rpm, *HERBI-4* (Micron Sprayers Ltd., UK) and electrostatic charge sprayer Jehade-Isfahan, Iran were used to spraying 2, 4-D at tillering stage of wheat to control broadleaved weed in cultivated wheat. Plot size measured 30×30 m, separated to be a distance of 5 m. Seedbed preparation was accomplished based on common local practices. Wheat population was 400 plants m^{-2}. The spray head was kept about 200 mm above the ground or weed foliage. The effective rate of 0.7 kg ha^{-1} 2, 4-D manufacturer's recommended dose, was used in all treatments. Sprayers were operated at a speed of 0.75 m s^{-1} at air temperatures of 20-25 ^{0}C and a relative humidity of around 36%. The wind speed at 2 m above the ground level was measured at 1-2 m s^{-1} using a direct reading cup anemometer, and the temperature and relative humidity were measured by a psychrometer whirled in the shade. Micron sprayers had a gravity feed reservoir and were powered with 6-V DC batteries. Weed population was measured separately for each quadrate to be counting the number of weeds and shoot weed biomass. Wheat grain yield were measured at maturity stage.

Water sensitive papers coated with Bromo Phenol Blue (30×100 mm) were used to determine drop density and size when the herbicide was applied. The water sensitive papers were evaluated using standard cards in WINDIAS software, Delta-T devices LTD, UK. Weeds shoot biomass was measured for each replicate of spray applications. The wheat yield was measured at crop maturity by hand harvesting the plots. The yields were adjusted to 13-14% moisture content. At harvesting time, all weed species were cut separately from soil surface and weighed. The effectiveness for herbicide on wheat crop was evaluated to be measuring wheat grain yield and weed shoot biomass. ANOVA from RCBD design was used for all data analyses with five replications. All the data met the assumptions of normality, so transformations of the data were not necessary. Significant mean values were tested with LSD at $P<0.05$.

3. Results and Discussion

The greater weed density and more variation of weed species were observed in the second year compared to the first year of the experiment (Table 1). *Bromus sp., Convolvulus arvensis, Galium sp.* were the most common weeds in the first year of the experiment and *Geranium sp., Descurainia sophia*, and *Bromus sp.* were the most infested weeds in the second years of the experiment. According to the analysis of variance, spraying herbicide on the wheat grain yield was significantly affected (P<0.05), but no significant differences were observed as a result of sprayer nozzles. The lowest yield was obtained with control treatment that had no spraying (Table 2).

It would be imprudent to extrapolate results from the present study to other species or herbicide mixtures because the demonstrated deposit size effect is likely dependent on the properties of the active ingredient or the adjuvant included in the mixture. Some spray components may have phytotoxic effects at high concentrations per unit leaf area, which may become important with large, no spreading deposit sizes (Wolf *et al.*, 1992). Previous research showed that the deposition was substantially influenced by factors such as charging voltage, application speed, plant target height, and target orientation (Maski and Durairaj 2010). Chemical weed control reduced weed competition in wheat, thereby giving the crop a better growing environment for enhanced growth and development. The results for weed control with spinning disc nozzles varied from poor to acceptable control when used in combination with herbicides or other agents compared with conventional nozzles (Walker 1986; Mohan and Nelson 1982; Scoresby and Nalewaja 1982). In our study, no significant differences were observed among different spraying methods. Due to more competition, grain wheat yield generally was lower in 2008 compared to in 2007. The varied relationship between the density of weeds and crop yield can be explained partially with the different environmental conditions during the growing season prevailing in two years. Weed dry matter production was the least in 2008 and the most in 2007 (Table 3). These results are in agreement with those reported in Mason *et al.* (1998). The plants may not have been conductive to electric charges and may, therefore, not have been a preferred ground for the charged spray compared to other weeds.

Improved deposition, distribution, and penetration of charged spray into the plant canopy considerably increase the biological efficacy (Hislop, 1988). It seems that the effectiveness for electrostatic spraying was higher in dense weed populations in the first year. The trends may be due to the fluctuation in

the environmental conditions of the experimental site. Spinning disc dispense the spray solution horizontally rather than downward as do the electrostatic sprayer. Therefore, gravity is the major force moving the droplets into the plant canopy. Possibly, smaller VMDs with spinning disc nozzles in the warm and windy conditions caused the inefficiency of herbicides in weed control. Buhler and Burnside (1987) speculated that increased weed control at larger droplet sizes may be due to greater canopy penetration of the herbicide solution. Increasing droplet frequency should increase the number of droplets penetrating the crop canopy. Droplet diameter could have effect on changing the efficacy of herbicides when applied with nozzles. Knoche (1994) reported that decreasing droplet size generally caused an increase in the performance of foliage to which herbicides had been applied, whereas decreasing carrier volume mainly caused a decrease in the performance. Droplets with small diameters can be affected with environmental conditions such as wind and temperature with drifting without reaching the target leaf surface. *HERBI-4* with 2000 rpm disc speed had a bigger VMD and had more effect, but electrostatic sprayer had lower uniformity and used more water. Pearson *et al.* (1981) found that spinning disc nozzles gave better results with 250 µm, VMD than smaller VMDs. Factors such as target (leaf) height from nozzle, target position on the plant, and plant species significantly influenced the depositional efficiency of electrostatic spraying (Sopp and Palmer, 1990). Derksen *et al.* (1991) reported that the low volume electrostatic sprayer performed better than the high volume sprayer while using only 1/25th of the carrier volume and treating the plants in one-third of the time.

4. Conclusions

Electrostatic forces on small droplets are more prominent than the gravitational forces and therefore, electrostatic charging of spray droplets can provide an improved deposition with reduced drift. The spinning disc nozzle had more droplet uniformity, but it did not significantly improve herbicide efficacy in dense canopy compared with the electrostatic charging sprayer. Spinning disc sprayers decreased water use and so was cheaper to operate, but did not improve herbicide efficacy. Spray penetration through dense weeds enhanced with electrostatic charging. If the problem of poor redistribution and poor retention of coarse sprays can be addressed, then such sprays may provide an opportunity for increasing spray penetration through a weed stubble canopy. Further work is required to identify the relative capture efficiencies of weed stubbles for a variety of sprays so that both spray penetration and retention on weeds can be optimized.

The Influences of work support and family support on Work-Family Conflict (W-FC) Among Married Female Nurses in Shiraz-Iran

Hajar Namayandeh[1], Siti Nor Yaacob [1], Rumaya Juhari [1]

[1.] Faculty of Human Ecology, University Putra Malaysia
h_nemayandeh@yahoo.com

Abstract: The present study highlights the significance of work support (supervisor and coworker support) on work-family conflict. Furthermore, this paper also examines the effects of family support (husband and family members/relatives support) on work-family conflict. This study examines 198 married female nurses in Shiraz-Iran. The findings revealed that low support received from husband, family members/relatives and supervisor might increase perceived conflict between work and family. Unlike previous studies, the finding also indicates that there is no significant relationship between the respondents' support from co-worker with work- family conflict, which may be explained by the specific cultural context in Iran. Implications are discussed and recommendations are made regarding future researches in this area.

Keywords: Work- family conflict, Work support, Family support

1. Introduction:

The rise in women's participation in the workforce has introduced new challenges for most families (Davidson & Burke, 2004). Families in which both husband and wife work, are more likely to create even more important conflicts between work and family (Livingston & Judge, 2008). In such families employed women have higher combined pressures from work and family responsibilities that lead them to experience work-family conflict (Pleck, 1977; Rexroat & Shehan, 1987). Based on this situation, scientists dedicated many investigations on this issue. However, according to Karimi (2008), more than 80% of investigations in this domain have been carried out in developed western society and very few comprehensive studies have been conducted in developing countries such as Iran. The results of the studies in developed countries are not necessarily interpretable in developing countries due to different cultural beliefs and practices (Grzywacz et al., 2007; Aryee 1992).

The participation of women in the workplace has increased in Iran. Statistics from 1956 to 1986 showed that about 9% of women in Iran were employed (Moayedi, 1994). The reported statistics for 2004 further revealed that 79.5% of women were employed (Statistical Bureau of Iran, 2004). Although women are working out of the home in Iran today, the structure of traditional way of thought about domestic works does not change much. Iranian women who already have a traditional role as housewives have to assume additional responsibility as an employee out of the home (Rastegarkhaled, 2004).

Nurses, like other female employees are faced with the demands of work and home responsibilities as their main daily tasks. According to Ministry of Health, nurses in Iran are mainly women. As of 2009, it was reported that 79.5% of Iranian nurses are female (ISNA, 2009). Nurses basically have to work in critical situation that includes dealing with high workloads and time pressures, number of hours worked, shift work, death and life situation, and stressful and demanding responsibilities. These situations have been denoted as the major issues in the nature of nurses' job (Adibhajbagheri, Mehnosh & Fazlallah, 2004).

Working outside and inside the house has formed two of the most central domains in women's life, each containing its own duties. According to Pleck (1977) work and family are two fundamental and interdependent systems for dual-career live that inconsistency in any one system may consequently influence the other one as well. This construct

represents conflict, namely, work interference with family (WIF). Accordingly, work-family conflict (W-FC) can be defined as the amount of conflict an individual experiences between her job or career and home-life (Mirrashidi, 1999).

The present study focuses on the role of social support in two dominant spheres of our lives, work and family. Studies of social support within the family and work could be relevant to the system theory. Both work and family could be classified into two subsystems. In the current investigation, the subsystem of work includes supervisor and co-workers support and subsystem of the family includes husband and family members/relatives support. Each of these subsystems might emotionally and/or instrumentally support the individual. This may suggests that support from each subsystem may influence other system. The present study aimed to consider the relationships between work support (supervisor and co-workers) and family support (husband and family members/relatives) with W-FC among nurses in the developing country with specific culture like Iran.

2. Social Support

Social support involves the exchange of resources between at least two persons, with the aim of helping the person who receives the support (House, 1981). For employed individuals, source of social support can be from work and family context. Social support can also be discussed in terms of emotional support (love, empathy, trust, concern) and instrumental support (time, money, goods, and services) (House, 1981). Further, two dimensions of social support sources have been identified: work support and family support. Both work and family setting may provide individuals with emotional and instrumental support.

3. Work support and W-FC

Social support at work can be derived from supervisor and co-worker. Previous studies successfully demonstrated relationship between social support and work interference with family. According to Yildirim and Aycan (2008) supervisory support included both instrumental and emotional supports. Instrumental support implied providing assistance and advice whereas emotional support referred to supervisor's emphatic understanding and sensitivity to work-family issue. Yildirim and Aycan found that social support could be best conceptualized as the main effect directly influencing work-family conflict among nurses in Turkey. Ahmad (1997) investigated the relationship between perceived support from supervisors, co-workers, and spouse, family and friends and work-family conflict among 239 married female production operators. The results showed that about two third of the operators experienced moderate to high intensities of conflict. In general, the operators received less support from their supervisors and they stated that if they received support from their supervisors, they may experienced less conflict.

In a different study, Thomas and Ganster (1995) examined the effects of supportive supervisors on work-family conflict. The respondents of study were 398 health professionals who had children aged 16 years or younger. The finding by Thomas and Ganster indicated a direct positive effect of supportive supervisors on employee perceptions of control over work and family matters. Control perceptions, in turn, were associated with lower levels of work-family conflict. The research study by Rastegarkhaled (2004) also found significant relationship between support from work and family with work-family conflict. The finding suggested that supportive supervisor provide more support for employee and this may reduce the conflict experienced by employees in their occupation and family environment.

Prominent among the sources of support from work is co-worker support. Michael et al. (2004) investigated on work-family conflict and social support received by the respondents from work colleagues and family members. Their research showed that colleague support reduced work interference with family sphere. Furthermore, Payamibosari (1995) concluded that support from co-worker is effective in reducing the work-family conflict of nurses in one of the hospital in Tehran. In contrast, the study by Kirrane and Buckley (2004) indicated that support of co-workers and supervisors at the workplace did not influence work-family conflict among 170 Irish working cohorts. The insignificant relationship may be due to the belief that after having a young child (6 years of age), the spouse-partner instrumental support becomes more important in determining W-FC.

4. Family Support and W-FC

Social support can be derived from husband and the family members/relatives. Past studies showed that family support functions to ameliorate work-family conflict. The study by Kim and Ling

(2001) indicated that if men provide greater support in terms of household chores and childcare, work-family conflict would not be a major problem for working women. However, this study indicated that spouse support plays an important role in reducing work-family conflict. Spouse emotional support has the greatest influence in reducing the level of work-family conflict among Singapore women. In another study, Aryee (1992) examined the impact of some antecedents of work and family domain variables on three types of work-family conflict (job-spouse, job-parent, and job-homemaker) among 354 married professional women from dual-career families in Singapore. Results indicated that spouse support reduces work-family conflict for these professional women.

Likewise, Thomas and Ganster (1995) reported that emotional support from one's partner in a dual earner relationship reduces the negative effects of work on family life among 398 health professionals who had children aged 16 years or younger at home. The results of this study suggested that organizations could take steps that can increase employees' control over family responsibilities and that this control might help employees better manage conflicting demands of work and family life. According to Chee (1997) respondents did not experience much work-family conflict primarily because they received a lot of support from their spouses. The above findings contradict the study by Aryee et al. (1999). Aryee et al. examined the relationship between role stressors, interrole conflict, and wellbeing and the moderating influences of spousal support and coping behaviours. The respondents were 243 Hong Kong Chinese parents from dual-earner families. The results of the study revealed that spousal support was unrelated to work-family conflict.

Another important source of family support is support from family members/relatives. According to an investigation by Rastegarkhaled (2004), family support for women could lead to lower level of work-family conflict experience among working women. Michael et al. (2004) investigated work-family conflict in relationship to the role of social support from work colleagues and family members. Their result indicated that family support was significantly correlated with work-family conflict. Those with higher family support tend to experience lower W-FC. The study by Carlson and Perrewé (1999) examined the role of social support in work-family conflict. The respondents of study were 403 from a department of a state government in the southeast. Their result indicated that family support was negatively associated with work-family conflict. Support from one's partner in a dual earner relationship reduces the negative effects of work on family life.

5. Methodology

The main objective of this study is to determine the relationship between work support (supervisor and co-workers), family support **(**husband and family members/relatives) and W-FC, among married female nurses in Shiraz-Iran. The population of the study consists of N = 647 married female nurses in 13 public hospitals in Shiraz. There were four criterias established for the selection of the population of this research; firstly, married female nurses who work for public hospital; secondly, the married female nurses who live together with their husbands; thirdly, nurses who have a minimum of 6 months job experience and have at least one child.

The method of data collection used was self-administered questionnaire and the study is correlation in nature. The respondents were selected by using simple random sampling technique. Initially, the identified and eligible sample size for the study was 323 respondents. Out of the total questionnaire distributed to the eligible respondents, only198 (61.30%) questionnaires were returned. Pilot study was conducted before the actual data collection to assess the adequacy of the questionnaire. In the present study, the Cronbach's Alpha for all measures used is mostly more than 0.70 indicating that the instruments are reliable to be used.

6. Measures

6.1 Work Family Conflict (W-FC)

Work-family conflict was measured by using work-family conflict and family-work conflict scale developed by Netemeyer, Boles, and McMurrian (1996). The scale consisted of 2 subscales: W-FC and F-WC. Each subscales consisted of 5 items. In this study W-FC subscale was used. Responses were obtained using a seven point Likert type scale where 1= strongly disagree, 2= disagree, 3= slightly disagree, 4= neutral, 5= slightly agree, 6= agree and 7= strongly agree. A sample item from this scale is "The amount of time my job takes up makes it difficult to fulfill family responsibilities". The scale scores range from 5 to 35, with high score indicates a high level of perceived

conflict between work and family and low score will indicate a low level of perceived conflict between work and family. The Cronbach's Alpha estimate in the present study for work-family conflict scale is .86.

6.2 Social Support: Work Support, Family Support

Social support from the work and from family was measured by using social support scale developed by Caplan, Cobb, French Jr, Harrison, and Pinneau Jr (1975) with minor adaptation. The scale consisted 4 items related to emotional support (the extent to which the sources of support will help, how easy to talk to the sources of support about your personal problems) and instrumental support (sources of support include things easier and can be relied on). This measure has been widely used and has remained one of the most established scales used to measure social support in a job (Lim, 1996). One new item was added to respondents' satisfaction with the support received from sources of support. Altogether, 5 items was used to measure support from:

1. Husband
2. Family members / relatives
3. Supervisor
4. Co-workers

The item were answered on a 4 point likert-type scale option from 0 = not at all, 1 = a little, 2 = somewhat and 3 = very much for the four items, while the score for additional item range from 0 = very dissatisfied, 1 = dissatisfied, 2 = satisfied and 3 = very satisfied. The scores for each source of support range from 0 to 15. High scores show that respondents perceived high support from each source of social support. The Cronbach's Alpha estimates for social support in the present study are husband (.89), family members/relatives (.88), co-worker (.83) and supervisor (.83).

7. Results and Discussion

7.1 Descriptive Statistics

Table 1 presents descriptive data that includes mean, standard deviations, minimum and maximum scores of all variables of the study. The finding of this study shows that most of the participants (56.1%) are below 36.50 years old. More than half of the respondents (56.1%) have been married for less than 11.68 years. Moreover, more than half of the respondents (56.6%) have less than 12.49 years job experience.

Figure 1 presents categories of the scores for all variables of the study. The finding shows that most of the respondents received high support from husbands and family members/relatives while large proportion of respondents received moderate and low level of supervisors and co-worker support. Respondents' total scores in W-FC are illustrated in Figure 1. A large proportion of the respondents perceived moderate and high level of work-family conflict. The remaining respondents have low level of work-family conflict.

Table 1: Descriptive Statistics

Variables	Min	Max	Mean	SD
Age (Years)	23	59	36.50	7.15
Job Experience	1	30	12.49	6.86
Duration of Marriage	1.90	40	11.68	7.55
Work-family conflict	8.00	35.00	24.36	6.51
Support from husband	0.00	15.00	9.42	4.10
Family members/relatives' support	0.00	15.00	9.00	4.20
Co-worker' support	0.00	15.00	6.53	3.55
Supervisor' support	0.00	15.00	5.89	3.79

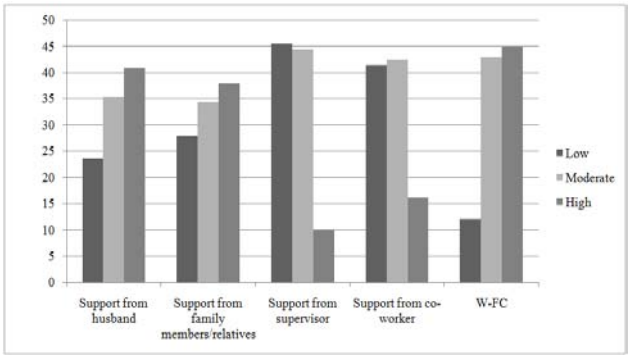

Figure 1: Categories of the scores of variables

7.2 Hypotheses Testing

Ho1: *There is no significant relationship between respondents' support from supervisor and W-FC.*

The finding from Pearson Correlation analyses showed a significant negative relationship between the respondents' support from supervisor with W-FC ($r = -.143$, $p \leq .05$). Hence Ho1 was rejected. The finding indicates that decreasing support from supervisor is associated with increasing W-FC. The finding is consistent with findings of past studies by Yildirim and Aycan (2008), Rastegarkhaled (2004) and Ahmad (1997), which have successfully recognized that supervisory support

could be best conceptualized as having effect on W-FC. Considering the available evidence, it appears that support from supervisor in work will influence respondents' life with family. Married female nurses require supervisors to provide enabling conditions at the hospital to minimize work interference with family responsibilities.

Ho2: *There is no significant relationship between respondents' support from co-worker and W-FC.*

The finding indicated that there was no significant relationship between the respondents' support from co-worker with W-FC ($r = .071$, $p>.05$). Hence Ho4 was failed to be rejected. This direction of relationship is consistent with finding of past study by Kirrane and Buckley (2004) that reported co-workers did not influence W-FC among 170 Irish working adults. In contrast, Payamibosari (1995) concluded that support from co-worker is the more effective support reducing the W-FC of nurses in one of the hospital in Tehran. Furthermore, Michael, Brough, and Kalliath (2004) showed that colleague support could reduce the consequences of work interference with family in some situations. It should be mentioned that despite the lack of significant relationship between the respondents' support from co-worker with W-FC there was discrepancy in regard to two variables. One possible explanation for this result may be due to difficult conditions of work in hospital, support from co-worker is not common among nurses in these hospitals. According to Adibhajbagheri, Mehnosh and Fazlallah (2004) feeling of lack cohesion among nurses create an atmosphere of lack of support and mutual trust between them.

Ho3: *There is no significant relationship between respondents' support from husband and W-FC.*

The finding showed a significant negative relationship between the respondents' support from husband and W-FC ($r = -.183$, $p\leq.05$). Hence Ho3 was rejected. The finding indicates that increasing support from husband is associated with decreasing W-FC. This direction of relationship is consistent with finding of past studies by Aryee (1992) and Kim and Ling (2001) which found that spouse support reduces W-FC for Singapore women. Another studies by Greenhaus and Beutell (1985), Chee (1997) and Thomas and Ganster (1995) also mentioned that social support from supportive spouse is a factor that can reduce W-FC. Considering the available evidence, it appears that respondents' support from husband has consistently been shown to be the most significant antecedent of W-FC. Based on this finding, it would be of interest to elucidate that support from husband in family would influence work. Respondents need the husband support to provide enabling conditions at home to minimize the interference of work with family responsibilities.

Ho4: *There is no significant relationship between respondents' support from family members/relatives and W-FC.*

The finding from Pearson Correlation analyses showed a significant negative relationship between the respondents' support from family members/relatives and W-FC ($r = -.198$, $p\leq.01$). Hence Ho1 was rejected. The finding indicates that increasing support from family members/relatives is associated with decreasing W-FC. This direction of relationship is consistent with findings of past studies by Michael, Brough, and Kalliath (2004) and Carlson and Perrewé (1999) who found that respondents who received higher family support experienced less conflict between work and family. The present finding also support Rastegarkhaled's (2004) study which concluded that family support reduce W-FC. Considering the available evidence, it appears that respondents' support from family members/relatives has consistently been shown to be the most significant antecedent of W-FC. Based on this finding, support from family members/relatives in family will influence work. Respondents' need the family members/relatives support to provide enabling conditions at home to minimize the interference of work with family responsibilities.

8. Conclusion and implication

In conclusion, results from the present study suggest that low support received from husband, family members/relatives and supervisor might increase perceived conflict between work and family. Establishing and reinforcing family support policies that include emotional family support and sharing of household chores can be effective in balancing cohesion and adaptability among family members. Consequently, balance in cohesion and adaptability in family could affect work positively and hence reduce W-FC. In addition, according to Adibhajbagheri, Mehnosh, and Fazlallah (2004), difficult work condition in hospital has increased feelings a lack of support and cohesion among nurses in Iran.

Therefore, administering work support policies (e.g. child care and elder care services, flexible working schedules and welfare of nurses) may result in higher work satisfaction and motivation among nurses; and ultimately culminated a sense of cohesion and closeness among them. Hence, these policies might help working women manage the demands from work and family domain, and consequently reduces the W-FC.

9. Recommendations for Future Study

There are several recommendations and limitations that have been identified throughout this study, which may direct future studies. Primarily, having a low response rate and relying on one city for data collection limit the generalizability of the findings. Also, findings cannot be attributed to nurses of private hospitals. Accordingly, the results are not generalizable to the entire nurse population in Iran. Assessing the variables of the model across gender would contribute to the generalizability of the results. This study also needs to be replicated with a more heterogeneous population such as other ethnic groups, religions, occupational variations and different cultural values. More studies of this nature should be conducted especially among women in Middle Eastern countries. Finally, this study used a self-report measure (questionnaire). Thus, future researches can use combined methods of data collection to strengthen and enrich the findings.

Effect of using pectin on lead toxicity

Dalia, M. El-Nahal

Special Food and Nutrition Dep., Food Technology Research Institute, Agric. Res. Center, Giza, Egypt
daliaelnahal@hotmail.com

ABSTRACT: Lead has many undesired effects on humans and animals, including neurological, behavioral, respiratory, visual, growth retardation, hematological immunological, renal, hepatic. **The aim of** the present study was to investigate the alterations in biochemical parameters in serum and blood due to lead retention in blood, organs and estimating the role of low and high esterified pectin in alleviating the negative effects of lead. **Material and Methods**: Sixty male *albino* rats which were divided into ten groups (6 rats for each). The first group (was fed on basal diet ;normal control). Groups 1,2 and 3 [which were fed on basal diet and administrated lead acetate (LA) daily once a time for 30 days by gavages at three different concentrations 61.94, 30.97 and 15.49 mg /Kg bw (1/4, 1/8, and 1/16 of lead acetate LD_{50};positive control]. Groups 4,5 and 6 [were fed on basal diet containing 10% low esterified pectin (LEP, DE 31%) and administered the same LA doses]. Groups 7,8 and 9 [were fed on basal diet containing 10% high esterified pectin (HEP, DE 73.5%) with the administration of the same LA doses]. **Results** obtained showed that LA significantly induced a decrease in body weight, serum total protein, albumin, globulin, total billirubin, direct billirubin, indirect billirubin, RBCs and WBCs counts, blood haemoglobin (Hb), heamatocrite values (PVC), serum triidothyronine (T3)and thyroxin (T4) levels. In the contrary, alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (AlP), gamma glutamyl transferase (γ-GT) activities, serum urea, uric acid and creatinine were significantly increased in positive control rat groups. Additionally, treatment of rats with LA led to a considerable increase in accumulation of the metal in the blood, liver, kidney, brain, heart and bones compared with the normal group. LEP and HLP significantly decreased the effect of LA on the tested parameters and level of lead in different organs. Histopathological examination clearly indicated that LEP or HEP eliminated from the harmful effect of LA on liver, kidney and brain tissues. **In conclusion**, LEP and HLP have beneficial effects which could be able to antagonize lead toxicity. Moreover, LEP was contributed to fast elimination of the lead acetate to blood, organs and bones, whereas HEP removed lesser amount of lead. It could be recommended that LEP has a good effect to bind material of lead and should be incorporated into human food to reduce the hazards toxicity of lead pollution of food and water.

Key words: Lead toxicity, esterified pectin, Histopathological examination

1-INTRODUCTION

Lead is a pervasive and persistent environmental pollutant that can be detected in almost all phases of environment and biological systems. Lead dispersion in ambient air, in many foods, in drinking water, and in dust, Khotimchenko *et al,* (2007) and especially in the 20th century, because of the industrial applications, Landrigan *et al.*, (2000). Although lead is one of the most useful metals, it is also one of the most toxic, Shotyk and Le Roux (2005). It was indicated that lead can cause neurological, hematological, gastrointestinal, reproductive, circulatory, and immunological pathologies, Hao *et al.*,(2002); Patrick, (2006), reproductive dysfunctions ,Marchlewicz *et al.*, (1993). Moreover, lead acetate and lead phosphate are listed as carcinogens.Inorganic lead compounds were classified as 2B chemicals by IARC, Pulido and Parrish, (2003). It was reported that lead increased the level of lipid per-oxidation,Upasani *et al.*, (2001). It can lead to inhibition of the activities of antioxidant enzymes, including glutathione peroxidase, catalase and superoxide dismutase, Silbergeld *et al.*, (2000). Furthermore, generation of reactive oxygen species (ROS), stimulation of lipid peroxidation and depletion of antioxidant reserves which was postulated to be major contributors to lead-exposure related diseases ,Patrick, (2006).

Pectin is the ionic plant polysaccharides widely used in food industry because of their gelling and thickening properties, Thakur *et al*, (1997). Pectin is a group of complex polysaccharides that contain 1,4-linked-d-galacturonic acid , Willats *et al*, (2001). There are three major pectic polysaccharides: homogalacturonans, rhamnogalacturonans-I, and rhamnogalacturonans-II. Natural pectins are highly esterified and contain more than 50% of esterified carboxyl groups, whereas LE pectins can be prepared Ridley *et al, (*2001). The number of esterified carboxyl groups determines the degree of

esterification, which is one of the important chemical parameters of pectins ,Schols and Voragen (1996).

It was shown that some physiological effects, for example, interactions with bile acids or drugs, may depend on the pectin structure, Dongowski *et al*, (1997).

The goal of this study was to determinate the relationship between structure of the pectin compounds with a high degree of esterification (HE pectin), and low esterified pectin (LE pectin) and their effects on lead absorption, retention, and removal in laboratory rats.

2-MATERIALS AND METHODS

2.1.Materials:

2.1.1.Chemicals and kits:

1. Pure lead acetate was purchased from Sigma Chemical (St. Louis, Mo). All other chemicals were of the highest available quality.

2. Genu® citrus pectin type 105 rapid set has high degree of estrification (DE) 73.5% and partially esterified Genu® citrus pectin type LM 104 As (31%DE) were obtained from Copenhagen pectin, Lille Skenved, Denmark.

3. Nitric acid 69% analar BDH and perchloric acid 70% Aldrich.

4. Biomerieux kits were obtained from Randox Laboratories Ltd., Diamond Road, Crumlin Co., Antrim, United Kingdom, BT294QY.

2.1.2. Experimental animals:

-Sixty male *albino* rats weighing 100 ± 5 g were obtained and housed in Food Technology Research Institute, Agricultural Research Center, Giza, Egypt. The rats were kept under normal health laboratory conditions and fed on basal diet for one week. Water and basal diet were provided *ad libitum.* The basal diet consisted of protein (casein) 20%, cellulose 10 %, salt mixture 4%, vitamin mixture 1%, corn oil 10% and corn starch 55% according to (Pell *et al.* 1992). The adaptation period was one week.

-Rats were weighted twice weekly, total feed intake of each rat was weighted and feed conversion efficiency (gain weight of rat/ total feed intake, g) was calculated.

-Animals were weighted and randomly divided into 10 groups each one containing six rats, as follows:

Normal control: fed on basal diet.

Group 1: Positive control 1, fed on basal diet and administered 1/4 LD_{50} of LA.

Group 2: Positive control 2, fed on basal diet and administered 1/8 LD_{50} of LA.

Group 3: Positive control 3, fed on basal diet and administered 1/16 LD_{50} of LA.

Group 4: Fed on basal diet containing10% low esterified pectin (LEP) and administered 1/4 LD_{50} of LA.

Group 5: Fed on basal diet containing 10% low esterified pectin (LEP) and administered 1/8 LD_{50} of LA.

Group 6: Fed basal diet containing 10% low esterified pectin (LEP) and administered 1/16 LD_{50} of LA.

Group 7: Fed basal diet containing 10% high esterified pectin (HEP) and administered 1/4 LD_{50} of LA.

Group 8: Fed basal diet containing 10% high esterified pectin (HEP) and administered 1/8 LD_{50} of LA.

Group 9: Fed basal diet containing 10% high esterified pectin (HEP) and administered 1/16 LD_{50} of LA.

2.2. Methods:

2.2.1. Low and high esterified pectin:

2.2.1.1. Determination of galactouronic acid: The pectin content of low and high esterified pectins were determined as galactouronic acid by high performance liquid chromatography as described by Hicks *et al.,* (1985) with modification: 200 mg of low and high esterified pectin, dispersed in 1 ml of iced-cold 80% sulfuric acid, was allowed to set at 25 ºC for 18 hours. The sample was then diluted to 13 ml, sealed in a vail, and placed in a boiling water bath for 5 hours. The resulting dark solution was neutralized with solid calcium carbonate, filtered (0.2 µm) and injected into the chromatography.

Galactouronic acid was identified by a Hewlett Packard HP 1050 High performance liquid chromatography (HPLC) equipped with refractive index 1047 HP, Column compartment was set at 85 ºC, degaser and autosmpler. The chromatograph was fitted with Bio Rad HPX-87-C model (30cm× 7.8m id.) Isocratic elution system was used by deionized water at the flow rate 0.8ml/min.

2.2.2.1. Determination of degree of esterification: Methoxyl content was determined by the measurement of methanol liberated on saponification of the pectin according to the method described by Speirs *et al.,* (1980) as follows: 2 g of tested high and low pectins were homogenized with 150 ml water; the samples were saponified by the addition of 20 ml of 1M NaOH then allowed to stand for 30 min. at room temperature. The alkali was then neutralized by the addition of an equivalent amount of 0.5M HCl. The resulting acid mixture was transferred to 250ml volumetric flask and made up to the volume with distilled water. The contents of the flask were centrifuged at 12000 rpm for 20 min. the supernatant

was decanted off and retained until analysis of methanol released by using gas chromatography (Knuth, *et al.,* 1984 and litchman and Upton, 1972).

Gas chromatography condition: Analysis was performed on Hewlett- Packard Model 5890 gas chromatography equipped with flame ionization detector. The instrument was also equipped with HP-1 column (cross-lanked methyl silicone) 30 m x0.53 mmx 0.88 µm film thickness. Detector and injection port temperature was 250 ºC for each, nitrogen (15ml/min) was used as a carrier gas and hydrogen (15 ml/min and air 240ml/min was used for the flame operation. On-column injections of 1.0µl were used for all samples and standards. Columns were pre-conditioned with a nitrogen flow (15 ml/min) for 1 hr. at 30 ºC, then programmed at 4 ºC/min to 150 and held for 15 min. The reactive area under the peaks obtained from the chromatogram may be used to calculate the methoxyl content of the sample using the following relationship.

Methoxyl content (W/W)% = $1.211A_1 / (A_2 \times W)$. When: A_1 = area under the peak of sample. A_2 = area under the peak of standard. W = weight of sample (g).

Degree of esterification (DE) = (methoxyl content × 612%)/ galactouronic acid%.

2.2.2. Biochemical assay:

Blood samples were collected from the animals. Heparin was used as an anticoagulant. Serum was kept frozen at –20 ºC for biochemical assayas following:

-Alanine aminotransferase (ALT; EC 2.6.1.2) and aspartate aminotransferase (AST; EC 2.6.1.1) activities were assayed by the method of Bergmeyer and Harder (1986).

-Alkaline phosphatase (Al P; EC 3.1.3.1) activity was measured at 405 nm using the method of Varley *et al* (1980).

- Gamma -GT was measured according to the method described by Szasz (1960).

-Serum total protein (TP) was analyzed using the method of Lowry *et al* (1951).

- Albumin concentrations were determined by the method of Doumas *et al* (1977)

- Globulin concentrations were determined by difference (TP - albumin).

-Serum total billirubin and direct billirubin was measured using the method of Walters and Gerade (1970). Indirect billirubin was calculated by difference between Serum total billirubin and direct billirubin. - Creatinine, urea and uric acid were determined by using the methods described by Larsen (1972), Patton and Crouch (1977) and Caraway (1955).

-Total Triiodothyronine (T3) and Total Thyroxin (T4) hormones were estimated in serum samples using DIMA GmbH Diagnostics kits, Goettingen, Germany according to the method described by Young *et al,* (1975) and Sterling (1975), respectively

2.2.2. Hematological evaluation:

Leucoytes count (WBC_s), red blood cell (RBC_s), blood haemoglobin (Hg) and haematocrite value (PVC) estimated by Wintrobe (1967); Dacie and Lewis (1975); Leong *et al* (2003) and Burch and Siegel (1971),respectively.

2.2.3. Measurement of lead concentration:

2.2.3.1. In the blood;

Approximately 1 ml of blood was digested with nitric and perchloric acid mixture (Kolmer *et al.*, 1951). Two to three blank samples were run simultaneously with each batch of the digestion where bio-sample was substituted by de-ionized distilled water. The equal quantity of acid mixture was added to the blank, standard and test digestion tubes during low heat digestion.

2.2.3.2. In organs and feces;

At the end of the experimental period, organs (liver, kidney, brain, heart and bones) were isolated and feces were collected and stored at -20ºC for wet digestion and analysis of lead content.

To accurately weight of tissue and feces in 125 ml Erlenmeyer flask, add glass beads and 25ml deionized water, add 10 ml 1:2 (equal volumes) mixture of concentrated HNO_3 and $HClO_4$. Boil the sample until the solution is clear ,Parker *et al*, (1967). Transfer the solution quantitatively to 100 ml volumetric flask. Dilute to volume with deionized water and mix well.

The lead concentrate in blood, organs and feces was estimated using a Perkin Elmer Plasma 400, Emission spectrometer, Koirtyohann (1994). The average reading of the blanks was first subtracted from that of standard and test samples and then calculation was made for their lead concentration in µg/dl of blood and µg/g of wet tissue and feces.

2.2.4. Histopathological studies:

Tissue specimens from rat's liver, kidney and brain were fixed in 10 % neutral buffered formalin solution. The fixed specimens were trimmed, washed and dehydrated in ascending grades of alcohol, cleaned in xylene, embedded in paraffin then sectioned (4-6 micron) and stained with hemato-xylene and eosin according to Bancroft *et al* (1996). The degree of injury was estimated using an ordinal scale modified from Palaa and Charbonneau (1994).

2.2.5. Statistical analysis:

Each parameter was analyzed separately by using one-way analysis of variance (ANOVA). For determining differences between groups, the Duncan test was used. All *p* values of <0.05were considered to be significant.

3. RESULTS

As a majority of polysaccharides, pectins are heterogeneous compounds regarding structure, molecular weight, and physicochemical properties. These parameters of pectins vary from one fruit species to another and also during the different developmental stages of the fruit (Chang *et al*, 1994) as well as in the process of chemical and enzymatic modifications.

The galactouronic acid concentration in high and low esterified pectin were 75.72 and 78.53%, respectively. The assay showed degree of esterification to be approximately 73.5 and 31% respectively in high and low esterified pectin respectively**.**

3.1. Growth of rats:

Data in Table (1) show changes in the weight and the feed conversion efficiency (FCE) of the tested rat groups. Significant differences between groups in weight gain were noticed. The highest accumulated weight gain was recorded by G9 and normal control which fed 10% HEP + 1/16 LD_{50} of Pb and normal control, respectively. However, the lowest accumulated weight gain was observed in positive control rat groups (G1, G2 and G3). No significant difference appeared for feed intake of all tested rat groups. At the same time, feed conversion efficiency (FCE) was also decreased by administered oral doses of lead acetate without fed HEP or LEP (G1, G2 and G3).

Data presented in Table (3), show significant differences among tested rat groups in their serum total protein, albumin, globulin, total billirubin, direct billirubin and indirect billirubin at the end of experimental period. Positive rat groups (G1, G2 and G3) had significant decrease compared with treated rat groups and normal control. There were no significant differences observed between the tested rat groups in A/G ratio.

3.2. Biochemical assay:

3.2.1. 1.Liver function

The level of serum ALT, AST, ALP and γ-GT activities are presented in Table (2). Significant increases were observed in these enzymes activity in rat groups administered lead acetate doses without fed HEP or LEP. There was friary difference between normal control, G6 (fed 10% LEP + 1/16 LD_{50} of Pb) and G9 (fed 10% HEP + 1/16 LD_{50} of Pb) at the end of experimental period in serum ALT and AST activities. Moreover, No significant difference was observed in serum ALP and γ- GT activities among tested rat groups expect positive control rat groups (G1, G2 and G3) at the end of experimental period.

Table (1): Weight gain, feed intake and feed efficiency ratio of rats fed on 10 % LEP or HEP and administrated different doses of lead acetate

3.2.2. **Kidney function:**

The level of serum urea, uric acid and creatinine are showed in Table (4). There was slight significant difference among the rat groups at zero time and rat groups fed 10 % LEP or HEP and administered different doses of lead acetate at the end of experimental period.

Table (3): Serum total protein (TP), albumin, globulin, A/G ratio, total, direct and indirect bilirubin of rats fed on 10 % LEP or HEP and administrated different doses of lead acetate

3.2.3. **Level of thyroid hormones, triidothyronine (T3) and thyroxin (T4):**

The effect of feeding on LEP or HEP on serum T3 and T4 levels of rats administrated different doses of lead acetate were studied and the results are shown in Table (6). Normal control rats group had significantly the highest serum T3 and T4 levels. Meanwhile, group 1 (administered 1/4 LD_{50} of Pb) had significantly the lowest serum T3 and T4 levels.

3.3. Hematological evaluation:

Hematological parameters observed in the normal control and experimental rat groups are shown in Table (5).The RBCs and WBCs counts, blood haemoglobin (Hb) and haematocrite values (PVC) significantly decreased in positive control rat groups compared to normal control group at the end of experimental period. However, these parameters significantly increased in rat groups fed on 10% LEP or HEP. It could be noticed that, RBCs and WBCs counts in rat groups fed with LEP were higher than others being fed with HLP in the same concentration of lead acetate. There was a fairly significant difference among all treated rat groups and normal control rats group in Hb. Meanwhile, there was no significant differences in heamatocrite values (PVC) between all treated rat groups and normal control rats group expect G7 (fed on 10 % HEP and administrated 1/4 LD_{50} of lead.

Table (4): Serum urea, uric acid and creatinene of rats fed on10 % LEP or HEP and administrated different doses of lead acetate

3.4.Concentration of lead retention in blood, organs and feces:

The blood lead level of 0.35 lg/ml is the critical level of poisoning, but the deaths commence at 1.0 lg/ml (Radostits *et al*, 2000). Sometimes, blood lead level above this critical level may not be manifested by characteristic clinical signs in animals (Koh and Babidge, 1986), particularly in chronically exposed cases. Moreover, uptake by bone mineral is a function of the metal's plasma concentration, its affinity for the bone mineral, and its effect on the extracellular matrix. It is also a function of the degree of mineralization of the skeleton.

Treating the rats with Pb in the form of acetate led to a considerable increase of accumulation of the metal in the blood, liver, kidney, brain, heart and bones compared with the normal group. Data in Table (7) showed that significant increase was observed in all rat groups administered lead acetate. At rat groups fed on LEP or HEP, there was decrease in lead concentration of blood, organs and bones. It could be noticed that, the efficiency of LEP on removal lead from tested blood and organs were higher than HEP in the presence of the same doses of lead acetate. Also, there was no significant difference in the lead concentration of heart compared to normal control group and G6 (fed on 10 % LEP and administrated 1/16 LD_{50} of lead. In all groups of animals fed on LEP or HEP, there was significant increase lead concentration in feces compared to the positive control rat groups (G1, G2 and G3) indicating continuous lead elimination through the digestive tract. LEP was helped to increase the amount of lead being excreted with feces. Amount of lead in feces of rats fed on HEP was significant decrease from that of rats fed on LEP in different doses of lead.

In this study, the use of the pectin substances in animals preliminary exposed to high doses of lead acetate contributed to fast elimination of the metal from the organs, in particular, the bones. Low esterified pectin prevented lead absorption in the intestine, resulting in slowed tissue retention of lead, whereas HE pectin removed lesser amount of lead. These results were confirmed by enhanced concentration on lead in feces of rats treated with LEP and HEP.

Table (7): Lead content of blood, liver, kidney, brain, heart, bone and feces of rats fed on 10 % LEP or HEP and administrated different doses of lead acetate

Rat groups	Blood (µg/dl)	Liver (µg/g)	Kidney (µg/g)	Brain (µg/g)	Heart (µg/g)	Bone (µg/g)	Feces (µg/g)

3.5.Histopathological studies:

3.5.1. Liver:

Histopathological changes of rats administered different doses of lead acetate with or without LEP or HEP are presented in Fig (1), where, liver samples of normal rats group showed normal

hepatic lobule. Liver of rats administered ¼ LD_{50} of LA (positive control 1) showed congestion of hepatoportal blood vessel and edema in the portal tract. Moreover, liver of rats administered 1/8 and 1/16 LD_{50} of LA (positive control 2 and 3) appeared focal hepatic hemorrhage and vacuolar degeneration of hepatocytes. Additionally, liver of rats administered ¼ LD_{50} of LA + fed on 10% of LHP clearly slight hydropic degeneration of some heptocytes. There was vacuolar degeneration of some hepatocytes of rats liver administered ¼ LD_{50} of LA + fed on 10% of HHP. No histopathological changes were observed in rats liver administered 1/8 LD_{50} or 1/16 LD_{50} of LA + fed on 10% of LHP or HHP.

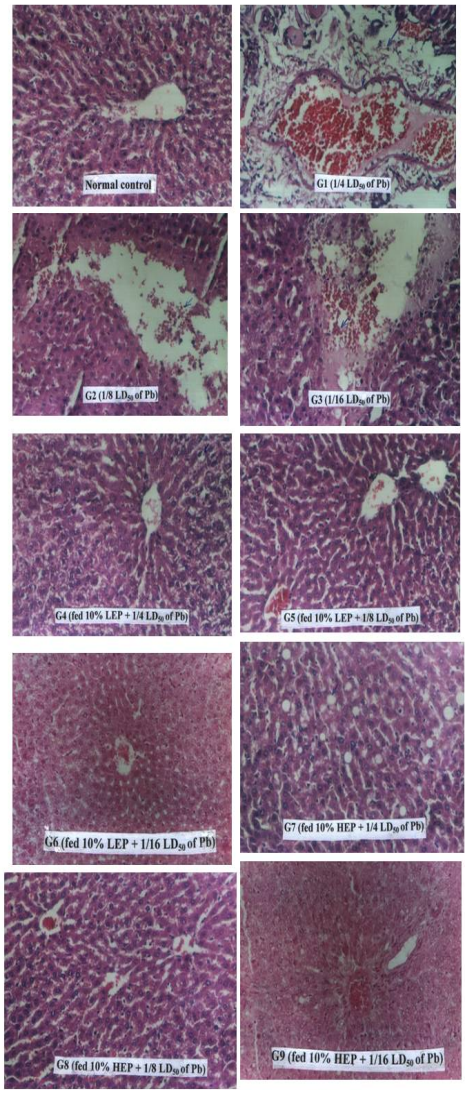

Fig. 1. Histopathological examination of rats liver fed on 10 % LEP or HEP and administrated different doses of lead acetate

3.5.2. Kidney:

Concerning kidney of normal control rats group, it showed the normal histology of renal parenchyma, Fig (2). Kidney samples of group positive control 1 appeared congestion of renal blood vessel and swelling of epithelial liming some renal tubules. Furthermore, kidney of rats administered 1/8 LD_{50} of LA (positive control 2) observed marked dilation and congestion of renal blood vessel. Additionally, there were vacuolation of epithebal lining renal tubules and thickening of the glomerular basement membrane of rats kidney administered 1/16 LD_{50} of LA (positive control 3). All the tested rat groups administered different doses of LA +fed on 10% of LHP or HHP showed no histopathological changes of kidney samples. It could be observed that LHP or HHP had the same effect to protect the kidney tissues from the harmful of lead acetate.

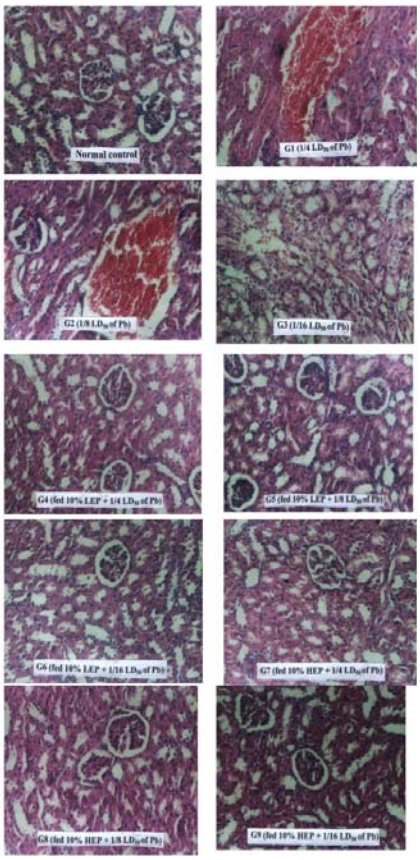

Fig. 2. Histopathological examination of rats kidney fed on 10 % LEP or HEP and administrated different doses of lead acetate

3.5.3.Brain:

Regarding the brain samples of normal control rats group, there was normal histological structure, Fig (3). In contrast, brain of rats from positive control 1 showed neuronophagia of

degenerated neurons. Moreover, there were pyknosis of neurons, focal gliosis and congestion of cerebral blood vessel in brain samples of positive control 2 and 3. The feeding on LHP had protected effect of brain tissues. There was no histopathological changes of brain rat groups fed LEP. Brain of rats administered ¼ LD_{50} of LA + fed on 10% of HHP showed neuronophagia of pyknotic neurons. However, cellular edema was the only change observed in brain of rats administered 1/8 LD_{50} of LA + fed on 10% of HHP. Some examined sections of brain rats administered 1/16 LD_{50} of LA + fed on 10% of HHP showed apparent normal structure.

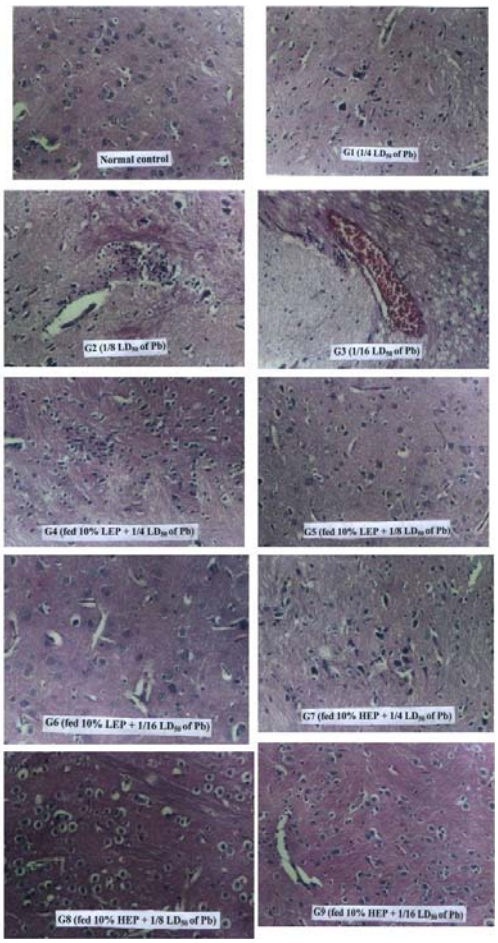

Fig. 3. Histopathological examination of rats fed on 10 % of LEP or HEP and administrated different doses of lead acetate 4.DISCUSION

Lead is a common environmental occupational toxic heavy metal, is known to have direct and indirect effects on biological systems and cells . It is an ubiquitous toxic agent, and its toxicity remains an important public health problem because of the great amount of sources in any household and environment .Its toxicity affecting the nervous system, blood, and blood-forming organs, kidneys, and gastrointestinal tract, Paoliello and De Capitani,(2005).

Our results revealed that the lowest accumulated rat weight gain was observed in positive control rat groups. In addition, there were no significant difference appeared for feed intake of all tested rat groups. At the same time, feed conversion efficiency (FCE) was also decreased by administered oral doses of lead acetate without fed HEP or LEP .This is in accordance to Kang *et al.* (2004) ; Berrahal *et al* (2007);El Nekeety *et al* (2009) ; who reported that mean body weight of the animals treated with LA was significantly lower than that of the other groups. With other organisms also, Hiraga *et al* (2008) exposed young chickens to five lead shot and found that rate of growth was slightly lower in the Pb-exposed group from day 6.

Liver is considered to be the principal target organ for lead toxicity, Abdel-Wahhab *et al.*,(2007).To test for liver function in the present study, results of indicated that HEP or LEP had positive effect on level of serum ALT, AST, ALP and γ- GT activities which were raised by different doses of lead acetate especially at the lowest doses of LA. These results agreed with results obtained by many investigators who studied the effect of lead on liver function; Othman *et al, (*1998); Sivaprasad *et al* (2003) ;Shalan *et al.* (2005) . On the contrary, experiments conducted by Pande *et al*,(2001);Singh *et al.*, (1994) in rats receiving oral administration of lead acetate they reported a significant decrease in the activities of these two enzymes compared to the controls. Studies conducted by Jarrar and Mahmoud (2000); Jevtovic-Stoimenov *et al,(* 2003); Shalan *et al.*, (2005) showed significant increase in the γ- GT activity after a period of Pb exposure for the rats.

Studies in humans have indicated an increase in the activity of these enzymes. Nehru and Kaushal (1993) ;Goswami and Bhattacharya (2000) .Serum total proteins and albumin level, normally used to assess the ability of synthetic function of the liver is well understood and documented ,Adeyemi *et al* (2009). Billirubin is regarded as a member of the antioxidant family, even though it is known to have toxic effects at high concentrations ,Hagymàsi *et al.*, (2003) . It has been regarded for many years as cytotoxic, mainly because of its association with neonate jaundice and its possibility of provoking irreversible brain damage at high concentrations ,Tomaro and Batlle,(2002).

Our results reported that serum billirubin of test rat was found to be about two folds that of control while the serum albumin concentration of test rat was about half that of the control. This result agreed with experiments conducted in rats receiving

lead acetate reported similar decrease in the serum total protein and albumin levels ,Jevtovic-Stoimenov *et al,(* 2003) ,Swarup *et al(,*2007). The decreased level of protein may indicate protein catabolism dysfunction ,Abdel-Wahhab *et al.*,(2008). Moreover, Berrahal *et al* (2007); Adeyemi *et al* (2009) noted a significant increase in the billirubin level (*p* the group of rats treated with Pb compared to control, while serum globulin and albumin concentrations of serum of test rat was significantly lower ($p < 0.05$) than those of control.

Urea and uric acid are the principal waste products of protein catabolism. They are synthesized in the liver from ammonia produced as a result of the de-amination of amino acids ,Young, (1972). Creatinine is the major waste product of creatine metabolism by muscle. In the kidney, it is filtered by the glomerulus and activity excreted by the tubules. Moreover, free creatinine appears in the blood serum ,Baker *et al*, (1979).

There was increase in serum urea, uric acid and creatinine appeared in positive rat groups of our results. Which situation agreed with results of Abdel-Wahhab *et al.* (2007); El Nekeety *et al* (2009); Adeyemi *et al* (2009) studies who illustrated that the exposed to lead increase levels of serum urea may indicate kidney dysfunction than normal control. Scientists explained cause of diseases of the kidney for two consequences; The first is failure to retain substances such as protein, amino acids, sugar, water and ions. The second consequence is failure to excrete substances such as urea, creatinine and the waste products. The presence of lead might have caused impairment of the brush border epithelial cells and making them impermeable to urea and creatinine thereby causing their elevated levels in the blood. The over all effect of this may be impaired kidney function, Oloyede *et al,(*2003).

Serum T3 and T4 levels are considered valuable indicators of thyroid function in animals ,Bruker, (1998); Chaurasia and Kar, (1998). It was clearly from our results that LEP and HEP had a positive effect to keep the level of T3 and T4 in serum nearly within normal especially in group that fed on 10% LEP and administered 1/16 LD_{50} of Pb. In this concern, Wade *et al* (2002) cited that altered serum thyroxine (T4), triiodothyronine (T3) and histomorphology of thyroid gland were recorded following subchronic exposure to a complex mixture of 16 organochlorine chemicals, lead and cadmium in male rats for 70 days. Decreased serum thyroxine (T4) and triiodothyronine(T3) level was also noticed by Pratima *et al,(*1997)in fresh water fish (*Clarias batrachus*) after subchronic exposure to lead and cadmium. Chaurasia and Kar, (1998) noticed that in chicken exposed to dietary lead at 1 mg/kg bodyweight for 30 days ,a significant reduction in T3 level and T4 in their serum . Contradictory reports were also available in human subject on the level of circulating thyroid hormones after lead exposure ,Schantz and Widholm, (2001). In addition, Dundar *et al* (2006) mentioned that long-term low-level lead exposure may lead to reduced T4 level without significant changes in T3 level in adolescents even at low Pb-Blood levels.

The hematological system is the major target of low level lead exposure ,Warren *et al.*, (1998). Therefore, lead exposure induces severe oxidative damage in RBCs by inhibiting heme , hemoglobin synthesis and changing erythrocyte morphology and survival , as a result from direct interaction of lead with RBCs membranes, inducing lipid peroxidation , Leggett (1993) ;Sandhir *et al.*,(1994).

From our results ,it could be noticed that, RBCs and WBCs counts in rat groups fed with LEP were higher than others being fed with HLP in the same concentration of lead acetate. Also, there was a fairly significant difference among all treated rat groups and normal control rats group in Hb. Meanwhile, there was no significant differences in heamatocrite values (PVC) between all treated rat groups and normal control rats group expect G7 (fed on 10 % HEP and administrated 1/4 LD_{50} of lead. In concerning that, Simsek *et al* (2009) found that RBCs and WBCs counts, Hb, PCV and values significantly decreased in rats group exposed to lead acetate compared to the control group. Also, Ancheva *et al* (2003) illustrated that lead cause damage to the erythrocyte membrane resulting in hemolysis or a decrease of blood iron level which may be the cause of decreased concentration of haemoglobine and hematocrit value.Chronic oral lead administration cause the development of hypochromic anemia and hemolytic anemia.

Treating the rats with Pb in the form of acetate led to a considerable increase of accumulation of the metal in the blood, liver, kidney, brain, heart and bones compared with the normal group. O'Flaherty (1991) in accordance, showed that the average Pb concentration in bone of rats administered lead acetate rapidly increased. Timchalk *et al* (2006) exposed the rats to oral gavages doses of 1, 10, or 100 mg Pb-acetate/kg/day daily. They cited that Pb-acetate when administered by oral gavages weres rapidly absorbed, since peak blood Pb concentrations were attained within 30 min to 1 h post-dosing and the Pb rapidly redistributed (within 5-days post-treatment) from the blood into the bone compartment based on the substantial decrease in WBcs and RBC Pb concentration, and the concurrent increase in bone Pb following repeated exposure at all dose levels. Moreover, Adeyemi *et al* (2009) found that possible

damage to the tissues of rats placed on water contaminated with lead (0.015 lg/l). The heart and liver were the last sensitive tissues to lead retention.In addition, all groups of tested animals in the present study, fed on LEP or HEP, showed a significant increase lead concentration in feces compared to the positive control rat groups indicating continuous lead elimination through the digestive tract. In this situation, lead concentration in serum and organs was reduced after pectin administration. Dongowski *et al,(*1999) stated that application of native pectin as well as oligogalacturonic acids increased lead elimination through blood and organs. And addition of rhamnogalacturonic parts of pectin into the lead-enriched diet in rats contributed to slow absorption of lead in rats and enhanced lead excretion with feces during the period of the experiment. Moreover, the structural parameters of pectin influence by its microbial degradation in the intestinal tract. Also, enzymes from intestinal microorganisms involved in pectin fermentation include pectatelyase, polygalacturonase and pectinesterase (Dongowski and Lorenz, 1998 and Tierny *et al*, 1994). Additionally, Serguschenko *et al* (2004) proved that pectin exerts high metal binding activity regarding bivalent metal ions. Drawing of absorption isotherms showed that pectin possesses pronounced affinity to lead ions in comparison to other bivalent metals, and some types of natural pectins may be more effective than chelating agents currently used to manage lead toxicity. In some cases, orally administered pectins contributed to increased retention of heavy metal in tissues (Rose and Quarterman,1987).

Many studies illustrated the effect of degree of methylation on the degradation of pectin in the intestinal tract of rats. Dongowski *et al* (2002) found that Low-methoxyl pectin was fermented faster than high-methoxyl pectins in *vivo* and in *vitro*. Kim *et al* (1978) illustrated that high esterified pectins require large amounts of sugar and low pH values for gel formation. While low- ester pectins form gel with or without sugar in the presence of divalent cations. So that the quantity of metal bound to pectin is determined by the number of free carboxyl groups ,Serguschenko *et al.,* (2007). This could enhance the concentration of lead acetate in feces of rats treated with low esterified pectin than high esterified pectin. Moreover, Kartel *et al* (1999) illustrated that high esterified pectin is characterized by a major part of carboxyl group in galacturonan pattern to be occupied with methyl radicals preventing interaction with metal. Therefore, the lowest binding activity of lead was registered in animals treated with different doses of high pectin sample. Also, using high doses of lead acetate and pectins contributed to a considerably rapid elimination of the lead from the rat body. Fast elimination of metal from tissues as a result of treatment with pectin substances led to redistribution of lead in the body of the animals. This could be confirmed by several fold increases of the metal contents in the liver and heart. This phenomenon is sometimes called “rebound” effect ,Gerhardsson *et al*, (1999).

Through our histological study, it was noticed that there was vacuolar degeneration of some hepatocytes of rats liver administered ¼ LD_{50} of LA + fed on 10% of HHP. There were no histopathological changes observed in rats liver administered 1/8 LD_{50} or 1/16 LD_{50} of LA + fed on 10% of LHP or HHP.

The histopathological examination of the liver tissue of the animals treated with lead showed that, lead(Pb)-induce DNA damage (Fracasso *et al.* 2002; Danadevi *et al.,* 2003 and Xu *et al.* 2003). On the other hand, Shalana *et al.* (2005) found that lead reduced hepatic total RNA content indicating a lower rate of hepatic protein synthesis. Furthermore, El-Zayat *et al.* (1996) reported a decrease in hepatic total protein content in response to lead intoxication. These authors attributed that to a decreased utilization of free amino acids for protein synthesis. In another report, Pagliara *et al* (2003) showed that lead-induced liver hyperplasia followed by apoptosis mediated by oxidative stress in kupffer cells. It could be observed that LHP or HHP had the same effect to protect the kidney tissues from the harmful effect of lead acetate.

Many investigates illustrated that the exposed of experimental rats to lead induced significant histopathological changes of kidney tissues ,Patra *et al.*, (2001) and El-Sokkary *et al*,(2005).

brain of rats from positive control , showed neuronophagia of degenerated neurons. Moreover, there were pyknosis of neurons, focal congestion of cerebral blood vessel in brain samples of positive control. The feeding on LHP had protected effect of brain tissues. There was no histopathological changes of brain rat groups fed LEP. Results clearly showed that LA had a harmful and stressful influence on the hepatic, renal and brain tissues consistent with those reported in the literature ,Nehru and Kaushal,(1993) and Singh *et al.,* (1994).

In conclusion, many chelating agents are currently used to manage lead toxicity. At the same time, the most common, however, are nonspecific and have some adverse effects in humans such as induction of misbalance of essential microelements . Because pectins are both specific and effective in complexion with lead, these compounds may be considered as nutritional products that could be used to decrease lead intestinal absorption, prevention of

lead accumulation, and amelioration of lead toxicity. In the present investigation, LE pectin was contributed to fast elimination of the lead acetate to blood, organs and bones, whereas HE pectin removed lesser amount of lead. However, additional studies in rats and humans are required before developing the pectins as preventive or curative agents of lead exposure and toxicity in humans.

Chemopreventive effect of celecoxib and expression of cyclooxygenase-2, Casapase-3 and AGNOR on chemically- induced rat submandibular salivary gland neoplasm.

Mohamed Zayed

Lecturer, Oral Biology, Oral Histopathology Department, Misr International University (MIU).
dr_zayed2@yahoo.com

Abstract: BACKGROUND: Cyclooxygenase-2 (COX)-2 inhibitor (Celecoxib) is a non-steroidal anti-inflammatory drug (NSAIDs) and over-expression of COX-2 protein and mRNA has been reported in various cancer tissues. Therefore, it has been suggested that COX-2 is related to carcinogenesis. **METHODS:** Twenty five albino rats were used .They were divided into 3 groups; group I (normal control) and group II and III which was delivered 4-NQ in the drinking water .Meanwhile group III was given 1500 ppm celecoxib. Submandibular salivary glands were obtained after 32 weeks. Immuno-histochemical staining for COX-2 was performed to determine the COX-2 level and Caspase-3 immuno-expression was done for detection of apoptosis and silver nitrate staining of nucleolar organizer regions (AgNORs) was done for estimating the proliferating cells. The data were analyzed using Student's independent t-test and one-way analysis of variance (ANOVA). **RESULTS:** The group II and III showed pathological evidence of cancer. COX-2 immuno-staining was stronger in group II than in Group III. Caspase-3 immuno-reaction was statistically highly significant in group III ($p<0.05$) .Meanwhile proliferation estimated by AgNOR nuclear count was statistically highly significant group II ($p<0.05$). **CONCLUSION:** The COX-2 expression was increased in group II (untreated group) than group III. Administration of celecoxib demonstrated the chemo-preventive potential against the carcinogenesis through induction of apoptosis and suppression of tumor growth and proliferation.

[Mohamed Zayed. Chemopreventive effect of celecoxib and expression of cyclooxygenase-2, Casapase-3 and AGNOR on chemically- induced rat submandibular salivary gland neoplasm. Journal of American Science 2010;6(12):555-363]. (ISSN: 1545-1003). http://www.americanscience.org.

Key words: Oral cancer, Cyclooxygenase-2, submandibular salivary gland

11. Introduction

Oral cancer is one of 10 most frequent cancers in the world. Squamous cell carcinoma (SCC) is the most common malignant tumor of the oral cavity, accounting for over 90% of the malignant neoplasms in this region. Furthermore; recent epidemiologic data have indicated that the incidence of oral cancer is increasing, Nishimura et al. (2004). Despite a better understanding of the disease and the advent of modern technology and rationally targeted drugs, the incidence and cure rate of cancer have not improved, Bharat and Shishir (2006). Therefore, new molecular targets are needed for the prevention and treatment of oral cancer.Chemoprevention is to use of pharmacological or natural agents to prevent, suppress, interrupt, or reverse the process of carcinogenesis Garay & Engstrom (1999). Regular use of aspirin has been shown to lower the risk of colon cancer in man, Thun et al. (1991) and also Reddy et al. 1993; Rao et al. 1995 added that NSAIDs can suppress colon carcinogenesis induced by azoxymethane in rats ,Schreinemaches & Everson (1994); Harris et al. (1996). They demonstrated that there are significant reductions of breast cancer risk with the use of NSAIDs. In this field Lin and Nelson (2003) added that the experimental and epidemiologic studies have demonstrated that the NSAIDs are effective in the prevention of human cancers.

It is known that NSAIDs decrease prostanoid synthesis through the inhibition of cyclo-oxygenase (COX) activity, Van (1971). There are two different isoforms of COX, COX-1 and COX-2. COX-1 is constitutively expressed in most normal tissues to maintain stable physiological conditions such as cytoprotection in the stomach, vasodilatation in the kidney, and production of the pro-aggregatory prostanoid thromboxane by platelets Vane, (1994). Where as COX-2 is transiently induced by pro-inflammatory cytokines and growth factors of epithelial cells involved in inflammation and mitogenesis, Herschman (1996) and its patho-physiological role has been primarily connected to PG production in response to inflammation ,O'Banion et al. (1992); Crofford et al. (1994).

COX-2 has been recently reported to be up regulated and over-expressed in various of human malignancies, such as colon, lung, stomach esophagus, pancreas, endocervix, urinary bladder, prostate and skin and breast cancers, and also in squamous cell carcinoma of the head and neck Leong *et al.* (*1996*)*;* Wilson et al. (1998); Chan et

al. (1999); Tucker et al. (1999); *Stolina* et al. (2000); Yoshimura et al. (2000) and can be modulated by a variety of cytokines, hormones and tumor promoters Parrett et al. (1997;Wolff et al. (1998). In addition COX-1 and COX-2 have been detected in rat mammary gland tumors induced by various carcinogens, including DMBA,Robertson et. al. (1998), N-nitrosomethyl urea,Hamid et al. (1999) and 2-amino-1-methyl-6-henylimidazo[4,5-b] pyridine ,Nakatsug et al. (2000). Moreover, COX-2 has been implicated in the development of colon cancer and may play a role in promoting invasion, metastasis, and angiogenesis in established tumors ,Dubois et al. (1998) and Tsujii et al.,(1998).

Conventional NSAIDs such as aspirin, sulindac and indomethacin block both COX-1 and COX-2, resulting in unwanted side effects including gastritis and gastric ulceration. Therefore, when NSAIDs are used over long period as chemo-preventive agent, a selective COX-2 inhibitor must be used ,Jang et al. (2002). Celecoxib is new NSIADs that inhibits COX-2 and has significant anti-inflammatory and analgesic properties ,Seibert et al. (1994). Harris et al. (2000) reported that the celecoxib shows inhibitory effects on the development of rodent mammary cancer.

In this study, we examined the COX-2 expression in rodent sub-mandibular salivary gland neoplasm induced by 4-NQ and the chemo-preventive effect of celecoxib, a selective COX-2 inhibitor, for tumor development with correlation to its induction of apoptosis and proliferation.

2. MATERIALS AND METHODS

This study was performed in accordance with the Public Health Service Policy on Humane Care and Use of Laboratory Animals, the National Institute of Health Guide for the Care and Use of Laboratory Animals, and the Animal Welfare Act (A 3775-01).

2.1. Materials:

2.1.1. Celecoxib and an animal model

Twenty five adult male albino rats weighing (150-200 gm) were selected and divided into three groups.

The rats were watched for 1 week before the study. Three rats were allocated to each cage and were fed standard laboratory chow and water and libitum. The animals were housed and caged separately in the animals' house of the Faculty of Medicine, Cairo University.

Celecoxib (Celebrex) was manufactured and supplied by Pfizer Egypt S.A.E under Authority of G. D. Searle &CO.USA.

The rats have been then randomly divided into 3 groups: (I) control – 5 rats; (II & III) 10 rats for each.

The weight of all hamsters was recorded prior to the medication and subsequently on the end of this study.

2.2. Methods:

2.2.1. Induction of cancer

Carcinogenesis was induced in the animals of both group **II** and group **III** in which the carcinogen 4-NQ was obtained as a powder (Sigma, St. Louis, MO, A, cat. # N8141) and dissolved in the drinking water for rats of both groups to a final concentration of 0.02 g/l (20ppm). The prepared drinking water was changed once a week and the rats were allowed access to the drinking water at all times during the experiment is given in the drinking water in addition to the standard laboratory chow *diet.*

2.2.2. Chemoprevention and follow-up

Celecoxib was given to group III only from the beginning of the experiment after addition of one capsule, 100 mg into fine powder which was added to the laboratory chow of the rats every day. Clinically, physicians usually use daily 200 mg or 400 mg Celecoxib for treatment of rheumatoid arthritis or other diseases, and both doses have been approved by FDA. There is no specific guidance and dose for its application in animal model. However, currently 1,500 p.p.m probably is the most common dose to be used in rodent models. Kawamori et al. (1998) reported their findings to establish a therapeutic blood level of Celecoxib for chemoprevention in such models. The study identified daily administration of 1,500 p.p.m as an ideal dose to significantly suppress the colonic aberrant crypt foci formation. These findings served as the basis for our dose selected for this study. Rats were allowed access to the drinking water at all times during the experiment. At the 20th week of the experiment, two rats from each group were sacrificed and analyzed for precancerous and cancerous lesions. The study period was extended for thirty two weeks. After that all the remaining rats were sacrificed and the submandibular salivary glands were dissected.

Salivary glands biopsy specimens were taken for histological examination. The specimens were fixed in 10% formalin, processed in a standard manner, and stained with hematoxylin and eosin and examined under light microscope.

2.2.3. Immuno-histochemical analysis:

For immuno-histochemical staining, paraffin embedded tissues, sectioned at 4 μm and collected at

serial sections on positive charged slides (SuperFrost Plus-Menzel GmbH) were deparaffinized and dehydrated. Antigen retrieval was performed by boiling the slides in 10Mm citrate buffer, pH 6.0 for 20 minutes in a domestic microwave. Slides were left to cool for 30 minutes at room temperature. Sections were incubated in 3% hydrogen peroxide for 20 minutes. Novocastra protein block (RE7102 Novocastra, UK) was applied for 10 minutes after which the slides were incubated with the primary monoclonal Mouse anti body COX-2 [(CX-294) Dako,Glostrup, Denimark] for COX-2 immunostaining and while the other slides with the primary rabbit monoclonal antibody: anti-caspase 3 for caspase-3 immunostaining [(CPP32) Ab-4 Thermo Fisher Scientific, USA] diluted 1:100; for 30 min. at room temperature in a humidified chamber. After rinsing twice with TBS (Tris Buffered Saline, Amresco-USA), sections were treated with biotinylated secondary antibody (RE7103 Novocastra, UK) then labeled with streptavidin-biotin kit (RE110-k Novocastra, UK). The sections were then incubated in 3,3'diaminobenzidine (RE7190-k Novocastra, UK) for 5 minutes and counterstained with Mayer's hematoxylin (RE7107 Novocastra, UK).

2*.2.4. Silver nucleolar organizer regions (AgNOR) staining technique*:

Equal proportions of 50% silver nitrate soln. and gelatin soln. were mixed immediately before use. Sections were dewaxed in xylene and hydrated through ethanols to water then the slides were rinsed in distilled water. The Sections were then incubated in freshly prepared AgNOR working solution for 45 minutes at room temperature. After that the slides were washed in distilled water for one minute, then dehydrated, cleared and mounted in non aqueous mounting medium.

***2*.2.5. Cox-2, Caspase-3 and AgNOR staining assessment:**

The histological sections were examined using light microscope to assess the prevalence of positive ones. For Cox-2 and caspase-3 positive cytoplasmic immuno-expression, the percentage of positive cells was measured in the form of an area and area percent inside a standard measuring frame of area 11434.9 micrometer^2 per 10 fields using a magnification (x200), using image analysis software (Leica-Qwin) system. In addition, the number and area percent of AgNOR positive dots were counted per 10 fields using the image analysis. The nuclei that were overlapped or those with indiscernible AgNORs were excluded.

2.2.6.Statistical analysis: Quantitative data of the image analyzer were statistically evaluated and presented as means and standard deviation (SD) values. Student's t-test was used to compare mean values of Cox-2 and caspase-3 immuno-expression related parameters in group II & III; however the ANOVA (analysis of variance) test was used to compare the mean values of AgNOR obtained data between the two experimental groups. The significance level was set at $P \leq 0.05$.

3. Results:

3.1.H&E examinations revealed the rodent submandibular salivary glands showed signs of dysplasia and malignancy after administration of 4-NQ which appeared sever in group II while in group III (treated by celecoxib) appeared to be less affected.

In Group II the serous acini showed dramatic changes ranged from shrinkage of the lobules to total atrophy. As the serous cells demonstrated disruption of its characteristic acinar arrangement, with appearance of isolated acinar cells and significant shrinking of the acinar cells and necrosis were termed as ‘‘abnormal acini’’ the acinar cell become disrupted, distorted and detached from adjacent acinar cells. (Fig. 1A). The nuclei were hyperchromatic and showed pleomorphism (Fig. 1A) the intralobular Ducts that demonstrated considerable cellular hyperplasia and atypia with extravasation of red blood cells (fig. 1A), while inter lobular duct showed hyperplasia where as in other areas revealed atrophy and necrosis (Fig. 1C). While mucous acini were more resistant to effect of carcinogenic agent (Fig. 1B).

In group III, by administration of celecoxib the evidence of cancer appeared to be reduced or cured. The serous cells were arranged in abnormal acinar arrangement (Fig. 2A). The acinar cells became smaller in size. In other area showed loss their acinar arrangement (Fig. 2B). The nuclei showed piknosis and hyperchromatism (Fig. 2B). The duct did not show significant changes but show extravasations of RBC. (Fig. 2A).

3.2.COX-2 immunostaining:

The group II showed strong positive immunoreactivity in serous acini more than group I &III (Fig. 3A). While the mucous acini show positive peri-nuclear immunoreactions (Fig. 3B). The duct revealed strong cytoplasmic immuno-expression (Fig. 3 B). While in group III showed occasionally positive immunoreactions in serous acini and intralobular duct (Fig. 3C).

3.3. Caspase-3 immunostaining:

Occasional immunoreactivity was observed for caspase-3 in group II (4- NQ treated group) less than group I [Fig.3A]. On the other hand, sectionsof the serous acini of group III revealed a higher immuno-expression of caspase-3 (Fig.4B) immunostaining in duct cells (original magnification, x 400).

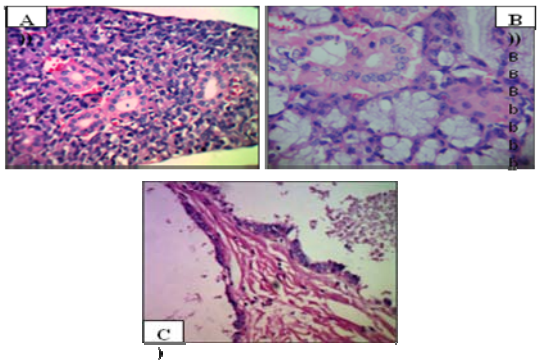

Fig. 1: Photomicrographs of serous and mucous glands of group II (A) show disruption and loss of the characteristic acinar arrangement, appearance ‘‘Abnormal serous acini’’ (ABS) of isolated acinar cells, and significant shrinking of the acinar cells (H&E. original magnification, x 200). (B) Mucous acini retain their normal morphology (H&E original magnification, x 400). (C) The interlobular duct shows in some areas hyperplasia and in other areas shows disruption, loss of continuity and atrophy arrows (H&E. original magnification, x 200).

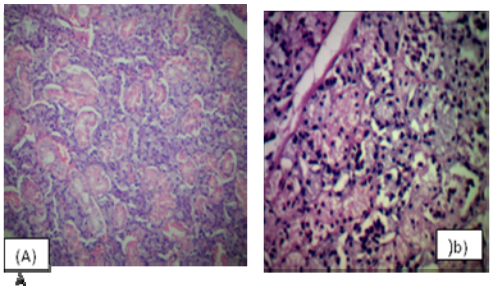

Fig.2: Photomicrographs of group III demonstrate (A). smaller serous acini and become atrophied. The duct appeared less effected and show lesser degree of extravasation piknotic and hyper chromatic. (H&E. original magnification, x 400).

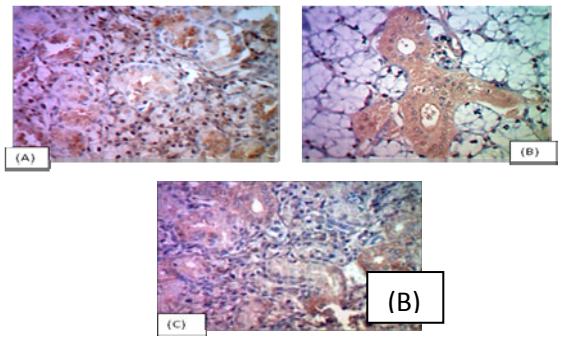

Fig. 3: photomicrographs of (A) group II show strong cox-2 immuno-expression in serous acini (original magnification, x 200). (B) A mucous acini show Cox-2 positive peri-nuclear immunoreaction & strong cytoplasmic immunostaining in ducts. (Original magnification, x 200). (C) Group III showing few positive cox-2 immuno-expression in acinar cell with positive immunoreactions in ducts (original magnification, x 400). of RBC. (H&E. original magnification, x 200). (B) The nuclei become.

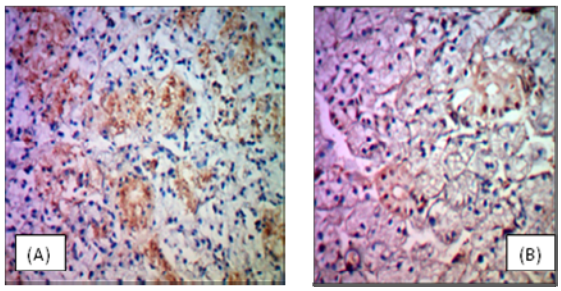

Fig. 4: photomicrographs of caspase 3 immunostaining (A) group II show negative immunoreaction with few positive cells (original magnification, x 400). (B) While in group III demonstrate higher positive immunoreactions in acinar cells with positive

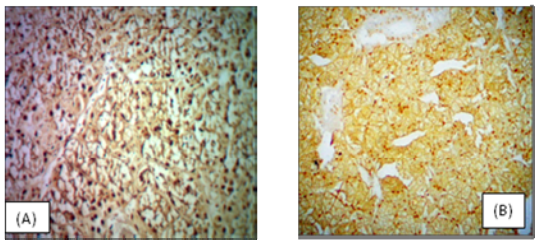

Fig.5: (A) Silver stained section of group II showing numerous silver stained nuclei in of serous cell (original magnification, x400). (B) Group III stained with silver showing less number of AgNOR dots in serous acini than group II (original magnification, x400)

3.4. AgNOR staining:

AgNOR were strictly located within the nucleus and were distinctly stained in black, being visible as dots. Silver stained dots were great in group II sections, almost all of the nuclei were stained (Fig.5a), meanwhile group III revealed lesser silver stained nuclei, restricted to acinar cell (Fig.5b)

3.5. Statistical analysis:

The results of the student's t-test revealed a non significant area percentage of the immunoreaction of COX-2 ($p>0.01$) between the group II & group III (table 1& fig. 6).

Table (1): Comparing the area percentage of COX-2 positive cells in group II and group III

Statistical profile	Group II	Group III
Mean± SD	110.6±0.8	108±1.0
Student's t-test	1.9	
P-value	0.084391	

** Significant at $P \leq 0.05$*

4. Discussion:

In the present study, we investigated the chemo-preventive effects of celecoxib in chemically induced 4-NQ cancer in submandibular rodent

salivary gland. We found that nearly all rats of (group II & III) that received 4-NQ suffered from developing salivary gland cancers 19/20 cases. This result is in accordance with Tang et al. (2004) as they demonstrated that murine 4-NQ induced oral and esophageal carcinogenesis model simulates many aspects of human oral cavity and esophageal carcinogenesis. They added that the availability of this mouse model should permit analysis of oral cavity and esophageal cancer development in various mutant and transgenic mouse strains. This model will also allow testing of cancer chemo-preventive drugs in various transgenic mouse strains COX-2 immuno-expression in group II was up regulated than in group III (treated by Celecoxib). These results are in accordance with Hwang et al. (1998); Mohammed et al. (1999); Kulkarni et al. (2001).They found that COX-2 was over expressed in various malignant tumor, such as cervical cancer, breast, skin also in squamous cell carcinoma of the head and neck. In this field, Nishimura et al. (2004) as they demonstrated that COX-2 was known to be over expressed in a variety of human pre-malignant and malignant lesions including oral ones. They also found that the administration of celecoxib produced inhibitory effects against oral SCC development both at the initiation phase ,during promotion and progression phases of carcinogenesis. The inhibition of COX-2 production led to marked lymphocytic infiltration of the tumor and reduced tumor growth, Stolina et al., (2000)

In this regard, Sawaoka et al., (1998); Chan et al., (1999) cleared that the mechanism(s) by which NSAIDs inhibit tumor growth was not clearly understood, but it could involve blockage of COXs, which suppress PGs production and might affect cell proliferation, apoptosis and immune response. And also, Tsujii et al.,(1998) added that there were evidences in colon cancer cells suggested that excessive PG production due to COX-2 over-expression played a role in tumor growth and spread. While, Lin and Nelson (2003) explained in more detail that COX-2 may be involved in carcinogenesis via 2 distinct mechanisms: (1). DNA damage and (2). PG-mediated effects. Reactions mediated by COX-2 form reactive oxygen species that could directly induce the oxidation of DNA or instigate the bioactivation of carcinogens. Prostaglandin E2, a byproduct of COX-2-mediated arachidonic acid metabolism, exhibits several biologic actions that have been shown to promote tumorigenesis and tumor progression. These actions include increased cell proliferation, promotion of angiogenesis, and the elevated expression of the antiapoptotic protein Bcl-2. In addition, PGE2 decreases natural killer cell activity and alters immune surveillance.

Caspase are fundamental component of the mammalian apoptotic machinery. Caspase 3 is a prototypical enzyme that becomes activated during apoptosis in a wide variety of tissues, Woo et al., (1998). The quantification of immuno-expression of caspase 3 might constitute a good method for measuring apoptotic activity in prostate cancer,Santamaria et al. (2005). In our study the immuno-expression of Caspase in group II was weak or negative while in group III the positive cell was abundant denoting the apoptosis process was markedly noticed. This result are in accordance with Pasricha et al., (1995) as they demonstrated that one of the most striking events in which PGs have been implicated in tumorigenesis is the inhibition of apoptosis in the colonic epithelium of familial adenomatous polyposis patients.. More directly, Tsujii and DuBois (1995) showed that rat intestinal cells increasing COX-2 expression by gene transfer became resistant to butyrate induced apoptosis, which can be overcome by addition of the non-specific COX inhibitor sulindac sulfide. In this field, Gupta and Dubois (2001) reported that the studies in colonic cancer showed that induction of COX-2 was associated with inhibition of apoptosis increased in angiogenesis, and metastatic potential. Also, Hashitani et al. (2003) reported that celecoxib induced apoptosis in cultured head and neck cancer cell lines to a significantly greater degree than sulindac Nucleolar organizer regions (NORs) are the sites of ribosomal RNA which reflects protein synthesis. AgNOR dots are the visualized structures of NORs that can be selectively stained by a silver colloid technique and can be visualized as black dots under the transmission microscope,Uno et al. (1998). According to Derenzini and Trerè (1994), the higher the number of NORs, the lower is the duration of the cell cycle and the higher is the velocity of cell proliferation. Such relationship makes the quantative analysis of NORs an excellent indicator of the proliferation activity of the cells and a valuable diagnostic tool, since it enables the differentiation of benign from malignant cells and even predicts the prognosis of different types of cancer ,Trerè et al. (1991). The results of this work showed that group II showed a higher number of AgNOR dots than group III. Chatterjee et al. (1997) demonstrated that the number of AgNORs rises with increasing the proliferative activity of cells, thus the number of AgNOR dots in malignant lesions is higher than normal or benign lesions. Moreover, Reddy et al. (1996) found that 1500 ppm celecoxib inhibits aberrant crypt foci multiplicity by 40–49% without

gross changes in the intestines. In this field, Wang, (2005) added that the over-expression of Cox-2 enhances cell proliferation, inhibits apoptosis and increases metastatic potential, thereby contributing to carcinogenesis. Eslami et al. (2006) concluded that there is an increase in the number of AgNOR dots with the advancement of malignancy.

Consequently, the findings of the present work suggested that celecoxib might exert a chemo-preventive effect on rodent salivary gland tumor through suppression PG production and inhibition of tumor growth and proliferation of cells and induction of apoptosis. In this regard, Ning et al. (2005) added Celecoxib is a highly selective inhibitor of COX-2, with less toxicity than traditional COX inhibitors. It may be used for reversing or stopping oral carcinogenesis at an early stage of disease.

In conclusion, our present results clearly indicated COX-2 protein to be increasingly expressed in the malignant salivary gland and provided the evidence that celecoxib, possessed the chemo-preventive potential by delayed onset of tumor development, retarded tumor growth and inducing apoptosis. From these findings, it was indicated that celecoxib could serve as a potent chemo-preventive agent with low toxicity against oral carcinogenesis. In addition, further studies are recommended on determining the mechanism of anticancer activity of celecoxib and its active components against oral cancers.

The Outcomes of Concomitant Radiation Therapy plus Capecitabine for Refractory Locally Advanced Breast Cancer Patients Pre-Treated with Anthracycline Based Regimens

Fatma Zakaria Hussen; Hanan Shawky Gamal El-Deen*; Amr Abd- El Aziz Ghanam; Samar Galal U and Omnia Abd –El-Fatah G.
Clinical Oncology Department, Faculty of Medicine, Tanta University Hospital, Tanta, Egypt
hannshawky@yahoo.com*

Abstract: Purpose: Anthracycline based chemotherapy is the first line treatment for most of patients with locally advanced breast cancer (LABC). However, some patients fail to respond to these regimens and no established second line treatment. Effective treatments options for patients with LABC resistant to anthracyclins based regimens are limited. We have conducted a phase II trial of capecitabine concomitant with radiation therapy to assess the safety, tolerability and efficacy of this regimen as a second line for down staging those inoperable patients with LABC. Patients and methods: Between February 2008 and September 2009, 27 patients with infiltrating ductal carcinoma, locally advanced breast cancer , who were refractory to first line anthracycline based regimens were planed to receive radiation therapy (50Gy/25f) and concomitant capecitabine (850 mg/m^2) twice daily for 14 days every 3 weeks, at Clinical Oncology Department , Faculty Of Medicine, Tanta University Hospital. All patients were assessed for objective response rate (ORR), progression –free survival (PFS), overall survival (OS), safety and tolerability. Results: Eighty five percent of patients (23 out of 27) became operable. The remaining four patients didn't undergo surgery because of progressive disease. Objective response rates (ORR) including those with complete clinical response 0.0% and partial clinical response in 10 (37%) patients. A complete pathological response for primary tumor and axillary lymph nodes was seen in 1 patient (3.7%). Pathologically negative axillary lymph nodes were seen in 5 patients (18.5%). The median follow up period was 16 months (range 6-26 months), the median PFS for all patients was 10 months (range 2-22 months), the one –year PFS was 29%. The median OS was not reached, the mean OS was 20.8 months (95% CI 17.78 - 23.84) and the two-year OS rate was 69.5%. Positive significant correlations were observed for PFS in patients with age ≥ 45 years , postmenopausal , +ve estrogen receptors (ER), +ve progesterone receptors (PR), -ve human epidermal growth factor receptors (HER-2), non triple negative patients, patients with ER/PR positive tumors, non inflammatory breast cancer (IBC) patients and those with axillary lymph node ratio (ALNR) <50%. There were no grade 3 or 4 adverse events with study protocol. Conclusion: The results of this phase II trial prove that concomitant capecitabine and radiation therapy is safe and effective in down staging of inoperable locally advanced breast cancer patients resistant to primary anthracycline based regimens. We are ongoing trial to use capecitabine as a maintenance monotherapy in patients with advanced breast cancer.

[Fatma Zakaria Hussen; Hanan Shawky Gamal El-Deen; Amr Abd- El Aziz Ghanam; Samar Galal U and Omnia Abd –El-Fatah G. The Outcomes of Concomitant Radiation Therapy plus Capecitabine for Refractory Locally Advanced Breast Cancer Patients Pre-Treated with Anthracycline Based Regimens. Journal of American Science 2010;6(12):564-574]. (ISSN: 1545-1003). http://www.americanscience.org.

Key Words: Locally advanced breast cancer, radiosensitizing agents, neoadjuvant treatment, capecitabine.

1. Introduction:

Locally advanced breast cancer (LABC) and inflammatory breast cancer (IBC) refer to a heterogeneous group of breast cancer without evidence of distant metastases (M0) and represents only 2% to 5% of all breast cancer in The United States[1]. Data from a population based registry in Tanta cancer center, Gharbia, Egypt, demonstrated that about 58% of breast cancer patients presented with a disease that extended to the loco-regional lymph nodes[2]. Patients with these cancers include those with, operable disease at presentation (clinical stage T3 N1), inoperable disease at presentation (clinical stage T4 and / or N2-3), and inflammatory breast cancer (clinical stage T4d N0-3) according to the 6th edition of the AJCC Cancer Staging Manual[3].

Locally advanced breast cancer was either presented as operable disease or inoperable disease. The current standard treatment for all patients with inoperable breast cancer is to proceed with neoadjuvant chemotherapy as the initial therapy. Approximately 80% to 90% of patients with advanced breast cancer showed partial or complete clinical response to neoadjuvant chemotherapy, and

most patients who presented with inoperable breast cancer became candidates for surgery[4,5].

First-line anthracycline–based, neoadjuvant chemotherapy is often effective, however, about 30% of the patients failed to respond to this regimen and to date there is no established second-line treatment[6].

Capecitabine (Xeloda, Hoffmann- La Roche, Basel, Switzerland) is a highly effective oral fluoropyrimidine that generates 5-fluorouracil (5-Fu) preferentially in tumor tissues through a three-step enzymatic process. The final step in the generation of 5-Fu from capecitabine is catalyzed by thymidine phosphorylase, an enzyme which is expressed at up to five times higher concentrations in tumor compared with healthy tissue[7,8].

We have studied the concomitant use of radiation therapy and capecitabine, to investigate the toxicity and efficacy of this regimen as a second-line neoadjuvant treatment in locally advanced breast cancer patients pre-treated with anthracycline based regimens.

2. Materials and methods

Patients

Between February 2008 and September 2009, twenty seven women more than 18 years old, with ECOG performance status of up to 2, had histologically confirmed diagnosis of infiltrating ductal carcinoma of the breast, at Clinical Oncology Department, Faculty of Medicine, Tanta University. All patients had locally advanced breast cancer (stage IIB, III, T3, T4 or N2) with measurable disease, which remained inoperable after primary anthracycline based chemotherapy.

Patients were ineligible for this study if they had metastases to distant sites, a white-cell count <4,000 per mm^3, an absolute neutrophil count (ANC) <1,800 per mm^3, a platelet count <100,000 per mm^3, a serum creatinine >1.5 mg/dL, a creatinine clearance of <50 ml/min (0.84 ml per second). Patients with non-malignant systemic disease that precluded them from receiving study therapy (eg, active infection, renal impairment, any clinically significant cardiac arrhythmia, or congestive heart failure) or patients who were pregnant or have dementia, altered mental status, or any psychiatric condition that would prohibit the understanding or rendering of informed consent were not eligible.

All were considered inoperable because they had either extensive edema of the skin, inflammatory breast cancer, fixation of the tumor to the chest wall, or involved axillary lymph nodes larger than 2.5 cm or fixed to the skin or deep structure. All patients received primary chemotherapy that included anthracycline, either, in the form of, FAC, AC, or TA. In patients found to be inoperable, staging was repeated and those without metastatic disease entered the study. All patients signed an informed consent.

Study design:

Eligible patients received irradiation to the whole breast through opposed parallel fields and also to the draining lymph node through direct fields. The total radiation dose was 50Gy given in 5 weeks (200 cGy/fraction/ day). Concomitant chemotherapy with capecitabine 850 mg/m2 was given orally twice daily for 14 days and repeated every 3 weeks during radiation therapy. After the end of radiation therapy by 3 weeks, patients were re-evaluated, if down staging was achieved and surgical interference became possible, patients were prepared for modified radical mastectomy. The median interval between the completion of radiotherapy and the date of surgery was 1.3 months (range 1-4 months). After mastectomy, hormone receptor- positive patients were assigned to receive hormonal therapy.

All patients followed for toxicity, response, PFS and OS with follow up period ranged from 6 to 24 months.

Evaluation:

Clinical response:

A complete physical examination was performed before each cycle of chemotherapy and before surgery. The product of the 2 greatest perpendicular diameters of the breast tumor was calculated. Objective response was defined as complete if there was disappearance of the known disease. Partial response was considered to be a ≥50% decrease in tumor area (calculated by multiplying the longest diameter by the greatest perpendicular diameter). Progressive disease was defined as a greater than 25% increase in the size of the target lesion or the appearance of any new lesion. Stable disease was defined as, a bi-dimensionally measurable decrease of less than 50% or increase of less than 25% in the sum of the products of the largest perpendicular diameters of the measurable lesion

Toxicity:

Acute toxicity was evaluated after each dose of concomitant chemotherapy and radiation therapy and classified according to the NCI common toxicity criteria version 2.0[9].

Pathological response:

Pathological response was assessed postoperatively. The surgical specimens were evaluated for pathologic tumor response by hematoxylin and eosin staining. A pathologic complete response (PCR) was defined as the absence of invasive carcinoma in the breast, along with

absence of any involved axillary lymph nodes. When residual tumor was present in the breast, it was estimated as ≤ 1cm (microscopic residual {MiR}, near-complete response) or > 1 cm (macroscopic residual {MaR})[10].

Immunohistochemistry was performed on formalin-fixed paraffin-embedded tissues from the diagnostic biopsies for estrogen, progesterone and human epidermal growth factor receptors (Her-2).

Statistical analysis:

Objective response rates were the primary end point; secondary end points were progression – free survival, overall survival and safety profile. SPSS package (version 12.0) was used for data analysis. Mean and standard deviation were estimates of quantitative data. Chi-square and Fischer exact were tests of proportion independence. Overall survival which calculated from time of study entry until death or last follow- up and progression free survival were assessed according to the Kaplan – Meier method. Progression –free survival was compared by the Kaplan –Meier method with statistical significance assessed by the Log -rank test. All P values were two-tailed; a value of ≤ 0.05 was considered significant.

3. Results

Patients' populations:

Twenty-Seven patients were recruited in the study with pathologically proven locally advanced breast cancer. The base line characteristics were listed in table (1), with the mean age 45.4± 8.0 years old years (range; 36-69), 16 patients (59.3%) were premenopausal and 11 patients (40.7%) were postmenopausal. Twelve patients (44.4%) had positive estrogen receptors (ER), while 44.4% of the patients had positive progesterone (PR) receptors and 10 patients (37%) had positive ER and PR. Six patients (22.2%) had positive human epidermal growth factor receptor (Her-2), six patients (22.2%) had triple negative hormonal receptors and four patients had inflammatory breast cancer (IBC).

Impact of concomitant capecitabine and radiation therapy on response:

Twenty three patients (85%) achieved good clinical response and became operable. Ten patients (37%) had partial clinical response, 13 patients (48.1%) had stable disease and 4 patients had progressive disease, (Table 2).

As regard pathological response, one patient (3.7%) achieved complete pathologic response, four patients (14.8%) had a near complete response ≤ 1cm and 18 patients (66.7%) had a residual primary tumor > one centimeter (Table 2). A completely, negative axillary lymph nodes was observed in 5 patients (18.5%). Median clinical tumor size before treatment was 143 cm^2 (range 36-272) and it was reduced to 36 cm^2 range (6-288) {p < 0.0001} (95% CI 54.6 – 97.5) with reduction rate (75%) after treatment. After surgery median pathologic residual tumor size was 12 cm^2 (range 4–48 cm^2).

The median number of dissected lymph nodes was 20 (range; 8 – 25) and the median number of involved lymph nodes was 7 (range; 0 – 24). The median follow-up period was 16 months (range 6-26 months). The median duration of response was 10 months (range 2-22 months) (95% CI SE 0.64 (8.7 - 11.25)). There were no significant correlation between clinical response rates and menopausal status (p=0.25), estrogen receptor status (p=0.19), progesterone receptor status (p=0.21), ER/PR positive receptors status (p=0.28), her-2- receptor expression (p=1.0). Only, triple negative patients had significant correlation with poorest clinical response (P=0.04) (Table 3).

Impact of treatment on survival:

At the time of this analysis, 8 patients had died. The median duration of follow-up was 16 months, (range 6-26 months). On the basis of Kaplan- Meier estimates, the median OS for all patients with LABC was not reached while the mean OS was 20.81 months (95% confidence interval, 17.78-23.84) and the two-year OS rate was 69.5%, (Fig, 1).The median PFS was 10 months (95% confidence interval, 8.75-11.25) (Fig, 2). The eighteen months PFS was 11%.

We analyzed the median PFS in relation to different prognostic factors, including age; in patients aged < 45 years old, the PFS was 0% at 18 months, while in patients aged > 45 years old, the 18 months PFS was 23% (P=0.0176). As regard menopausal status; in premenopausal patients, the 18 months PFS was 0% in comparison to 27% for postmenopausal patients (P=0.02), (Table 4).

In correlation of PFS to hormonal receptor status, we found that the 18 months PFS for ER –ve status was 0%, while it was 33% for ER +ve status (P=0.001). For PR status, PFS were 0% and 33% for –ve and +ve progesterone receptors respectively (P=0.014), (Table 4).

Among patients who did not have +ve Her-2-neu receptors at presentation, PFS was significantly better. Eighteen months PFS rate was 19% for patients without Her-2-neu receptors expression but dropped to 0% for patients with Her-2-neu receptors over-expression (P=0.0178), (Fig, 3). In triple negative patients the 18 months PFS were 0% while it was 14% for non triple negative patients (P=0.0987), (Fig, 4), (Table 4).

As regard to ER/PR +ve patients, the 18months PFS was 30% for ER/PR +ve patients, while it was 0% for non ER/PR +ve patients (P=0.002), (Fig, 5).

Among patients without IBC, the PFS was significantly better than patients with IBC. The 18 months PFS rate were 13% versus 0.0% respectively with no patient alive at 18 months with IBC (p = < 0.001), (Table 4).

The ratio between positive lymph nodes and total excised axillary lymph nodes (ALNR) were reported as <50% and ≥50% for all operable patients in this study, 18 months PFS rates was 21.4% versus 0.0% respectively, (P=0.0076), (Fig 6), (Table 4).

Toxicity profile:

All the 27 patients were assessable for toxicity according to the NCI common toxicity criteria version 2.0[9]. The treatment regimen was well tolerated with no grade 3 or 4 events. Hand-foot syndrome was not observed. Non-Hematological toxicities were observed in 12 patients (44%) (GI in 32% and GII in 12.4%). Hematological toxicities were observed in one patient (3.7%) in the form of GI anemia which didn't required hospitalization or treatment interruption. After 6 months of surgery, 20 patients were re-examined where lymphedema and functional restriction (GI) were present in 3 patients (11.1%), (Table 5).

4. Discussion:

This pilot study evaluates the efficacy and safety of the concomitant capecitabine and radiation therapy as second line treatment in locally advanced breast cancer patients pre-treated with anthracycline based regimens, at Tanta University Hospital, Clinical Oncology Department.

In this study, the operability rate was 85% (23/27 patients), the objective clinical response (PR) was 37% (10/27 patients), one patient with complete pathologic response (3.7%) and a near-complete pathologic response was seen in 4 patients (14.8%), while, 18 patients (66.7%) had a pathologic residual tumor more than 1cm. Pathologically, negative axillary lymph nodes were observed in 5 patients (18.5%). There was improvement for response with concomitant capecitabine and radiation therapy irrespective to menopausal status, ER, PR, and Her-2 receptors status. There was 75% reduction in initial tumor clinical size after treatment with capecitabine plus radiation therapy. Progression free survival (PFS) at 18 months for all patients was 11% with statistical significant correlation with age ≥ 45 years, postmenopausal status, +ve ER, +ve PR, –ve Her-2 neu receptors, non IBC and sector of patients with ALNR <50%. In our results, the median OS was not reached, while the mean survival was 20.8 months (limited to 26 months), 2-year overall survival was 69.5%. Minor adverse events which didn't need hospitalization or interruption of treatment were observed.

Several randomized trials in patients with LABC show that various chemotherapeutic regimens given pre-operatively result in a spectrum of objective response rates ranging from 10 to 66%[11,12] with variable rates of pathologic response ranging from 3.5% to 34%[11,12,13].

In many other trials where more than 90% of patients with LABC were pretreated with anthracycline, the mean response rate to cisplatinum\ vinorelbine regimen was 46% (25% to 74%)[14,15,16,17]. In another study carried out by Ali et al[18], used cisplatinum /vinorelbine on 13 patients with LABC, One patient achieved a complete clinical and radiological response 1/13, and 11 patients had a partial response for over all response rate of 92% but no pathologic complete response was documented[18].

Capecitabine is an oral drug, thereby avoiding the need for intravenous line and for hospital admission. Capecitabine seems to improve the survival of patients with advanced breast cancer

either as a single agent or in combination with docetaxel[19], and has shown promising activity in a phase II study in the neoadjuvant setting [20].

Vinorelbine – fluoropyrimidine has demonstrated to be an active combination for advanced breast cancer (LABC and MBC). Two multicentric phase II trials conducted to assess the efficacy and safety of vinorelbine- capecitabine combination (NavCap) and N+C followed by docetaxel (L) as sequential block regimen (Next) using the same selection criteria. Between April 2001 and September 2003, 73 consecutive patients were enrolled into these two trials (31 patients in NavCap and 42 patients in Next). Objective response rate were 68% and 75% respectively, median PFS were 10.8 months and 12.6 ms respectively, finally median survival was 30.4 months for NavCap and median survival was not reached in Next trial [21].

Our results revealed 85% of patients became operable, 37% ORR, 10ms (range 2-22) for median PFS and median survival was not reached with overall survival at 2 year (69.5%). The differences with our results may be due to smaller number of patients, less aggressive chemotherapeutic agent and poor prognostic features of our patients who were refractory to first line anthracycline based regimen in the neoadjuvant setting.

All those chemotherapeutic agents in the neoadjuvant setting were associated with higher rate of toxicities ; in vinorelbine / cisplatinum trial the adverse events were represented as follow, GII neutropenia in 10%, febrile neutropenia in 3% necessating hospital admission, GIII nephrotoxicity in 3%, GIII vomiting in 4%, and GII anemia in 8%[18]. With NavCap study, GIII neutropeina was 13%, GIII asthenia was 7%, and GIII Hand foot syndrome was 3%. For Next study, GIII neutropenia was reported in 15%, febrile neutropenia was recorded in 10%, while, asthenia occurred in 15%, and hand foot syndrome was seen in 2.5%. The combination of capecitabine / docetaxel had a high incidence of grade 3 adverse events (primarly hand foot syndrome)[22].

Another study carried out by Thomas et al[23] examined ixabepilone (40 mg/m^2 intravenously on day 1 of a 21-day cycle) plus capecitabine (2.000 mg/m^2 orally on days1 through 14 days of a 21-day cycle versus capecitabine alone (2500 mg/m^2 on same schedule) in advanced breast cancer patients, drug toxicity led to treatment discontinuation for 18% patients in combined arm and for 7% of patients in capecitabine group due to hand-foot syndrome, leucopenia and neutropenia. This study demonstrated superior PFS and OS after the addition of a second agent to capecitabine in patients resistant to anthracycline and taxanes, irrespective to Her-2 receptors expression[23].

Our results were in consistent with that reported in a land mark series of 38 patients from M.D Anderson Cancer Center treated with preoperative radiation therapy in refractory locally advanced breast cancer, in which 32 patients (84%) were able to undergo mastectomy. After completion of treatment, only 3 patients (9%) achieved a complete pathologic response. Completely negative lymph nodes were observed in 8 patients, (27%). The patients studied are quite different, tumor size was smaller before treatment in the radiation alone study and patients with inflammatory breast cancer were excluded. The rate of postoperative complications was highest in those who received radiation dose more than 54 Gys (70% versus 9%). The authors concluded that, despite the poor prognosis, radiation therapy alone improved the prognosis in these patients, however, in view of the high morbidity, they suggested that novel treatment strategies such as radiation therapy combined with radiosensitizing agents should be examined [24].

Another study by Gaui et al[25] examined the use of cisplatinum and 5-Fu continuous infusion as a radiation sensitizer for LABC. From January 1994 to February 1998, 58 inoperable patients who had anthracycline refractory LABC were treated with cisplatinum 25 mg/m^2 in bolus and 5-Fu 1gm/m^2 continuous infusion for 4 days, on days l and 28. Simultaneous radiation with 45 Gy was applied to the breast. Fifty seven patients (98%) became operable. After surgery a complete pathologic response in both the primary breast tumor and in the axillary lymph nodes was observed in 3 patients (5%), over all survival in 60 months was 27%[25].

The Brazilian investigators had conducted many studies to assess the role of radiation therapy in patients with LABC. One of them retrospectively examined the results of treatment with radiation therapy alone given to 38 patients with locally advanced infiltrating ductal carcinoma who were inoperable after first line chemotherapy from July 2000 to November 2002. After radiation therapy, only 23 patients (60%) were considered operable and underwent a mastectomy. Two patients (9%) achieved a pathologic complete response, one with a complete absence of residual and the other with microscopic disease. Only 2 patients were classified as a pathologic no response. The 3-year OS was 44%, and the 3-year failure free survival was 10% [26].

At 2007, the Brazilian investigators at Rio de Janeiro conducted a phase II trial evaluating the role of capecitabine as a radiosensitizer for patients with LABC, rendered 82% (23/28) of the patients operable, 38.8% reduction in the median clinical

tumor size after treatment. After surgery, a complete pathologic response was seen in 1 patients (4.3%), 3 patients (13%) achieved a near-complete pathologic response (less than 1cm), with minimal adverse effects[6].

As regard to the prognostic factors, our results showed that, Her-2 status had no effect on ORR in LABC which were comparable with the results of Chae et al[30]. ORR showed only significant correlation with non triple negative patients. Significant correlations of PFS were seen with , age > 45 years, post menopausal status , ER+ve, PR+ve patients with no IBC as reported in many other reports[18,31,32], while, ALNR <50% was in agreement with the report published by Hatoum et al[33].

Radiation therapy has been demonstrated to act synergistically with capecitabine in human tumor xenagrafts[29]. In our study, the concomitant capecitabine and radiation therapy has shown synergistic anti-tumor activity. This regimen can be given with an acceptable cost and tolerable toxicity with no need for extra supportive measures. Therefore, there is a need for addition of capecitabine to radiation therapy as a radiosensitizer, to act as a new treatment for hormone and chemotherapy-resistant, locally advanced breast cancer patients as reported in many other reports[27,28].

In conclusion, our results have confirmed the favorable safety profile of capecitabine that makes it specially suited for use in this group of patients with poor prognostic features with LABC. Capecitabine plus radiation therapy seems active and is feasible as secondary neoadjuvant therapy, in locally advanced breast cancer patients. We are ongoing trial to use capecitabine as maintenance monotherapy in patients with advanced breast cancer.

Abstract: The mycotoxin ochratoxin A (OTA) is a widespread contaminant in human food and animal feed. It is a carcinogenic, genotoxic, teratogenic, immunotoxic, and hepatonephrotoxic agent. Therefore, the present study was designed to assess the possible protective effect of *Lactobacillus rhamnosus* GG (LGG) against OTA-induced toxicity in mice. Four groups of 30 mice each were used: control group, LGG-treated group (1×10^{10} CFU), OTA-treated group (1.8 mg/kg b.w.) and a group of mice given LGG two hours before OTA gavage. The levels of malondialdehyde (MDA), glutathione (GSH) and superoxide dismutase (SOD) activity were measured in of liver and kidney. Bone marrow micronucleus test and chromosomal aberrations in spermatocytes, as well as mitotic and meiotic activities were performed to assess the genotoxicity; besides sperm parameters were evaluated. Results showed that OTA significantly decreased the body weight. OTA significantly elevated the tissue levels of MDA, whereas the levels of GSH as well as SOD activity were significantly decreased in both liver and kidney. OTA increased statistically the frequencies of MNPCEs in bone marrow and structural and numerical aberrations in spermatocytes. In addition, mitotic and meiotic activities of somatic and germ cells were declined significantly. Also, OTA caused a high significant reduction in cauda epididymal sperm count, sperm motility and increased sperm abnormalities, as compared to control. In mice received LGG before OTA gavage, a significant amelioration in LPO in liver and kidney, by increasing the contents of GSH and SOD activity, have been occurred. Cytogenetic analyses revealed that LGG administration before OTA gavage significantly reduced frequencies of MNPCEs in bone marrow and chromosomal aberrations in spermatocytes, and recovered mitotic and meiotic activities as well. Moreover, gavage LGG before OTA intoxication caused significant recovery in all sperm parameters studied. In conclusion, LGG was found to be safe and successful agent counteracting the oxidative stress and protected against the genotoxicity induced by OTA, in addition to reduction in spermatotoxic alterations.

Key words: ochratoxin A, *Lactobacillus rhamnosus*, oxidative stress, micronucleus, spermatocytes, sperm

1 Introduction

Ochratoxin A (OTA) is a ubiquitous secondary metabolite produced by a number of mold genera, including *Penicillium* and *Aspergillus* (Castella et al., 2002; Pardo et al., 2005). OTA is found in a wide range of foodstuffs including wheat, corn, oats, beans, nuts and coffee beans, and in dry foods such soybeans, garbanzo beans, nuts and dried fruit, also in grapes, coffee, and pork (Bennet and Klich, 2003; Sage et al. 2004). OTA is hepatonephrotoxic, neurotoxic, immunosuppressive, cytotoxic, genotoxic, mutagenic, teratogenic, and carcinogenic agent (IARC, 1993; IPCS 2001). OTA was classified by the International Agency for Research on Cancer, as a possible human carcinogen (2B) (IARC, 1993). Its toxicity has been associated with inhibition of protein synthesis, DNA and RNA synthesis, mitochondrial dysfunction, formation of DNA adducts, disruption of calcium homeostasis, and the generation of reactive oxygen species (Gekle et al., 2005; Ringot et al., 2006; Marin-Kuan et al., 2006; Rached et al., 2007). Chronic exposure to OTA in humans found to be associated with a high incidence of progressive nephropathy and urinary tract tumors (Pfohl-Leszkowicz and Manderville, 2007). Schwartz (2002) hypothesized that OTA is a causative agent for testicular cancer. OTA induced lipid peroxidation (LPO), formation of reactive oxygen species (ROS) and consequent oxidative DNA damage, and decreasing intracellular reduced glutathione (GSH) level. Schaaf et al. (2002) observed an elevation in ROS levels, depletion of

GSH levels and an increase in oxidative DNA damage in rat proximal tubular cells and in LLC-PK1 cells treated by OTA. Furthermore, *in vitro* gene expression data obtained in HK-2 cells suggested an induction of mitochondrial ROS production due to OTA exposure. LPO levels were significantly increased in rat serum and in liver and kidney exposed to OTA, whereas, the glutathione level and antioxidant enzyme activities (SOD, CAT, GPX and GR) were significantly decreased (Meki and Hussein, 2001). Moreover, gene expression data showed that OTA alters a battery of genes, in F344 rat's kidney, that are involved in antioxidant defense and detoxification (Marin-Kuan et al., 2006); these results suggested a reduction of antioxidant defence as mechanism of OTA nephrocarcinogenicity (Cavin et al., 2007). Furthermore, DNA-oxidative damage was detected in HK-2 cells, at cytotoxic concentrations (Arbillaga et al., 2007). Also, oxidative damage to DNA was detected in target (kidney) and non-target (liver) tissues in male F344 rats (Kamp et al., 2005; Mally et al., 2005). Chromosomal aberrations have been induced by OTA *in vivo* in mouse cells (Bose and Sinha, 1994) and *in vitro* in human-derived hepatoma cells (Ehrlich et al., 2002). Dose dependent increases in the frequency of DNA single-strand breaks and alkali-labile sites, as measured by the Comet assay, and in micronuclei frequency were obtained in primary kidney cells from both male rats and human of both genders treated with OTA (Robbiano et al., 2004). OTA induced micronuclei (MN), in a dose-dependent manner, in Syrian hamster fibroblasts (Dopp et al., 1999), in human hepatic (HepG2) cells (Ehrlich et al., 2002) and in V79 Chinese hamster fibroblast cells and in primary cultures of porcine urothelial bladder epithelial cells (Föllmann, et al., 2007). OTA induced, also, MN in cytokinesis-blocked lymphocytes and led to a clear decrease in the percentage of binucleated cells in human lymphocytes (Dönmez-Altuntas et al., 2003). It also induce DNA-ploidy in kidney after chronic exposure (Brown, et al., 2007), and causes increase in endoreduplicated cells (Mosesso, et al., 2008). OTA inhibits the catalytic activity of topoisomerase II and may interfere with chromosome distribution during cell division (Cosimi, et al., 2009). Concerning reproductive toxicity, OTA was found to be a reproductive toxicant and prolong exposure to it caused a significant decrease in sperm count and increased abnormalities in sperm morphology (Bose and Sinha, 1994; Biró et al., 2003). In a recent study, male albino mice were treated orally with OTA (50 and 100 μg/day) for 45 days; alterations in various reproductive parameters were observed (sperm count, sperm motility, sperm viability and fertility rate), in a dose-dependent way (Chakraborty and Verma, 2009).

Currently there is considerable interest in the potential antigenotoxic and anti-carcinogenic effects of probiotics. Lactic acid producing bacteria (LAB), particularly *lactobacilli* and *bifidobacteria* are considered as the most probable agents responsible for these effects. Probiotics have been proved to exert health-promoting influences in human and animals (Ouwehand et al., 2002; Saxelin et al., 2005). *Lactobacillus rhamnosus GG (LGG)* is one of the best-studied probiotic bacteria in clinical trials for treating and/or preventing several intestinal disorders, including inflammatory bowel diseases and diarrhea (Yan and Polk, 2002, 2006). Furthermore *LGG (*ATCC 53013*)* efficiently binds, *in vitro,* several mycotoxins, including aflatoxin B1 and aflatoxin M1 (Pierides et al., 2000; El-Nezami et al., 2002). It had been reported that some strains of lactobacillus could protect against toxins contained in foods such as heterocyclic aromatic amines, polycyclic aromatic hydrocarbons, mycotoxins and reactive oxygen species (Knasmüller et al., 2001; Stidl et al., 2007). Probiotic *lactobacilli* demonstrated antimutagenic activity against 4-nitroquinoline-1-oxide and N-methyl-NV-nitro-N-nitrosoguanidine by microbial and mammalian cell-based tests (Caldini et al., 2005). Protection against *in vivo* genotoxicity had been observed after co-administration of LAB with N-methyl-N-nitro-N-nitrosoguanidine ((Pool-Zobel et al., 1993). It had been claimed that lactic acid bacteria which are contained in fermented foods and are part of the intestinal microflora may protect human against colon cancer (Wollowski et al., 2001; Rafter, 2004; McGarr et al., 2005).

Strategies for minimizing the possible deleterious effects resulting from human and animals exposure to genotoxic and/or carcinogenic agents in our environment are of utmost need. The aim of the present study was to evaluate the *in vivo* antioxidant, antigenotoxic and antispermatotoxic effects of lactic acid bacteria (*Lactobacillus rhamnosus GG)* against the well-known mycotoxin ochratoxin A in male albino mice.

2-MATERIALS AND METHODS

2.1.Materials:.

2.1.1.Chemicals, reagents, and reagent kits,

Were purchased from Riedel-de Haën, Germany and Biodiagnostic, Cairo, Egypt. Ochratoxin A was obtained from Food Toxicology and Contaminants Dept., National Research Centre, Egypt as a crude mycotoxin.

2.1.2. Bacterial strain and culture preparation:

Lactobacillus rhamnosus strain GG (ATCC 53013) was a kind gift provided by Food Toxicology and Contaminants Dept., National Research Center, Egypt as lyophilized powder and stored at -80°C. LGG cultures were prepared according to the procedure of El-Nezami et al. (2002). In which, bacterial cultures of LGG were obtained by incubating 0.1 g of lyophilized bacteria in 10 ml of deMan-Rogosa-Sharpe (MRS) broth under aerobic conditions at 37°C for 24 h. The number of lactic acid bacteria cells was enumerated by serial dilution in peptone water (0.1 % w/v) and plate counts on deMan-Rogosa-Sharpe agar (MRSA) medium.

2.2.Methods:

2.2.1 Experimental Animals:

Male Swiss Albino mice (*Mus musculus*) three months old weighing 25-30 grams were obtained from the animal house colony, National Research Centre (Giza, Egypt). The animals were maintained on standard casein diet and water *ad libitum* and housed individually in a temperature-controlled and artificially illuminated room free from any source of chemical contamination.

2.2.2.. Experimental design

Mice were randomly divided into four groups each consisting of 30 mice, each group was divided into three subgroups (10 mice for each). Animals were treated orally for successive 7 days as follows: (1) untreated control given $NaHCO_3$ and MRS broth daily, (2) treated with OTA (1.8 mg/kg b.w.) in 0.4ml $NaHCO_3$, (3) treated with LGG (1×10^{10} CFU) in MRS broth and (4) treated with the LGG (1×10^{10} CFU) 2 hours before OTA gavage (1.8 mg/kg b.w.). On the 8th day of the study, the 1st subgroup was killed and femoral bones were removed, stripped and cleaned from extraneous tissues. Also, liver and kidney samples were dissected out and washed immediately with ice-cold saline to remove as much blood as possible, and then stored immediately at -80º C until analysis. On the 15th day of the study, the 2nd subgroup was killed and both testes removed and washed in warm citrate saline. At the end of the experiment (35th day), cauda epididymis, of the 3rd subgroup, were quickly isolated, blotted free of blood and utilized for the analysis of various reproductive parameters.

2.2.3.. Body weight

Mice were weighed at the beginning of the study, at the 8th day, 15th day and the 35th day from the beginning of the study. The percentage of weight gain or loss was then calculated.

2.2.4.. Biochemical analyses

2.2.4.1. Measurement of lipid peroxidation:

Liver and kidney tissues were homogenized individually in 20 mm Tris–HCl (pH 7.4). Homogenates were centrifuged at 6000 g for 30 min. MDA levels in the supernatants were determined using a spectrophotometric assay kit according to the manufacturer's instructions. Briefly, thiobarbituric acid (TBA) reacts with malondialdehyde (MDA) in acidic medium at temperature of 95°C for 30 min to form thiobarbituric acid reactive product the absorbance of the resultant pink product can be measured at 534 nm (Ohkawa et al., 1979). The lipid peroxidation values are expressed as nm MDA/mg tissue.

2.2.4.2. Reduced Glutathione (GSH) content

GSH levels were measured using a spectrophotometric assay kit according to the manufacturer's instructions. 5,5` dithiobis-2-nitrobenzoic acid (DTNB) is reduced by glutathione (GSH) to produce a yellow compound .The reduced chromogen directly proportional to GSH concentration and its absorbance can be measured at 405 nm (Beutler et al., 1963). GSH values are expressed as mmol/g tissue.

2.2.4.3. Superoxide dismutase (SOD) activity

Liver and kidney homogenates were prepared in cold Tris–HCl (5 mmol/L, containing 2 mmol/L EDTA, pH 7.4) using a homogenizer. The unbroken cells and cell debris were removed by centrifugation at 10,000g for 10 min at 4º C. The supernatant was used immediately for the assays for SOD. 100µl of supernatants were added to 2.8 ml tris HCL buffer containing 25µl pyrogallol and 20µl catalase (Marklund and Marklund, 1974). The activities of all of these enzymes were determined. The SOD activities were expressed as units per mg of tissue.

2.2.5 Micronucleus test

Bone marrow slides were prepared according to the method described by (Krishna and Hayashi, 2000). The bone marrow was washed with 1 ml of fetal calf serum and then smeared on clean slides. The slides were left to air dry and then fixed in methanol for 5 min, followed by staining in May-Grünwald-Giemsa for 5 minutes then washed in distilled water and mounted.

For each animal, 2000 polychromatic erythrocytes (PCEs) were examined for the presence of micronuclei. In order to evaluate bone marrow cytotoxicity, we scored 1000 erythrocytes per animal and the rate of polychromatic erythrocytes (PE) relative to the number of normochromatic erythrocytes was calculated.

2.2.5. Chromosomal aberrations examination

Metaphases for analysis of chromosome aberrations in spermatocytes were prepared according to the method of Evans et al. (1964) and recommendations by Russo (2000) were considered. Structural aberrations analysis was studied in metaphase I (MI): MI with only 20 bivalents was scored; the presence of univalents, chromosome breaks, fragments and chain or ring multivalents, which are classified as reciprocal translocations were considered. For aneuploidy assay, metaphase II (MII) was studied: MII with 18<n>22 chromosomes were recorded, and polyploidy was considered as 2n, 3n or 4n. Fifty metaphase spreads were analyzed per animal. For Meiotic activity of spermatocytes; meiotic index was calculated as the frequency of MII/MI, normal ratio should be equal 2.

2.2.6.. Sperm parameters:

Sperm parameters were prepared and analyzed according to the protocols of Wyrobek and Bruce (1975).

2.2.6.1. *Collection of Epididymal sperm*:

Epididymal sperm were collected by cutting the cauda epididymis and perfusing the cauda with normal saline (0.9%) at 37◦ C. The epididymal perfusate was centrifuged at 225×g for 10 min. The pellet was re-suspended in 1.0 ml of normal saline. An aliquot of sperm suspension was used for the sperm examination.

2.2.6.2. Epididymal sperm counts and sperm motility:

Epididymal sperm counts and evaluation of the motility were performed visually using counting chamber. The count was repeated three times for each sample to minimize error, and calculated as 10^6 per sperm dilution. Sperm motility was determined by counting both motile and non-motile sperms in at least 16 separate and randomly selected fields. These results were expressed as percent motility.

2.2.6.3. Epididymal sperm morphology

A drop of sperm suspension was smeared onto a slide, left to dry; then stained with Eosin A, the slides were washed in water and air dried again. The smears were microscopically analyzed at a magnification of ×1000 for observation of abnormalities.

2.2.7. Statistical analysis

Statistical analyses were performed by one-way ANOVA followed by Tuckey's test or by Two-way ANOVA followed by Bonferroni's test comparing all groups. Analysis was conducted with GraphPad Prism software V.5.0.3 (Inc., San Diego, CA; USA).

3. Results

3.1. Change in body weight:

The current results indicated that no mortalities were recorded among any treated groups; no specific symptoms occurred within all groups. At the 8th day of the study, OTA-treated mice showed a significant reduction in body weight gain in comparison with the control group at $p<0.001$ (Fig. 1). Furthermore, at the 15th day, OTA-treated mice showed significant weight loss which was significant (6.10 % at $p< 0.001$), this weight loss reached 9.74 % at the 35th day and it was highly significant compared to all other groups at $p < 0.001$. On the other hand, mice treated with LGG before OTA showed an insignificant decrease in body weight gain compared with the control ($p<0.05$). This group showed a very significant weight recovery when compared with OTA group for all time points. Mice given LGG alone showed an insignificant increase in body weight gain compared with control at $p<0.05$.

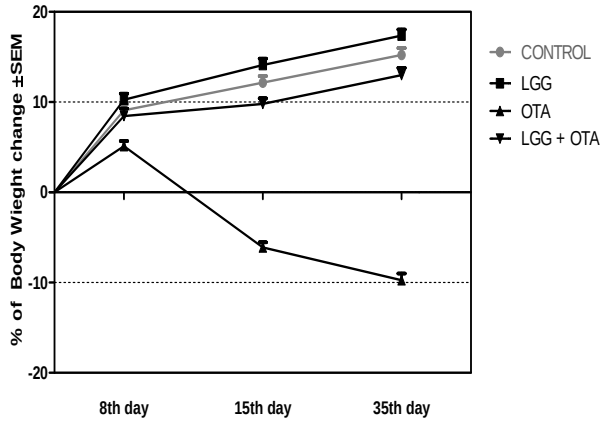

Figure 1: Effects of LGG on ochratoxin-induced mice body weight change.

3.2. Biochemical study

3.2.1. Effect on MDA levels

In OTA-treated mice, MDA level showed a high significant increase ($p<0.01$) in liver and kidney tissues as compared to that of control (table 1). LGG gavage before OTA-intoxication normalized MDA levels in liver tissues to that of control group, which was non significant in comparison with control, while it was still significantly higher in case of kidney tissue compared to control group ($p<0.01$). Whereas, the reduction in MDA in both liver and kidney in this group was statistically significant at $p<0.01$, when compared to the OTA group. In mice

receiving LGG alone, no significant differences were found in MDA level in kidney tissue when compared with control, while data showed a significant decrease in liver MDA level when compared with control at $p < 0.01$.

Table 1: Effects of LGG on MDA, GSH levels and SOD activity in liver and kidney of mice treated with OTA.

Experimental Groups	Parameters					
	MDA		GSH		SOD	
	LIVER	KIDNEY	LIVER	KIDNEY	LIVER	KIDNEY
Control (Broth/NaH CO_3)	339.0± 12.8^{a}	258.0± 6.60^{a}	13.1± 0.40^{a}	17.3 ± 0.31^{a}	29.1± 1.76^{a}	70.7± 3.11^{a}
Ochratoxin (1.8 mg/kg b.w.)	751.0± 15.0^{c}	798.0± 13.3^{c}	4.28± 0.39^{c}	8.12± 0.62^{c}	15.9± 1.56^{c}	26.8± 2.82^{c}
LGG (1×10^{10})	273.0± 8.70^{b}	214.0± 5.80^{a}	13.9± 0.28^{a}	19.4± 0.54 a	37.6± 1.22^{b}	78.4± 2.66^{a}
LGG plus Ochratoxin	352.0± 15.4^{a}	390.0± 14.3^{b}	10.6± 0.46^{b}	14.5± 0.37 b	27.6± 1.10^{a}	53.2± 1.85^{b}

Means with different superscript letters (a, b, c) are -significantly different ($P < 0.01$).
-All data are expressed as means ± SEM.

3.2.2 Effect on the reduced glutathione (GSH level)

Reduced glutathione content in both liver and kidney decreased significantly in OTA-treated group as compared to the control or LGG groups at $p < 0.01$. Mice received LGG before OTA intoxication showed a significant increase in GSH level when compared with the OTA-treated group at $p<0.01$. This increase was significantly below the GSH level of control and LGG groups at $p<0.01$. Mice given LGG alone exhibited increase in GSH content as compared to control, which was insignificant in liver and significant in kidney tissue at $p < 0.01$.

3.2.3 Effect on Superoxide dismutase (SOD) activity

OTA administered group showed high significant decrease in superoxide dismutase activity (in both liver and kidney) as compared to other groups ($p < 0.01$). However, the activity of SOD in the group received LGG before OTA was significantly increased as compared to the OTA-treated group in liver and kidney tissues (Table 1) at $p < 0.01$. This enhancement reached the value of controls in both liver and kidney, which was statistically nonsignificant ($p<0.01$) compared to control. Mice received LGG alone showed an insignificant increase in SOD activity in kidney tissue, while it was statistically significant in liver tissue, as compared with the control group at $p < 0.01$.

3.3. Cytogenetic studies:

3.3.1. Effects of LGG on OTA genotoxicity in bone marrow cells

Results for the MNPE rate are indicated in Table 2, mice treated with OTA showed a high significant increase in MNPCEs (with mean value of 32.8 at $P< 0.01$) when compared with other groups; where insignificant differences can be seen between the control and the LGG treated mice (a mean of 3.0 and of 2.4 per 2000 MNPCEs at $P< 0.05$, respectively). Mice received LGG before OTA gavage revealed a significant reduction in MN value (mean 11.0) with respect to the OTA-treated group, but this reduction was not enough to lower the MN to the basal level of control group, where it remained significant high. The mitotic index values were shown in table 2. OTA intoxication caused a high significant reduction in mitotic division compared with control ($p<0.01$). Whereas, administration of LGG before OTA treatment restored the division ability of bone marrow cells close to that of control, which was statistically significant when compared to the OTA-treated group at $p<0.01$. LGG given group exhibited no statistically differences in mitotic division, when compared to control or LGG plus OTA groups at $p<0.01$.

Table (2): Mean values of the frequencies of Micronucleated polychromatic erythrocytes (MNPCEs) in bone marrow cells of mice administred ochratoxin and/or LGG.

	Untreated Control	OTA	LGG	LGG plus OTA
MNPCEs/2000 cells	3.0± 0.32^{a}	32.8± 1.65^{c}	2.4± 0.24^{a}	11.0± 0.71^{b}
% PCE/NCE	0.49± 0.005^{ab}	0.32± 0.011^{c}	0.52± 0.010^{b}	0.46± 0.10^{a}

Means with different superscript letters (a, b, c) are -significantly different ($P < 0.001$).
- All data are expressed as means ± SEM.

3.3.2. Effects of LGG on OTA genotoxicity in germ cells (spermatocytes MI, MII)

The results of our study revealed that oral treatment with ochratoxin induced structural and numerical chromosomal aberrations in germ cells of

male mice (Table 3). The administration of OTA caused a high increase in X-Y univalents and autosomal univalent which was highly significant at p<0.01 compared with control or LGG groups. The total structure aberrations (x-y and autosomal univalents) increased significantly (P < 0.01) in OTA-treated mice compared to other groups. In mice given LGG before OTA, structural aberrations were decreased significantly compared to the OTA-treated animals at p < 0.01, but still revealed a significant difference compared with the control group. The LGG only treated group showed no significant differences in structure aberrations in respect to the control. Periploidy, polyploidy and the total numerical aberrations observed in spermatocytes were significant elevated (p<0.1) in the OTA treated group compared to all other groups. The LGG plus OTA group showed a significant reduction in numerical aberrations compared to the OTA-treated group and no significant differences compared to the control and LGG groups, except for the total numerical aberration when compared with the LGG group. Meanwhile, the LGG only treated group showed no significant differences in numerical aberrations in respect to the control.

The meiotic index (Table 3) revealed a significant meiotic delay in mice treated with OTA with respect to all other groups (p < 0.01). In the LGG and LGG plus OTA groups, there were no significant differences observed compared with them or the control group.

Table 3: Mean values of different types of chromosomal aberrations in spermatocyte of male mice OTA-treated with or without LGG

Experimental Groups	Structural aberrations (MI)			Numerical aberrations (MII)			Meiotic Index
	X-Y univalents	Autosomal univalents	Total	Aeuploidy	Polyploidy	Total	
Untreated Control	1.2 ± 0.20^{ab}	1.0 ± 0.32^{a}	2.20 ± 0.32^{ab}	$0.8\pm.37^{a}$	1.40 ± 0.25^{a}	2.40 ± 0.25^{ab}	1.99 ± 0.028^{a}
OTA	5.8 ± 0.37^{c}	6.0 ± 0.71^{b}	11.80 ± 0.37^{d}	4.80 ± 0.37^{b}	6.40 ± 0.51^{b}	11.60 ± 0.68^{c}	1.22 ± 0.028^{b}
LGG	0.8 ± 0.20^{b}	0.60 ± 0.25^{a}	1.40 ± 0.40^{b}	0.60 ± 0.26^{a}	1.20 ± 0.20^{a}	2.00 ± 0.31^{b}	2.08 ± 0.053^{a}
LGG plus OTA	2.4 ± 0.26^{a}	1.8 ± 0.20^{a}	4.20 ± 0.37^{c}	1.40 ± 0.25^{a}	2.20 ± 0.20^{a}	3.60 ± 0.25^{a}	1.87 ± 0.072^{a}

Means with different superscript letters (a, b, c, d) are significantly different (P <0.05).

-All data are expressed as means ± SEM.

3.4. Spermatological parameters:

3.4.1. Sperm count and motility

Data on sperm concentration, motility and morphology are presented in Table 4. There was a highly significant change in the sperm concentration of mice treated with OTA showing drastic reduction in sperm concentration (6.8×10^6). Administration of LGG before OTA intoxication caused a significant increase in sperm count respect to the OTA-treated group (18.4×10^6); this increase was significantly below that of control and LGG groups at p < 0.01. In mice given LGG alone, a significant increase in sperm count was observed compared to the control at p<0.05.

The motility of the sperm was affected dramatically in OTA-intoxicated mice which was 26.0 %, this reduction was statistically highly significant at p <0.01. In LGG plus OTA group, there was a significant enhancement in sperm concentration (63.8%) when compared to the OTA-treated group. Again, this increase is still below the basal count of the control. LGG group showed no significant increase in sperm count in respect to that of the control. LGG group showed non-significant enhancement in sperm concentration, compared with control at p<0.05.

3.4.2. Sperm Morphology:

OTA induced a high significant increase in sperm abnormalities in comparing with control at p<0.001 (Table 4). The various head abnormalities were existed, specially head without hook, unusual head shapes, big head and decapitation (Plate 1 B, D). The mid-piece abnormalities consisted of hair-pin, folded, and disrupted neck (Plate 1 E). The tail abnormalities essentially consisted of angular and bi- or coiled tail (Plate 1 F, J). In OTA-treated mice, 10.6 % of sperm head was detached from the flagellum, which was significant compared to control at p<0.01. In addition, OTA caused a fairly high percentage of sperm (13.4 %) that had sticky flagellum (agglutination), where several sperms remained fused in various numbers over short to long distances (Plate 1H, 1G), it was statistically significant at p<0.01.The retention of cytoplasmic droplet (CD) by the cauda epididymal sperm of control as well as OTA-treated mice was observed (Plate1 K). The retention of CD by the cauda epididymal sperm was 10.6% in control mice whereas it was 44.6 % in the OTA-treated mice, this difference was statistically highly significant. In mice receiving LGG before OTA intoxication, different sperm abnormalities significantly reduced in comparing with OTA-treated group, this enhancement showed significant differences with respect with either control or LGG groups at p <

0.05. Meanwhile, LGG group, mice showed a significant reduction in CD retention when compared with the control group ($p<0.01$).

Table 4: Effect of LGG on ochratoxin-induced changes in sperm parameters in male mice.

Experimental Groups	Sperm Count ($\times 10^6$)	% Sperm Motility	Sperm Morphology %						
			Head Abnormality	Mid-piece Abnormality	Tail Abnormality	Decapitation	Agglutination	Total Abnormality	Cytoplasmic Droplets
Untreated Control	22.6 ± 1.18^a	85.0 ± 1.58^a	2.8 ± 0.24^a	3.40 ± 0.24^a	2.40 ± 0.25^a	3.20 ± 3.7^a	0.00 ± 0.00^a	12.2 ± 0.74^a	10.6 ± 0.50^a
OTA	8.6 ± 0.98^c	26.0 ± 1.87^c	24.2 ± 1.16^d	19.6 ± 0.68^d	11. 0 ± 0.70^d	10.6 ± 0.75^d	13.4 ± 0.81^d	78.8 ± 1.28^d	44.6 ± 1.03^d
LGG	26.8 ± 1.21^a	89.0 ± 1.00^a	2.4 ± 0.25^a	2.80 ± 0.37^a	2.20 ± 0.20^a	3.2 ± 0.37^a	0.00 ± 0.00^a	10.6 ± 0.51^a	5.0 ± 0.32^b
LGG then OTA	18.4 ± 0.71^b	63.8 ± 1.87^b	10.0 ± 0.71^c	7.60 ± 0.40^c	3.80 ± 0.37^a	8.0 ± 0.55^c	5.20 ± 0.58^c	34.6 ± 1.10^c	19.6 ± 0.93^c

The various abnormalities of the sperm of OTA-treated mice (B–D) abnormal head shape; e.g, amorphous head, big head, banana-like; (E), hair-pin; (F-J) tail angulation bi- and coiled tails; (G), sperm agglutination ; (K), sperm retained CD

4. Discussion

Chronic exposure to OTA is believed to be an important factor for several diseases in human and animals, including renal tumors (Abdel-Wahhab et al., 2005; Brown et al., 2007). Therefore, many intervention strategies are set to prevent or alleviate OTA-induced disorders; probiotics are one of them, but still needed to be evaluated as protective agents for human health. In current study, the role of LGG on the OTA-toxicity was investigated in male albino mice. The present results clearly indicated that OTA treatment resulted in a significant reduction in body weight gain. These results are consistent with study in rats where the reduction in body weight was attributed to OTA and not to reduced food intake (Abdel-Wahhab et al., 2005). In the present study, this reduction in body weight may explained by the ability of OTA to generate free radicals (Pfohl-Leszkowicz et al., 1993), which may lead to DNA breakage, inhibition of protein biosynthesis and gluconeogenesis, lipid peroxidation, disruption of oxidative phosphorylation in mitochondria, inhibition of blood clotting and apoptosis (Hohler, 1998; Petzinger and Ziegler, 2000). LGG gavage alone resulted in insignificant increase in body weight gain; on the other hand, the pretreatment with LGG before OTA intoxication resulted in a significant improvement in body weight gain, comparable with the intoxicated group. This might be attributed to the alleviation of overall oxidative status, improved antioxidant defenses and decrease in genotoxic and cytotoxic effects (Bruno-Barcena et al., 2004; Klinder et al., 2004; Chen et al., 2005; Koller et al., 2008).

The results of the experiment showed that OTA treatment elevated MDA concentration in liver and kidney tissues, which indicated to the increase of lipid peroxidation. MDA is an end product of lipid peroxidation, and this may be considered a late biomarker of oxidative stress and cellular damage (Vaca et al., 1998). The results of this study confirm and extend previous data which have demonstrated that OTA induces a significant increase in LPO in liver and kidney induced by OTA as increasing in malondialdehyde (MDA) production (Petrik et al., 2003; Abdel-Wahhab et al., 2005, 2008). Previously, Gautier et al. (2001) stated that OTA did evoke oxidative stress, which might contribute, at least in part, to OTA renal toxicity and carcinogenicity in rats during long-term exposure. To assess the balance of reactive oxygen species (ROS) production in liver and kidney, levels of non-enzymatic antioxidants GSH and enzymatic antioxidant (SOD) activity were measured. Current results showed that OTA caused significant decrease in the levels of GSH, along with decrease in the activity of SOD; this decrease indicated the cell damage of liver and kidney tissues (Doorten et al., 2004). Soyöz et al. (2004) stated that intracellular GSH status appears to be a sensitive

indicator of cell's overall health and its ability to toxic challenges, whereas, the decrease in SOD activity will increase the level of superoxide radicals, leading to an increase in oxidative stress enhancing early cell death, probably by apoptotic mechanisms. Our finding of decrease in the activities of SOD and GSH corroborates with that of previous studies (Ozcelik et al., 2004; Abdel-Wahhab et al., 2008). The results of the experiment with LGG showed that treatment with LGG before OTA gavage ameliorated the biochemical parameters in liver and kidney, where MDA level decreased and SOD activity increased, along with an increase in GSH contents. Many *in vitro* studies, reported that LAB strains possess antioxidant properties and inactivate ROS via enzymatic mechanisms, e.g. by a coupled NADH oxidase/ peroxidase system, superoxide dismutase and catalase (Kullisaar et al., 2003; Bruno-Barcena et al., 2004; Lee et al., 2005). *Bifidobacterium longum ATCC 15708* and to a lesser *extent L. acidophilus ATCC 4356* inhibited linoleic acid peroxidation and scavenged free radicals (Lin and Chang, 2000). Also, it was found in human and animal studies that some LAB strains, which inactivate ROS, decrease biochemical parameters of oxidative stress (Han, 2004; Songisepp et al., 2005; Han et al., 2006). In a recent study, Koller et al. (2008) investigated the prevention of oxidative DNA damage in human derived colon (HT29) cells by 55 strains of lactic acid bacteria, they indicated that the reduction of oxidative damage was only seen with viable bacteria but not with heat inactivated cells and that it took place when the colon cells were separated from the LAB by permeable filter membranes indicating that the bacteria release ROS protective factors into the medium.

Considering the genotoxicity, the present study indicated that OTA caused high significant increase in DNA damage and cytotoxic effects in both cell types; we have investigated the OTA genotoxicity by induction of micronuclei (MN) in somatic cells (bone marrow), as an endpoint suitable to detect both aneugenic and clastogenic effects and chromosomal aberrations in germ cells (spermatocytes). The present data revealed that OTA induced a very high significant increase in MN in bone marrow cells, and increased structural and numerical aberrations in spermatocytes. Moreover, mitotic and meiotic activities had declined in a significant way. These findings are in agreement with the previous studies; OTA induced micronuclei in ovine seminal vesicle cells (Degen, 1997), in Syrian hamster fibroblasts (Dopp et al., 1999) and in human hepatic (HepG2) cells (Ehrlich et al., 2002). Significant dose-dependent increases in the frequency of micronucleated cells were also obtained in primary kidney cells from both male rats and humans of both genders with OTA (Robbiano et al., 2004). A statistical increase of structural chromosomal aberrations and sister chromatid exchanges associated with a decrease of the mitotic index was observed in bovine lymphocytes (Lioi et al., 2004). *In vivo*, oxidative damage to DNA was detected in target (kidney) and non-target (liver) tissues in male F344 rats (Kamp et al., 2005; Mally et al., 2005). Also, OTA induced structural and numerical chromosomal aberrations in bone marrow and germ cells of male mice (Ezz El-Arab et al., 2006). As shown in table (2, 3), data showed that OTA reduced the mitotic and meiotic ability significantly in somatic and germ cells; these results are in agreement with many studies which had demonstrated that even at very low concentration, ochratoxin was able to induce apoptosis in kidney cells in rats (Soyoz et al., 2004), and inhibit cell cycle progression by arresting cells at G2/M phase (Palma, et al., 2007). In addition OTA modulates key regulators of chromosome segregation and progression through mitosis (Adler et al., 2009). OTA found to inhibit the catalytic activity of topoisomerase II and might interfere with chromosome distribution during cell division (Cosimi, et al., 2009). Pfohl-Leszkowicz et al. (1993) reported that the ability of OTA to generate free radicals and to enhance lipid peroxidation has been linked to the genotoxicity expressed by DNA adduct. Free radicals may lead to DNA breakage, inhibition of protein biosynthesis and gluconeogenesis, lipid peroxidation, disruption of oxidative phosphorylation in mitochondria, inhibition of blood dotting and apoptosis (Petzinger and Ziegler, 2000). Pfohl-Leszkowicz and Manderville (2007) proposed that OTA genotoxicity might be caused by direct (covalent DNA adduction) and indirect (oxidative DNA damage) mechanisms of action. Gautier et al. (2001) and Baldi et al. (2004) reported that oxidative stress is an important factor in OTA cytotoxicity. Arbillaga et al. (2006) suggest that oxidative stress precedes cytotoxicity and genotoxicity and plays an important role regarding the mechanisms involved in OTA nephrotoxicity and carcinogenicity. Also, El Golli-Bennour et al. (2010) found that OTA induced genotoxic and cytotoxic effects in cultured monkey kidney Vero cells. On the other hand, results showed that the administration of LGG before OTA-intoxication reduced the OTA-induced genotoxicity (somatic and germ cells by around three folds) and cytotoxicity in both cell types. These data are consistent with other experimental studies which had evidenced the ability of *lactobacilli* and *bifidobacteria* to decrease the genotoxic activity of some chemical compounds (Tavan et al., 2002;

Burns and Rowland, 2004; Caldini et al., 2008). Also, our results revealed that LGG gavage before OTA treatment, enhanced the mitotic and meiotic activities of bone marrow cells and spermatocytes in OTA-treated mice to nearly to the basal level of control animals; this finding is going along with the mechanistic studies by Yan et al. (2007) who found that LGG prevent cytokine-induced apoptosis in intestinal epithelial cells through secreting two soluble proteins (p75 and p40).

Regarding the reproductive toxicity, the present study clearly indicated that oral administration of OTA caused adverse effects on male reproductive parameters in mice (Table 4). In OTA-treated mice cauda epididymal sperm count was reduced significantly (6.8 $x10^6$), along with a decrease in motility (26.0%) and a dramatically increase in sperm abnormalities (78.8 %). These findings are in agreement with some authors who reported similar kind of observations in different animals emphasizing ochratoxin as a reproductive toxicant; OTA induced chromosomal abnormalities and a decrease in spermatogenic numbers in mice (Bose and Sinha, 1994), decreased motility and longevity of breeding boar semen (Solti et al.,1999), impaired spermatogenesis and caused accumulation of premeiotic germinal cells (Fenske and Fink-Gremmels, 1990), inhibited testosterone secretion in isolated testicular interstitial cells of gerbils in *in vitro* condition (Gharbi et al., 1993). In human, sperm motility reduction might be due to mitochondrial disruption and/ or an increase in lipid peroxidation (Lodish et al., 2003). The lipid peroxidation of unsaturated fatty acids in sperm membranes is one of the most important effects from ROS-induced cell damage (Hsieh et al., 2006), and might impair sperm motility (Saradha et al., 2006; Hsieh et al., 2006). Chitra et al. (2003) observed that increased levels of lipid peroxidation caused the reduction of sperm count and viability. Moreover, the results of the present study showed that OTA intoxication rendered a significantly higher percentage of the cauda epididymal sperm (44.6 %) to retain cytoplasmic droplets (CD) than in the control mice. The residual cytoplasm contains high concentration of certain cytoplasmic enzymes (G_6PDH, SOD), and are also a source of ROS (Gomez et al., 1996). ROS damages phosphatides of cell membrane by peroxidized metabolites of fatty acids, whereby damaging the sperm function and morphology (Alvarez et al., 1987). Our data substantiated these claims where midpiece and tail of OTA-treated mice showed a very high percentage of malformation (hair-pin, disruption, folding, tail angulation, tail coiling), which might caused by peroxidation of cell components and disrupted the cytoskeletal proteins (44.0 %). The sticky flagellum (13.4 %) observed in this study might formed by fusing of two or more spermatozoa, where two or more axonemes are in a common cytoplasm ((Agnes and Akbarsha, 2003). These data reflected the aberrant spermatogenesis and/ or spermiogenesis caused by OTA treatment.

On the other hand, pre-treatment with LGG significantly mitigates OTA-induced alterations in reproductive parameters in mice, where sperm count elevated to reach 18.4 x 10^6 and the motility recovered to 63.8 %. Also, sperm morphology showed a significant enhancement (44.2 %). Moreover, LGG reduced CD retention by about 2.3 folds with respect to the OTA-treated group, which might due to the reduction in ROS.

Some authors attributed the protective effect of these bacteria to different mechanisms such as binding of OTA *in vitro* (Del Prete et al., 2007; Fuchs et al., 2008; Mateo et al., 2010). Previous work with more than 250 strains of lactic acid bacteria showed that *Lactobacillus rhamnosus* strains, LGG and LC705 were the most efficient strains in binding a range of mycotoxins, including aflatoxins (El-Nezami et al., 1998). Piotrowska and Zakowska (2005) verified that *L. acidophilus* and *L. rhamnosus* caused OTA reductions of 70% and 87% of 1 mg OTA/L after five days at 37 °C, and that significant levels of the OTA were present in the centrifuged bacteria cells. Gratz et al. (2006) suggested that LGG treatment reduced the hepatotoxic effects caused by a high dose of AFB_1, by increasing the excretion of orally dosed aflatoxin via the fecal route and suggested that LGG was able to retain additional AFB_1 and AFM_1 inside the intestinal lumens of rats. Nevertheless, Fuchs et al. (2008) consider that metabolism may also be involved, where viable cells of *L. acidophilus* removed OTA more efficiently than unviable. In addition, LAB found to cause reduction of the formation of secondary bile acids (Mirasoli et al., 2002) and enhancement of the immune system (Wallace et al., 2003; Schultz et al., 2003; Bengmark and Martindale, 2005).

In conclusion, the overall data indicate that the LGG have a broad range of biomodulatory properties; alleviates the OTA-oxidative stress (by decreasing in LPO and enhancing the activity of antioxidant enzymes and glutathione content) and protects against OTA-genotoxicity; as well as mitigates the spermatotoxic effects induced by OTA. However, further studies are needed to better understand the *in vivo* possible mechanism(s) by which LGG may reduce OTA toxicity.

*nadiaelwan@yahoo.com

Abstract: Nonalcoholic fatty liver disease (NAFLD) includes hepatic steatosis, nonalcoholic steatohepatitis (NASH), fibrosis, and cirrhosis .NAFLD has also the potential to progress to hepatocellular carcinoma (HCC) or liver failure. NAFLD is linked to obesity, insulin resistance, hyperlipidaemia and genetic factors. Our objective was to study the risk factors that involved in the progression of non alcoholic fatty liver disease. Subjects and methods: Thirty-three patients and ten healthy controls were included in our study. Patients were classified into 3 groups. Group I included12 patients with simple liver steatosis. Group II included 11 patients with NASH. Group III included 10 patients with cirrhosis most probably a late sequel of NASH. Results: BMI, fasting blood glucose, insulin and HOMA-IR were significantly higher in patients with fatty liver, NASH and cirrhosis, also, NASH patients showed a significant high serum triglycerides and ALT. All previous parameters were significantly increased with the increased severity of histopathological score in patients with fatty liver and NASH. Serum AST levels and AST / ALT ratio were significantly increased in NASH and cirrhotic patients as compared to patients with steatosis alone and controls. Mitochondrial ATP levels in patients with fatty liver and NASH showed a statistically significant decrease. Also patients with NASH showed a statistically significant decrease when compared to patients with fatty liver. Finally, patients with fatty liver and NASH showed a significant decrease in mitochondrial ATP with increased BMI and histopathological score. Conclusion: Increased BMI, hyperglycemia, hypertriglyceridaemia, insulin resistance and depletion of mitochondrial ATP in hepatocytes can be considered risk factors involved in the development and progression of fatty liver to NASH and cirrhosis.

Key words: BMI, insulin resistance, mitochondrial ATP, NAFLD

1. Introduction:

Nonalcoholic fatty liver disease (NAFLD) is a significant health problem and affects 70 million adults in the United States. NAFLD occurs in up to 53% of obese children [(1)]

NAFLD is defined as an excess of fat in the liver in which at least 5% of hepatocytes display lipid droplets that exceed 5% - 10% of liver weight in patients who do not consume significant amounts of alcohol. [(2)]

Non alcoholic fatty liver disease refers to a spectrum of diseases of the liver ranging from steatosis (i.e., fatty infiltration of the liver), nonalcoholic steatohepatitis (NASH) (i.e., steatosis with inflammation and hepatocyte necrosis) to cirrhosis [(3).] Nonalcoholic steatohepatitis (NASH) is defined as necroinflammatory disorder with fatty infiltration of hepatocytes, this term is employed when steatohepatitis occurs in individuals whose alcohol consumption is nil or negligible i.e less than 20g ethanol/day in women and less than 40g in men.[(4).]

Nonalcoholic fatty liver disease, NAFLD is now considered a metabolic pathway to advanced liver disease; cirrhosis and hepatocellular carcinoma but hepatic steatosis without concomitant inflammation or fibrosis usually considered a benign condition.[(5)]

Two types of NASH exist: primary NASH (which is associated with metabolic syndrome–related conditions, such as insulin resistance, obesity, type -2 diabetes, and hyperlipidemia) and secondary NASH (which occurs after obesity-related intestinal surgery, rapid weight loss in the obese, total parenteral nutrition, treatment with drugs such as amiodarone or corticosteroids, lipodystrophy, or Wilson's disease). Many aspects of the disease are common to both presentations.[(6)]

Hepatic steatosis can be reversible or progress to NASH depending on the cessation or persistence of the underlying provocative cause respectively.[(7)]

The first step of the pathophysiology of nonalcoholic steatohepatitis is the lipid accumulation in the liver causing steatosis. This increases the sensitivity of the liver to injury, inflammation and fibrosis.[8]

The second step involves the cytokines and other factors causing oxidative stress and lipid peroxidation, in time leading to steatohepatitis.[9]

Our objective were studying the risk factors such as obesity, insulin resistance, type -2 diabetes, hyperlipidemia and mitochondrial ATP, that involved in the progression of non alcoholic fatty liver disease.

2. Subjects and methods:

All patients were selected from inpatient and outpatient clinics of Tropical Medicine and Infectious Diseases Department and Surgery Department of Tanta University Hospital in the period from August 2004 to January 2008.

This study was conducted on thirty-three patients and ten healthy controls, subjects were divided into the following groups:-

***Group I*:** Included (12) patients with steatosis.

Group II: Included (11) patients with NASH.

Group III: Included (10) patients with cirrhosis most probably a late sequel of NASH;

Diagnosis of this group was based on history of fatty liver and absence of history of any chronic liver disease, drugs causing NAFLD, abdominal ultrasonography, negative viral markers for HBV and HCV and negative laboratory tests of autoimmune hepatitis, primary biliary cirrhosis, Wilson's disease, alcoholic liver diseases, and haemochromatosis.

Group IV: Included (10) normal healthy individuals as a control group.

All patients were subjected to full history and clinical examination, body mass index (BMI), was calculated by the weight in kilograms divided by the square of the height in meters. (BMI; kg/m2), ultrasonography, urine and stool analysis, biochemical tests including complete blood count, lipid profile, liver function tests. Two-hour a 75-g oral glucose tolerance test (OGTT) was done for patients not known to have diabetes mellitus and measurement of level of fasting insulin and glucose in the blood during the test, insulin resistance was calculated using the homeostasis assessment model (HOMA-IR)) on the basis of fasting glucose and fasting insulin. HOMA-IR was calculated using the following equation: -

[Fasting glucose (mg/dl) x fasting insulin (µU/ml)] /405.

A HOMA-IR greater than 2.0 is considered to indicate the presence of insulin resistance.

Serum in sulin level was measured using kit IMMULITE 2000 Insulin which is a solid-phase, two-site chemiluminescent immunometric assay.

Serological tests for HBV; HBsAg and HBcAb and HCV; HCV Ab.

liver biopsy was done for group I and group II. Liver biopsies of controls were obtained intraoperatively from surgery department from individuals admitted for cholecystectomy. Each liver biopsy was examined for steatosis, inflammation, fibrosis and mitochondrial ATP level was estimated.

Different histological parameters were evaluated including steatosis, lobular inflammation, ballooning degeneration, and pericellular fibrosis, portal/septal fibrosis.

Histological grading of steatosis was done according to kleiner et al. (2005)[10]:

The main histological features commonly described in NALFD/NASH including:- Steatosis,inflammation (portal and lobular), hepatocyte ballooning and fibrosis .

Histological criteria of NASH were based on steatosis (≥5 % of lobular hepatocytes affected) and two of the following three: lobular inflammation, ballooning degeneration, and pericellular fibrosis.

The main histological features were scored according to the scoring system for NAFLD, recently developed by Kleiner et al.(2005)[10]; NAS-II (NASH activity score) (NASH clinical research network revision).

NASH activity score; is defined as the sum of the scores for steatosis (0–3), lobular inflammation (0 - 3) and ballooning degeneration (0–2).

Scores therefore ranged from 0 to 8. Cases with NAS- II of 0 to 2 were considered not diagnostic of NASH.

Finally, ATP concentration of mitochondrial suspension was measured by luminometer using commercial kits.

3. Results

BMI, fasting blood glucose and insulin and HOMA-IR were significantly higher in patients with fatty liver, NASH and cirrhosis (Fig,1,2,3,4) also, NASH patients showed a significant high serum triglycerides (Table,1) and ALT. histological examination of group I and group II is illustrated in (Table 2, 3)

According to score of Kleiner, et al, (2005)[10]; NAS-II (NASH activity score) (NASH clinical research network revision), the results were as follows:

Group I: 41.7% of patients had S1; steatosis

< 33%, 50% had S2; steatosis 33%-66% and 8.3% had S3; steatosis > 66%. All fatty infiltration was macrovesicular except one patient had mixed macrovesicular and microvesicular.

Group II: 18.2% of patients had score 3, 54.5% of patients had score 5, 18.2% of patients had score7 and 9.1% of patients had score 8.

Fibrosis was scored as 0 (no fibrosis) in 18.2% of patients, 1 (Perisinusoidal fibrosis) in 27.3% of patients, 2 (Perisinusoidal and portal / periportal fibrosis) in 18.2% of patients and 3 (Bridging fibrosis) in 36.3% of patients

All previous parameters were significantly increased with increase severity of histopathological score in patients with fatty liver and NASH. (Table,4,5).

Serum AST levels and AST / ALT ratio were significantly increased in NASH and cirrhotic patients as compared to patients with steatosis alone and controls.

Mitochondrial ATP levels in patients with fatty liver and NASH showed a statistically significant decrease. Also patients with NASH showed a statistically significant decrease when compared to patients with fatty liver (Table 6). Finally, patients with fatty liver and NASH showed a significant decrease in mitochondrial ATP with increase BMI and histopathological score. (Table 7).

4. Discussion:

In our study, patients with fatty liver, NASH and cirrhosis showed a significant higher BMI as compared to control group. This finding agrees with Wanless and Lentz (1990) [(11)], Abhasnee Sobhonslidsuk et al, (2007) [(12)] and Fabbrini E et al,(2009[(13)] who reported that, obesity was found in 40%-100% of fatty liver. Fatty liver has been documented in up to 70% to 80% of obese individuals, also Clark and Diehl (2003) [(14)], who reported that patients with steatosis and NASH had elevated BMI.

Patients with NASH and steatosis alone showed increased serum triglycerides with significant high serum triglycerides in NASH patients as compared to control group and patients with cirrhosis.

Our findings were in agreement with Ender Sern et al, (2002) [(15)] and Joong-Won; et al, (2007) [(16)] who reported that serum triglyceride did not show significant differences between steatosis and NASH groups and triglyceride, was significantly associated with NASH.

Fasting blood glucose increased in patients with fatty liver, NASH and cirrhosis and showed a significant high level in patients with NASH as compared to control group. This finding agreed with James and Day, et al ,(1998) [(17)] who stated that up to one third of patients have diabetes or fasting hyperglycemia at the time of diagnosis of NASH .
Bookman et al, (2006) [(18)] reported that fasting serum glucose showed significant increase in NASH patients. This finding is supported by data showing the profibrogenic role of hyperglycemia in experimental animals. (Paradis, et al, 2001). [(19)]

Fasting blood insulin showed statistically significant increase in all patients as compared to control group. Our findings were in agreement with Bookmanm, et al (2006) [(18)] who reported that the patients with steatosis and NASH had high levels of fasting blood insulin. This hyperinsulinaemia basically results from compensatory hypersecretion by beta-cells in fatty liver and NASH patients and from reduced insulin breakdown in liver as a result of cirrhosis. (Marchesini, et al, 2003). [(20)]

Insulin resistance was significantly increased across all patients as compared to control group, and the difference between NASH patients and fatty liver alone was statistically significant. These findings are consistent with many published studies done by Marchesini, et al (2003)[(20)] Bookman, et al (2006)[(18)], they stated that Insulin resistance was higher in both NASH and fatty liver patients than healthy controls and subjects with NASH had more severe insulin resistance when compared to those with simple fatty liver.

The patients with steatosis and NASH had varying degrees of steatosis, parenchymal inflammation and fibrosis. A significant positive correlation had been found between BMI and histopathological score in patients with fatty liver alone and histopathological and fibrosis score of patients with NASH.

This finding agreed with Abhasnee Sobhonslidsuk, et al, (2007) [(21)]; they reported increased BMI was positively correlated with the grades of parenchymal inflammation and stages of fibrosis in patients with NASH. Other study by Luyckx, et al (2000) [(22)] concluded that, the grade of steatosis correlates with the severity of obesity and obesity also correlates with the stages of fibrosis in NASH.

The fasting serum glucose and insulin level in patients with fatty liver and NASH were positively correlated with the histopathological score. These results were in agreement with Ender Sern, et al, (2002)[(23)] who found that serum insulin levels correlated with severity of steatosis and inflammation in NASH patients, Klein, et al, (2004) [(24)] who reported that hyperinsulinemia was positively correlated with severity of histopathology of fatty liver and NASH and Pierre, et al, (2007) [(25)] who stated that hyperglycemia was strongly associated with the presence of NASH.

The fasting serum glucose and insulin level in our study were not significantly correlated with the fibrosis score of NASH patients. These results were in agreement with Bookmanm, et al (2006) [18] who reported that fasting blood glucose levels were not significantly correlated with any stage of fibrosis and Chow, et al, (2007) [26] who stated that high serum glucose was not significantly correlated with hepatic fibrosis in NASH.

Our work, showed significant positive correlation between HOMA-IR levels and histopathological and fibrosis scores in patients with fatty liver and NASH respectively.

This finding was in accordance with many different studies. Bookman (2006) [18] reported a significant positive correlation between liver histopathology in patients with fatty liver alone and NASH and insulin resistance, also Rector, et al, (2008) [27] who mentioned that insulin resistance associated with the exacerbation of NAFLD.

Our results agreed with Cortez-Pinto, et al (1999) [28] who found that; a greater association of severity of histopathology with triglyceride values in NASH. These findings could suggest that hypertriglyceridemia may be considered as a risk factor for development of steatosis and progression to NASH.

Mitochondrdial ATP levels in patients with fatty liver and NASH were significantly decreased when compared to the control group. Also patients with NASH showed a statistically significant decrease when compared to patients with fatty liver. These results were in accordance with many different studies. Cortez-Pinto, et al, (1999) [28] demonstrated that patients with NASH have decreased mitochondrial ATP levels and Fan, et al, (2005)[29] reported that, mitochondrial ATP levels were significantly reduced in rats with NAFLD compared with the control group. Finally, Serviddio, et al, (2008) [30] reported that, the mitochondrial ATP content was significantly lower in NASH livers in a rodent model.

This may be explained by mitochondrial injury as a one cause of reduced hepatocellular ATP stores in NASH. This is supported by Dominique Pessayre, et al, (2002) [31] that, identified crystalline structures of uncertain composition coupled with the mitochondrial matrix in patients with NASH, these ultrastructural mitochondrial lesions, decreased activity of respiratory chain complexes, and impaired ability to synthesize ATP. These data were in agreement with our work as they reported that mitochondrial ATP levels negatively correlated with severity of obesity in NAFLD.

These findings could be explained by the following, in obesity hepatocytes induce uncoupling protein-2 (UCP-2) mRNA and protein expression. Thus, when confronted with an abundant substrate supply i.e free fatty acids (FFA), hepatocytes activate pathways that are not efficiently coupled to ATP synthesis i.e uncoupling of oxidative phosphorylation (Skulachev, et al, 1996)[32]. Additionally, there is growing evidence that uncoupling protein -2 (UCP-2) may be a tumor necrosis factor- α (TNF- α) inducible gene that involved in pathogenesis of NASH. (Gimeno, et al, 1997).[33]

In our study, an insignificant negative correlation was found between mitochondrial ATP levels in fatty liver and NASH patients and fasting serum glucose, fasting serum insulin and HOMA-IR. i.e mitochondrial ATP was decreasing with increasing these parameters but the relation was not statistically significant. This could be supported to some extent with significant correlation between these parameters and obesity that significantly associated with hepatic ATP depletion. (Fan, et al, 2005).[29]

Patients with fatty liver and NASH showed a significant negative correlation between mitochondrial ATP levels and histopathological score. This finding may be explained by ATP depletion that may predispose to hepatocellular injury because ATP is critical for maintaining cellular integrity (Chavin, et al, 1999)[34] and the patients had factors lead to increased free fatty acids and reactive oxygen species (ROS) oxidize accumulated unsaturated fatty acids, causing lipid peroxidation, which releases reactive aldehyde that increase hepatic fibrogenesis in two ways. First, these lipid peroxidation products enhance the hepatic production of transforming growth factor -β1 (TGF- β1), which activates hepatic stellate cells into collagen-secreting myofibroblasts. Second, lipid peroxidation products also directly enhance collagen production by hepatic stellate cells.

ROS also increase the synthesis of several cytokines in the liver, particularly TNF- α, which can cause both apoptosis and necrosis .Finally, ROS-associated lipid peroxidation and cytokines may be involved in the inflammatory cell infiltrate, because, lipid peroxidation products, TGF-β1, and interleukin-8 are chemoattractants for neutrophils. (Pessayre, et al, 2001).[35]

These data suggest that, mitochondarial dysfunction and decreased mitochondrial ATP levels are involved in progression of simple fatty liver to NASH and cirrhosis. This is supported by, the fact that ATP is critical for maintaining cellular integrity so its depletion may predispose to hepatocellular injury and necrosis.

5. Conclusion:

Nonalcoholic fatty liver disease, NAFLD is now considered a metabolic pathway to advanced liver disease; cirrhosis and hepatocellular carcinoma. Increased BMI, hyperglycemia, hypertriglyceridaemia, insulin resistance and depletion of mitochondrial ATP in hepatocytes can be considered risk factors involved in the development and progression of fatty liver to NASH and cirrhosis.

Abstract: Optimization of Cd (II), Zn (II) and Cu (II) biosorption from contaminated water were performed as function of parameters (pH, contact time, initial metal ions concentration and yeast dose). The experimental results showed that the highest equilibrium adsorption capacity at the optimum pH were 8.5 for Cd (II) and 6 for Zn (II) and 6 for Cu (II). Optimum pH values were carried out to evaluate other parameters. Results demonstrate that removal efficiency increased with increased contact time for the three metal ions. Results indicated that removal efficiency increased with increased yeast dose up to 2 g/ 100ml, and removal efficiency decreased with increased yeast dose from 2.2 g/100ml to 4 g/100ml. The results also showed that increasing removal efficiency from 1 to 20 mg/L concentration for the three metal ions and the removal efficiency decreasing with increasing initial concentration from 25 to 50 mg/L. It is evident that the highest removal efficiency for Cd (II) ion compared to Zn (II) and Cu (II). This study revealed that use of baker's yeast is suitable for removal of these ions from contaminated water in order Cd > Zn > Cu at these conditions. The negative values of the standard free energy change (ΔG°) indicate spontaneous nature of the process. Competitive biosorption of (Zn and Cu) ions was investigated in terms of sorption quantity. The amount of Cu metal ion adsorbed onto unit weight of biosorbent (q_e) decreased with increasing the competing metal ion (Zn), in contrast, the amount of Zn ion adsorbed onto unit weight of yeast has been increased with increasing the competing metal ion (Cu). The binding capacity for Zn (II) is more than for Cu (II). Ion exchange is probably one of the main mechanism during adsorptive process.

Keywords: Optimization; Cadmium; Zinc; Copper; biosorption; *Saccharomyces cerevisiae*

1. Introduction:

Biosorption can be defined as the removal of metal or metalloid species compounds and particulates from solution by biological material Gadd, (1993). Heavy metal pollution has become one of the most serious environmental problems today. Biosorption, using biomaterials such as bacteria, fungi, yeast and algae is regarded as a cost-effective biotechnology for the treatment of high volume and low concentration complex wastewater containing heavy metals in the order of 1 to100 mg/L. Veglio and Beolchini, (1997). Some strong toxic metal ions, such as Hg and Cd (II), are very toxic even in lower concentration of 0.001–0.1 mg/L Alkorta *et al.,* (2004).

There is always a possibility that metals will be taken up by plants such that they end up in the human food chain. Metal studies have shown that various oxidation states of metals are toxic to humans and also that they are associated with several types of diseases Atwood *et al.,* (2000). In order to facilitate the analysis of metal ions in aquatic environments, analytical methodologies that address aspects of sampling; sample clean-up and analyte enrichment are necessary. If possible, such methodologies should be simple, robust and inexpensive as well as address limitations associated with collecting samples from remote sampling sites. Biological substrates including the baker's yeast, *Saccharomyces cerevisiae* has been shown to have good sorption characteristics for several Heavy metals Volesky and May-Phillips (1995). As will as it's abundance of yeast as a by-product of fermentation processes Blackwell *et al*., (1995). For biosorption of heavy metal ions, pH is one of the most important environmental factors. The biosorptive capacity of metal cations increases with increasing pH of the sorption system, but not in a liner relationship. Esposito *et al*., (2002). Yeast cells of *S. cerevisiae* are able to remove heavy metals from wastewaters between pH 5 and 9 Wang, (2009).

The biosorption capacity and the removal efficiency of metal ions by *S. cerevisiae* became higher with prolonging the contact time Wang, (2006). The uptake rate of the metal ion will be increased with increasing the initial concentration if the amount of biomass is kept unchanged Wang,

(2002). Evidenced that the use of a large excess of yeast biomass comparatively to metals allowed an efficient removal of metals from real and synthetic effluents, reducing the amount of metal in solution to the limit of discharge of wastewater in natural waters Machado *et al*.. (2010)

Although copper and zinc are essential trace elements, high levels can cause harmful health effects. Copper is also toxic to a variety of aquatic organisms, even at very low concentration Sheng *et al*., (2004).

Cadmium, Zinc and Copper ions were chosen for biosorption studies with regard to their wide use in industry. Zinc and Copper are very widely used metal in our daily life, but like any other heavy metal it is potentially toxic for all the living organisms. Volesky, (1990). Cadmium can contaminate the environment from anthropogenic sources as well as natural geochemical processes. It can accumulate along the food chain and is not amenable to biological degradation Dursun, (2003).

This investigation aimed to use baker's yeast for adsorption of some metal ions from contaminated aqueous solutions, In addition, to study the influence of the uptake of Cd (II), Zn (II) and Cu (II) by *S. cerevisiae* in different adsorptive conditions and to compare the biosorption behavior of a single-metal system and two-system.

2. Materials and methods

Baker's yeast

The baker's yeast employed in this study was DSM-70460 strain of *Saccharomyces cerevisiae* used in baking industry. It is supplied in the form of dry matter and it's supplied from Deutsche Sammlung Von Mikroorganismen und Zellkulturen GmbH (Germany).

Optimized of pH

In this study, three sets of experiments were conducted to study the effect of pH. The tested solutions 5 mg/L metal ions and yeast dose 0.2 gm/100 ml were adjusted at pH 3, 4.5, 6, 7, 8.5, 9.5 and 11 using 0.1 M HCl or 0.1 M NaOH. All pH measurements were carried out with a HANNA digital pH meter HANNA Instruments and left for 30 min. to reach the equilibrium.

Analytical methods

Samples were analyzed for Cd (II), Zn (II) and Cu (II) using Perkin Elmer (3300) Atomic Absorption-Flame Absorption Spectrophotometer, a Calhodeon Ltd. Hollow Cathode Lamp as light source for Cd (II), Zn (II) and Cu (II) and mixture of air-C_2H_2 as the flame atomizer gas. A standard calibration curves were prepared using Cd (II), Zn (II) and Cu (II) solutions of known concentration in the range 1-100 mg/L.

Evaluation of the effect of various parameters on uptake of metal ions at optimized pH for three metals:

1 - Biosorption experiments

The experiments were conducted with Cd (II), Zn (II) and Cu (II) aqueous solution of initial concentration from 1 to 50 mg/L, yeast dose from 0.2 to 4.0 g/100ml, were mixed at pH range from 3 to 11 and Shaken at a constant speed of 120 RPM in a shaking at temperature 298 K for 15 to 120 min. The samples were centrifuged at 2000 rpm for 15 min. (Hermale Z 200A) the supernated were analyzed and the experiment were carried out at least twice the values used in calculations were mostly the arithmetic average of the experiment data.

2 - Sorption studies

Cd (II), Zn (II) and Cu (II) uptake were calculated by two equations according to Cojocaru *et al.,* (2009).

3 - Effect of contact time on biosorption

Samples were withdrawn at 15, 30, 60, 90 and 120 min. intervals during the biosorption experiments and analyzed for Cd (II), Zn (II) and Cu (II). This factor that influence time was examined in 5 mg/L metal ions and 0.2 g of yeast dose /100 ml.

4 - Effect of yeast dose on biosorption

This factor that influence yeast dose were examined in 5 mg/L for 30 min. yeast dose of 0.2, 0.4, 0.8, 1.0, 1.2, 1.6, 2.0, 2.4, 2.8, 3.2, 3.6 and 4.0 gm were added to test solution taken in series of 250 ml Erlenmeyer flasks with 100 ml tested solution and biosorption experiments were carried out.

5 - Effect of initial metal ions concentrations on biosorption

This factor that influence initial metal ions were examined in 0.2 g/100 ml for 30 min. Test solutions containing 1, 5, 10, 15, 20, 25, 30, 35, 40, 45 and 50 mg/L for $CdSo_4$, $ZnSo_4$and $CuSo_4$ were subjected to biosorption. The salt was chosen a sulphate since sulphate ions exist in most wastewater and mine drainage and thus simulating the potential application of biosorption for Cd (II), Zn (II) and Cu (II) ions removal.

6 - Competitive adsorption in binary metal system

In this group of experiments, competitive adsorption of Zn (II) and Cu (II) ions from their binary solutions was investigated by following a similar procedure as described above. These studies

were performed at a initial pH of 6 at 298 K. Experiments of competitive adsorption of Zn (II) and Cu (II) included two parts: (i) the competitive adsorption of Zn (II) and Cu (II) in the total metal concentration was fixed (5 mg/L); (ii) in a serious of two metal ions solution, the initial concentration of Zn (II) was fixed to 5 mg/L, where as, concentration of Cu (II) were varied from 0 to 4 mg/L. In another binary system, initial concentration of Cu (II) was constant in 5 mg/L, and concentrations of Zn (II) were varied from 0 to 4 mg/L.

3. Results and Discussion:

The biosorption has attracted the attention as low-cost treatment technology for the removal of heavy metals from wastewaters.

Optimized of pH

The charge of the adsorbate and adsorbent often depends on the pH. The adsorption of Cd (II), Zn (II) and Cu (II) as a function of pH were measured. As shown in Table (1) there were increases in biosorption uptake equilibrium adsorption capacity (q_e) of Zn (II) and Cu (II) with increasing pH from 3 to 6 for both metal ions. On the other hand maximum Cd (II) uptake observed at pH 8.5. The lowest metal uptake values were determined at pH 3 for three metal ions. At pH values above the isoelectric point, there is a net negative charge on the cell wall components, which will be promate reaction with metal ions. As the pH is lowered, however, the overall surface charge on the cells will be positive, which will inhibit the approach of positively charged metal ions Goksungur *et al*., (2005).

Table (1): The optimization initial of solution pH on biosorption for Cd (II), Zn(II) and Cu (II) at 5 mg/L metal ions and yeast dose 0.2 (gm) after 30 min and 25 °C.

	pH	C_o mg/L	C_e mg/L	q_e mg/g	q_{max} mg/g	Y %

C_o : initial metal concentrations (mg /L) C_e : final metal concentrations (mg /L)
q_e : equilibrium adsorption capacity (mg /g) q_{max} : amount of bioaccumulated ions in yeast (mg/g)
Y : removal efficiency yeast (%)

Similar results were detected by Volesky (1990) who found that the optimal pH value is 5 – 9 for Cu (II) biosorption by *S. cerevisiae*. Also Mapolelo and Torto, (2004) proved that the optimal pH values are greater than 5 for Cu^{2+} and Zn^{2+}. In this study maximum Cd (II) uptake was observed only at alkaline pH 8.5.

However; Mullen *et al*., (1992) have reported an increased trend in biosorption of Cd (II) by *A. niger* to the tune of 2.9 times when pH was increased from 4 to 7. Also Parvathi *et al*., (2007) found that biosorption of Mn (II) increased with rise in pH, and maximum manganese uptakes were observed at initial pH 9 by *S. cerevisiae*.

Generally, an increase of pH causes deprotonation of metal ions binding sites exposed by cellular surface. However, a decrease of pH causes competition between protons and positively charged metal ions. However these rules concern only cations .Since biosorption is reversible process, decreasing pH would result in deprotonation. This property is used in regeneration of biosorbents Naja and Volesky, (2010).

Effect of time:

As shown in Fig. (1); It was found that the equilibrium adsorption capacity increased as the contact time increased. The biosorption of Cd (II), Zn (II) and Cu (II) on yeast was rapid for first 15 min. and equilibrium was nearly reached after 90 min. Results revealed that the highest removal efficiency Cd (II) occurred after 15 min., then the increased removal efficiency occurred slowly. This trend emphasizes that sorption times have an important effect on recovery efficiency, which decreases with increase biosorbent contact time with metal solution. Metal accumulation inside the cell may resulted from bioaccumulation, slow metabolic dependent removal mechanism, or by simple metal diffusion Gaad, (1990).

Tavares *et al*., (1995) mentioned that, biosorption kinetics with an initial rapid metal uptake followed by slow uptake was observed, this kinetic model has been accepted for various biosorbents such as bacteria and fungi (yeast) under similar operation conditions. A similar trend was observed for the uptake of three metal ions.

The data shown in Fig. (1) indicate that selected sorption time for biosorption capacity was 120 min., this sorption period equilibrium adsorption capacity reached maximum at 90 min. for Zn (II) and Cu (II). The highest Cd (II) biosorption capacity was observed compared with Zn (II) and Cu (II), the explanation based on it's most noxious valency, may readily participate in cell metabolism Salem, (1994).

Goyal *et al*., (2003) reported that the uptake of metal ions by microorganisms in batch systems has been shown to occur in two stages: an initial rapid stage (passive uptake), followed by much slower process (active uptake). The first stage is physical adsorption or ion exchange at the surface of the biomass, which is biosorption. The biosorption equilibrium occurs at the end of rapid physical adsorption stage (first-stage). Adsorption isotherm equation is frequently used to represent this equilibrium. The same behavior was observed by Han *et al.,* (2006a) equilibrium time for Zn (II) and Cu (II).

Özer *et al.,* (1999) found that the adsorption equilibrium of Cd (II) on *S. leibleinii* was established in 15 – 20 min. and the adsorbed amount did not change with time.

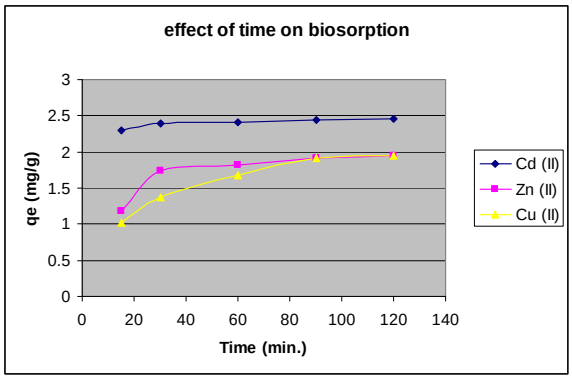

Fig. (1) Effect of time on biosorption for Cd (II), Zn (II) and Cu (II) at 5 mg/L and yeast dose 0.2 (gm) at 25^{o}C.

Effect of yeast dosage

The effect of yeast dosage on removal efficiency (Y) % showed in Fig. (2). Results showed that increasing metal removal as increased yeast up to 2 g/ 100 ml solution. As expected (Fig. 2), the uptake of Cd (II) was much more sensitive to increase amount of yeast in solution compared to that Zn (II) and Cu (II). The increase in metal uptake with yeast dosage confirms the increase in binding sites for metal ions. On the other hand, it was observed that the metal uptake decreased with increasing the amount of yeast dose from 2.2 to 4.0 g/ 100 ml. Decreased removal efficiency may be due to aggregation of yeast. Al-Asheh and Duvnjak, (1995) reported that higher uptake at lower biomass dosage could be due to metal ions and biosorbent ratio, which decrease upon an increase in biomass dosage due to of high biomass dosage resulted aggregates of biomass and may cause interference between binding sites at higher biomass dosage or insufficiently of metal ions in the solution with respect to available binding sites. It is likely that protons will then combine with metal ions for the ligands and thereby decrease the interaction of metal ions with the cell components Saĝ and Kutsal, (1996). It should be mentioned that the cadmium ion adsorption capacity decreased with increase of biosorbent dosage Vasudevan *et al.,* (2002). Their theory is similar to that advanced by Zou *et al*. (2006) to account for the cell surface remaining unsaturated at higher biosorbent dosage.Uslu and Tanyol, (2006) found that the initial adsorption rates of Cu (II) decreased with increased biosorbent concentration. Fig. (2) shows that the uptake of Zn (II) reached a maximum at 2 g/ 100 ml yeast dosage. These data probably

indicate that low uptake values reflect a sluggish adsorption process. Wilhalmi and Duncan, (1996) reported that the Zn (II) is preferable that the adsorption process on the membrane take places over short period of time to avoid interalisation of metal ions which would result in lower ions would result in lower desorption and enrichment of metal ions.

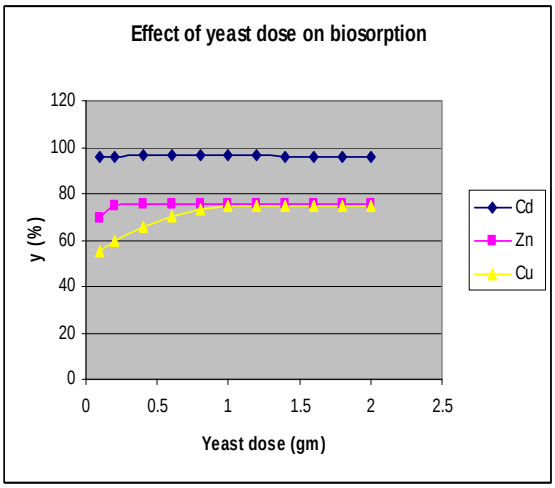

Fig. (2) Effect of yeast dosage on biosorption for Cd (II), Zn (II) and Cu (II) at 5 mg/L after 30 min and 25 oC.

Effect of initial concentration ions:

As shown in Fig. (3); Removal efficiency increased with increasing the metal ions concentration from1 to 20 mg/L in three metal ions. On the other hand, after 20 mg/L of Cd (II), Zn (II) and Cu (II), ions decreasing uptake for three metal ions. As increase initial concentration from 25 to 50 mg/L decreasing removal efficiency from 84.80, 66.14 and 45.65 to 77.52, 38.44 and 33.52 for Cd (II), Zn (II) and Cu (II), respectively. This could be attributed to the strong effect of initial concentration, which is very high comparing with the relatively low sorption capacity of biosorbent. This agrees with Cojocaru *et al*., (2009) who found that increase in density of the negative charge on the cell surface, causing proton removal from solution, thereby decreasing biosorption capacity of Cu (II) because of competitively adsorption of protons. A similar observation was reported by Ferraz and Teixeirain, (1999) who suggested an increase of electrostatic interaction at high biomass concentration inhibited metal biosorption. When the biomass concentration is low, metal ions in the solution would not only be adsorbed to the surface of the biomass, but also enter into intracellular part through facilitating the concentration gradient of metal ion Wang, (2002).

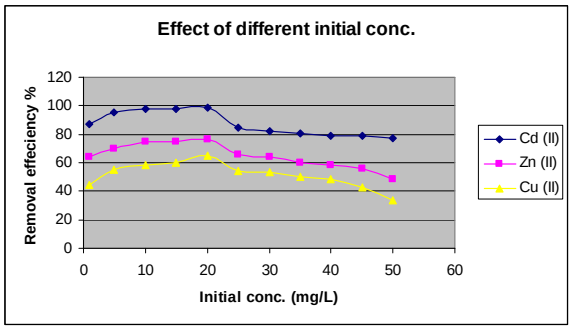

Fig. (3) Removal efficiencyof Cd (II), Zn (II) and Cu (II) at different initial concentrations.

Adsorption equilibrium

Adsorption isotherms show the distribution of solute between the liquid and solid phases equilibrium conditions. Many different isotherm models have been proposed for the adsorption of solutes in a liquid solution onto a solid surface. Langmuir model is probably the most popular isotherm models due to its simplicity and its good agreement with experimental data. The Langmuir model, the saturated monolayer isotherm, can be described by the linear form Langmuir, (1916). Although the Langmuir constant q_{max} is dependent on experimental conditions such as solution pH and temperature, it is a good measure for comparing different sorbents for the same (metal) sorbate. Another important factor in evaluating sorbent performance is the initial gradient of the adsorption isotherm, since it indicates the sorbent affinity at low metal concentrations. In the Langmuir equation, this initial gradient corresponds to the affinity constant (b). A high value of the affinity constant is thus desirable Sheng *et al*., (2004). The equilibrium established between the adsorbed metal ions (q_e) and that remained free in the solution (C_e) was also represented by the Freundlich adsorption isotherm, the linear equation as following Freundlich, (1906).The equilibrium data of (Cd), (Zn) and (Cu) ions adsorption by baker's yeast obtained at 25 ^oC (298 K) was applied to Langmuir and Freundlich models. The relative parameters and correlation coefficients (R^2) were listed in Table (2). The mono-component Langmuir constant, q_{max}, represents the monolayer saturation at equilibrium or the total capacity of yeast for (Cd), (Zn) and (Cu) ions. From table (2), the maximum loading capacities of yeast was obtained as 4.545 mg/ g for (Cd) 0.6676 mg/ g for (Zn) and 0.4833 mg/ g for (Cu). So the ability of Cd (II) adsorption on yeast is biggest than Zn (II) and Cu (II). From Table (2), the values of k_f showed easy uptake of metal ions with high adsorption capacity of baker's yeast. As $0.1 < 1/n < 1.0$, indicating that (Cd)

and (Zn) ions are favorably adsorbed by yeast at temp 25 °C. studied Aksu , (2002). The Gibbes free energy of biosorption determined Han *et al.,* (2005). The free energy changes for Cd (II), Zn (II) and Cu (II) sorption onto yeast were determined at 25 °C and at optimum pH, are -7.60, -2.075 and -0.495 and kJmol^{-1}, respectively. The negative values of ΔG^{o} valid at the feasibility of the biosorption process Cd (II), Zn (II) and Cu (II) the spontaneity of biosorption.

Effect of coexistence ions on the biosorption of zinc and copper ions on baker's yeast:-

Table (2): Constants of Langmuir and Freundich isotherms for Cadmium, Zinc and Copper biosorption by *S.cerevisiae* at optimum pH and 25 °C.

Metals	pH	Langmuir			Freundich		
		B L/mg	qmax mg / g	R2	1/n	kf mg/L	R2
Cd	8.5	4.545	2.368	0.981	0.322	1.62	0.810
Zn	6	0.6676	1.731	0.952	0.497	0.384	0.793
Cu	6	0.4833	1.347	0.999	0.982	0.524	0.999

1 - The effect on biosorption of Cu ion with the presence of Zinc ion in the solution

As shown in Fig (4 down curve); with increasing Zn (II) concentration the biosorption quantity of Cu (II) decreased. Also, the adsorptive quantity of Cu (II) decreased with the increasing Zn (II) initial concentration. The biosorption quantity of copper ion decreased from 1.374 mg/g to 1.132 mg/g. Thus it can be seen that the existence of Zn (II) has greater effect on the biosorption of copper on yeast. When the Zinc ion existence in the solution it will be adsorbed by yeast and compete to the copper ions and it will hold some activated sites on yeast, hence the adsorption capacity of copper will decrease. So when the ions of Zn (II) existence it will be a disadvantage condition to the biosorption of copper ion by yeast. Furthermore, the concentration of Zn (II) is more, the effect is serious. The biosorption capacity of one metal ion is interfered and reduced by co-ions, including other metal ions and anions presenting in solution, however the gross uptake capacity of all metals in solutions remains almost unchangeable Wang, (2006).

2 - The effect on biosorption of Zn ion with the presence of Copper ion in the solution

As shown in Fig. (4 upper curve); with increasing the copper concentration, the biosorption quantity of Zn ion increased. Also, the adsorption quantity of Zn (II) increased with the increasing of Cu (II) concentration. The biosorption quantity (q_e) of Zn (II) increased from 1.731 to 1.905 mg/g when the concentration of Cu (II) ranged from o to 4 mg/L. As the copper ions existence in solution, similarly, it will be adsorbed by yeast and compete to the Zn ions. So where the ions of copper existence, it will be advantage condition to the biosorption of Zn ion on yeast, Furthermore, the concentration is higher, the effect is also serious. The decrease of metal uptake in competitive conditions was thought to be a response to increased competition between same charged species for binding sites of the yeast cells Goksungur *et al.*, (2005).

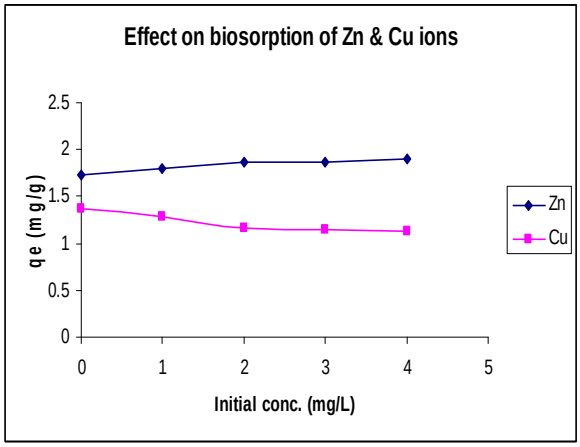

Fig. (4) The effect on biosorption of zinc when copper in existence (upper curve) and the effect on biosorption of copper when zinc in existence (down curve).

3 - The competitive adsorption of Cu (II) and Zn (II) in the total concentration fixed

As shown in Fig (5); it was observed that when increased the concentration of copper, reduced the concentration of zinc, the uptake increased for Zn (II) while decreasing for Cu (II) when there was two metal ion existence, the value of q_e about zinc was bigger than copper, so the binding ability for zinc is strong than copper. The baker's yeast can be used to remove copper and zinc ions in solution when there was two metal ions coexistence. Above all, competitive biosorption of two metals was investigated in terms of sorption capacity and found that the biosorption capacity of biomass decreased with increasing the competing metal ion concentration. Han *et al.*, (2006b) found that the amount of one metal ion adsorbed onto unit weight of

biosorbent decreased with increasing competing metal ion concentration, but from our investigation showed in Fig. (5) it can be concluded that the total capacity for adsorbing copper ion decreased while zinc ions increased.

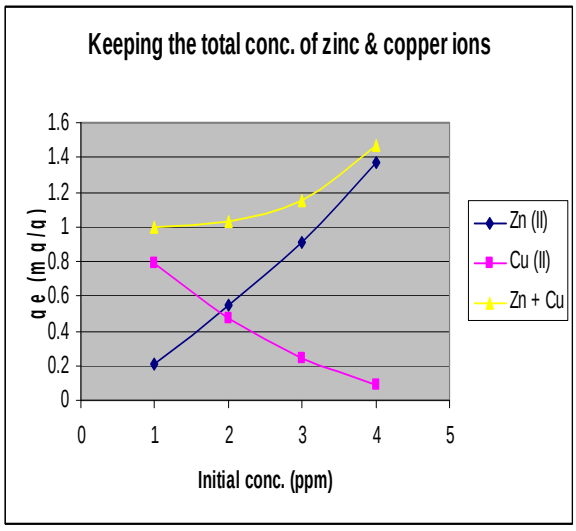

Fig. (5) Keeping the total concentration of zinc and copper ions fixed, the equilibrium level of zinc and copper ions onto baker's yeast.

4. Conclusion:

The analysis of our results shows the possibility used of baker's yeast in dried form for remove Cd, Zn, Cu ions from contaminated aqueous solutions .Results obtained for the removal of initial metal ions concentration in an aqueous solution using *Saccharomyces cerevisiae* showed a decrease of biosorption efficiency at low and high value initial pH. The removes percentage for Cd (II),is the highest removal efficiency in optimal condition (pH=8.5)compared with Zn (II) and Cu (II) (pH=6). The degree of removal of this hazards ions were depend on the pH, contact time and initial concentration of the contaminated water.

Competitive biosorption of two metals (Zn & Cu) ions was investigated in terms of sorption capacity and found that the biosorption capacity for Cu ion decreased with Zn metal ion concentration.

Abstract: The techniques of artificial intelligence based in fuzzy logic and neural networks are frequently applied together. The reasons to combine these two paradigms come out of the difficulties and inherent limitations of each isolated paradigm. Hybrid of Artificial Neural Networks (ANN) and Fuzzy Inference Systems (FIS) have attracted the growing interest of researchers in various scientific and engineering areas due to the growing need of adaptive intelligent systems to solve the real world problems. ANN learns from scratch by adjusting the interconnections between layers. FIS is a popular computing framework based on the concept of fuzzy set theory, fuzzy if-then rules, and fuzzy reasoning. The structure of the model is based on three-layered neural fuzzy architecture with back propagation learning algorithm. The main objective of this paper is two folds. The first objective is to develop Fuzzy controller, scheme for the prediction of the changing for the NO2 or SO2, over urban zones based on the measurement of NO2 or SO2 over defined industrial sources. The second objective is to develop a neural net, NN; scheme for the prediction of O3 based on NO2 and SO2 measurements.

Keywords: Neuro Fuzzy Modeling Scheme for the Prediction of Air Pollution

1. Introduction:

The modern techniques of artificial intelligence have found application in almost all the fields of the human knowledge. However, a great emphasis is given to the accurate sciences areas; perhaps the biggest expression of the success of these techniques is in engineering field. These two techniques neural Networks and fuzzy logic are many times applied together for solving engineering problems where the classic techniques do not supply an easy and accurate solution. The neuro-fuzzy term was born by the fusing of these two techniques. As each researcher combines these two tools in different way, then, some confusion was created on the exact meaning of this term. Still there is no absolute consensus but in general, the neuro-fuzzy term means a type of system characterized for a similar structure of a fuzzy controller where the fuzzy sets and rules are adjusted using neural networks tuning techniques in an iterative way with data vectors (input and output system data). Such systems show two distinct ways of behavior. In a first phase, called learning phase, it behaves like neural networks that learns its internal parameters off-line. Later, in the execution phase, it behaves like a fuzzy logic system. Separately, each one of these techniques possesses advantages and disadvantages that, when mixed Together, theirs cooperage provides better results than the ones achieved with the use of each isolated technique.

The advantages of a combination of ANN and FIS are obvious. There are several approaches to integrate ANN and FIS and very often it depends on the application. We broadly classify the integration of ANN and FIS into three categories namely concurrent model, cooperative model and fully fused model. This paper starts with a discussion of the features of each model and generalizes the advantages and deficiencies of each model. We further focus the review on the different types of fused neuro-fuzzy systems and citing the advantages and disadvantages of each model.. In fact, this model consists of if then rules with fuzzy antecedents and mathematical functions in the consequent part. The task of system identification is to determine both the non-linear parameters of the antecedents and the linear parameters of the rules consequent.

Air pollution is the introduction of chemicals, particulate matter, or biological materials that cause harm or discomfort to humans or other living organisms, or ,damages the natural environment into the atmosphere.

The atmosphere is a complex dynamic natural gaseous system that is essential to support life on planet Earth. Stratospheric ozone depletion due to air pollution has long been recognized as a threat to human health as well as to the Earth's ecosystems.
Indoor air pollution and urban air quality are listed as two of the world's worst pollution problems in the 2008 Blacksmith Institute World's Worst Polluted Places report.[1]

An air pollutant is known as a substance in the air that can cause harm to humans and the environment. Pollutants can be in the form of solid particles, liquid droplets, or gases. In addition, they may be natural or man-made.[2]

Pollutants can be classified as either primary or secondary. Usually, primary pollutants are substances directly emitted from a process, such as ash from a volcanic eruption, the carbon monoxide gas from a motor vehicle exhaust or sulfur dioxide released from factories.

Secondary pollutants are not emitted directly. Rather, they form in the air when primary pollutants react or interact. An important example of a secondary pollutant is ground level ozone — one of the many secondary pollutants that make up photochemical smog.

Air pollution has become an exceedingly inescapable part of urban living. The presence of pollutants is reported to cause adverse effects on human health as well as damage to structures [1, 2, 3]. Air quality in Cairo City is an important public concern. Average daily emissions of primary pollutants, such as hydrocarbons, nitrogen oxides, carbon monoxide, and others are among the largest in the world. Private and public transportation as well as industrial activities contribute the most to these emissions. When primary pollutants are exposed to sunshine, they undergo chemical reactions and yield a wide variety of secondary pollutants, Ozone, O3, being the most important one. Besides the health problems this molecule may cause, ozone is considered as an indicator of air quality in urban atmospheres [1, 2]

Modeling of urban air pollution is an important facet of pollution control and abatement [1, 2, 3]. Models explain the occurrence, intensity, and movement of pollutants in order to predict pollutant levels at locations away from defined sources. Air pollution prediction is inherently a difficult problem for conventional and stochastic modeling methods due to its intrinsic dynamic, random, and nonlinear nature. In this paper, however; a sophisticated modeling scheme for the prediction of air pollution (nitrogen dioxide NO2, sulpher dioxide SO2 and ozone O3) using neural nets is proposed. Neural network modeling scheme provides an efficient computational tool for mapping input-output or cause-effect relationships and establish an intelligent what if scenarios based on robust learning mechanisms. The proposed prediction schemes have been applied to study the effect of industrial and traffic areas: Tabbin, Shoubra, Fum elkhalieg, Gomhorya and Kulaly on urban areas: Maadi and Giza.

2. Problem Formulation

The prediction problem has been formulated as follows:

(a) For given measured readings of NO2 and SO2 emissions at measured values of temperature, wind speed, and wind direction in industrial and dense traffic areas; what will be the predicted emission values of NO2 and SO2 at urban areas?

(b) For given measured readings of NO2 and SO2 emissions at measured values of temperature, wind speed, and wind direction in industrial and dense traffic areas; what will be the predicted emission values of O3 at urban areas?

Due to the complex relation between inputs and outputs, neural net stands as a reliable mapping tool for this application. The proposed neural net first prediction scheme takes industrial area readings (NO2 or SO2 level, temperature T, winds speed WS and wind direction WD) as input values and computes NO2 or SO2 estimates for urban areas. The second prediction scheme computes estimates of O3 levels as output values based on NO2, SO2, temperature, wind speed, wind direction input values. The neural net schemes are reconfigured to provide category or class (safe, acceptable, not acceptable, and dangerous) for output (NO2 or SO2 or O3) levels.

The neural net forecasting scheme works in two sequential modes of operation [4, 5, 6, 7]. The first mode is learning under supervision, and the second mode is autonomous operation and testing.

3- Fuzzy Systems

Fuzzy systems propose a mathematic calculus to translate the subjective human knowledge of the real processes. This is a way to manipulate practical knowledge with some level of uncertainty. The fuzzy sets theory was initiated by Lofti Zadeh [16], in 1965. The behavior of such systems is described through a set of fuzzy rules, like:

IF <premise> THEN <consequent>

that uses linguistics variables with symbolic terms. Each term represents a fuzzy set. The terms of the input space (typically 5-7 for each linguistic variable) compose the fuzzy partition. The fuzzy inference mechanism consists of three stages: in the first stage, the values of the numerical inputs are mapped by a function according to a degree of compatibility of the respective fuzzy sets, this operation can be called fuzzyfication. In the second stage, the fuzzy system processes the rules in accordance with the firing strengths of the inputs. In the third stage, the resultant fuzzy values are transformed again into numerical values; this operation can be called defuzzyfication. Essentially, this procedure makes possible the use fuzzy categories in representation of words and

abstracts ideas of the human beings in the description of the decision taking procedure. The advantages of the fuzzy systems are: capacity to represent inherent uncertainties of the human knowledge with linguistic variables; simple interaction of the expert of the domain with the engineer designer of the system; easy interpretation of the results, because of the natural rules representation; easy extension of the base of knowledge through the addition of new rules; robustness in relation of the possible disturbances in the system. And its disadvantages are: incapable to generalize, or either, it only answers to what is written in its rule base; not robust in relation the topological changes of the system, such changes would demand alterations in the rule base; depends on the existence of a expert to determine the inference logical rules;

4 Neural Networks

The neural networks try to shape the biological functions of the human brain. This leads to the idealization of the neurons as discrete units of distributed processing. Its local or global connections inside of a net also are idealized, thus leading to the capacity of the nervous system in assimilating, learning or to foresee reactions or decisions to be taken. W. S. McCulloch, W. Pits, described the first Neural Network model and F. Rosenblatt (Perceptron) and B. Widrow (Adaline) develop the first training algorithm. The main characteristic of the neural networks is the fact that these structures can learn with examples (training vectors, input and output samples of the system). The neural networks modifies its internal structure and the weights of the connections between its artificial neurons to make the mapping, with a level of acceptable error for the application, of the relation input/output that represent the behavior of the modeled system. The advantages of the neural networks are: learning capacity; generalization capacity; robustness in relation to disturbances. And its disadvantages are: impossible interpretation of the functionality; difficulty in determining the number of layers and number of neurons.

5 Neuro Fuzzy Systems

Since the moment that fuzzy systems become popular in industrial application, the community perceived that the development of a fuzzy system with good performance is not an easy task. The problem of finding membership functions and appropriate rules is frequently a tiring process of attempt and error. This lead to the idea of applying learning algorithms to the fuzzy systems. The neural networks, that have efficient learning algorithms, had been presented as an alternative to automate or to support the development of tuning fuzzy systems. The first studies of the neuro-fuzzy systems date of the beginning of the 90's decade, with Jang, Lin and Lee in 1991, Berenji in 1992 and Nauck from 1993, etc. The majority of the first applications were in process control. Gradually, its application spread for all the areas of the knowledge like, data analysis, data classification, imperfections detection and support to decision-making, etc. Neural networks and fuzzy systems can be combined to join its advantages and to cure its individual illness. Neural networks introduce its computational characteristics of learning in the fuzzy systems and receive from them the interpretation and clarity of systems representation. Thus, the disadvantages of the fuzzy systems are compensated by the capacities of the neural networks. These techniques are complementary, which justifies its use together.

5 Models of fuzzy neural systems

In response to linguistic statements, the fuzzy interface block provides an input vector to a multi-layer neural network [15]. The neural network can be adapted (trained) to yield desired command outputs or decisions as shown in Fig. (1). Fig. (2) shows the second model of fuzzy neural system. Fig (3) shows the SimuLink Model of fuzzy Logic Controller

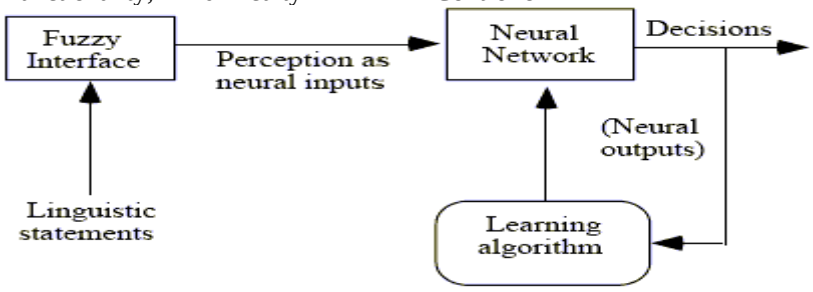

Fig. (1) First Model of Fuzzy Neural Systems

• A multi-layered neural network drives the fuzzy inference mechanism.

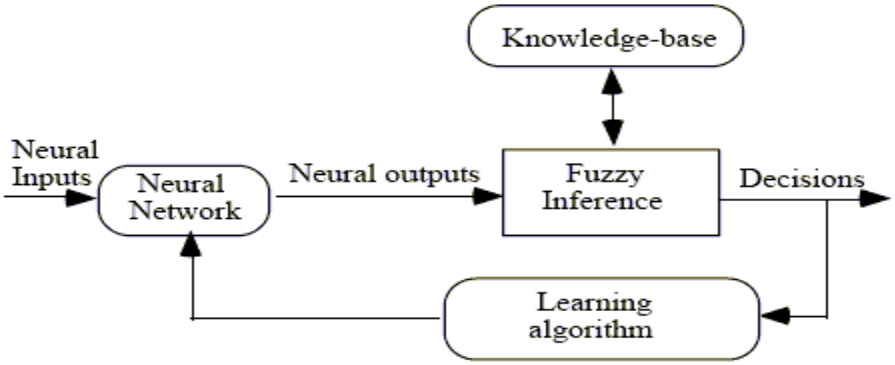

Fig. (2) Second model of fuzzy neural system

In this paper we are using the First Model of Fuzzy Neural Systems. The structure of Fuzzy Model is presented in Fig (11). The initial membership function is shown in Fig (12, 13, 14) for inputs. Fig (17) Membership from inputs to outputs flow of rule base. The system response SO2, NO2, O3 are shown in Fig(18, 19, 20). Fig(21, 22, 23) show the three dimensional of SO2, NO2, O3. The simplification rule base used in the implementation as follow.

Rule Base

1-If (error is small) and (c_of_error is Small) then (So2 is Small)(No2 is Small)(O3 is Small)

2-If (error is Medium) and (c_of_error is Medium) then (So2 is Medium)(No2 is Medium)(O3 is Medium)

3-If (error is small) and (c_of_error is big) then (So2 is Big)(No2 is Big)(O3 is Big)

4-If (error is Big) and (c_of_error is Big) then (So2 is Big)(No2 is Big)(O3 is Big)

5-If (error is small) and (c_of_error is Small) then (So2 is Small)(No2 is Small)(O3 is Small)

6-If (error is Big) and (c_of_error is Small) then (So2 is Small)(No2 is Small)(O3 is Small)

7-If (error is Big) and (c_of_error is Medium) then (So2 is Medium)(No2 is Medium)(O3 is Medium)

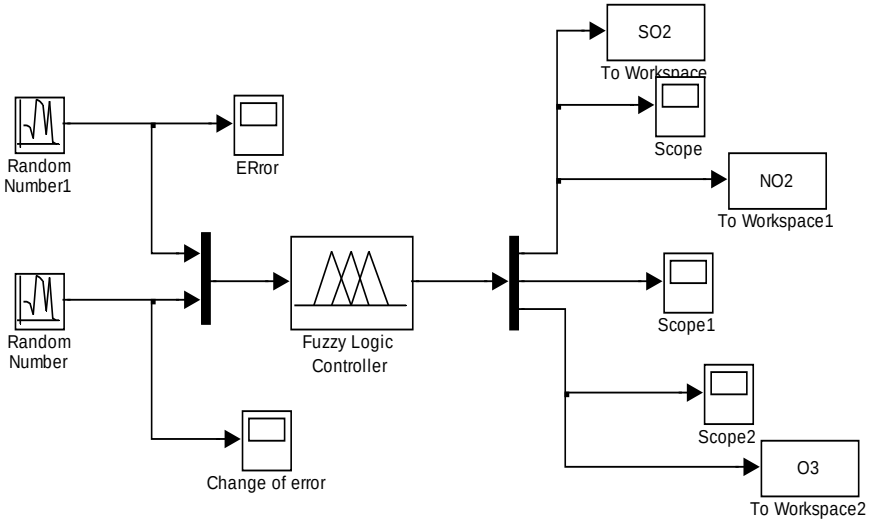

Fig (3) SimuLink Model of fuzzy Logic Controller

6. Data preparation

Recorded Data for the amount of NO2, SO2, and O3 in air have been obtained from Egyptian environmental affairs Authority (EEAA) in the form of average value per month for the years 1998, 1999 for the following areas:

(One) Industrial areas: Tabbin and Shoubra. (b) Traffic areas: Fum elkhalieg, Gomhorya, and Kulaly. © Urban areas: Maadi and Giza.

Normally distributed emission data have been generated using given mean values, and assuming variance values. Available data lie mainly only in the first two classes or categories. In order to completely perform the learning or training phase of the classifier, data samples for the second two classes have been generated within the limits of each class.

Data of temperature, wind speed, and wind direction have been obtained from weather Forecasting Authority for the years 1998, 1999. Data of temperature has been provided in the form of: (minimum, maximum, and average) temperature values (in degree centigrade) per month. Wind speed has been provided as average value in knots per month. Wind directions have been provided in the form of a table with rows representing twelve dominant wind direction sectors, columns representing range of dominant wind speed values, and cell value representing time duration of specific wind speed range within a specific wind direction sector. Based on theses available statistically abstracted data, thirty (assuming one reading/day) normally distributed temperature values and thirty normally distributed wind speed values have been generated, see Fig.4 and Fig.5. Thirty wind direction values have also been generated based on relative time duration ratio.

7. Neural Networks Modeling Schemes

Neural network is based on computer simulation of activities of human brain; neural network performs modeling without defined mathematical relation between variables. Neural network has two distinct learning techniques unsupervised Learning and supervised Learning.

The proposed prediction schemes use three-layered neural nets with supervised back propagation learning algorithm [4, 5, 6, 7]. The first neural net for the prediction of O3 level is shown in Fig.6. The input layer has five nodes (NO2, SO2, WS, WD, T), the middle hidden layer has (on the average) 15 nodes, and the output layer has one complex node (O3). The second neural has the same architecture as the first neural net, but with four input nodes (NO2 or SO2, WS, WD, T). The output node provides either NO2 or SO2 level based on the input feature vector first element value (NO2 or SO2). Neural nets are also reconfigured to have four nodes in the output with only one node is firing at a time representing the category or class (safe S , acceptable A, not acceptable NA, dangerous D) of output O3 level in the first neural net, and NO2 or SO2 category in the second neural net, see Fig.7.

6. Results and Performance Evaluation

Emissions of NO2 or SO2 on urban area can be categorized as shown in table1**.** The neural net schemes have been set as follows: train data set: 85 %, validation data set: 5%, and test data: 10% where data order is set to be random.

Results of NO2, SO2, and O3 classification nets are summarized in performance tables 2, 3, and 4, where diagonal data represent correct class and off-diagonal represent misclassify data. Sample of the results of neural net prediction schemes for NO2, SO2, O3 are shown in figures 8, 9, and 10. The performance of the prediction scheme is evaluated in terms of mean squared error MSE as recorded in table 5, where the first column provides the range of reading values for NO2, SO2 or O3.

Table1.Range and categories of NO2 and SO2 emissions

7. Conclusion

This paper presented proposed fuzzy neural schemes for forecasting and classifying of NO2; SO2 emissions over urban areas based on measured emissions over industrial areas. The scheme also provides predictions of O3 emissions based on NO2 and SO2 measurements. The performance of the proposed scheme is evaluated in terms of average percentage of correct recognition and mean squared error value, however the accuracy of the performance is limited to the available data. In other words some of the data are provided in terms of mean value per month like NO2, SO2, O3 emissions, other data are either provided in terms of range of values like wind directions, or minimum and maximum values per month like temperature. Data have been generated from normal distributions with available provided mean, variance (or proposed), and range parameters. However, correlation of specific day data (temperature, wind speed, wind direction, NO2 or SO2 or O3 measurement) is not guaranteed since day data are statistically generated assuming one measurement per day. System performance could be more accurate and more reliable if detailed true daily-recorded data are used.

Abstract

In Egypt most potato chip factories used palm oil for frying. The quantity of palm oil resulting from frying processes as discarded represents more than half of the total other oils used in the Egyptian food factories. Discarded palm oil resulting from frying processes was preliminary treated by purification and bleaching as well as characterized via its physico-chemical properties and fatty acids composition. Therefore, this work was devoted to explore the application of the discarded palm oil in leather industry as fat-liquoring agent.

Fat-liquors help to prevent the loosening of leather grain and ugly appearance of chrome tanned leather after drying. In addition, fat-liquoring process improves leather characters such as soft handle, full, flexibility, and pliability as well as enhancement its mechanical properties. The study involved preparation of discarded palm fat-liquor via phosphoration process. The importance of the prepared fat-liquor is due to their environmentally friendly nature, relatively safe utilization by human being, in addition to their economical feasibility. The fat-liquored leather led to an improvement in the mechanical properties of the leather e.g. tensile strength, elongation at break and tear strength. In addition a great enhancement in the texture of the treated leather by discarded palm fat-liquor as indicated from the scanning electron microscope (SEM).

[M. G. Megahed and El-Shahat H. A. Nashy. Ester Phosphate of Discarded Palm Oil from Potato Chip Factories as Fat-Liquoring Agent. Journal of American Science 2010;6(12):617-626]. (ISSN: 1545-1003). http://www.americanscience.org.

Keywords: Discarded Palm Oil, Fatty Acids, Fat-liquor, Phosphoration, Chrome Tanned Leather, FT-IR, HLB, Strength Properties, Scanning Electron Microscope, Frying wastes.

1. Introduction

In the leather industry, hides and skins proceed via various chemical and mechanical processes to produce finished leather. Chrome tannage has been the state of the art, it accounts over 80% of the activity in the tanning process [1] and used for the production of various types of leather [2]. But chrome-tanned leather when dried out becomes bony, hard and thus will not be suitable for use in most purposes, besides its color becomes dark and gains a disagreeable appearance. This means that, as water is removed during the drying stage, cohesion of the fibers takes place resulting in hard intractable leather which is difficult to rehydrate [3]. Thus, incorporation of fatty matter into leather through fat-liquoring process will decrease the effect of air oxidation and improves leather full and soft handle, flexibility, pliability and at the same time enhance its mechanical properties [4-6]. Therefore, introducing a lubricant into the leather keeps the fibers apart during drying and reduces the frictional forces within the fiber weaves thus allowing the fibers to move laterally over each other.

The palm oil used essentially for frying can be blended with various plant oils in different proportions to obtain liquid oil [7]. Most discarded edible oils (include palm oil & palm kernel oil) and fats are of immense importance for industrial applications as surfactant and soap manufacture [8-12]. Therefore, this work was devoted to explore the application of the discarded palm oil in leather industry as fat-liquoring agent.

The potato chip factories, in Egypt, use palm oil for frying of potato chips which are considerably popular as food in Egypt. Potato chip factories produce a large quantity of discarded palm oil. The large quantity of these oils resulting from frying processes causes pollution of environment. In nearly all countries on the earth the protection of the environment has become increasingly a very serious concern. As a result, we can utilize these quantities of wasted oils to obtain useful product.

Therefore, this work was devoted to study the phosphoration of purified discarded palm oil as well as explore its application for further use as leather fat-liquoring. Evaluation of the resulting chrome leather fat-liquored will be taken into consideration. This will add an economical value to this waste and at the same time prevent its environmental pollution. For this purpose a commercially available discarded palm oil (by-product) was used as a starting material.

2. Materials and methods

Materials

- Palm oil samples before and after frying were collected from some Egyptian potato chip factories.
- Chemicals used for different analysis of oil were supplied by international companies (Merk, Germany and BDH, England).
- Ortho- Phosphoric acid (98.5%) was pure chemical grade.
- Local commercial full grain chrome tanned leather was used for the present investigation from Radio Tannery, Cairo, Egypt.

Note: All chemical additives doses were calculated on the basis of leather weight (w/w).

Methods

Analysis of palm Oil

a- Purification of discarded palm oil

Discarded palm oil was heated to 90 ± 5°C and washed with a hot brine solution [5% Na Cl, w/v]. The ratio of discarded oil and brine solution was 10: 1 (v/v). The hot mixture [discarded oil and brine solution] was stirred using a stirrer at a speed of 60 rpm for 60 min. After that, the mixture was left to rest for 8 hrs in order to separate the mixture into two phases. The bottom phase [brine solution +impurities] was separated by siphoning. Sodium sulfite anhydrous was added to catch the traces of moisture from discarded palm oil, which was then filtered through filter paper (Whatman no. 1), Girgis [13]. The color was measured using Lovibond tintometer, model E, using 5.25 inch cell, and impurities of discarded palm oil before and after purification were determined according to the methods described in the A.O.C.S., 1997 [14]; while the odor was evaluated according to the method reported by Shyam [15].

b- Bleaching of purified discarded palm oil

Purified discarded palm oil was heated to 70 ± 5°C and bleached with a 2% H_2O_2 solution (v/v). The sample was stirred using a stirrer at a speed of 80 rpm for 30 min while maintaining a temperature of 70 ± 5°C. The discarded palm oil was filtered through filter paper [Whatman no. 1], Girgis [13], and the color was measured.

c- Physical and chemical characteristics

Palm oil and discarded palm oil were analyzed for its physical and chemical characteristics according to the American Oil Chemists Society Methods, (AOCS, 1998) [16]. Refractive index, acid value, peroxide value, saponification value, iodine value and unsaponifiable matters were measured. The ester value was estimated by subtracting the acid value from saponification value (SV-AV).

d- Fatty acid composition

Fried palm Fatty acid methyl esters were prepared by IUPAC standard methods, 1987 [17], and according to A.O.C.S. method [16]. Determination of fatty acid composition was performed as described by Mitruke [18] using Hewlett Packard HP 5890 series II gas chromatography, equipped with flame ionization detector (FID), operated under the following conditions:

Detector, flame ionization (FID); column, capillary, 30.0 m x 530 µm, 1.0 µm thickness, polyethylene glycol phase (INNO Wax); N_2 with flow rate, 15 ml per min with average velocity 89 cm/s (8.2 psi); H_2 flow rate, 30 ml per min; air flow rate, 300 ml per min; split ratio, 8:1, split flow, 120 ml per min; gas saver, 20 ml per min. Detector temperature, 280ºC; column temperature, 240ºC; injection temperature, 280ºC. Temperature programming starting from 100ºC to reach a maximum of 240ºC was used for eluting the fatty acid methyl esters. The identification of peaks was made as compared with chromatograms of standard fatty acids methyl esters (Sigma, USA).

Phosphoration processes

- phosphoration of the oil (100 g) were carried out in a three necked flask fitted with a stirrer, a thermometer and also with an inlet for the addition of the reagents. Phosphoric acid (H_3PO_4, 30% of the oil weight) was added drop wise at interval times with slow stirring while maintaining the temperature below 30°C during the addition. The overall reaction time was 3 hours.
- The phosphated oil was washed by 10% sodium chloride at ambient temperature and neutralized with ≈ 30% sodium hydroxide with agitation for 30-40 min.
- The phosphated products so obtained were analyzed according to official methods [19, 20]. The product was prepared at a concentration of about 60-70% prior (pH≈7) to its uses as a fat-liquor.

FT-IR Analysis

The change in functional groups of oils were studied using FT-IR analysis, it was performed using Mattson 5000 FTIR, USA spectrophotometer with resolution 4 cm^{-1}.

Hydrophile-Lipophile Balance (HLB)

Hydrophile-lipophile balance of emulsifiers was calculated using the following equation of Griffin [21]:

HLB = 20 (1 — S/A)

Where:

S= (Saponification value of the phosphated fat-liquor).

A = (acid value of the total fatty acids of the original sample).

Fat-Liquoring Process

The leather pieces were first washed with water for about 15 minutes and water drained off. Then neutralization process was carried out using 1% sodium formate and running the drum for 15 minutes. Thereafter, 0.5 % sodium bicarbonate was added and the drum was run for further 10 min. The leather pieces gave a greenish blue color with bromo cresol green throughout the whole thickness (pH 5.0- 5.3). The neutralized leather pieces were washed with water and dyed with acid dye, 5 % for 30 minutes. Then, 6% fat-emulsion was added to the dyeing bath at room temperature. After complete addition of the fat liquor, the drum was run for 40 minutes. The leather pieces were washed with water for about 10 minutes, removed from the drum, sammed, set out and left to dry in air through hanging up at room temperature. The dried leather pieces were used for investigation.

Mechanical Measurements

Fat-liquored leather samples were cut with special steel press knives from the position parallel to the backbone and about 5 cm away from it as specified in the Egyptian Standard Methods, ES-123 [22].

Dumbbell shaped specimens 50 mm length and 4 mm (neck width) were prepared according to ES-123 [22] for mechanical properties measurements using Rauenstein-Tensile force up to 500 Kg. The measured data are the average of four transverse and longitudinal measurements. The cross-head speed was controlled at 50 mm/min and the tests were done at room temperature (25°C).

Tensile Strength

Tensile Strength is calculated in kg/cm^2 from the load required to rupture the test specimen under tension (breaking load) divided by the area of the original cross section of the same specimen.

$$\text{Tensile strength (kg / cm}^2\text{)} = \frac{\text{Breaking load (kg)} \times 100}{\text{Thickness (cm)} \times \text{width (cm)}}$$

Elongation (at break)

The reading on the scale of the machine at the instant when the rupture occurred was taken to calculate the percentage of elongation.

$$\text{Percentage of elongation, \%} = \frac{\text{Increase of length (mm)} \times 100}{\text{Length of specimen, middle part (mm)}}$$

Stitch tear (single hole)

A hole (1×10 mm) was punched on the long axis of the leather specimens. The stitch tear was then calculated from the load required to tear the leather specimen from a steel rod passing through the hole of the specimen.

$$\text{Stitch tear (kg / cm)} = \frac{\text{Breaking load (kg)} \times 10}{\text{Mean thickness of leather sample (mm)}}$$

Scanning Electron Microscope

Specimens of experimental and control were prepared as circular samples (10 mm) and then subjected to sputter coating of gold ions to prepare a conducting medium (sputter coater-Edwards-Model S -150 A, Eng). A Jeol scanning microscope (Japan) JSM-T20 was used for the microscopic study.

3. Results and Discussion:

Purification of Discarded Oil

The effect of washing with brine solution and bleaching with H_2O_2 on the color, impurities and odor of the discarded palm oil are illustrated in Table (1).

Table (1): Effect of washing and bleaching on the color, impurities and odor of the discarded palm oil

Discarded palm oil	Lovibond color	Impurities, (%)	Odor
Before washing	36.0 Y+ 12.7 R+ 1.2 B*	1.4	Like odor to potato frying
After washing (Before bleaching)	36.0 Y+ 12.2 R+ 1.0 B*	0.8	Slight odor to potato frying
After bleaching	35.0 Y+ 6.6 R + 0.5 B*	0.7	Slight odor to potato frying

*** Where: Y= Yellow, R = Red, B = Blue**

Table (1) reveals that, washing with brine solution induces some improvements of the color, odor and impurity levels. Also, it is noticed that addition of H_2O_2 improves the color due to its action as oxidizing agent which reduces the color level of

the oil pigments. These results are in good accordance with previous results reported by Woollatt [23] and Girgis [13]. The improvements may stem from the mutual solubility of the impurities isolated at the bottom [13,24].

Physical and Chemical Properties

Physical and chemical characteristics of palm oil before and after frying have been extensively investigated. The obtained results are shown in Table (2).

Table (2): Physico- chemical properties of palm oil before and after frying.

Properties	Palm oil	
	Before frying	After frying
Refractive index at 40 ºC	1.4570	1.4597
Saponification value, mg KOH / g oil	199.2	199.8
Iodine value, mg I_2 / g oil	49.10	40.5
Acid value, mg KOH / g oil	0.2	1.1
Peroxide value, m Eq/Kg	1.3	6.5
Unsaponifiable matter, (%)	0.3	0.7
Ester value (S.V- A.V), mg KOH /g oil	199.0	198.7

It was noticed from table (2) that, the saponification and ester values of both palm oil before and after frying are almost the same (199.2 , 199.0 and 199.8, 198.7 mg KOH/g oil) respectively. While iodine value before frying had a higher value (49.1 mg I_2/g oil) compared with after frying (40.5 mg I_2 / g oil) [8,13].

It is also clearly seen that, the acid, peroxide values and unsaponifiable matter of palm oil increased after frying (1.1mg/g, 6.5 mEq/kg and 0.7%) compared with palm oil before frying (0.2 mg/g, 1.3 mEq/kg and 0.3%) respectively. These results are similar to those obtained by many investigators [13, 25, 26].

Fatty acids composition

Fatty acids composition of palm oil before and after frying is illustrated in Table (3).

Table: (3) Fatty acids composition of palm oil before and after frying.

Fatty acids (%)	Palm oil	
	Before frying	After frying
Saturated fatty acids:		
Myristic ($C_{14:0}$)	1.82	3.22
Palmitic ($C_{16:0}$)	43.96	45.20
Stearic ($C_{18:0}$)	4.87	7.41
Total:	**50.65**	**59.83**
Unsaturated fatty acids:		
Oleic ($C_{18:1}$)	39.50	36.29
Linoleic ($C_{18:2}$)	9.40	7.57
Linolenic ($C_{18:3}$)	0.45	0.31
Total:	**49.35**	**40.17**

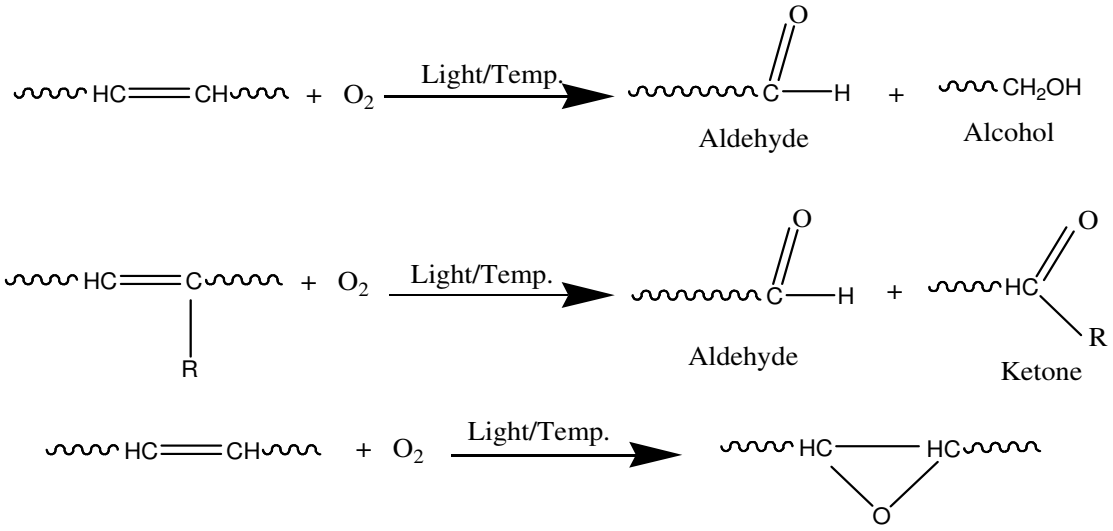
It can be seen from Table (3) that, the saturated fatty acids contents of palm oil before and after frying are (50.65% and 59.83%) and unsaturated fatty acids are (49.35% and 40.17%). Also, it is noticed that, the ratio of total unsaturated fatty acids of palm oil is almost equal to the total saturated fatty acids (1:1.03), while this ratio is different after frying (1:1.49). Oleic acid constitutes more than 80.0% and 90.0% of the unsaturated fatty acids of palm oil and discarded palm oil respectively, while palmitic acids

show more than 43.0% and 45.0% of the total fatty acids, respectively. On the other hand linoleic acid of palm oil has slightly higher value (9.40%) compared with discarded palm oil (7.57%).

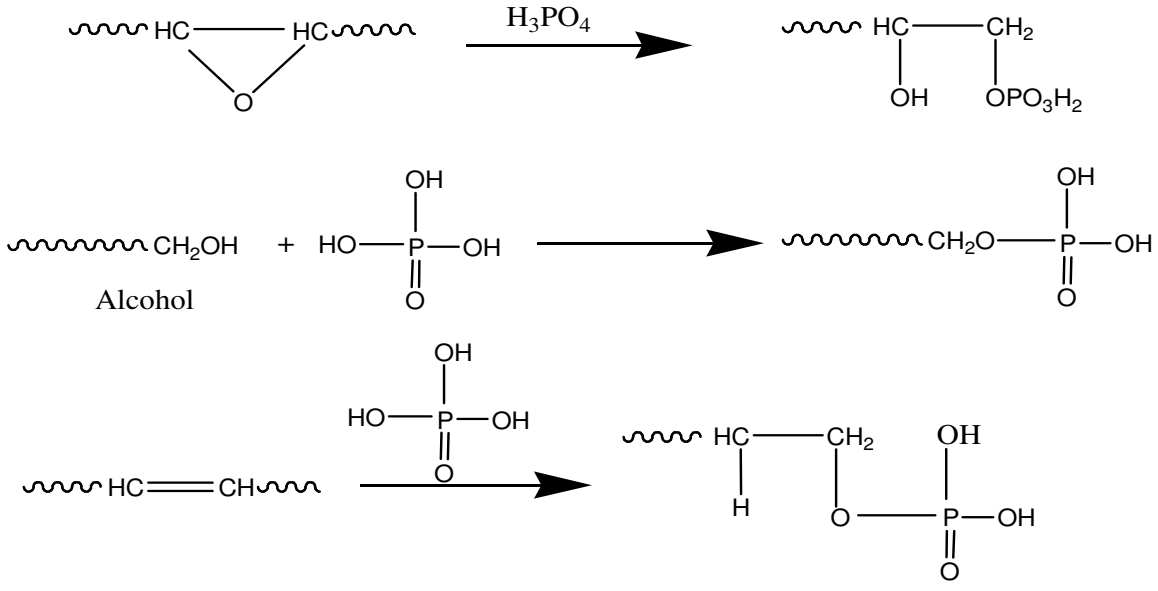
These results are in a good accordance with those reported by Helmy & Megahed [8], Girgis [13], Tyagi & Vasishtha [26], and Megahed [27] whos found that during frying, a progressive decrease in unsaturation was observed in the oil by the determination of iodine value. This decrease in unsaturation could be due to the destruction of double bonds by oxidation, Tables (2,3).

Phosphoration Reaction

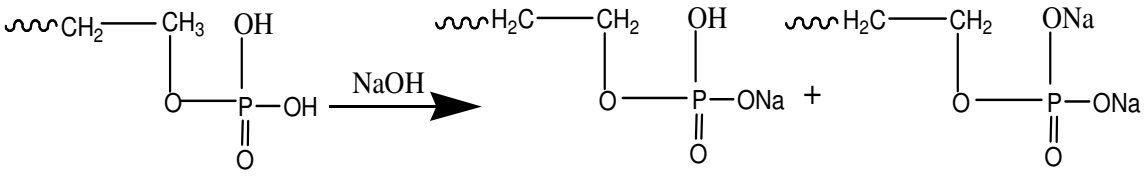
The discarded palm oil is oxidized by air under high temperature resulting in the scission of double bonds leading to increase the reactive centers of the fried oil which easily reacts with H_3PO_4, as illustrated in schemes (1-3). This is confirmed by decreasing the percent of unsaturation fatty acids and iodine value as shown in tables (2,3) and appearance of carbonyl groups in FT-IR spectra, figure (1).



Scheme (1): Oxidation reactions and possible products



Scheme (2): Phosphoration reactions and ester-phosphate products



Scheme (3): Neutralization of Phosphated products

It can be seen from schemes that, the hydrophilicity of the Phosphated product increased due to the formation of polar groups (hydroxyl and ester phosphate groups) as confirmed by FT-IR, Figure (1).

FT-IR Analysis

Figure 1 illustrates the spectrum of palm oil, discarded palm oil and phosphate palm oil samples with the FT-IR/ Absorbance in the range of 4000 to 500 Cm^{-1}. The spectrum of palm oil before frying shows characteristics absorption band associated with common oil. The stretching and bending absorption peaks at 3004 and 723 cm^{-1} are given by olefinic (cis = CH). The strong absorption peaks at around at 2900 to 2850 cm^{-1} are assigned to CH_3 and CH_2 asymmetric stretching vibration. Also, the spectra show stretching absorption bands at 1652 cm^{-1} and 1467 cm^{-1} which correspond to non-conjugated (cis C= C) bond and C-H scissoring respectively, Guillen and Che Man [28, 29]. The spectra of discarded palm oil show stretching absorption bands at 1745 cm^{-1}, 1172 cm^{-1} and 3527 cm^{-1} corresponding to C=O, C-O and OH groups respectively. The appearance of bands at 2720 cm^{-1} indicates the presence of C-H aldehydic group.

While the spectrum of phosphate discarded palm oil shows characteristic absorption peaks at 1090 cm^{-1} corresponding to sym. dihydrogen phosphate and at 1035 cm^{-1} corresponding to asym. groups. It can also be seen from Figure (1) that, a strong broad band appeared at 865 cm^{-1} and (3527 & 3475) cm^{-1} which corresponds to the mono hydrogen phosphate and hydroxyl groups respectively.

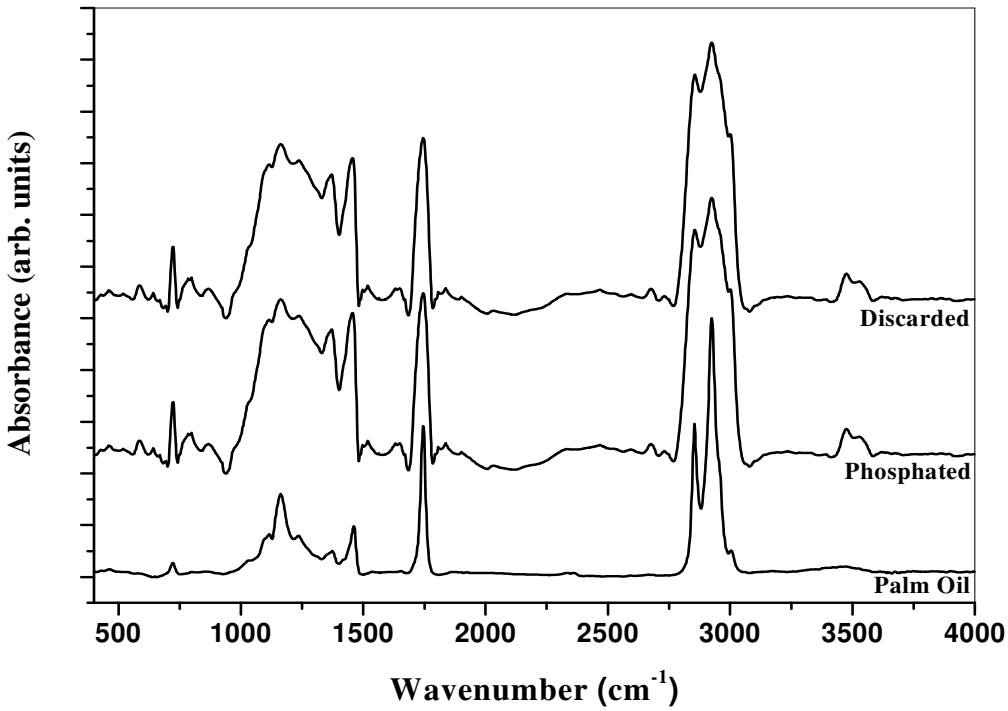


Figure (1): FT-IR Spectra of Palm oil, discarded palm oil and phosphated discarded palm oil.

HLB of the Prepared Fat-liquor

The HLB is an expression of the relative simultaneous attraction of surfactant for water and/or for oil (or for the two phases). The HLB of surfactant (Phosphoated oil) determines the emulsion types that tend to be formed, Griffin [21].

As previously mentioned, fat-liquoring is one of an important step in leather manufacturing, as it is intended to lubricate the leather fibers resulting in softness, pliability, flexibility, full and stretchy depending upon its final utility. Fat liquor helps to prevent both loosening of the leather grain and ugly appearance after drying and at the same time, improving the mechanical properties of leather. Thus, the fat separated from the emulsion is deposited inside the leather and fixed to the leather fibers. Therefore, the stability of fat-liquor in its water emulsion is an important factor in fat-liquoring of leather. i.e., if the fat-liquor is unstable, it cannot give a proper fat-liquoring effect. So that, for the application of the prepared Phosphated fat-liquor in leather treatment, it's necessary to evaluate the stabilization of the fat-liquor emulsion by Hydrophile-Lipophile Balance (HLB).

Therefore, the prepared Phosphated fat-liquor has HLB value of 11.06 i.e., it forms a "O/W" emulsion type, and simply dispersible in water. This means that a fineness of emulsion is formed since Phosphated ester or acids as well as the non-Phosphated portion of the ester present in the fat-liquor are emulsifiable. So that the prepared fat-liquor can form a stable emulsion and transfers from the aqueous bath to the leather and penetrates in it. The fat molecules and the fiber undergo physical bonding. However, the physically bonded fat molecules might undergo some chemical reactions with its surroundings [30].

Mechanical Properties of Fat-liquored Leather

The fat-liquoring process was carried out on neutralized leather using about 5% per 100 g leather. The mechanical tests include the measurement of the tensile strength, elongation at break and stitch tear. The mechanical properties have been given the greatest consideration on the evaluation of fat liquored leather, because, it gives an indication of fiber lubricity. The mechanical properties were evaluated according to Egyptian standard specification of leather [31].

It is found from figures (3,4) that, elongation at break and stitch tear are higher than that one of famous fat-liquor TRUPONOL® PEW2, (Phosphoric esters of synthetic fatting substance, pH ≈7) used in Egyptian tanneries, but tensile strength figure (2) is relatively high.

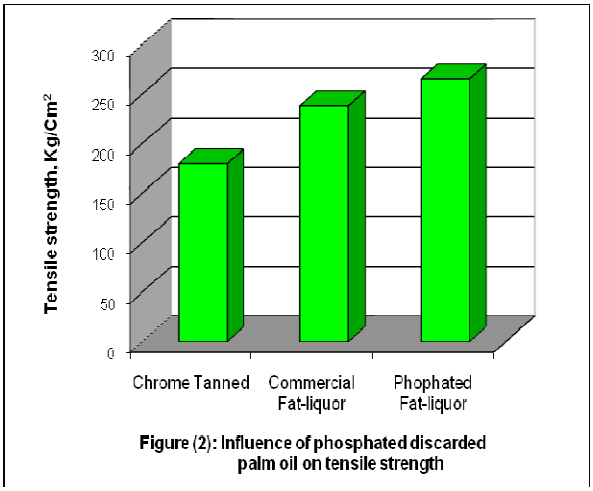

Figure (2): Influence of phosphated discarded palm oil on tensile strength

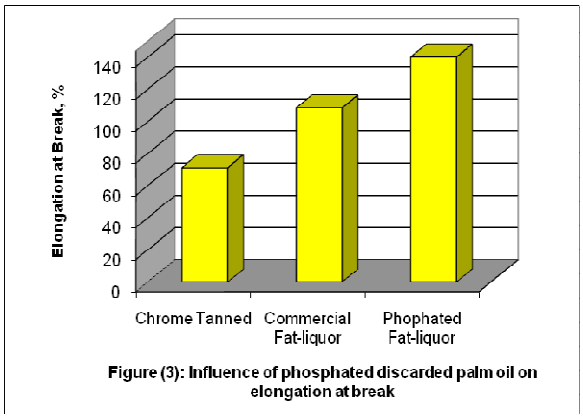

Figure (3): Influence of phosphated discarded palm oil on elongation at break

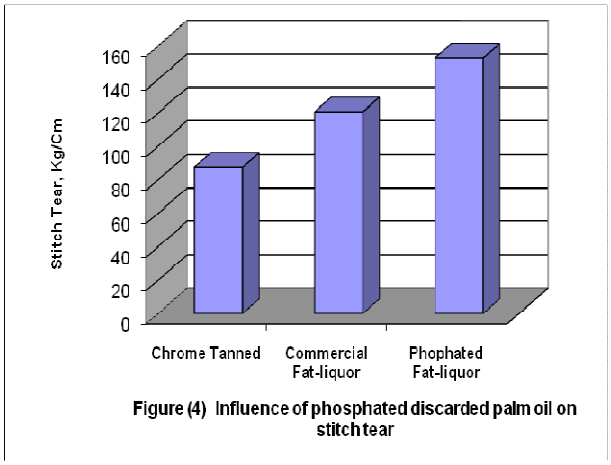

Figure (4) Influence of phosphated discarded palm oil on stitch tear

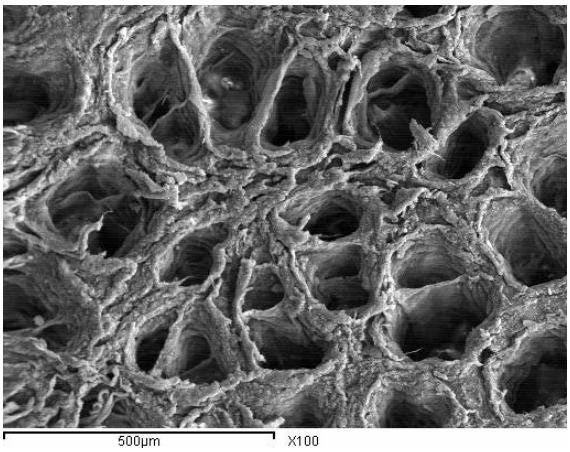
The improvement in the mechanical properties of the treated leather is due to good lubrication of the fibers as shown in SEMicrograph. The phosphated portion of oil (hydrophilic fatty matter) during liquoring of chrome tanned leather is chemically bound to the leather fibers, i.e. interacts with active centers in the collagen molecules of

leather fibers, while the emulsified portion (hydrophobic portions) is mainly located between the fiber bundles. Because the prepared fat-liquor contains hydrophilic and at the same time hydrophobic portions can penetrated into the leather fibers with the prepared fat-liquor because of its good penetration power and the stability of its emulsion (HLB concept).

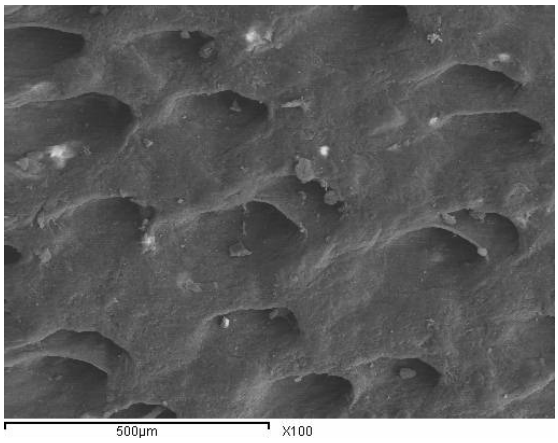
In general, the physical properties which are recorded above demonstrates to a far extent the suitability of the prepared phosphated local fried palm oil for fat-liquoring of chrome tanned leather, where by values which lie more or less within the limits of the Egyptian standard specifications, are attained.

Scanning Electron Microscopy (SEM)

SEM looks deeply into hide fiber structure and shows the effect of fat liquor on fiber and grain surface. SEM of the grain surface (x 100) of the fat liquored leather exhibits a soft grain without any fatty-spew; Figure (5-a & b). Also, the cross-section (x 500) of leather fiber before and after fat liquoring showed a significant lubrication of fiber bundles; Figure (6-a & b).

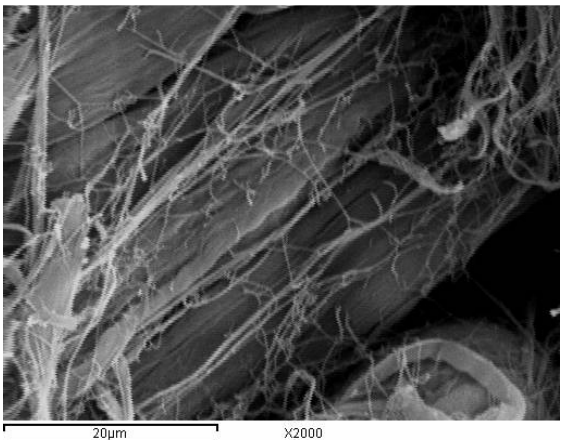


a) Chrome tanned leather

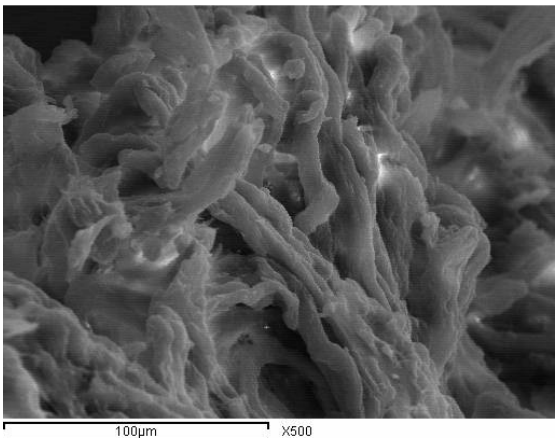


b) Fat-liquored leather.

Figure 5: SE-Micrograph for fiber bundles (X500).



a) Chrome tanned leather.



b) Fat-liquored leather.

Figure 6: SE-Micrograph for grain surface (X100).

Conclusion

In conclusion, it can be stated that this study on fat-liquoring of chrome tanned leather proved that:

1- The utilization of phosphated discarded palm oil (by product) as fat-liquoring agent.
2- An Improvement the texture and strength properties of leather fat-liquored using Phosphated discarded palm oil.
3- Substituting successfully part of the imported leather fat-liquoring agents.

Reuse of Industrial Materials in Buildings to Activate their Application in Egypt

Nermin Mokhtar Mohamed
Civil and Architectural Department, Engineering division, National research centre, Egypt
Nermin_farag@yahoo.com

Abstract: Increasingly stringent rules and regulations on construction and demolition waste, diminishing landfill space and depletion of natural resources are all reasons for the push for industrial byproduct materials recovery. In Egypt, Industrial byproduct materials are generated in large volumes every day that are potentially usable materials, and must be disposed of. The main goal of this paper is to change the way Egyptians' think about waste—to see the value of a used material as a product or commodity, not as a waste, and encourage the use and recycling of these rich, largely untapped resources. Positive economic rewards and environmental results are moving our partners toward more waste reduction and materials management. This paper summarizes the proposed Egyptian industrial materials waste management guidelines to reuse in building, which cover: (1) Identify the parties involved and the distribution of responsibilities; (2) Complementarily of roles of parties(owner, engineer, designer, and contractor) involved in the process of re-use to remove the causes that hinder the management of such material in Egypt; and (3) Participation of the Parties to the proposed project to achieve sustainable development fields at the actual application of the project.
[Nermin Mokhtar Mohamed. **Reuse of Industrial Materials in Buildings to Activate their Application in Egypt.** Journal of American Science 2010;6(12):627-639]. (ISSN: 1545-1003). http://www.americanscience.org.

KEYWORD: reuse –industrial byproduct materials, waste management, sustainability, Egypt.

1. Introduction:

The world is becoming increasingly conscious of the environmental implications not only of production processes but also of products discarded after use. The recycling of waste materials as a means of tackling the solid waste problem is attracting growing interest.

This is the problem of solid waste currently producing and increase with increasing Census world population of the most serious problems and will remain polluted environment for long periods of up to thousands of years which cause environmental damage and health problems.

In Egypt, the traditional method to get rid of Industrial wastes is send to landfill as waste. Industrial wastes are more damaging to environment, and public health, In addition, Construction and demolition (C&D) materials led to urban pollution image around, as well as the economic burden and the cost of waste transportation.

In pursuit of sustainable development principles, which aims to rely on recycling waste came importance of research on alternatives, Salvaging materials for reuse can be both an economical and environmentally sound alternate to waste stream disposal, and it also saves energy and environmental impacts of producing new products from virgin materials that help communities be sustainable in infrastructure renovation, construction, and maintenance.

With the pursuit of Egypt now to the sustainable development of areas and provide jobs for young graduates, In urgent need for alternative construction materials with rising cost of wood universal waste and demolition and construction that represent a high proportion of solid waste, Find the possibility of reuse industrial materials in building that Re-cycling building materials is an essential part of ecological sustainability.

And therefore need to find research benefit from industrial materials in the possibility of exploitation as an economic environment friendly housing in Egypt organization management process participation and funding for projects on physical development, to activate application construction for environmental development, economic, social and physical in areas

Despite the government attempts to impose penalties or fines or recourse to academic studies and research centers to develop solutions for waste management but it is still a deficiency in complete control of the problem in Egypt.

Research aims to propose a comprehensive and integrated approach to establishing industrial materials and its activation in Egypt by identifying the parties involved and their respective roles for the protection of areas affected by the effects of disposal opening alternatives to creating markets for reuse

industrial materials in physical development, and to conserve energy and preserve natural resources.

The main objective of research can be achieved through several sub-objectives, namely: monitor problems resulting from industrial materials pollution in Egypt, current status assessment and study of causes that hinder the proper management of residues in Egypt, finance and operations planning part of the parties involved to upgrade the project such areas, Identify the areas of development environmental, economic, social, physical and role of parties involved in achieving these areas

2. 1- Sustainable

Sustainable development meets the needs of the present without compromising the ability of future generations to meet their own needs. Basically, it's another term for "green" or "environmentally friendly".

Implementing sustainable projects means achieving an ecologically, socially and economically acceptable future[i].

By taking into consideration all economical aspects and the effects on people, and the environment during the planning and development phases, minimize the use of energy and resources to protect the environment, and increase the efficiency of all projects[ii].

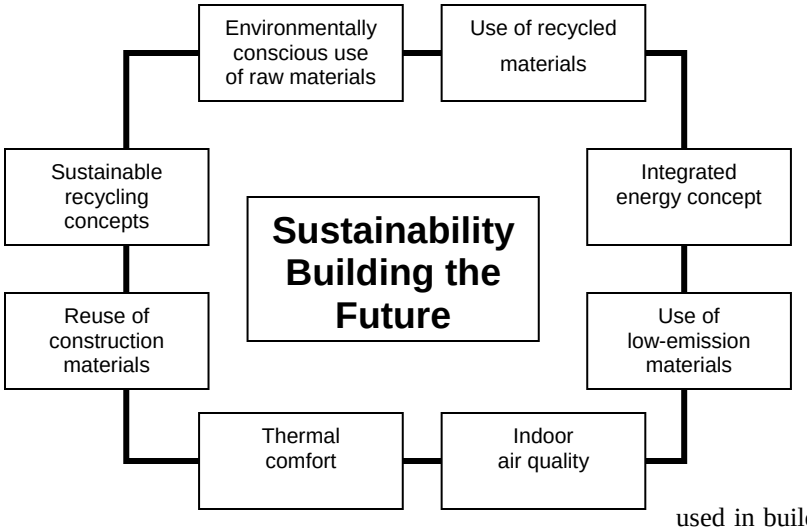

Fig. (1)Aspects of the Sustainability

1-1 Choosing sustainable materials

It can be difficult to assess exactly how sustainable a product is and which materials are preferable to others[iii]. There are some tools that can help you to choose the building materials, table (1).

There are many considerations that should be taken into account when choosing building materials. Since many different definitions exist concerning what constitutes an environmentally friendly or green material, this study use the following set of terms as factors in determining environmentally preferred materials and products[iv].

By-product

Unused or waste material from one manufacturing or energy-producing process that can be used in another manufacturing or energy-producing process [v]

Agricultural by-product: Unused or waste material from farming operations, several of which can be used in building products such as strawboard panels, etc.

Industrial by-product: Unused or waste material from power plants or manufacturing operations, several of which can be used in building products, e.g. fly ash concrete, etc.

2- Industrial materials

Industrial materials recycling, referred to as beneficial use, means reusing or recycling byproduct materials generated from industrial processes. These materials can be used as substitutions for raw materials in the manufacture of consumer products, roads, bridges, buildings, and other construction projects. Thousands of manufacturing and industrial processes and electric utility generators create hundreds of millions of tons of nonhazardous industrial materials that are often wasted[vi].

2-1 Examples of practical recycling applications

Nonhazardous industrial materials, such as coal ash, foundry sand, construction and demolition materials are valuable products of industrial

processes. Each material may be recycled in a variety of diverse applications, table (2). These materials have many of the same chemical and physical properties as the virgin materials they replace - they can even improve the quality of a product[vii].

3- Advantages and disadvantages of the process of recycling waste

The process of recycling has some of the advantages and disadvantages[viii], Table (3).

Table (1): Evaluation tools to choose the building materials

Evaluation tools	**Life-cycle assessment**	This means considering the impact during the extraction of the raw materials, manufacture, transport, handling, installation, the lifetime of its use, recycling and disposal.
	Embodied energy	The total amount of energy that is needed to produce, transport it to site and install it. For building products, it is commonly measured in Mega Joules (MJ) per unit of product.
	Renewable resources	These are resources that will be replenished with time; they include plant and animal products such as timber, paper, cork, wool and leather.
	Sustainable resources	Sustainable resources are the products of cyclic closed systems that do not require outside inputs, and do not generate waste.
	Local resources	Locally sourced products need less energy for transport and they support your local economy.
	Toxicity	Some materials are relatively harmless for humans, but their production might cause habitat destruction or release toxins into the environment. Toxic materials can also be a problem for installers or when they are disposed of at the end of their life cycle.
	Quality	The expected lifetime of the building is short; it makes little sense to use very durable materials.
	Re-use and recycling	Using second-hand or recycled materials is another option for reducing resource use.
	Uncertainty	Materials that have been tested for a long time in your local conditions are a safer choice than new materials or those which have not been proven locally.

Table (2): The properties of industrial materials and recycling applications in building

industrial materials	The properties and the problem	recycling applications in building
Cement dust produced during the cement industry	Produced from the burning and grinding of raw materials used in the manufacture of cement, contains a high proportion of the components of the cement but in different proportions, and fails to plant one of the factories of the Egyptian cement per day at least 300 tons in the Mediterranean.	It has been used in many engineering applications, including: Partially replace cement in some industries of construction materials such as bricks, tiles, the cement industry, glass, rubber, sewage treatment, the foundation layer for roads.
Steel slag	It is a byproduct of iron and steel industry and contains a high proportion of the components of the cement, but in different proportions. The amount of (steel slag) from iron and steel sector about a million tons annually, which is a national problem as well as emissions generated from the accumulation of slag	It is used in many engineering applications, including: as heap in concrete works of traditional and light production, types of cement (Ferro-cement - high iron slag - high resistance to sulfate).
Foundry Sands	It is sand that is used to make molds and cores in the metal casting process. Although generally recycled many times internally by the foundries, about 3-4 million tons of foundry sand is discarded each year. The recycling of nonhazardous, spent foundry sand can save energy, reduce the need to mine virgin materials, and may reduce costs for both producers and end users.	the spent foundry sands is used As partial replacement for fine aggregate in asphalt mixtures; in Portland cement concrete; As source material for the manufacture of Portland cement; and As a sand used in masonry mortar mixes, And in the other applications
Coal combustion	CCPs include the following materials:	Fly ash can be used as a replacement for

products	Fly Ash; Ash; Boiler; Flue Gas Desulphurization Material (FGD); and Other types of material such as fluidized bed combustion ash, and scrubber residues The characteristics and physical properties of CCPs vary. In general, the size, shape, and chemical composition of these materials determines their beneficial reuse as a component of building materials or as a replacement to other virgin materials such as sand, gravel, or gypsum.	the Portland cement that binds traditional concrete mixes. The manufacture of Portland cement requires large inputs of energy, and it is estimated that its manufacture constitutes about 8% of all carbon dioxide emissions from human sources. Approximately 75% of the fly ash produced annually is disposed of in landfills, which makes incorporating it into concrete a resource-efficient alternative.
Pulp and paper byproducts	Two significant byproducts from the paper industry are WWTP residuals and boiler ash	There are numerous examples of other uses Building board/fixture, Brick or concrete additive, Glass or lightweight aggregate
Construction and demolition (C&D) materials[ix]	It consists of the debris generated during the construction, renovation, and demolition of buildings, roads, and bridges. C&D materials often contain bulky, heavy materials, such as concrete, wood, metals, glass, and salvaged building components[x]. In Egypt, the daily quantity of construction and demolition (C&D) waste has been estimated as 10,000 tones. That is equivalent to one third of the total daily municipal solid wastes generated per day in Egypt[xi].	It can make a number of products (solid cement bricks, hollow bricks, paving blocks) using the broken bricks and broken ceramics. As possible, get a light concrete using broken bricks as an alternative partial or total ruins of the great used in industry. You can also use the surplus concrete and rubble after rounding heap for the production of concrete suitable for the various structural elements.

Table (3) Advantages and disadvantages of the process of recycling waste

disadvantages of recycling waste	Advantages of recycling waste
- Some materials are generally more difficult to recycle - other materials are dangerous or require more energy inputs to be recycled - The durability of some materials can be extended if they properly protected and maintained while in use - Environmentally preferable materials may be more expensive or difficult to locate - Determining a product's environmental preferability can be a complex process for which no tools exist - Prepare the materials may need more time - Need efficient labors	- Conserves energy and reduces greenhouse gas emissions by decreasing the demand for products made from energy intensive manufacturing processes - reduce the volume of materials which are sent to landfill as waste to achieve the continued development - save the embodied energy content - Preserves our natural resources by decreasing the demand for virgin materials - Saves money by decreasing disposal costs for the generator and decreasing materials costs for end users. - Local employment creation - Reuse of old buildings and use of recycled materials.

4- Building Applications for Industrial Materials

The beneficial use of industrial materials that were previously considered wastes has been expanding with a number of applications gaining market and regulator acceptance. Environmental and economic benefits derived from the recycling and beneficial use of industrial materials are becoming more evident:

- Conserving energy and reducing greenhouse gas emissions by decreasing the demand for products made from energy-intensive manufacturing processes;
- Preserving natural resources by decreasing the demand for virgin materials - recycled materials have many of the same properties as the virgin material they replace, and may improve the quality of the products in which they are used;

- Decreasing the economic and environmental burdens of disposal, as well as reducing the cost of material for end users.

This diagram illustrates a variety of common building applications for industrial materials. Note that the availability of specific industrial materials can vary regionally, fig. (2)[xii].

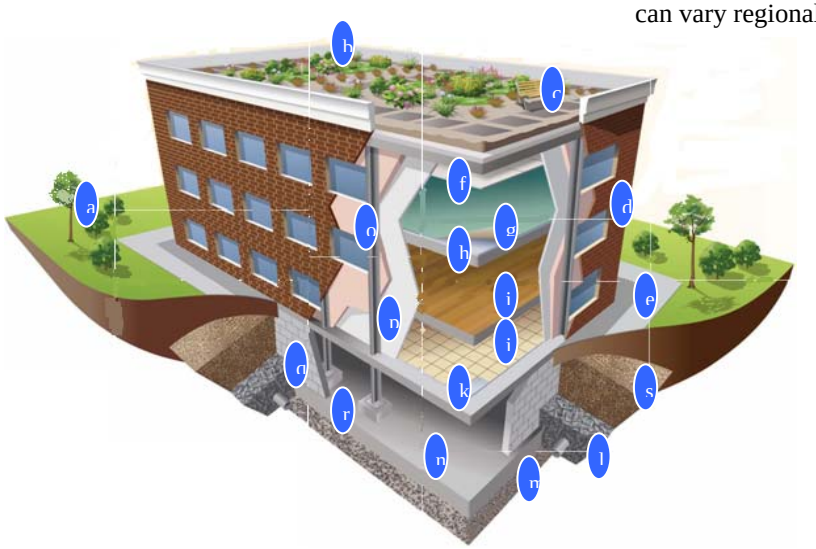

Fig. (2) Building Applications for Industrial Materials

Table (4) : a variety of common building applications for industrial materials

(a,b) Green Roofs & Landscaping	Green roofs are roofs covered with plants; they reduce storm runoff and provide insulation. Scrap tires can be used to make rubber tile for walkways. Bottom ash can be used as bedding material. Clean wood, recycled gypsum wallboard, and cardboard can be ground and used as soil amendments in both green roofs and landscaping applications.
(c) Landscape Furniture	Benches can be made with plastic lumber containing fly ash or with recycled C&D wood.
(d) Building Facing Material	Manufactured stone, which is concrete mixed with aggregates, is commonly used as building facing materials. fly ash can be used in the production of manufactured stone
(e) Sidewalks	Industrial materials can be used to make concrete sidewalks, and used tires can be recycled to create rubberized sidewalks. Asphalt concrete sidewalks can be made with recycled asphalt pavement and recycled asphalt shingles.
(f) Ceiling Tile	Ceiling tile can contain flue gas desulfurization (FGD) gypsum (a material resulting from burning coal to produce electricity), fly ash, recycled gypsum wallboard, or air-cooled blast furnace slag.
(g) Flooring	Industrial materials can be used in various flooring applications. (h) Carpet backing: Used tires, fly ash, or recycled carpet. (i) Wood flooring: Salvaged lumber or recycled wood. (j) Flooring tile: Fly ash, blast furnace slag. (k) Tile underpayment: Fly ash.
(l) Backfill (Foundation Support)	Backfill surrounds the building foundation, supporting it and providing drainage. Scrap tires provide superior drainage, insulation, and wall pressure relief. Blast furnace slag and recycled concrete also can be used for drainage.
(m) Foundation Structural Fill	Structural fill is an engineered fill that is constructed in layers and compacted to a desired density. Coal fly ash, bottom ash, slag, and spent foundry sand can all be used as structural fill. Concrete can be crushed and used onsite as structural fill.
(n) Poured Concrete	Concrete, which is composed of cement, aggregate, and water, is used in a

Foundation	wide array of building applications. Industrial materials can be recycled in cement and concrete in many ways. Here are a few examples: • Fly ash and ground granulated blast furnace slag can be used as partial cement replacements. Using these materials can produce stronger, longer-lasting concrete. • Portland cement itself can be made with fly ash, FGD gypsum, foundry sand, recycled gypsum wallboard, blast furnace, and steel slag. • Concrete aggregates can include bottom ash, foundry sand, crushed concrete, and blast furnace slag.
(o) Insulation	Air-cooled blast furnace slag can be used to produce mineral or rock wool insulation (also known as slag wool insulation).
(p)Drywall/Wallboard	FGD gypsum and recycled gypsum wall board can be used to manufacture drywall.
(q) Mortars, Grouts, Stucco	Mortars, grouts, and stucco contain aggregate (sand), binder, and water. Fly ash, foundry sand, silica fume, and slag cement can all be used as partial cement replacements.
(r) Masonry Blocks	Masonry blocks are made from cement and aggregate. Slag cement, fly ash, or silica fume can substitute partially for cement. Bottom ash, blast furnace slag, and recycled concrete aggregate can substitute for newly mined materials.
(s) Base Material	Spent foundry sand can be used in place of natural soil as base material for the building site. Recycled concrete is also commonly used as base material.

5-Case study

Some of the experiences of the World created by using industrial materials reused, table (5)

Case study	Location & Building Specs	Design	Materials Reused or Recycled	Positive Community Impacts
The Lazarus Building[xiii] is one of the most significant green rehabilitation projects in Columbus.  *Lazarus Before Redevelopment*  *Lazarus After Redevelopment*	 Renovation of a 600,000 square foot  commercial building in downtown Columbus, Ohio.	-Reducing, reusing, and recycling materials during renovation and construction -Using recycled-content products and materials in construction -Cost savings and environmental benefits -Environmental awards and recognition -Local community revitalization	Developers retained over 75 percent of the original structure, significantly reducing the amount of materials needed for the project. The renovation employed -Coal fly ash in concrete; -Recycled glass and tile flooring containing up to 100 percent recycled materials; -Carpets containing recycled nylon; -Restroom partitions containing 100 percent post-consumer recycled plastic; -Drywall containing at least 96 percent recycled materials, including flue gas desulphurization gypsum; and -Building siding containing 60 percent recycled metal.	-cost savings and avoided local community impacts from trucks hauling debris away. - The project created local jobs, improving the local economy. -a showcase of innovative ways to reduce waste.

Case study	Location & Building Specs	Design	Recycled	Positive Community Impacts
EPA's new building[xiv]  **ARCHITECTURAL SCALE MODEL**  **The exterior environment**  **The interior environment**	200,000 square foot EPA Regional Headquarters office building in downtown Kansas City, Kansas.  	-Many building features contribute to exceptional energy efficiency - The building's operations and maintenance environmentally friendly. -building products and materials are more environmentally sensitive, or "greener"	-Utilizing Fly Ash in concrete design -The aluminum mullions and trim on the windows, sheer wall, sunscreens, cable trays and skylight are all constructed from recycled aluminum. -In restrooms, the floors and walls were constructed with ceramic tile made from over 70% post-industrial recycled waste glass. -The Shaw carpet is made of 25% recycled material - The wood wall base in the atrium is 100% recyclable. - The ceiling tile is made from 93%-recycled slag and the grid system from light gauge steel made from 67% recycled material.	-the reduction of smog was considered when selecting building materials. In order to help reduce the contribution of VOCs into the atmosphere. -a showcase of innovative ways to reduce waste.

6- Waste Management in Egypt

Waste Management is a component of sustainable development, which seeks to reduce the impact of human activities on public health and the environment and development.

The industrial development in Egypt is the main engine of economic growth, where is the advantage of good Waste and exhaust for different industries, one of indicators of progress in the United. Industrial waste are serious environmental problem and that the lack of local industries based on Exploitation of the waste in other industries, making it a burden and a waste of environmental resources used In production processes, fig. (3). In fact, it can be exploited to become the waste materials with high economic value.

To sustainable improve waste and materials management in Egypt[xv] will focus on the active involvement of industrial waste generators in the reduction of waste volumes at source, and will also encourage private sector participation in solid waste management services, particularly collection and recycling.

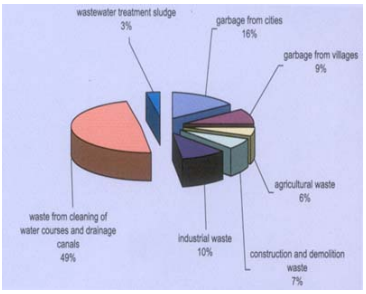

Fig. (3) The proportion of solid waste in Egypt

6-1 About a method to organize and manage the re-use of industrial materials in construction in Egypt:

This part comes to address the negative aspects which appear in the overlapping of roles and responsibilities of the parties involved in the project and overcome the causes that impede the management of re-use of industrial materials in Egypt to achieve urban development[xvi].

6-1-1 Identify the parties involved and the distribution of responsibilities

Parties to the proposed approach are different bodies responsible for policy development re-use of industrial materials in construction.

They are the government, institutions of technical advisory, executive agencies (investors and a group of capital and local governance), popular participation (beneficiaries), research centers, contractors and specialists (architects). In order to integrate the curriculum leading to activation of the application re-use of industrial materials in construction in Egypt should be considered interested parties and their respective roles to achieve the restructuring of the curriculum by ideal integration of limbs.

(I) the role of government

The success of the reuse industrial materials in building depends heavily on local government engagement and action. Their role is large and vital[xvii].

- Coordinate and facilitate partnerships to implement the reuse materials action plan.
- Lead by example in government
- Provide incentives that encourage green design, construction, and deconstruction and begin removing disincentives
- Expand capacity and markets for reusing and recycling construction and demolition materials.
- Increase awareness, knowledge, and access to reuse industrial materials
- Encourage innovative product design
- To encourage beneficiaries to participate in these projects beneficial to the environment
- Amend laws and existing environmental legislation

(Ii) The role of NGOs non-governmental organizations:

- Implementation of development projects in the environment and recycling waste.
- Training of local technical staff
- Coordination between the professional societies and funding for the implementation of various development programs.
- Galvanize the efforts of various parties (government, individuals, and investors) with the coordination between them.
- Support salvaged materials collection centers.
- Subsidize warehouse space to support the collection and distribution of salvaged materials.
- Create incentives for deconstruction, recycling, and the use of salvaged or recycled materials into construction procurement contracts.

(III) The role of professional engineers[xviii]

Specialists are planners, architects, economists, social, the most significant roles played by professionals in the following:

- Create new buildings that save energy and water, use fewer material resources, and create less waste.
- The design appropriate to the building to suit the Egyptian environment, according to the needs of the population and location
- Created propose a method suitable for the Egyptian environment and the work of drawings.
- Technical guidance and training courses for users and individuals to create technical staff can participate in all phases of the project.
- building designers have a responsibility to specify preferred materials and methods of construction which are suited to recycling

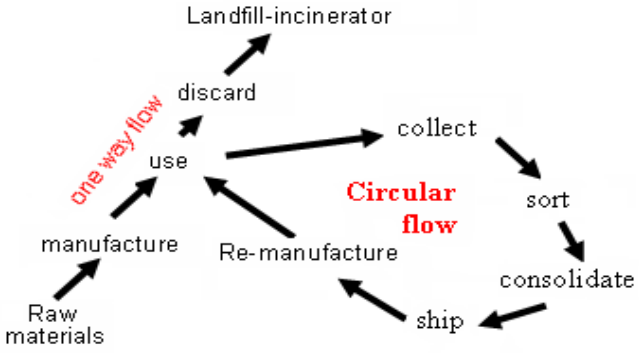

Fig. (4): Circular and linear flows of materials

(IV) Contractor` Role

- Design and plan to Prevent Waste, and develop a Construction Waste Management Plan
- Survey the Site Before Demolition or Deconstruction, Plan for Recyclable Materials
- Identify Reusable or Salvageable Items, all materials should be examined using a precautionary approach to eliminate possible toxicity or future regulatory constraints to their use and disposition.
- Select Salvage Removal Alternatives
- Estimate the Costs and Savings
- Prevent Contamination
- Separating the components will facilitate adaptation and reduce the complexity of deconstruction
- Building contractors need to exercise care during demolition, and should be prepared to re-use suitable materials on projects.

Fig. (5) Reuse –recycle can occur onsite and offsite [xix]

(V) The role of research centers

- Examine the adequacy of recycled materials used with the Egyptian environment.
- Insurance system building against fire, moisture and insects, and the work of all the tests required, and improve the implementation of this new technology.
- Study ways to improve the properties of the construction of the building using this new technology.
- Employment training to create this type of installations.
- the use of certain programs to achieve energy efficiency within enterprises, and may remove energy consumption to the minimum (Zero Energy)
- Monitoring of constraints and variables that occur in the region and draw conclusions to contribute to approve the project with the environment and the needs of the user, the study of the potential physical and technical implementation, and improve the economic viability of the project.

(Vi) The role of Group Capital (investors and businessmen, banks, real estate specialist)

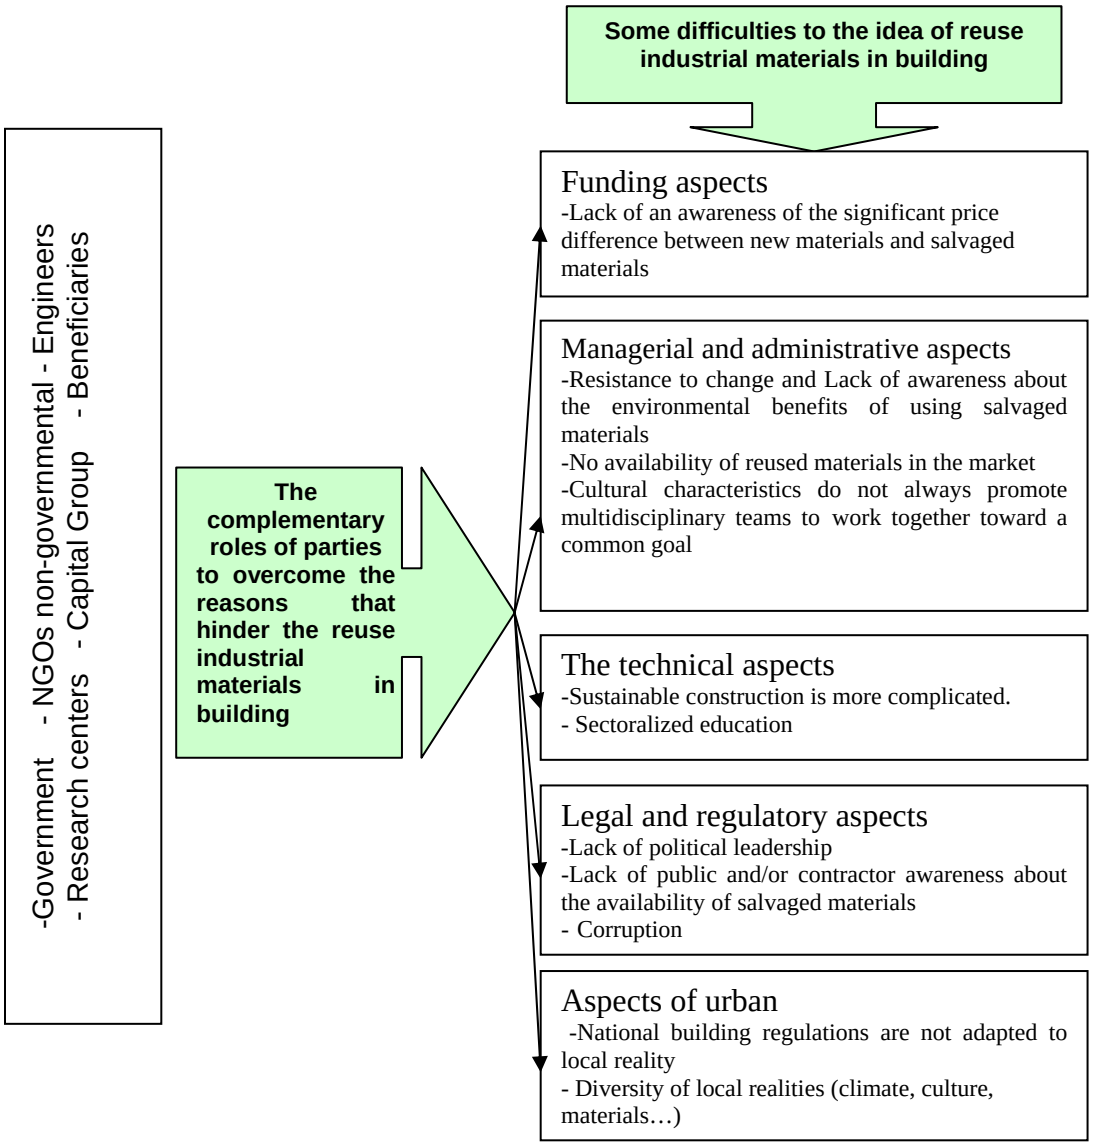
- Develop and/or fund training programs. Subsidize training costs for participants.
- receipt of the site, and provide the necessary potential for re-use of building materials to be used
- coordination between manufacturers and specialists to bring in industrial materials and re-use in construction
- Follow-up after implementation of changes in operations and maintenance

(Vii) The role of beneficiaries / individuals the user is the basis of urban development which is capable of maintaining the physical output, and can be user participation in several areas.

- participate in the implementation of self-help
- participate in the maintenance and improve the local environment
- Participating home improvement loans to upgrade facilities and infrastructure and public services.
- Owners should insist on the use of recycled materials… in the interest of ecologically sustainable development.

6-1-2 Complementarily of roles of parties involved in the process of re-use to remove the causes that hinder the management of such material in Egypt, figure (6).

(a) between industry and regulators to increase the understanding of the beneficial use of industrial materials and regulatory programs; (b) among state regulators to share information and experiences on beneficial use regulations and determination processes; (c) among industries to share experiences on successful reuse and recycling, and to assess the potential to utilize each others' materials, and (d) among researchers, nonprofit representatives, industry, and regulators to share information and concerns regarding risk assessment, beneficial use determinations, environmental safety, and new research.



Fig(6) overcome the reasons that hinder the reuse industrial materials in building in Egypt

6-1-3 Participation of the Parties to the proposed project to achieve sustainable development fields at the actual application of the project.

Integration of the roles of the participants in the process of re-use of industrial materials in construction is conducive to the development of environmental, economic, physical and social**,** figure(7).

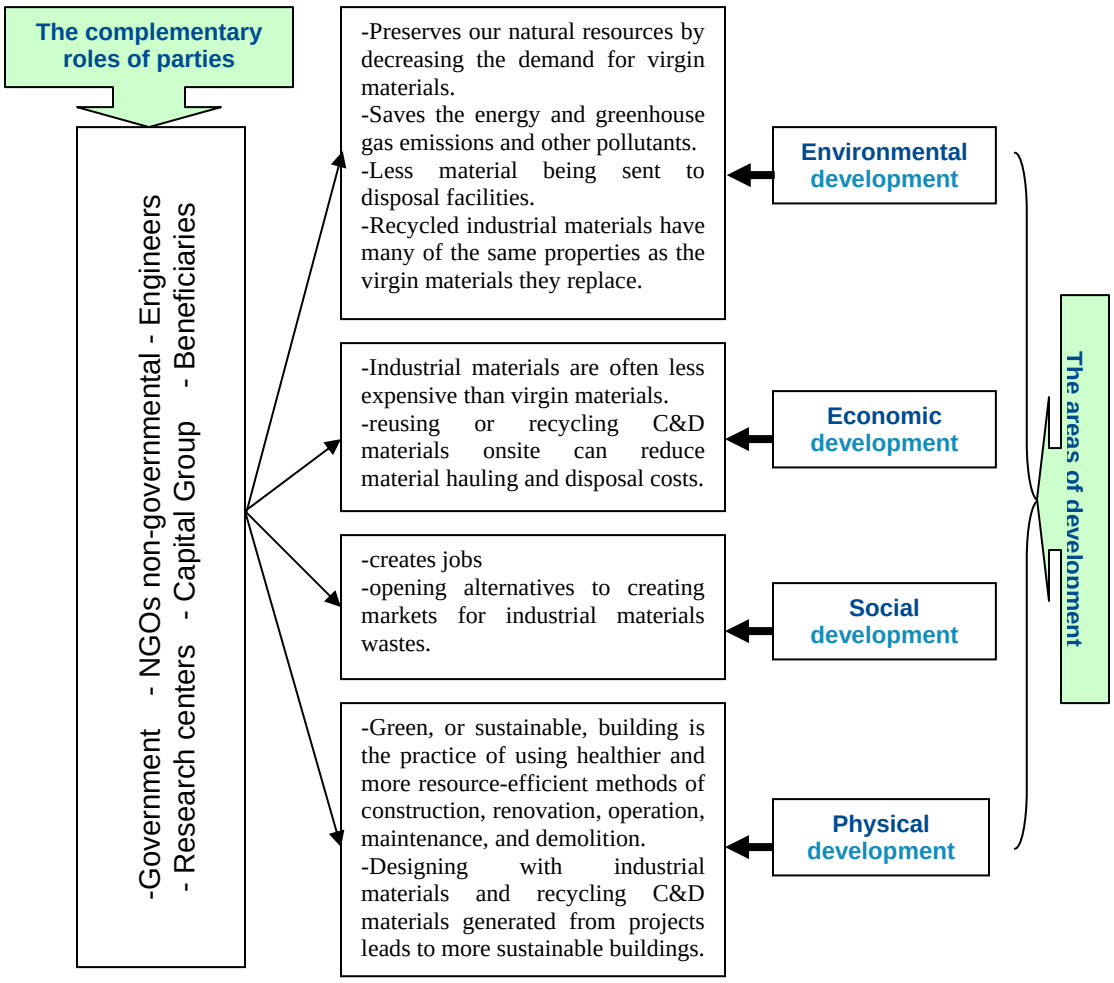


Fig (7) increase the effectiveness of the parties involved in the process of reuse industrial materials in building in various facets of development (environmental, economic, social and physical) for sustainable development

7- CONCLUSIONS

Based on the data collected from the literature su rvey, it is revealed that the production of industrial materials waste is escalating both on the international and national scales. Furthermore, environmental, safety, visual and technical related problems generated from these wastes has severely added to the long-term negative impacts of these wastes on the surrounding environment.

The essence of the recommended guidelines in this paper is to offer systematic procedures that could help in minimizing the magnitude of the industrial materials waste problem in Egypt. Therefore the disposal option can be avoided by the implementation of reuse them in building.

Waste reduction opportunities begin with the earliest choices made in the building process, including architectural design and material selection.

Effectively balancing resource-efficient design concepts requires the attention of skilled and environmentally conscious building professionals. These concepts include waste prevention, durability, and recyclables.

And has been monitoring some of the negatives facing the potential to activate the application of construction materials industry and are summarized as follows:

(1) Limited NGO non-governmental organizations concerned with the field of urban development in general and re-use of industrial materials in particular.

(2) Does not represent low-income housing a sufficient degree of urbanization, culture and enable them to participate in such environmental projects in an effective manner.

(3) Difficulty of maintaining such environmental projects for low-income.

(4) Building design re-use of industrial materials zero energy consumption in Egypt still needs some time.

5. Non-participation of specialists sometimes leads to delays in implementation and increase the cost and other obstacles that may face the project when actual implementation.

8- Recommendations

(1) Increased awareness, acceptance and proactive government policies are critical in order to continue the upward trend of recycling and reusing materials whenever possible

(2) More political support is required to enforce the implementation of waste management scheme in the construction/building field, collect industrial material wastes under the direct supervision of authorities. Imposing a special tax levied on wastes when exceeding a certain level determined by the government.

(3) It is also recommended to extend research on the area of recycling and reusing techniques of industrial materials in building to induct feasibility studies, including cost/benefit and payback period analysis for each technique. The research should survey the Egyptian market and seek the potential possibility of using waste as raw materials in factories. This research should integrate both the construction industry and the manufacturing industry to bridge the gap between the two disciplines.

(4) Overcoming these challenges may require advocacy work to strengthen policies and incentives to reduce construction and demolition waste, intensive education and marketing to expand the demand for reused building materials, as well as smart partnerships and inventory management to keep the right mix of reused materials in stock to meet local demand.

Mitochonderial Cytochrome C Oxidase Subunit 1 (*cox 1*) Gene Sequence of the *Hymenolepis* Species.

Omnia M. Kandil*, Mona S. Mahmoud, Nesreen A.T. Allam, Amira H. El Namaky

Parasitology and Animal Diseases Department, National Research Center, Dokki, Giza, Egypt,
kandil_om@yahoo.com*

Abstract: In the current study, Mitochondrial Cytochrome *c* oxidase gene especially codons within subunit 1 (*cox1*) of *H. diminuta and H. nana* Egyptian isolates from two stages (adult worms and eggs) and hosts origin (human and rat) were amplified, sequenced and aligned. PCR products were approximately 700 bp, 702 bp and 715 bp of *H. nana* rat isolates, *H. diminuta* rat isolates, and *H. nana* human isolates, respectively. Moreover, despite their host susceptibility differences they all gathered in one cluster with three genbank published isolates of *H. nana*; AB033412.1, AB494472.1 and AY121842.1), forming one clade with 100% similarity, which was non significantly decreased on internal nodes. In addition, clearly far away from *H. diminuta* published sequence AB033412.1 who's assumed to be genetically closely related to Egyptian *H. diminuta* than all other *H. nana* isolates. Both Egyptian murine isolates of Hymenolipidid; *H. diminuta* and *H. nana*, were closer to each other than being to *H. nana* of human origin. The annotated sequences of Egyptian isolates were deposited in GenBank under the following accession numbers; *H. diminuta* (GU433102), *H. nana* rat isolate (GU433103), and *H. nana* human isolate (GU433104). Finally, the development of effective control strategies will only be possible if complete understanding of the epidemiology of infection is elucidated.

[Omnia M. Kandil, Mona S. Mahmoud, Nesreen A.T. Allam, Amira H. El Namaky. Mitochonderial Cytochrome C Oxidase Subunit 1 (*cox 1*) Gene Sequence of the *Hymenolepis* Species. Journal of American Science 2010;6(12):640-647]. (ISSN: 1545-1003). http://www.americanscience.org.

Keywords: Hymenolepidid, Phylogeny, Cytochrome *c* oxidase subunit 1 gene (*cox1*), Sequencing.

1. Introduction:

Hymenolepis nana and *H. diminuta* are the most common cestodes in humans, mice, domestic and wild rats (Macko and Hanzelova 2008). It is believed that infections with *Hymenolipis* spp., in general, may have been under diagnosed due to sporadic egg shedding (Thompson et al. 2001; Raether and Hänel 2003). Since isolates of *H. nana* infecting humans and rodents are morphologically identical, the only way they can be reliably distinguished is comparing the parasite in each host using molecular techniques (Macnish et al. 2002a, b).

Mitochondrial (mt) genomes are small (usually less than 20000 bp), circular, and maternally inherited (Boore 1999). In addition to high copy-number per cell which has made them attractive and more tractable targets for characterization, population genetic and phylogenetic studies (Hu et al. 2004; McManus et al. 2004). Regions within the mitochondrial DNA (*mt*DNA) have been proven useful in biology, epidemiology and diagnosis of several parasitic infections of human and veterinary importance (Ngarmamonpirat et al. 2005; Ando et al. 2006). Methods used to obtain data from flatworm *mt* genomes have included DNA sequencing, restriction fragment length polymorphism (RFLP) analysis and single-strand conformation polymorphism (PCR-SSCP) (Boore and Brown 1998; Avise, 2000). Intraspecific sequence variation in coding portions (genes) of the *mt* genomes seems to range from small to moderate, especially when compared with interspecific variation that have demonstrated the deep separations among strains of same species (Littlewood et al. 2008).

Complete or near-complete *mt*DNA sequences are available for 12 species of parasitic flatworms; six cestodes including *Taenia crassiceps* (Le et al. 2000), *Echinococcus multilocularis* (Nakao et al. 2000) and *Hymenolepis diminuta* (von Nickisch-Rosenegk et al. 2001). Cytochrome c oxidase (COX) is a 13-subunit protein complex located on the inner mitochondrial membrane that catalyzes electron transfer, proton translocation processes, production of up to 95% of the energy of eukaryotic living cells (Saraste 1999; Johnston 2006), thus directly influence metabolic performance. *mt cox* sub unit 1 is the most highly conserved among 3 genes coding for cytochrome oxidase, therefore has been employed in several phylogenetic studies (Traversa et al. 2007).

DNA sequencing of informative regions within the gene encoding for the COX1 protein have emphasized specific comparative aspects without yet making a detailed genome description but revealed data for basic and applied potential differential studies on *Hymenolopis* spp. determining host

specificity and transmission patterns (Macnish et al. 2003). Therefore, allow more appropriate approach for control of endemic infestations in Egypt, particular where rodent's population is above control limits and hygienic measures are not strictly applied. Furthermore, for diagnostic purposes since using techniques able to overcome inherent limits of the classical approaches (Constantine 2003; Thompson et al. 2004). Epidemiologically, despite this infection is a hand-to-mouth rote that in general not very pathogenic, however it is extremely difficult to be controlled (Littlewood et al. 2008). Till now education in hygiene is probably the only practical way to reduce the incidence in addition to rodent's eradication (Behera et al. 2008). The genotyping of *Hymenolepis* isolates in different hosts will help in determine host specificity and transmission patterns and thus allow more appropriate approach to control infections in endemic communities. From a public health perspective, a better understanding of the transmission dynamics of a parasite species previously believed to be infective only to rodents will be required to answer questions about the potential for transfer of this parasite to humans and/or animals.

Since control of parasitic disease is dependent on the rapid and accurate detection of causative agents this necessitated traditional techniques being complemented by molecular tools that provide predictive data on genetic variation in and among parasites (Thompson et al. 2004). Thus the present work aims is to characterize, for the first time, partial sequences of *cox1* genes of *H. diminuta* and *H. nana* Egyptian isolates to promote basic knowledge on their *mt*DNA composition, to assess the sequence variation level within local Hymenolepidid from different sources, different developmental stages (adult worms and eggs) and hosts origin (human and rat), and to discuss the potential benefits of such molecular information as record sheets for ecological, epidemiological, transmission and host-parasite interaction and as diagnostic approach of infection in Egypt.

2. Materials and methods

Parasites Samples:

H nana eggs were obtained from infected humans in Endemic Diseases institute. Approximately 2000 *H. nana* eggs were inoculated into 5-week-old male white mice (Movsesyan et al. 2008). Adult worms were dissected from the small intestine approximately 14 days post-inoculation (Tanowitz et al., 2001). *H. diminuta* worms were obtained from naturally infected *norvegicus* rat from Abu Rawash, Giza, Egypt. Rats were killed by cervical dislocation and entire small intestine was removed from gut. The worms and eggs washed repeatedly in phosphate buffered saline (PBS) and stored at -80 ^{o}C until used for DNA extraction.

Isolation of DNA from Adult Worms and Eggs

Templates DNA were purified from *H. nana* and *H. diminuta* using QIAmp tissue purification kit (Qiagen, Hilden, Germany) according to manufacturer's instructions (Macnish et al. 2002a). DNA was eluted in 200 µl Tris-EDTA (TE) buffer and 1 µl of the extract was added to the polymerase chain reaction mix. Single adult worm and/or eggs for each isolate were used for DNA extraction.

Oligonucleotide Primers Design

Entire *mt* genomes of the following species were aligned *Hymenolepis diminuta* (accession number AB033412.1), *Taenia crassiceps* (accession number NC_002547), *T. solium* (accession number NC_004022), *T. asiatica* (accession number NC_004826), *Echinococcus granulosus* (accession number NC_008075), and *E. multilocularis* (accession number NC_000928); and annotated sequence of *Hymenolepis nana* (accession number AF314223.1) (Nakoo et al. 2000, 2002; von Nickisch-Rosenegk et al. 2001). It was not deemed necessary to include all the available sequences from *Taenia* or *Echinococcus* as conservation of alignable positions between genera and being > 30% GC was more important for PCR primer design. PCR primers pair designed *cox1*-F 5`-ACTTCATTGCTTTTGCTTTTTAGA-3` and *cox1*-R 5`-TGCTGTCATAAATGAACCAACAGT-3` were synthesized by Metabion International AG (Martinsried/Deutschland).

PCR Amplification Protocol

Fragments of the mitochondrial cytochrome *c* oxidase subunit 1 gene were amplified using designed primers and each PCR mix was prepared in 50 µl total volume with 1 µl of template (50 ng), 10 pMoles of each primer, 45 µl of Ready TaqMix Complete (Mater Mix, AllianceBio, USA), and nuclease free water (Qiagen, Germany) to complete the total volume of the reactions. PCRs were performed in a PTC-100™ Thermal Cycler (MJ Research Inc., USA) using the following cycling protocol: initial denaturation at 95^{0}C for 3 min and then 40 cycles of 94^{0}C for 1 min 50 sec, 58^{0}C for 1 min 30 sec, and 72^{0}C for 1 min. Final extension was carried out at 72^{0}C for 7 min. A reagent blank was run as control in every PCR procedure. Positive results by PCR were retested on two further occasions several days later to examine the reproducibility of PCR. Amplified products from the PCRs were electrophorised on 1.5% agarose gels

(Bioshop Canada, Burlington, Ontario, Canada) stained with ethidium bromide (0.5 µg/ml) (Bioshop Canada) (Sambrook et al. 1989). A 100 bp ladder (Jena Bioscince, GmbH, Germany) was loaded in each gel then photographed under UV light with gel documentation system.

Sequencing of *cox1* Gene Products

PCR-product of each isolates were purified with QIAquick-spin PCR purification kit (Qiagen, Germany) then directly sequenced from both directions using ABI Prism™ Dye Terminator Cycle Sequencing Ready Reaction Kit (Applied Biosystem, FosterCity, California) according to manufacturer's instructions on a 3130XL Genetic Analyzer (Applied Biosystems). At least two independent PCR products were used for sequencing per isolate.

Sequences Analysis

The resulting aligned output was manually adjusted (Lee et al. 2007). Sequences corresponding to the PCR amplification primers were excluded prior to multiple sequence alignment and phylogenetic analysis. The confirmed sequences were then deposited in the EMBL/GenBank Data Libraries of the NCBI. In order to improve the homology statements out group included *Taenia saginata* (AB465239.1), *T. solium* (AY211880.1), *T. multiceps* (GQ228818.1), *Echinococcus granulosus* (AF314223.1), *E. multilocularis* (AF314223.1) and *Spirometra erinaceieuropaei* (AB374543.1), as well as all annotated sequences of *Hymenolepis diminuta* (AB033412.1) and *Hymenolepis nana* (AF314223.1, AY121842.1, AB494471.1, AB494472.1, AB033412.1, AF314223.1) by Basic Local Alignment Search Tool (nBLAST) (www.ncbi.nih.gov/BLAST/) in the NCBI database (National Center for Biotechnology Information, NIH, Bethesda, Maryland, USA) (Tatusova and Madden 1999). The alignment gaps were treated as missing data. Phylogeny of Egyptian *Hymenolipis nana* and *H. diminuta* human and rat isolates based on *coxI* gene partial sequences and multiple alignment analysis were performed with CLUSTAL W computer program (Thompson e al. 1994).

Phylogeny Construction

The bootstrap consensus tree inferred from 500 replicates is taken to represent the evolutionary history of the taxa analyzed (Felsenstein 1985). Branches corresponding to partitions reproduced in less than 50% bootstrap replicates are collapsed. The percentage of replicate trees and node reliability in which the associated taxa clustered together in the bootstrap test is shown next to the branches (Felsenstein 1985). The tree is drawn to scale, with branch lengths in the same units as those of the evolutionary distances used to infer the phylogenetic tree. The evolutionary distances were computed using the Poisson correction method (Zuckerkand and Pauling 1965) and are in the units of the number of amino acid substitutions per site. All positions containing gaps and missing data were eliminated from the dataset (Complete deletion option). There were a total of 99 positions in the final dataset. Phylogenetic analyses were conducted in MEGA4 (Tamura et al. 2007). Neighbor-Joining and UPGMA methods were used to calculate the evolutionary relationship of the Egyptian isolates with genbank references strains (Saitou and Nei 1987).

3. Results

PCR Products of *mt cox1* Gene

PCR products were amplified from *mt* genomes using synthesized primers set. Across the alignment of *mt* genomes few regions were suitably conserved to allow primer design. The PCR products were approximately 700 bp, 702 bp and 715 bp for *mt cox1* gene of *H. nana* rat isolates, *H. diminuta* rat isolates, and *H. nana* human isolates, respectively, (Figure 1).

Sequences Analysis

Variation occurred in terms of sequence length and nucleotide differences and gaps (nucleotide insertions, deletions, and substitutions), but not G+C percentage where the overall numbers did not differ between amplified fragments; A (23%), C (10%), G (22%) and T (45%). Where Nucleotide alterations were found to be variable and several nucleotide insertions, deletions and substitutions were detected with gaps in the same or different positions (Figure 2).

Phylogeny Construction

Similar topologies were observed in the Egyptian isolates with genbank references strains. Optimal phylogenetic tree with the sum of branch length = 1.91459848 is shown (Figure 3). Egyptian species were genetically distinct from other species used in this study that are phylogenetically relating to Hymenolipidid. In addition, despite their host susceptibility differences they all gathered in one cluster with three genbank published isolates of *H. nana*; AB033412.1 (gi|6045204), AB494472.1 (gi|2262378), and AY121842.1 (gi|2221354), forming one clade with 100% similarity, which was non significantly decreased on internal nodes. Moreover, obviously far away from *H. diminuta* published sequence AB033412.1 (gi|1399136) who's assumed to be quite genetically closely related to Egyptian *H. diminuta* than all other *H. nana* isolates.

Both Egyptian murine isolates of Hymenolipidid; *H. diminuta* and *H. nana*, were closer to each other than being to *H. nana* of human origin.

GenBank accession numbers of Egyptian amplicons

The annotated sequences of Egyptian isolates were then deposited in the GenBank of NCBI under the following accession numbers; *H. diminuta* (GU433102), *H. nana* rat isolate (GU433103), and *H. nana* human isolate (GU433104).

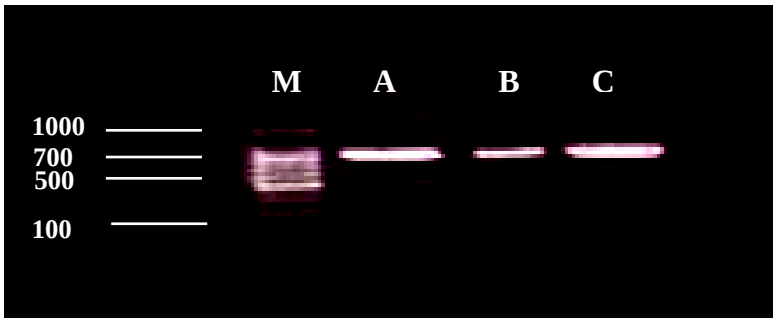

Fig. 1 PCR products of *mt cox1* gene amplified by specified primers pair from Egyptian isolates of (A) *Hymenolipis diminuta* 703 bp fragment, (B) *H. nana* rat isolate 699 bp fragment, (C) *H. nana* human isolate 715 bp fragment, and (M) 100 bp DNA Ladder.

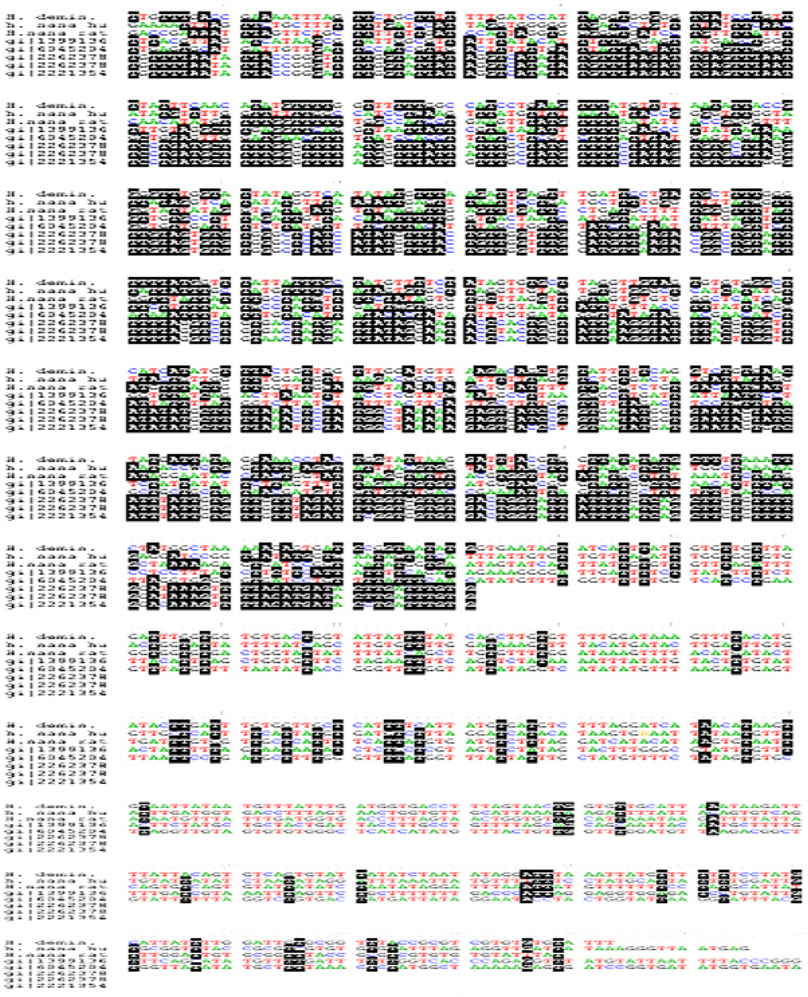

Fig. 2 Nucleotides multiple alignment of partial *mt cox1* gene sequences of Egyptian *H. diminuta*, *H. nana* human isolate, *H. nana* rat isolate, and reference gi|13991366: *H. diminuta*, gi|226237884: *H. nana* isolat: HnanaMon, gi|22213549:*H. nana*, gi|6045204: *H. nana*, gi|14009612: *Echinococcus granulosus* genotype 1, gi|15042575: *Echinococcus equinus* , gi|193884329: *Spirometra erinaceieuropaei*, gi|239997751: *Taenia multiceps*, gi|28856111: *Taenia solium*, and gi|260162222: *Taenia saginata*, isolate: TsagT017KANTH. Black columns represent identical nucleotide sequences between aligned isolates.

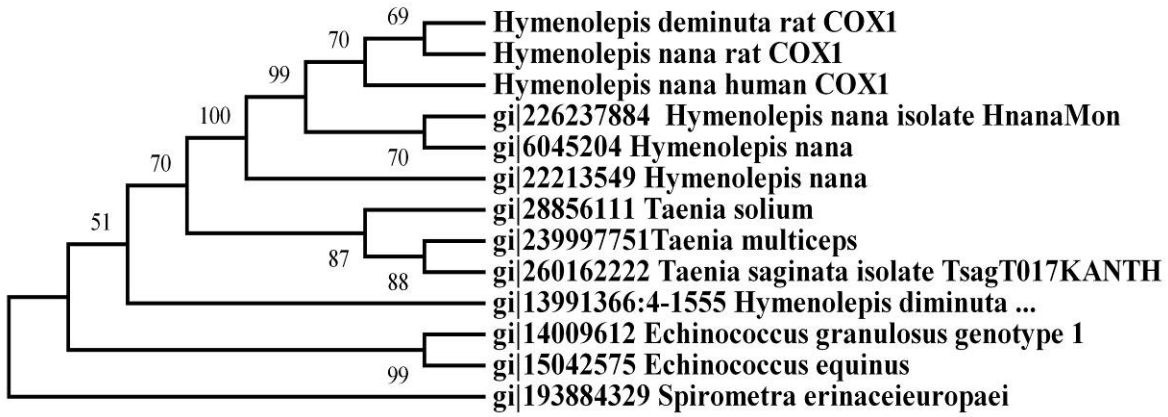

Fig. 3 Rooted phylogenetic tree based on amino acids sequences of in silico translated partial *mt cox1* gene sequences of Egyptian *H. diminuta, H. nana* human isolate, *H. nana* rat isolate and reference gi|13991366: *H. diminuta*, gi|226237884: *H. nana* isolate: HnanaMon, gi|22213549: *H. nana*, gi|6045204: *H. nana*, gi|14009612: *Echinococcus granulosus* genotype 1, gi|15042575: *Echinococcus equinus*, gi|193884329: *Spirometra erinaceieuropaei*, gi|239997751: *Taenia multiceps*, gi|28856111: *Taenia solium*, and gi|260162222: *Taenia saginata*, isolate: TsagT017KANTH. Similar topologies were developed when both Neighbor-Joining and UPGMA methods were applied (MEGA4 software).

4. Discussion:

Mitochonderia play a central role in metabolism, apoptosis, disease, and aging (Le et al. 2002). They are the site of oxidative phosphorylation, essential for the production of ATP, as well as a variety of other biochemical functions. Within these subcellular organelles is a genome, separate from the nuclear chromatin, referred to as mitochondrial DNA (mtDNA), very commonly used in studies of molecular phylogenetics (Avise 2000). Flatworm mitochondrial genomes have a number of distinct features including all genes are coded on the same strand (von Nickisch-Rosenegk et al. 2001), utilize a unique mitochondrial genetic code (Boore 1999) and truncated stop codons have also been found among a number of genes (Nakao et al. 2000, 2003).

In the current study the earliest genbank records of *cox1* gene of Egyptian *Hymenolepis* spp. are declared. So far, only a few is known about the relative divergence rates of mitochondrial DNA in *hymenolipis species* especially Egyptian isolates (Vilas et al. 2005), hence only one species belonging to *H. diminuta* is completely sequenced and published in genbank (Littlewood et al. 2008). However, PCR technology and DNA sequencing techniques permit the identification of species, strains, and populations from any stage in their life history to distinguish among morphologically similar parasites (Boore 1999).

Egyptian species were genetically distinct from other species used in this study that are phylogenetically relating to Hymenolipidid. Both Egyptian murine isolates of Hymenolipidid; *H. diminuta* and *H. nana*, were closer to each other than being to *H. nana* of human origin. WHO annual reports maintained the traditional host specificity of hymenolepidid till few years ago (Lee et al. 2007). Unfortunately, the unexpected discovery of a mixed infection with specie which is known to infect rodent as definitive host in surveyed individuals (Thompson et al. 2001; Macnish et al. 2003) as well as in dogs living in the same locality as their infected owners declared the public health impact of new infections, and meditating urgent thorough understanding of the epidemiology of these parasites (Jenkins and Andrew 1993; Thompson et al. 1993; Macnish et al. 2003). Since such deviation in patency of infection was not previously recorded thus highlights the growing importance of using molecular techniques in both the detection and characterization of parasite species in human and animals' populations especially between morphologically similar species (Okamoto et al. 1997; Nakao et al. 2000; von Nickisch-Rosenegk et al. 2001; Macnish et al. 2003).

In a comparison of genetic makeup, our result suggests that *cox1* gene is generally conserved by each isolate nucleotide sequence analysis. Despite of variation occurred in terms of sequence length and nucleotide differences and gaps (nucleotide insertions, deletions, and substitutions), but not G+C percentage where the overall numbers did not differ between amplified fragments mostly triggered by a variety of hosts' biological conditions (Macnish et al. 2002a, b). Such data showed consistent patterns with other researcher groups in this regard. They reported that mitochondrial DNA sequences of the Platyhelminthes accumulate nucleotide substitutions at a much higher rate than sequences in comparisons

of genetic distances (Littlewood and Bray 2001; Vilas et al. 2005). Base substitutions and additions are characterized by high T content which can, at times, represent poly-T structures. In addition, this may be a consequence of frame-shift mutations or premature stop codons, however, protein-coding genes of the *mt*DNA are error-checked by translating the nucleotide sequences (Benasson et al. 2001). Specific substitution rates include metabolic rates and body mass, generation time, differential fixation of slightly deleterious mutations, DNA repair mechanisms, and nucleotide composition (Vilas et al. 2005).

According to the inferred topology of amino acids phylogeny of Egyptian hymenolipidid, hosts effect on the evolutionary relationship between isolates was clear despite their intra species differences which agree with Johnston (2006). This could explain the closer relation of *Hymenolipis* spp. (*H. nana* and *H. diminuta*) collected from rat to be arranged in one cluster despite the disparities in host species and morphology which is in continence with Littlewood et al. (2008). These results agree with previous reports supported variant biological features of *H. diminuta* that are not always identical between isolates is built on genetic background (Okamoto et al. 1997). However, there results are conflicting with both the characteristic cryptic species of *H. nana* (Macnish et al. 2002a, b), and Schmidt classification where *H. nana* should be closer to *H. microstoma* than *H. diminuta* (Schmidt 1986). These observations that were revealed from the present study which should not be applied unambiguously to host-parasite associations since it does not take into consideration other factors related to the ecology of the hosts and the dynamics of the host-parasite assemblages (Johnston 2006). However, it should highlight the danger of triggering changes in genetic interspecificity subsequently definitive host susceptibility. Since, *mt cox1* resultant phylogenetic tree did not support the current hypotheses on the basis of morphological evidence for the separation of species (Littlewood et al. 2008).

In conclusion, molecular protocol developed in this study will provide the tools for achieving supplementary comprehensive epidemiological portrait of infection in Egypt. Consequently, should be applied on much broader scale in screening for *Hymenolipis* spp. infections. Sufficient clarification of evolutionary relationship of *Hymenolipis* spp. by other ribosomal DNA content, and complete *mt* genome sequencing and its genes arrangement are essentials. These data will ultimately aid investigations on dynamics of morphological and developmental evolution, as well as the biology of parasitism.

Abstract: Acrylamide was copolymerized with acrylic acid at different ratios using potassium persulphate initiation system in presence of a crosslinking agent and different doses of silver nitrate to yield hydrogels containing silver nanoparticles upon post treatment with sodium hydroxide. Swelling capacity and kinetics of swelling of these hydrogels were studied. Size and distribution of the nanoparticles and their dependence on acrylamide / acrylic acid ratios as well as on the dose of silver nitrate were also studied using Transmission Electron Microscopy (TEM). Furthermore, the antimicrobial and antifungal activities of the hydrogels in correlation with TEM results were reported. Hydrogels samples having relatively large number of Ag nanoparticles and widely distributed smaller particle size inhibit bacterial and fungal growth.

Asem. **Synthesis and Characterization of Poly (Acrylamide - co - Acrylic acid) Hydrogel Containing Silver Nanoparticles for Antimicrobial Applications.** Journal of American Science 2010;6(12):648-656]. (ISSN: 1545-1003). http://www.americanscience.org.

Key words: hydrogel; silver nanoparticles; kinetic study; antimicrobial activity.

1. Introduction:

By definition, hydrogels represent polymeric networks capable of absorbing large quantities of water, but remain insoluble due to chemical or physical crosslinks between individual polymeric chains [1]. Recently, there is a great deal of interest concerning the production of nanoparticles in the hydrogel networks since they have enormous valuable applications in bio-related fields [2]. Indeed the design and development of nanoparticles and nanostructural materials have opened a new era for constructing well designed nanostructures that have been considered as a novel class of materials for catalytic, optical, electronic and biomedical application.

Previous studies concerned with metal nanoparticles especially those of silver, gold and copper were found to exhibit resistance to microorganisms [3, 4]. It was also reported that among these nanoparticles, nanosilver displayed acceptable antimicrobial properties [5, 6]. Nanosilver particles were introduced to a wide range of medical applications and water purifying systems [7, 8]. Silver nanoparticles proved to be non-toxic and eco-friendly antibacterial agents. The problem of their weak binding properties was overcome via preparation of stabilized nanoparticles in a polymer, notably hydrogel networks where the nanoparticles were embedded therein [9, 10].

Gels of importance are of polymeric nature due to the possibilities they offer to design systems with well defined and controlled properties. Silver and silver ions have long been known to have strong inhibitory and anti bacterial effects as well as a broad spectrum of antimicrobial activities [11]. But silver is expensive and the antibiotic introduction in the last century made it out of use. In recent years, however, the nanoscale techniques were developed for producing silver nanoparticles which may assist the medical use resurgence of silver, especially in applications where fighting germs is a concern.

Silver nanoparticles, which have a high specific surface area and a high fraction of surface atoms, have attracted the attention of the industry because of their unique characteristics, high efficiency and antimicrobial activity, even at low concentrations [12, 13]. The exact antimicrobial mechanism of silver is not well established; however, it was reported that the free silver ion is the active agent, combining the thiol (SH) groups, which leads to the protein inactivation [14]. There is evidence that antibacterial potency of silver is directly proportional to the concentration of silver ions in the medium [15–16].

Polymer nanocomposite containing metal nanoparticles can be prepared by several methods. Methods used for preparation comprise mechanical mixing of a polymer with metal nanoparticles, the in situ polymerization of a monomer in the presence of metal nanoparticles and the in situ reduction of metal salts or in a polymer [17]. Copolymeric hydrogel networks are composed of two or more different monomer species with at least one hydrophilic component, arranged in a random, block or alternating configuration along the chain of the

polymer network. The copolymeric hydrogel networks are generally covalently or ionically crosslinked structures, which are not water soluble.

In the present work, in situ synthesis of silver nanoparticles within swollen hydrogel networks is undertaken. Thus, copolymer gels were prepared by simultaneous polymerization of acrylamide (AAm) and acrylic acid (AAc) using potassium persulphate (KPS) as free radical initiator and N,N`-methylenebisacrylamide (MBA) as crosslinking agent in presence of silver nitrate. Swelling behavior and swelling kinetics of the so obtained hydrogels were evaluated. Distribution of the silver nanoparticles through their characterization within the hydrogels using TEM was studied. Also studied were the antibacterial and antifungal activities of the hydrogels under investigation.

2. Experimental

2.1. Materials

Acrylamide (AAm) and acrylic acid (AAc) in the monomeric form were provided by Sisco Research Lab. PVT. LTD, India; while N,N`-methylenebisacrylamide (MBA), crosslinking agent, potassium persulphate (KPS), initiator and silver nitrate (AgNO3) were supplied by Sigma – Aldrich, Inc. These reagents were used as laboratory grade chemicals.

Escherichia coli NRRL B-210 (Gram -ve bacteria), *Bacillus subtilis* NRRL B-543 and *Staphylococcus aureus* (Gram +ve bacteria), *Candida albicans* NRRL Y-477 (Fungi) were obtained from Northern Utilisation Research and Development Division, U.S. Department of Agricultural Peoria, Illinois, USA.

2.2. Procedures

2.2.1. Preparation of Ag nanoparticles

Hydrogel loaded with silver nanoparticles were prepared according to the procedure described elsewhere [17]. The hydrogel disks were prepared by free radical aqueous copolymerization of AAm and AAc in presence of MBA as crosslinker and KPS for initiating the polymerization system. A weighed amount of $AgNO_3$ was dissolved in double distilled water; desired amounts of AAm/AAc and MBA were added and the final volume was made 10 ml. A certain amount of KPS was dissolved and the whole reaction mixture was transferred to the test tube and then heated gently up to 70°C for 30 minutes. The test tube was broken and the resulting hydrogels were cut into slices of same thickness and then washed thoroughly with double distilled water. The hydrogel was then added to an aqueous solution of NaOH (5 wt %), and kept overnight till complete reduction of Ag^+ ions as indicated by faint yellow color of the colloidal Ag nanoparticles within the hydrogel network, washed several times in double distilled water and kept therein till complete swelling.

Blank experiment (omitting Ag^+ ions) and Ag/PAAm/AAc hydrogel prepared using different molar ratios of AAm/ Ag^+ ions were also performed. The prepared hydrogels were air-dried followed by vacuum drying and kept for characterization. Table I contains the monomers ratios and silver nitrate doses used throughout nanosilver hydrogel composite preparation.

Table I: Monomers ratio and silver nitrate dose.

Sample	AAm/AAc Ratio (g/g)	Silver nitrate dose (g/g monomer mixture)
HG_o (Blank)	50/50	------
HG_1	100/0	0.01
HG_2	70/30	0.01
HG_3	50/50	0.01
HG_4	30/70	0.01
HG_5	0/100	0.01
HG_6	50/50	0.02
HG_7	50/50	0.03
HG_8	50/50	0.04

1.3. Characterization

2.3.1. Swelling studies

The swelling characteristics of the prepared hydrogel were measured through gravimetric analysis [18]. The dried samples were placed in 50 ml of distilled water at room temperature (25 ± 1 ^{0} C) and taken from water at regular time intervals. The surface water on the swollen hydrogel was removed by soft pressing the sample between the folds of a filter paper; an increase in weight was recorded. The swelling equilibrium of the gels was determined as follows: gels were dried for a day at room temperature and were then dried in vacuum at 60°C. After the weight of the dried samples was determined, the samples were equilibrated in distilled water for 3 days at room temperature and then weighed again. The swelling ratio (S) and equilibrium swelling ratio (S_{eq}) were determined and calculated by application in the following equations [17]:

$$S(g/g) = \frac{W_t - W_o}{W_o} \quad (1)$$

$$S_{eq}(g/g) = \frac{W_{eq} - W_o}{W_o} \quad (2)$$

Where, W_o, W_t, and W_{eq} are the weights of the

samples in the dry state, the swollen state at a certain time, and the completely (equilibrium) swollen state, respectively.

2.3.2. Antimicrobial assay

The prepared hydrogel samples were screened in vitro for their antimicrobial activities against *Escherichia coli* NRRL B-210 (Gram -ve bacteria), *Bacillus subtilis* NRRL B-543 and *Staphylococcus aureus* (Gram +ve bacteria), *Candida albicans* NRRL Y-477 (Fungi).

The agar diffusion method [19] was used for this purpose. Bacteria and fungi were maintained on nutrient agar and Czapek's-Dox agar media, respectively. The assay medium flasks containing 50 ml of nutrient agar for bacteria and Czapek's-Dox agar medium for fungi respectively were allowed to reach 40-50^{o}c to be incubated with 0.5ml of the test organism cell suspension.

The flasks were mixed well and poured each into a Petri dish (15 x 2 cm) and allowed to solidify. After solidification, holes (6 mm diameter) were made in the agar plate by the aid of a sterile cork poorer. The prepared hydrogel samples were cut to small pieces and allowed to swallow using sterile distilled water then left on agar surface. The Petri dishes were kept at 5°C for 1 hour to allow diffusion of the samples through the agar medium and retard the growth of the test organism. Plates were incubated at 30 ^{o}C for 24 hours for bacteria and 72 h of incubation at 28 ^{o}C for fungi. The diameter of the resulted inhibition zone was measured in mm [19].

2.3.3. Transmission Electron Microscopy (TEM)

Images for the blank hydrogel and nanosilver hydrogel composites were recorded using a JEOL JEM-1230 electron microscope operating at an acceleration voltage of 100 kV. Specimens for TEM were prepared by the placement of a swollen sample of hydrogel on a 400-mesh copper grid followed by evaporation of excess water in air under ambient conditions (25 ± 1^{o}C).

3. Results and Discussion

The concept of producing nanoparticles in the networks of hydrogel systems was recognized as an important approach due to its direct applicability in various biomedical applications. That is why, a number of composite systems were evaluated [20]. The P(AAm-co-AAc)/silver nanoparticles hydrogels prepared as described above were investigated. In accordance with previous reports [17] the free network spaces between hydrogel networks reserve and stabilize nanoparticles. Moreover, the in situ reduction of metal ions and the stabilization of particles can be verified by the following: (a) metal ions are attached to reactive sites of hydrogel networks, and larger amounts of these ions are embedded in the network spaces of hydrogels; (b) the reduction process proceeds under the action of sodium hydroxide; and (c) the resulting particles are well stabilized through the hydrogel network interspaces**.**

3.1. Swelling behaviour

Swelling experiments were carried out with a view of evaluation the swelling capacity of the hydrogels under investigation in distilled water. Results of these experiments indicated that the increase in weight of the swollen hydrogels is directly related to the duration of swelling. The swelling behaviour observed could be associated with the absorption mechanism, which, in turn, is determined by the diffusion process.

Figure 1 illustrates the effect of AAm /AAc ratio in presence of silver nanoparticles on the swelling characteristics of the prepared hydrogel. It is evident that the swelling ratio increases sharply upon prolongation of swelling time up to ca 60 minutes then levels off. It was also observed that the swellability of the prepared hydrogel increases at higher concentrations of Polyacrylic acid (PAAc) ratio in the matrix. This is expected since abundance of the hydrophilic groups of AAc causes an improvement in the swelling characteristics of the hydrogel prepared under these conditions.

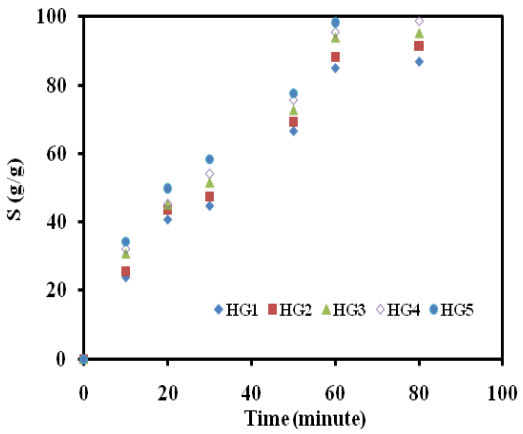

Figure 1: Effect of variation in AAm/AAc ratio on the swelling behavior of P(AAm-co-AAc)/silver nanoparticles hydrogel at different swelling durations

3.2. Kinetic study of swelling

The swelling kinetics of the prepared hydrogel was undertaken with view of clarifying the controlling mechanism of the swelling processes. This was visualized through kinetic models. The

latter were used to examine the results concerning swelling efficiency of the prepared hydrogels at different durations derived from the experimental work. A simple kinetic analysis represented by a second-order equation was applied in this study using the following relationship [17]:

$$\frac{dS}{dt} = k_s (S_{eq} - S)^2 \qquad (3)$$

Where:

k_S is the swelling rate constant and,
S_{eq} is the degree of swelling at the state of equilibrium.

After integration, when the initial conditions S = 0 at t = 0 and S = S at t = t, are applicable, equation (3) is modified to be as follows:

$$\frac{t}{S} = A + Bt \qquad (4)$$

Where

$A = 1/k_S.S_{eq}^2$ is the reciprocal of the rate of swellin at the initial state $[(dS/dt)_o]$ of the hydrogel, $B = 1/S_{eq}$ is the inverse of the maximum or equilibrium swelling and, k_S represents the swelling rate constant.

The kinetic models were examined by plotting **t/S** vs. **t** for the HG_1, HG_2, HG_3, HG_4 and HG_5. Figure 2 shows the linear regression of the swelling curves obtained by means of Equation 4 for the P(AAm –co-AAc)/ silver nanoparticles hydrogels in question. The initial swelling rate (r), the swelling rate constant (k_S) and the values of theoretical equilibrium swelling $(S_{eq})_{max}$ of all hydrogels were calculated from the slope and the intersection of the lines. The results are presented in Table II.

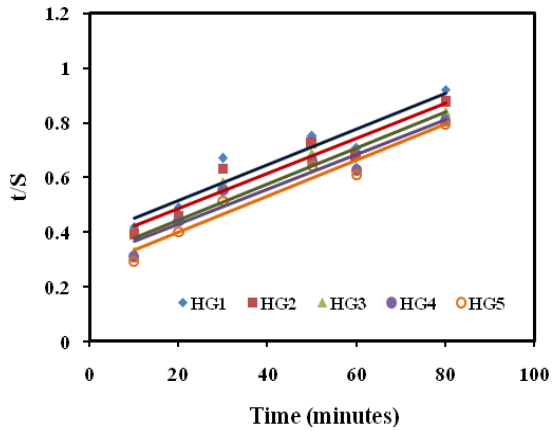

Figure 2: Swelling kinetic relations of P(AAm-co-AAc)/silver nanoparticles hydrogels at different ratios of AAm/AAc.

When a hydrogel is brought into contact with water, water diffuses and the hydrogel swells. Diffusion involves migration of water into pre-existing or dynamically formed spaces between hydrogel chains. Swelling of the hydrogel involves larger scale segmental motion resulting, ultimately, in an increased distance of separation between hydrogel chains. Analysis of the mechanisms of water diffusion in swellable polymeric systems is of prime importance due to applications of swellable polymers in the biomedical, pharmaceutical, environmental, and agricultural engineering fields. The swelling mechanism of the samples was determined by applying in the following equation **[17]:**

$$S\ (g/g) = \frac{[W_t - W_0]}{W_0} = Kt^n$$

Where

K is the swelling constant and
n is the swelling exponent calculated from the slopes of the lines of Ln(S) – Ln(t) plots.

For cylindrical shapes, n = 0.45-0.50 and corresponds to Fickian diffusion, whereas $0.50 < n < 1{:}0$ indicates that diffusion is non-Fickian. This equation is applied to the initial stages of swelling and plots of Ln(S) versus Ln (t) yield straight lines. For the hydrogels, Ln(S) versus Ln (t) plots was drawn using the kinetics of swelling and some representative results are shown in Figure 3. The swelling exponents ***n*** were calculated from the slopes of the lines and are listed in Table II. The values of the diffusional exponent range are generally between 0.5405 and 0.6387. Hence, the diffusion of water into P(AAm –co-AAc)/silver nanoparticles hydrogels had a non-Fickian character. The value of ***n*** higher than 0.5 indicating diffusion of water to the interior of all the hydrogels, follows an anomalous mechanism. The anomalous behaviour of the hydrogel is due to the regularity of the chain and strong interaction via the formation of hydrogen bonding, leading to a compact structure which would prove the anomalous aspects of diffusion even for a molecule as small as water [17].

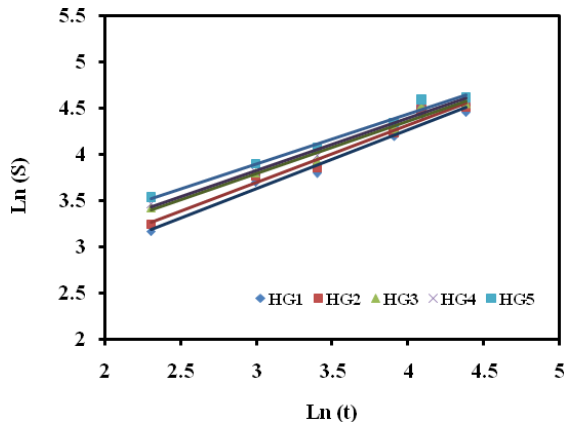

Figure 3: Swelling kinetic relations of P(AAm-co-AAc)/silver nanoparticles hydrogel at different ratios of AAm/AAc.

Non-Fickian diffusion processes have been thoroughly investigated [**21-24**]. Depending on the relative rates of chain relaxation and diffusion, non-Fickian diffusion has been classified into: "Case II transport" and "Anomalous transport" (Figure 4). Case II transport is dominated when the diffusion is very rapid compared to relaxation ($R_{diff} >> R_{relax}$), with relaxation occurring at an observable rate. Here, the rate of mass uptake is directly proportional to time. The anomalous transport is observed when the diffusion and relaxation rates are comparable ($R_{diff} \approx R_{relax}$).

Since most polymers swell when they are in contact with certain solvents, Fick's laws should be applied with modified boundary conditions and/or a generalized diffusion coefficient to address the non-Fickian behavior. An explanation of the swelling mechanism of the prepared hydrogels through their non-fickian characteristics can be illustrated by the scheme represented in Figure 4 **[25].**

Table II: Some Swelling Parameters of P (AAm-co-AAc)/silver Nanoparticles Hydrogel.

Swelling parameter	AAm / AAc Ratio				
	100/0	**70/30**	**50/50**	**30/70**	**0/100**

3.2. Antimicrobial study

A recent study indicated that the bactericidal effect of silver nanoparticles mostly depends on the size of particles where silver nanoparticles having smaller sizes are more efficient and concluded that 1-10 nm have a direct interaction with bacteria [26]. The antibacterial activity is a manifestation of the release of silver nanoparticles from the Ag/PAAm-co-AAc hydrogel. Silver nanoparticles exhibit relatively large surface area, thus increasing their contact with bacteria or fungi. Silver nanoparticles show powerful bactericidal activity by binding with microbial DNA, thereby preventing bacterial replication.

P(AAm-co-AAc) hydrogel (HG_o) showed no inhibition zone. Results of the antimicrobial activity test against *Escherichia coli* (Gram -ve bacteria) and *Bacillus subtilis* (Gram +ve bacteria) showed that HG_3, HG_6 and HG_8 have an antibacterial activity while the HG_o were generally inefficient. Table III represents the antimicrobial activity of the prepared hydrogels with different doses of silver nitrate upon

the selected bacteria and fungi, while figure 5 shows the growth of bacteria in a Petri dish containing hydrogels with different silver doses.

Table III: In vitro antimicrobial activity by agar method diffusion of tested materials

Sample in vials	*Candida albicans*	*Escherichia coli*	*Staphylococcus aureus*	*Bacillus subtilis*
HG_o	-	-	-	--
HG_3	+	+	+	+
HG_6	+	+	+	+
HG_8	+	++	++	++

+ve, zone of inhibition 10 mm or less

++ve, zone of inhibition 20 mm or less

-ve, no inhibition.

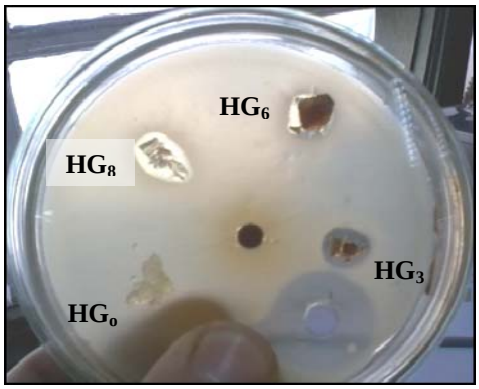

Figure 5: photograph showing the effect of nanocomposite upon bacterial activity

The same holds true for experiments carried out in parallel lines with fungi where silver nanoparticles derived from the prepared hydrogels show antifungal activity against *Candida albicans* as compared with the inactive blank sample HG_o.

The inhibition area follows the order: $HG_8 > HG_6 > HG_3$ as shown in Figure 9.This behaviour is expected where abundance and small sizes of silver nanoparticles (1-12 nm) in the prepared hydrogels are responsible for inhibition of bacterial and fungal growth.

3.3. Transmission Electron Microscopy

The size and morphology of silver nanoparticles formed on the P(AAm-co-AAc) hydrogel were determined through TEM imaging. Figure 6 represents a micrograph of a blank sample of, HG_o, of P(AAm-co-AAc) hydrogel in absence of silver nanoparticles.

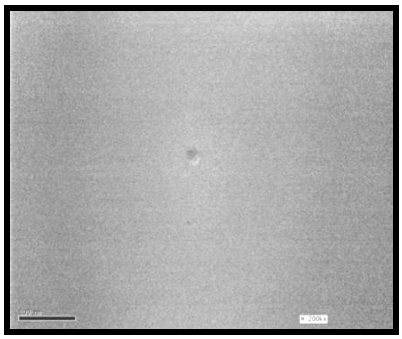

Figure 6: **TEM micrograph of P(AAM-co-AAc) hydrogel**

Figures 7-A, 8-A and 9-A represent images of micrographs for P(AAm-co-AAc) hydrogel/silver nanoparticles; referred here as HG_3, HG_6 and HG_8 using 0.01, 0.02 and 0.04 g silver nitrate respectively in preparation of these hydrogels. TEM micrographs revealed varieties in distribution of silver nanoparticles.

Careful examination of the images showed the silver nanoparticles with different variable sizes as well as smaller polydispersed particles. It should be noted, however, that the majority of the silver nanoparticles were scattered, a few of them showing aggregates indicating stabilization of the nanoparticles. The results represented by TEM images concluded that the particle size of individual nanoparticles seem to be 1-12 nm, whereas majority of silver nanoparticles exhibit smaller sizes.

Histograms of size distribution derived from TEM images for hydrogels HG_3, HG_6 and HG_8 are shown in figures 7-B, 8-B and 9-B. A detailed correlation between particle size and size distribution for each of these hydrogel systems is given below:

Figure 7-B shows the size range of silver nanoparticles formed on hydrogel; HG_3 prepared in presence of 0.01g silver nitrate. Sizes of these nanoparticles lie within the range 1-7 nm. TEM micrographs revealed also that a size range of 3-4 nm is prevailing. Size distribution of silver nanoparticles embedded in hydrogel HG_6 prepared under the action of 0.02 g silver nitrate as shown in Figure 8-B was found to be in the range of 1–12 nm. Nanoparticles having sizes ranging from 6-12 nm constitute the largest percentage within the specimen examined. Moreover, increasing the concentration of silver nitrate up to 0.04 g causes a considerable increase in the amount of silver nanoparticles with smaller sizes; 1-3 nm with some particles sized 4-5 nm and a low percentage of nanoparticles having sizes within the range of 6-12 nm. This is rather clarified by the data of the histogram represented in Figure 9-B.

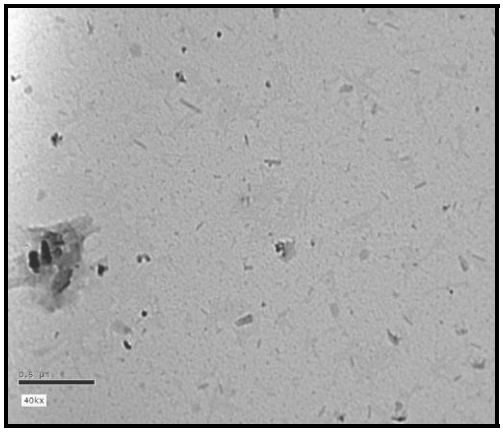

Figure 7-A: TEM micrograph of P(AAM-co-AAc)/ silver nanoparticles hydrogel prepared using 0.01g $AgNO_3$

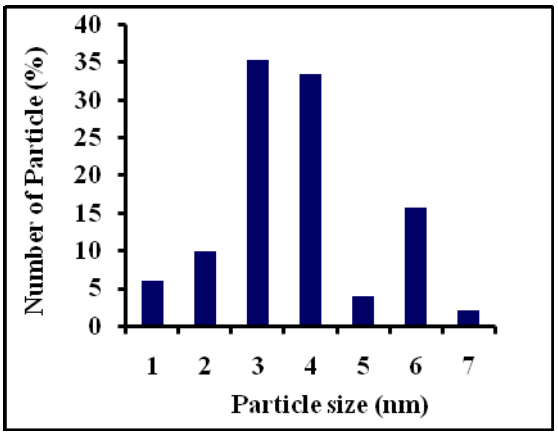

Figure 7-B: Histogram illustrating size distribution of silver nanoparticles via TEM micrograph of hydrogel prepared using 0.01g $AgNO_3$

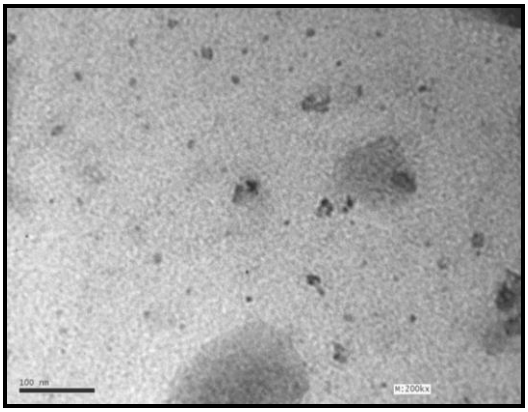

Figure 8-A: TEM micrograph of P (AAM-co-AAc)/ silver nanoparticles hydrogel prepared using 0.02g $AgNO_3$

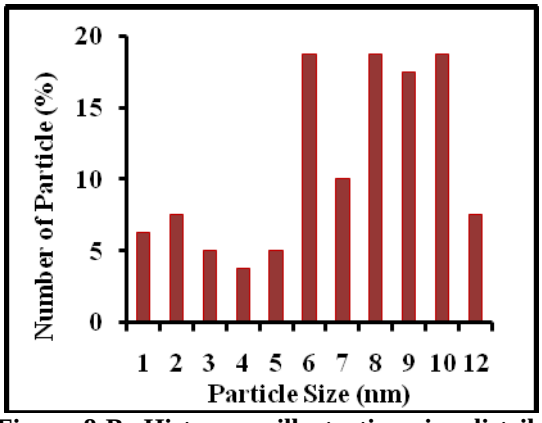

Figure 8-B: Histogram illustrating size distribution of silver nanoparticles via TEM micrograph of hydrogel prepared using 0.02 g $AgNO_3$

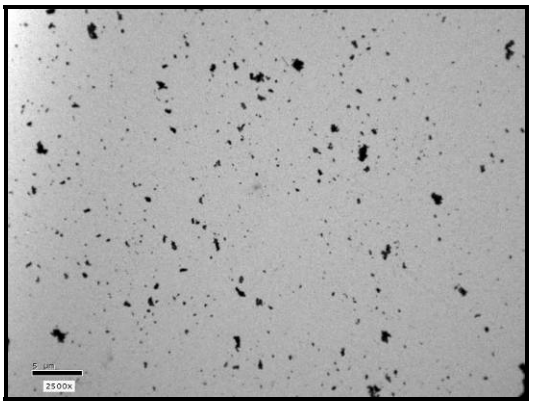

Figure 9-A: TEM micrograph of P (AAM-co-AAc)/ silver nanoparticles hydrogel prepared using 0.04g $AgNO_3$

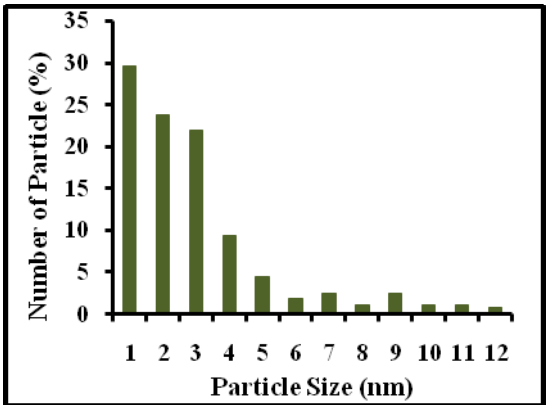

Figure 9-B: Histogram illustrating size distribution of silver nanoparticles via TEM micrograph of hydrogel prepared using 0.04 g $AgNO_3$

3.4. Antimicrobial activity and TEM micrographs

Correlation of the data of antimicrobial activity with those of TEM for hydrogels under investigation, conceive that both size and number of silver nanoparticles play an important role in the inhibition of bacterial and fungal growth. This can be exemplified by the study on sample HG_3 as shown by Figures 7-A and 7-B and Table III where low number and small size of silver nanoparticles resulted in a small inhibition zone, i.e. poor antimicrobial activity. Small sizes and larger number of silver nanoparticles observed with HG_6 sample, as shown in Figures 8-A and 8-B and Table III caused a slight improvement in bacterial and fungal inhibition.

On the other hand, hydrogel sample HG_8 exhibited a comparatively larger number of silver nanoparticles having widely distributed smaller particle sizes as illustrated by Figures 9-A and 9-B. The efficiency of this hydrogel sample to inhibit bacterial and fungal growth revealed a wide and distinct inhibition zone. This was confirmed by the data given in Table III.

It can be concluded that the results of TEM imaging of the prepared hydrogels are in accordance with those arrived at from the antimicrobial activities of these hydrogels.

4. Conclusion

P(AAm-co-AAc) hydrogels containing silver nanoparticles were successfully prepared via a free radical copolymerization, in presence of silver nitrate at varying doses along with concurrent, crosslinking and reduction of Ag^+ ions to develop silver nanoparticles in the hydrogel matrix. The swelling capacities of the resulting hydrogels were evaluated. Swelling was found to be directly related to swelling duration and AAm/AAc ratio used in the polymerisation process. Kinetic studies of swelling concluded that the diffusion of these hydrogels was of the non-Fickian type.The hydrogel products were also characterized for size distribution of silver nanoparticles through examination of micrographs and histograms obtained using TEM. Antimicrobial activity of these hydrogels was also investigated. Correlation of TEM results with those of the hydrogel capability to inhibit bacterial and fungal growth was made and confirmed that small sizes and abundance of silver nanoparticles determine the antimicrobial activity of the hydrogel.

Novel Switching H_2/H_∞ Control: Combination of Dwell Time Switching Signal and Multiple Lyapunov Function

Fatemeh Jamshidi [1], Mohammad Taghi Hamidi Beheshti [1]

[1] Communication and Control Lab, School of Computer and Electrical Engineering, Tarbiat Modares University, Tehran, Iran
Fjamshidi59@yahoo.com, mbehesht@modares.ac.ir

Abstract: In this paper, a switching strategy is employed to solve the H_2/H_∞ multi objective controller design. Two controllers are designed to meet the H_2 and H_∞ performance specifications. Linear matrix inequalities are used in the controller design process. New switching signal is defined which is the combination of dwell time switching signal and multiple Lyapunov function such that stability of closed loop system is guaranteed as well as desired performance. Simulation results show that proposed switching strategy improves the performance of the controller and reduces the conservation in comparison with the common H_2/H_∞ controller.

1. Introduction

There has been increasing interest in hybrid control in recent years, due to its potential to overcome limitations of adaptive control and benefits in controlling of systems that cannot achieve the desired performance by a single controller. Indeed, hybrid control scheme provides an effective mechanism when facing large modelling uncertainty and highly complex systems. Even for simple linear time invariant systems, controllers switching can be utilized in improving the performance (Sun, 2005, Feuer, 1997, and McClamroch, 2000). To date, Morse, Hespanha and Liberzon have established a theoretical backbone for hybrid controllers (Morse, 1997, Hespanha, 1999, and Liberzon, 2003). By now, stabilizing a continuous system via hybrid output feedback has attracted a number of authors, such as (Santarelli, 2008) where a comparison between the responses of the switching controller and two other forms of LTI control have been made. An experimental assessment of controller switching with state and control magnitude constraints is carried out in Kogiso, 2004. In Zheng, 2006, the multi-objective robust control of an induction motor with tracking and disturbance rejection specifications is proposed via switching. In Essounbouli, 2006, DeCarlo, 1988, and Jamshidi, 2010 controller switching has been proposed to improve the trade-offs in design multi objectives.

Supervisory control employs logic-based switching for adaptation, instead of continuous tuning of parameters as in conventional adaptive control. This type of switching-based supervisory control scheme consists of the following subsystems: a plant to be controlled, a bank of controllers, and a switching logic. Dwell-time method is representative of the trajectory independent switching logic for supervisory control (see Yoon, 2007 and its references). On the other hand, Lyapunov functions are employed in such trajectory dependent switching methods as in Yoon, 2007.

In an actual engineering control problem, different contradictory requirements must be satisfied such as attenuation of various types of disturbances, set point tracking, bounds on the signal peaks, and robustness to changing conditions and plant uncertainties. The synthesis problems with a combination of performances are known as multi objective control. General multi objective control problems are difficult and remain mostly open up to date. The usual approach for the general multi objective control problem is to find a controller transfer matrix for all objective designs and to use the same Lyapunov matrix for the separate design specifications. Though meeting all the objectives of a control application is desirable, the design of a single multi-objective controller is a trade-off among competitive problems such as disturbance rejection, tracking, regulation, constraints of the signals…. So a single controller may be restrictive (Boyd, 1991, Scherer, 1997, and Khargonekar 1991).

The mixed H_2/H_∞ control is an important robust control method and has been studied by many researchers. The mixed H_2/H_∞ control is concerned with the design of a controller that minimizes the H2 performance of the system with respect to some

inputs while guarantees certain worst case H_∞ performance with respect to other inputs. In engineering applications, the mixed H_2/H_∞ control is more attractive than the sole H_∞ control since the H_∞ control is a worst-case design which tends to be conservative whereas the mixed H_2/H_∞ minimizes the average performance with a guaranteed worst-case performance.

Here, the H_2/H_∞ control problem of complex systems is treated using switching controller. That is, the desired plant behavior is achieved by switching between pre-designed controllers, each to meet a set of relevant specifications. Our aim is using switching controller to reduce the conservatism of the controller synthesis and the resultant performance degradation; therefore, we apply the concept of multiple controllers and utilize the switching signal to orchestrate the switching among pre-designed controllers to improve performance of closed-loop system.

In this paper, we present a new switching logic. At every time instant, we search for a controller corresponding to the best performance. We then decide whether to switch to that controller or not by comparing the value of Lyapunov function at the previous switching instant to this controller with its prospective value that would result from the switching; if a certain inequality condition is satisfied, switching is allowed. We then further employ a dwell-time algorithm together. We show that asymptotic convergence is ensured by the proposed switching control scheme resulting from the combination of the Lyapunov-function-based switching and the dwell-time switching.

This paper is organized as follows: Section 2 presents the system definition, and the controllers used in this paper. The problem of synthesis switching signal is described in Section 3. A simple illustrative example is presented in Section 4. Section 5 contains some concluding remarks.

2. Problem Statement

This paper presents a controller design strategy for fulfilling H_2/H_∞ control objectives resulting in no compromise between distinctive specifications. Instead of considering all of the objectives in a single controller, switching between these controllers in the timely manner is proposed to meet the desired performance. In this case, we can obtain our multi-criterion goal without introducing conservatism to the problem, as each specification or a set of relevant objectives are assumed to be accomplished by a single controller without considering any contradictory objective in the design procedure. As switching can cause instability, a new switching strategy is introduced that lets switching based on either dwell time switching or multiple Lyapunov function.

The state-space realization of the LTI plant, P, for which H_2 and H_∞ output-feedback controller is designed is as follows:

$$P:\begin{cases}\dot{x} = Ax + B_u u_C + B_w w \\ z = C_z x + D_{zu} u_C + D_{zw} w \\ y = C_y x + D_{yw} w\end{cases} \quad (1)$$

$x \in R^{n_x}$ is state, $w \in R^{n_w}$ is the exogenous input signal (noise, disturbance and reference input), $u_C \in R^{n_u}$ is the control input, $y \in R^{n_y}$ is the measured output and $z \in R^{n_z}$ is the output to be regulated and defines the performance objectives of the closed loop system. The assumptions of H_2 and H_∞ controls are true. The diagram of the closed loop system is depicted in Figure 1.

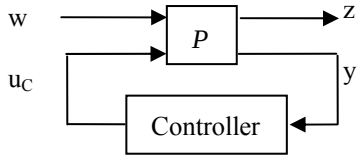

Figure 1. The Standard Diagram for H_2 and H_∞ Controls

The standard H_2/H_∞ performance criterion is considered: The objective is synthesis of the switching controller that internally stabilizes the closed loop system and minimize $\left\| T_{w_2 \to z_2} \right\|_2$ while $\left\| T_{w_\infty \to z_\infty} \right\|_\infty < \gamma$. $w_i = R_i^{-1} w$, $i \in I = \{H_2, H_\infty\}$ is the exogenous input and $z_i = L_i z$ is the controlled output (Scherer, 1997). The available design methods in addition to convex optimization problem defined by different Linear Matrix Inequalities (LMI) for H_2 and H_∞ closed-loop specifications given in Scherer, 1997 is used to find transfer matrices of the controllers.

Figure 2. illustrates the closed loop configuration used in this context, where u denotes the control input, y_P the process output, r a bounded reference signal (set point), d unknown but bounded input disturbance, and n unknown but bounded measurement noise. The process is a LTI system with strictly proper transfer matrix $H_P(s)$. $\{A_P, B_P, C_P\}$ is a minimal realization for $H_P(s)$. For the sake of conformity of the closed loop configuration in Figure 2. and the closed loop block diagram in Figure 1., the dashed line in Figure 2. is

considered as P in Figure 1., external inputs $\begin{bmatrix} r \\ d \\ n \end{bmatrix}$ in Figure 2. forms w in Figure 1.

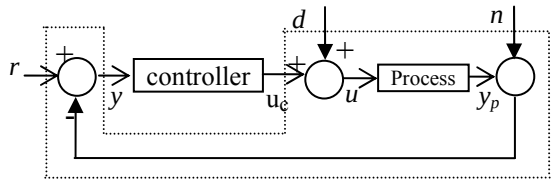

Figure 2. The Closed Loop Configuration

3. Purposed Switching Signal

We present a switching logic using the Multiple Lyapunov functions in Liberzon, 2003. The proposed algorithm is referred to as S_{MLF} and is given as follows: (Algorithm S_{MLF})

1- Initialize $\sigma(t)$ and Δt

2- Find the best controller: i := arg Best Controller

3. If $\sigma(t-\Delta t) \neq i$, and

$$V_i(t_i) \geq V_i(t) \qquad (2)$$

$V_i(.)$ is the Lyapunov function of the closed loop system with i th controller, t_i is the last time that switching to i th controller occurred, then let $\sigma(t^+) = i$ and $t_i = t$.

4. $t = t + \Delta t$ and go to step 2.

Switching takes place in S_{MLF} when two conditions are met: firstly there should be a better controller leading to the better performance, and secondly the inequality in (2) should hold to grantee the stability according to the following Lemma.

Lemma. 1. (Liberzon, 2003): Let $\dot{x} = f_i(x), i \in I$ be a finite family of globally asymptotically stable systems, and let $V_i, i \in I$ be a family of corresponding radially unbounded Lyapunov functions. Suppose that there exists a family of positive definite continuous functions $W_i, i \in I$ with the property that for every pair of switching times (t_p, t_q), $p < q$ such that $\sigma(t_p) = \sigma(t_q) = i \in I$ and ($\sigma(t_k) \neq$ i for $t_p < t_k < t_q$, we have $V_i(x(t_q)) - V_i(x(t_p)) \leq -W_i(x(t_p))$. Then the switched system is globally asymptotically stable.

In other words, switching is not allowed even when there is a better controller, if use of this new controller violates the condition given in (2). Checking the two conditions implies that both stability and performance is considered in S_{MLF} . Using this algorithm, switching system is asymptotically stable, the state variables are bounded and converge to zero, and all the signals remain bounded.

A dwell time, τ_D , is a lower bound for the difference between two consecutive switching instants; switching is allowed after waiting for the dwell time. Here we combine the dwell-time algorithm with switching logic proposed above. A switching logic using the dwell time switching is referred to as S_D which is time dependent and trajectory independent.

Lemma. 2. (Liberzon, 2003): The switched system $\dot{x} = A_i x$ is asymptotically stable if the time interval between consecutive switching instant between their asymptotical stable subsystems is not smaller than $\tau_D \geq \sup_{i \in I} \left(\frac{a_i}{\lambda_i} \right)$. Where $\left\| e^{A_i t} \right\| \leq e^{a_i - \lambda_i t}$ and $a_i = \log \left(\frac{\sigma_{\max}(M_i)}{\sigma_{\min}(M_i)} \right)$, M_i is the modal matrix (i.e. the matrix with eigenvectors as its columns) of the stable matrix A_i and $\sigma_{\max}(M_i)$ and $\sigma_{\min}(M_i)$ are the maximum and minimum singular values of M_i , respectively. The positive scalar λ_i is simply the absolute value of the real part of the eigen values A_i nearest to the imaginary axis (stability degree of stable matrix A_i).

As there are two switching logics involved, we use two subscripts for switching times to clarify which logic causes the switching; let $t_{p,q}$ denote the switching instant which is due to the q th switching by S_D in a row after the p th switching by the S_{MLF} . $t_{p,0}$ denotes the p th switching instant due to switching by S_{MLF} .

If there exists other controller with better performance but the condition (2) for S_{MLF} does not hold for $\bar{t} \in (t_{p,q} \quad t_{p,q} + \tau_D]$, then S_D forces switching to take place, leading to $t_{p,q+1} = t_{p,q} + \tau_D$. If the condition in (2) holds for some $\bar{t} \in (t_{p,q} \quad t_{p,q} + \tau_D)$ then switching results from S_{MLF} , leading to $t_{p+1,0} = \bar{t}$.

The two switching logics S_{MLF} and S_D are employed together in the proposed switching control scheme; as a result, switching takes place whichever logic allows without destroying stability as is shown

below. The proposed switching logic is referred to as $S_{MLF} \bigcup S_D$, and is depicted in Figure 3.

Plant with each controller forms a linear subsystem of switching signal. Suppose that at time instant $t_{p,0}$ switching to i th subsystem has occurred by S_{MLF} logic. The subsystems that switchings to them have occurred in the time interval $\left[t_{p,0} \quad t_{p+1,0}\right)$ by S_D logic can be considered as a subsystem of switching system with zero input nonlinear dynamic $\dot{x} = f_i(x)$ which is asymptotically stable according to Lemma 2.

As a result, the asymptotically stable linear subsystems, A_i, under switching logic $S_{MLF} \bigcup S_D$ is a combination of the asymptotically stable linear subsystems, A_i, and the asymptotically stable non linear subsystems, f_i, under S_{MLF} switching logic. If all the linear subsystems that switch together consecutively by S_D switching logic, and their switching start from i th subsystem are considered as one nonlinear subsystem, the number of subsystems is bounded. And according to Lemma 1 are asymptotically stable.

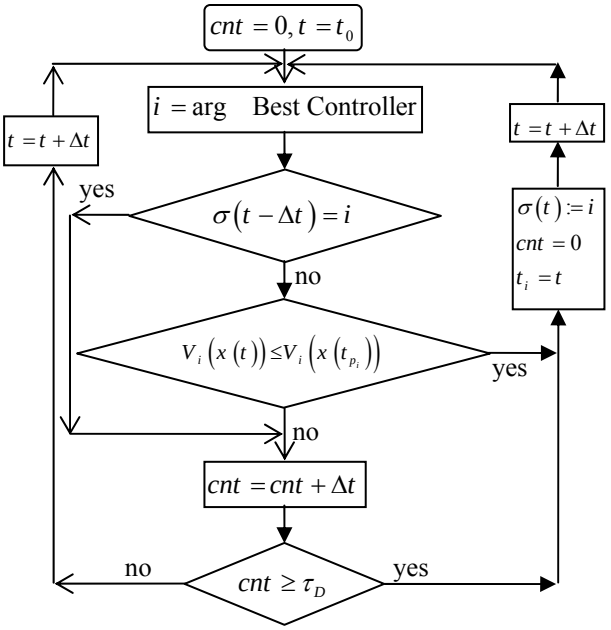

Figure 3. The Proposed Switching Logic $S_{MLF} \bigcup S_D$

4. Example

In this section, we briefly illustrate the enhancement of multi objective control performance via switching. The proposed approach is applied to the dynamic model of the roll angle of an aircraft taken from Vegte, 1994, and Hespanha, 2002:

$$H_P(s) = \frac{-1000}{s(s+0.875)(s+50)} \tag{3}$$

In this example, it is considered that white measurement noise with a large variance is injected in the time intervals $t \in [18 \quad 40]$, $t \in [73 \quad 93]$ and $t \in [128 \quad 148]$. In the presence of the measurement noise, noise rejection and the slower response are the objectives, while in the absence of the measurement noise a fast response and good tracking should be considered in the design procedure. This design problem is a multi-objective problem with conflicting criteria, because if a controller has low closed-loop bandwidth and is therefore not very sensitive to noise, it will exhibit a slow response and if a controller has high bandwidth and is therefore fast, it will be very sensitive to noise.

Following realization is considered for $H_P(s)$:

$$\dot{x} = \underbrace{\begin{bmatrix} -50.875 & -43.75 & 0 \\ 1 & 0 & 0 \\ 0 & -1000 & 0 \end{bmatrix}}_{A_P} x + \underbrace{\begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}}_{B_P} u$$

$$y_P = \underbrace{\begin{bmatrix} 0 & 0 & 1 \end{bmatrix}}_{C_P} x$$

It is easy to find that $\dot{y}_P = \begin{bmatrix} 0 & -1000 & 0 \end{bmatrix} x$.

Since $u = u_C + d$, $w = \begin{bmatrix} r \\ d \\ n \end{bmatrix}$ and $y = r - n - y_P$:

$$\dot{x} = \underbrace{\begin{bmatrix} -50.875 & -43.75 & 0 \\ 1 & 0 & 0 \\ 0 & -1000 & 0 \end{bmatrix}}_{A} x + \underbrace{\begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}}_{B_u} u_C + \underbrace{\begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}}_{B_w} w$$

$$y = \underbrace{\begin{bmatrix} 0 & 0 & -1 \end{bmatrix}}_{C_y} x + \underbrace{\begin{bmatrix} 1 & 0 & -1 \end{bmatrix}}_{D_{yw}} w$$

To have a good measurement noise rejection the controller, K_{H_2}, with more robust performance regarding measurement noise is designed using LQG/LQR. The regulator gains are computed by minimizing the cost $J = E\left\{\lim_{t\to\infty} \frac{1}{T} \int_0^T \left(y_P^2(t) + \dot{y}_P^2(t) + 100 u_C^2(t)\right) dt\right\}$. The design of the optimal LQG gain was done assuming that the load disturbance, d, and the measurement noise, n, were uncorrelated white noise processes with $E\left(d(t)d(\tau)\right) = \delta(t-\tau)$ and $E\left(n(t)n(\tau)\right) = \mu\delta(t-\tau)$, where $\mu = 10^{-1}$. It is easy to show that

$$J = E\left\{\lim_{t\to\infty}\frac{1}{T}\int_0^T \left(z_2(t)^T\ z_2(t)\right)dt\right\} = \left\|T_{w_2\to z_2}\right\|_2^2,$$

where $z_2 = \begin{bmatrix} y & \dot{y} & \rho u_C \end{bmatrix}$ and $w_2 = \begin{bmatrix} d \\ n \\ \frac{}{\sqrt{\mu}} \end{bmatrix}$, in other words

$$z_2 = \begin{bmatrix} y_P \\ \dot{y}_P \\ \rho u_C \end{bmatrix} = \underbrace{\begin{bmatrix} 0 & 0 & 1 \\ 0 & -1000 & 0 \\ 0 & 0 & 0 \end{bmatrix}}_{C_{z_2}} x + \underbrace{\begin{bmatrix} 0 \\ 0 \\ \rho \end{bmatrix}}_{D_{z_2 u}} u_C$$

. It is clear that, $B_{w_2} = \begin{bmatrix} 1 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}$ and $D_{z_2 w_2} = \begin{bmatrix} 0 & -\sqrt{\mu} \end{bmatrix}$.

To get a relatively good tracking and to prevent the extra increasing of the value of input signal, the controller, K_{H_∞}, is designed by minimizing $\left\|T_{w_\infty\to z_\infty}\right\|_\infty$ where $w_\infty = r$ and:

$$z_\infty = \begin{bmatrix} y \\ u_C \end{bmatrix} = \underbrace{\begin{bmatrix} 0 & 0 & -1 \\ 0 & 0 & 0 \end{bmatrix}}_{C_{z_\infty}} x + \underbrace{\begin{bmatrix} 0 \\ 1 \end{bmatrix}}_{D_{z_\infty u}} u_C + \underbrace{\begin{bmatrix} 1 & 0 & -1 \\ 0 & 0 & 0 \end{bmatrix}}_{D_{z_\infty w}} w,$$

$$z_\infty = \begin{bmatrix} y \\ u_C \end{bmatrix} = \underbrace{\begin{bmatrix} 0 & 0 & -1 \\ 0 & 0 & 0 \end{bmatrix}}_{C_{z_\infty}} x + \underbrace{\begin{bmatrix} 0 \\ 1 \end{bmatrix}}_{D_{z_\infty u}} u_C + \underbrace{\begin{bmatrix} 1 \\ 0 \end{bmatrix}}_{D_{z_\infty w_\infty}} w_\infty$$

In Figure 4, the left plots show the closed-loop response of controller K_{H_∞} and the right plots show the closed-loop response of controller K_{H_2} to a square set point. It can be seen from this Figure that the controller K_{H_∞} exhibits a faster response but is more sensitive to measurement noise. The top plots show the output, y_P, and the bottom plots the tracking error, y.

The left plots in Figure 5 show the closed-loop response of the switching controller, $K_{switching}$, to square reference. This structure inherits the fast performance of K_{H_∞} in normal cases, and a good noise rejection of K_{H_2} in the presence of the white measurement noise.

Using Lemma 2 the minimum time interval between consecutive switching between controllers K_{H_2} and K_{H_∞} is equal to $\tau_D = 22.9083s$. $V_{K_2}(t)$ and $V_{K_\infty}(t)$ denote the Lyapunov functions of closed loop system with controller K_{H_2} and K_{H_∞} at time instant t, respectively.

In time interval $[0\ \ 18]$ controller K_{H_∞} and in time interval $[18\ \ 38]$ controller K_{H_2} are in the loop. Since $V_{K_\infty}(0) > V_{K_\infty}(38)$, according to algorithm we can switch to controller K_{H_∞}. At $t = 73$, because of the time interval between consecutive switching is $73 - 38 > 22.9083$, according to Figure 3. without checking inequality (2) we switch to controller K_{H_2}. Since $V_{K_\infty}(38) < V_{K_\infty}(93)$, according to Figure 3, we check the constraint (2) until $\tau_D = 22.9083s$ after previous switching. Any time that the constraint is satisfied, we can switch to controller K_{H_∞}. Since during this time interval the constraint is not satisfied switching to controller is occurred at $t = 73 + \tau_D$. At $t = 128$ similar to $t = 73$ we switch to controller K_{H_2}. Since $V_{K_\infty}(93) < V_{K_\infty}(148)$, according to Figure 3, we check the constraint (2) until $\tau_D = 22.9083s$ after previous switching. Any time that the constraint is satisfied, we can switch to controller K_{H_∞}. At $t = 148.03$ the constraint is satisfied and switching to controller K_{H_∞} is occurred.

The right plots show the closed-loop response of the common multi objective controller K_{H_2/H_∞} that minimize $\left\|T_{w_2\to z_2}\right\|_2$, subject to $\left\|T_{r\to z_\infty}\right\|_\infty < \gamma$ (a single controller that considers both design objectives concurrently). The top plots show the output, y_P, and the bottom plots the tracking error, y.

The comparison illustrates the conservatism reduction by means of the switching controller in comparison with the performance of the common multi objective controller. As depicted in this Figure, it is apparent that we have approached meeting both design objectives better using the switching controller. It can be seen, from Table 1. that the switching controller minimizes the 2- norm and ∞-norm of tracking error, y, in comparison with other controllers.

Table 1. The Performance of the Controllers

	K_{H_2}	K_{H_∞}	K_{H_2/H_∞}	$K_{switching}$
$\sup_n \frac{\|y\|_\infty}{\|n\|_2}$	3.658	3.8836	4.7811	3.6575
$\sup_n \frac{\|y\|_2}{\|n\|_2}$	84.162	83.2744	100.334	82.0997

5. Conclusion

In this paper, a switching H_2/H_∞ controller is developed. This structure allows us to take the benefits of both H_2 and H_∞ controllers and to efficiently eliminate their disadvantages. The transients caused by switching may result in instability which is avoided by appropriate choice of switching signal. Purposed new switching signal is the combination of dwell time switching and multiple Lyapunov function. The simulations illustrate that a switching controller scheme inherits characteristics of all the controllers in the time intervals they have been in the loop, and diminish the performance degradation caused by considering all the control objectives in the design of a unique controller.

Abstract: Fourteen groundwater samples were collected from boreholes, springs and hand dug wells in and around Gubrunde in Borno State north-eastern Nigeria to investigate its quality for domestic and irrigation uses. The area investigated falls within longitude 11° 35' - 12° 05' and latitude 10° 10' - 10° 31'. The samples were analyzed using Atomic Absorption Spectrometer (AAS), multi-analyte photometer and Flame photometer while interpretation of the results was carried out with RockWare Aq•QA software, a spreadsheet for water analysis. Six of the samples investigated are of NaCl water type while fourteen were CaCl water types. Sodium Adsorption Ratio (SAR) values recorded ranges from 0.80 – 2.84, Exchangeable Sodium Ratio (ESR) 0.33 – 1.78, Magnesium hazard (MH) 5.19 – 47.9, Residual Sodium Carbonate (RSC) 0.00, Hardness 0.65 – 221.48 and Total Dissolved Solid (TDS) ranges from 130 – 407308mg/l. Twelve of the samples analyzed had medium Salinity Hazard (SH), and one each for high and low Salinity Hazard (SH), respectively. The variation in chemical composition of groundwater in the study area may be due to leaching of terrestrial salts, extensive use of chemical fertilizers and ion exchange between water and the host rock. The result of samples analyzed indicates that all the samples are undersaturated in calcite and aragonite, while most of the major anion and cations falls within World Health Organization and Nigeria Industrial Standard for Drinking water Values. Nine samples had NO_3 values ranging from 53 – 106mg/l exceeding the 50mg/l standards. NO_3 values exceeding 50mg/l has the tendency of causing asphyxia to infants less than three months old. A plot of SO_4, HCO_3 and Cl indicates that the groundwater samples are from intermediate water category (neither fresh nor old). Generally, the groundwater quality is fairly suitable for agricultural uses and suitable for domestic utilization.[Arabi, Suleiman Abdullahi; Funtua, Idris Isa; Alagbe, Solomon Ayodele; Zabosrki, Peter; and Dewu, Bala Bello Muhammad. Investigation of Groundwater quality for Domestic and Irrigation purposes around Gubrunde and Environs, northeastern Nigeria, Journal of American Science 2010; 6(12):664-672]. (ISSN: 1545-1003).

1. Introduction

Urbanization, population increase, dewatering of aquifers for irrigation and extensive use of chemical fertilizers are some of the factors that have direct effects on quantity and quality of groundwater resources especially in arid and semi arid region of northern Nigeria. Hydrochemical data has the potential uses for tracing the origin and history of water. Globally, the quantity and quality of groundwater reserves is diminishing day by day. Therefore, any study that can aid in identifying new sources or threats to groundwater is desirous not only around the study area but anywhere. There is no life without water, therefore, it is essential to safeguard the future of our water resources by studying its past and present both quantitatively and qualitatively. This Study of hydrochemistry of groundwater from Gubrunde and environs utilizes the results of the chemical analysis of water samples from different sources around the study area. The locations sampled falls between longitude 11° 35' - 12° 05' and latitude 10° 10' - 10° 31' in Borno State, north-eastern Nigeria, covering an area of about 2250km^2 (Fig. 1). Gubrunde village is central in the Geology of Nigeria because it is one of the three Uranium mineralization areas in north-eastern Nigeria. It can be accessed through Dadin-kowa from Gombe State and/or through Biu or Guyuk from Adamawa State. he Geology of the area (Fig. 2) is made of the tertiary basalt of the Biu plateau on the north, sedimentary sequence of Bryel and Zange grabens on the north-west and south-east, respectively. The area is underlain by the crystalline basement of north-eastern Nigeria.

Groundwater in the crystalline basement rock is confined to pockets and patches of weathered rock and to fractures. Wells usually encounter water at shallow depths but yields are often low and subject to

seasonal fluctuations. Boreholes are usually sited on basement along drainage lines where overburden is often thickest. On the basalt capped plateau, the weathered zone near some of the larger streams is up to 9m thick and yields moderate amounts of water, usually 2 to 3 liter per second (Nur, et al.).

The composition of water changes through reactions with the environment and the natural chemistry can have an important bearing on anything living that utilizes this resources including human beings, livestock and even plants, so a detailed analysis of major, minor and trace constituents of groundwater is very important. Fourteen groundwater samples were collected from boreholes, springs and hand dug wells from the study area (Fig. 1) using standard sample collection procedures and analyzed for major, minor and trace constituents at the Center for Energy Research and Training, Ahmadu Bello University, Zaria and The Regional Groundwater Laboratory, Gombe using an Atomic Absorption Spectrophotometer, multi-analyte photometer and Flame Photometer and the data was interpreted with the help of RockWare Aq•QA software, a spreadsheet for water analysis to determine its suitability for use in culinary and agricultural purposes.

Six of the samples investigated are of NaCl water type while fourteen were CaCl water types. Sodium Adsorption Ratio (SAR) recorded values ranges from 0.80 – 2.84, Exchangeable Sodium Ratio (ESR) 0.33 – 1.78, Magnesium hazard (MH) 5.19 – 47.9, Residual Sodium Carbonate (RSC) 0.00, Hardness 0.65 – 221.48 and Total Dissolved Solid (TDS) ranges from 130 – 407308mg/l. Twelve of the samples analyzed had medium Salinity Hazard (SH), and one each for high and low Salinity Hazard (SH), respectively. For water with high salinity hazard, adverse effect is expected on crops, medium salinity hazard has detrimental effects only on crop that are sensitive to salinity while low salinity is suitable for all crops. The variation in chemical composition of groundwater in the study area may be due to leaching of terrestrial salts, extensive use of chemical fertilizers and ion exchange between water and the host rock.

The investigation will serve as an avenue to update groundwater data bank of the study area for those whose responsibility is the provision of safe drinking water to the entire populace around the area. It will also help in planning agricultural practices in advising the farmers on choosing the appropriate crops to be cultivated around the study area.

2. Materials and Method

The water samples were collected in April, 2009 from boreholes, springs and hand dug wells with the aid of environmental sampler in order to have representative sample free from contamination from sampling tools. After each sample is collected, an in-situ measurement was made for conductivity, pH, TDS and temperature using Sension Platinum Series portable pH and Conductivity meter (HACH made). Also measured at the field are coordinates, elevation and static water level of each of the locations sampled (Table 1) using GPS and a deep meter. Samples were then stored in a plastic container after acidification with nitric acid before transporting them to the laboratory. The analysis of Si, K, O_2 and P were carried out using V2000 multi-analyte photometer, Na and K were carried out with a CORNING FLAME PHOTOMETER 410 after calibrating it with the analyte standard while the remaining analyte were carried out with BUCK SCIENTIFIC 210 VGP ATOMIC ABSORPTION SPECTROPHOTOMETER. The results obtained were then interpreted using RockWare (2006) Aq•QA spreadsheet for water analysis.

3. Results

The results of measurements obtained in-situ is presented in Table1, these include pH, conductivity, TDS, static water levels, coordinates of sampled locations, temperature and elevation of each point. Results of analysis of major and minor elements, determined water types, Sodium Adsorption Ratio (SAR), Exchangeable Sodium Ratio (ESR), Magnesium hazard (MH), Residual Sodium Carbonate (RSC), and Total Dissolved Solid (TDS) is presented in Table 2.

A graph of SO_4, HCO_3 and Cl distribution in groundwater samples is also presented in Figure 3
.

SAR = sodium Adsorption Ratio,
ESR = Exchangeable Sodium Ratio

4. Discussion

The results of chemical analysis of groundwater in the study area are discussed in the following order:

a) Water types and major and minor constituents
b) Sodium Adsorption Ratio (SAR)
c) Mineral Saturation (MS)
d) Hardness
e) Residual Sodium Carbonate (RSC)
f) Total Dissolved Solid (TDS)
g) Hydrochemical data
   - Piper diagram
   - Schoeller diagram.

a. Water type

The analysis of water samples allowed the categorization of water from the study area in to two water types with formulae Ca-Cl and Na-Cl indicating Calcium and Sodium water types.

Calcium is the most abundant of alkaline earth metal and a major constituent of vast common rock minerals. Sources of calcium (Ca^{2+}) in water include calcite, aragonite, dolomite, gypsum, anhydrite, fluorite, plagioclase, pyroxene and amphibole (Brian, et al. 1980). From health point of view, the content of calcium in groundwater is unimportant. Its concentration in natural waters is typically <15mg/l. concentration of calcium in water samples analyzed ranges from 6.7 – 84.33mg/l.

Sources of sodium are halite, sea spray, some silicate and rare minerals such as plagioclase, plagioclase variety of albite and nepheline. Most sodium results from natural ion exchange. Sodium and potassium are common constituents of natural waters with sodium being more prevalent than potassium. From health point of view, potassium is unimportant but sodium can have negative effects on people with heart disease. Sodium hydrogen carbonate mineral waters are important for treatment of gastric and biliary tract diseases. WHO(2008) and the NIS(2007) Nigeria Standard for Drinking water Quality has set limit for sodium in drinking water at 200mg/l. The highest value recorded for sodium in the samples analyzed is 93.8mg/l. Except for nitrate which exceeded the limited of 50mg/l in nine of the samples analyzed all the other parameters measured (Table 2) complied with the set standard. Nitrate levels exceeded 50mg/l in drinking water having the potential of causing cyanosis, and asphyxia (blue baby syndrome) in infants less than 3 months.

Based on the HCO_3, SO_4 and Cl recorded in the samples and plotted on bar graph (Fig. 3), the water samples analyzed belong to the intermediate water category (not fresh nor old) because $Cl > HCO_3 > SO_4$.

b) Sodium Adsorption Ratio (SAR)

Sodium Adsorption Ratio (SAR) is an estimate of the degree to which sodium will be adsorbed by the soil. It is used to evaluate the suitability of water for irrigation. High value of SAR means that sodium in the water may replace calcium and magnesium ions in the soil, potentially causing damage to the soil structure (Lloyd, 1985). SAR is calculated from the formula;

$$SAR = \frac{[Na^+]}{\sqrt{\frac{[Ca^{2+}] + [Mg^{2+}]}{2}}}$$

Most of the analyzed groundwater samples are medium sodium waters meaning that the water is most suitable when used on coarse-textured or organic soil with good permeability and plants with good salt tolerance. The sodium hazard is a function of both SAR and Salinity. Salinity hazard dividing points are 250, 750 and 2250µohms, resulting in four categories as given in Table 3 with corresponding µohms values.

.

Table 3: Sodium and Salinity control values (Wilcox, 1955)

	Salinity status	**Sodium status**
<250 µohms	Low salinity water	Low sodium water
250 -750 µohms	Medium salinity water	Medium sodium water
750 -2250 µohms	High salinity water	High sodium water
>2250 µohms	Very high salinity water	Very high sodium water

c) Mineral Saturation (MS)

The minerals calcite and aragonite have the same chemical composition ($CaCO_3$), but different chemical structures. The saturation index of these minerals is given as;

SI = log Q/K = log Q – log K,

where Q is the ion activity product and K the equilibrium constant and this tells whether they are;

1. supersaturated (Saturation Index > 1)
2. saturated (Saturation Index = 0) or
3. under-saturated (Saturation Index < 0)

All the samples analyzed are under-saturated in both calcite and aragonite with saturation values ranging from -4.34 to -0.71 for calcite and -4.89 to 0.88 for aragonite.

d) Hardness

Hardness is the sum of Ca^{2+} and Mg^{2+} concentrations expressed in terms of mg/l of calcium carbonate:

Hardness = 2.5 Ca (mg/l) + 4.1 Mg(mg/l) (Fournier,1981)

Calcium and magnesium form an insoluble residue with soap. The degree of hardness in water is commonly based on the classification listed in Table 5(Sawyer and McCarty, 1967).

Table 5: Classification of water hardness (Sawyer and Mc Carty, 1967)

Hardness range (mg/l of $CaCO_3$)	**Water classification**
0 – 75	Soft
75 – 150	Moderately hard
150 – 300	Hard
>300	Very hard

Most of the groundwater samples analyzed had hardness value ranging from 0.65 – 74.5mg/l except sample BH07GB and BH14GB which have hardness value of 163.07 and 221.48, respectively. Hardness value below 75mg/l indicate that the samples analyzed are soft water indicating that twelve of the fourteen water samples analyzed are soft water while the remaining two are hard water. These samples also

recorded the highest conductivity values of 664 and 962µs/cm, respectively. So, most of the samples analyzed passed the hardness limit set by WHO, 2008 and NIS, 2007 Nigeria Standard for Drinking Water Quality except samples BH07GB and BH14GB.

e) Residual Sodium Carbonate (RSC)

Residual Sodium Carbonate (RSC) value considers the bicarbonate content of the water. High concentration of bicarbonate leads to an increases in pH value of water that causes dissolution of organic matter. An increase in RSC value leads also to precipitate calcium and magnesium that can cause an increase in sodium content in the soil. The high concentration of bicarbonate ion in irrigation water leads to its toxicity and affects the mineral nutrition of plants.

According to Eaton's classification, water with RSC greater than +2.5epm is considered unsuitable for irrigation. The water with RSC of +1.25 to +2.5 is considered as marginal and those with a value less than +1.25 are safe for irrigation purpose. All the water samples analyzed had RSC values of less than 1.25 suggesting that the water can be used for irrigation purpose.

f) Total Dissolved Solid (TDS)

Increase in dissolved solids in irrigation water affects soil efficiency and growth and yield of plants. For long term irrigation under average conditions, the total dissolved solids should not exceed 2000mg/l. High increase in water salinity increases salts amount in soil and leads to salinization problem. Classification of water according to TDS values (Wilcox, 1955) is given in Table 4.

Table 4: Classification of irrigation water based on TDS value (Wilcox, 1955)

TDS (mg/l)	Status
200–500	Best quality water
1000–2000	Water involving Hazard
3000-7000	Used for irrigation only with leaching and perfect drainage

The highest TDS value recorded in the examined groundwater samples is 670mg/l and the lowest is 130mg/l which indicates that base on TDS categorization, the water in the area studied is good for irrigation purpose.

g) Graphical presentation of data

Piper diagram is a combination of anions and cations triangle that lies on a common baseline. It divides waters into basic types according to their placement near the four corners of the diamond. Water that plots at the top of the diamond is high in Ca^{2+} + Mg^{2+} and HCO_3^- and is the region of waters with temporary hardness. Waters plotted at the lower corner of the diamond is composed primarily of Na^+ + K^+ and HCO_3^- + CO_3^{2-}. The plot according to this arrangement is presented in Figure 4 where three classes of combinations were obtained. The Schoeller diagram represents the combination of major and minor constituents of groundwater in the study area in a diagram (Fig. 5) and the result obtained indicates that Cl is dominant and SO_4 as the least in the following order: Cl, Na + K, Ca, Mg, HCO_3,+ Co_2 then SO_4.

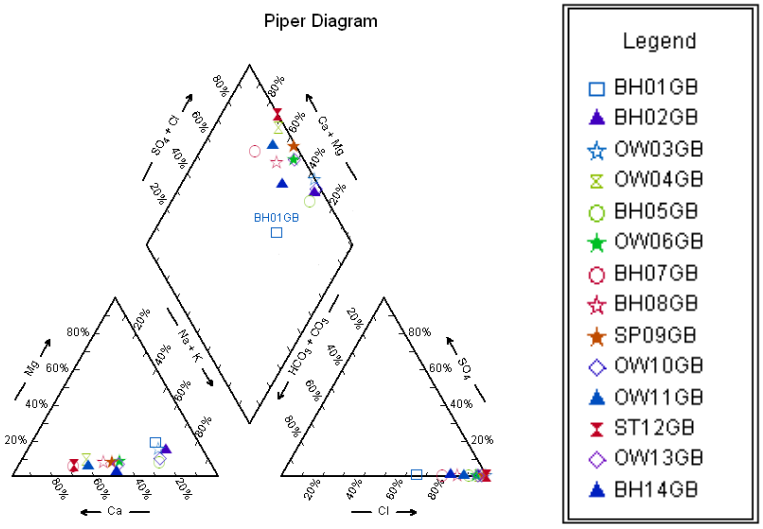

Figure 4: Piper diagram for water samples from Gubrunde and environs

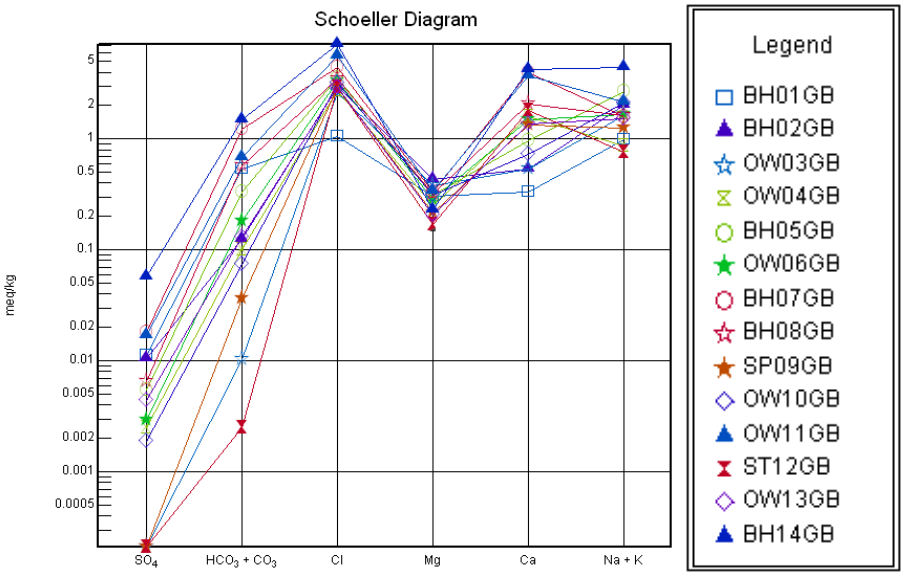

Figure 5: Schoeller diagram for water samples from Gubrunde and environs

5. Conclusions

The results of analysis and interpretation of groundwater from Gubrunde and environs for domestic and irrigation purpose indicates that samples BH14GB is not suitable for irrigation while sample BH01GB being most suitable, the remaining twelve samples is most suitable on coarse-textured or organic soil with good permeability and plants with good salt tolerance. For domestic uses and based on WHO, 2008 and NIS, 2007 Nigeria Standards, the water is good for drinking and other culinary purposes except the high concentration recorded for nitrate which can cause asphyxia in infants less than three months. Based on the findings, the groundwater in the area studied is fairly suitable for agricultural purpose and suitable for use in homes.

Effect of the Type of Aggregate on the Properties of Alumina Refractory Concrete

S.A. Ghonaim[1], H.B.G. Ghazal[2], and M.F. Abadir[*3]

[*]magdi.abadir@yahoo.com

Abstract: Low cement refractory concrete samples were prepared by mixing cement (containing 50% alumina) in percentages ranging from 10 to 20% with some aggregates and the necessary amount of water. Two types of refractory aggregate were used: Bauxite containing 81% alumina and grog containing 52% alumina. Four particle sizes of each aggregate were used. The cast samples were left in their moulds for 24 hours in a 100% relative humidity cabinet. The de–molded specimens were left in an open air until their moisture content reaches 3–6%, then kept in a drying oven at (110 ± 5) ºC until reaching constant weight. They were then tested for phase constitution, water absorption, bulk density, apparent porosity and cold crushing strength (after 28 days curing). It was found that bauxite based samples gave better results than those prepared with grog. It was also found using statistical analysis that the percent cement used affects all properties much more than does the particle size of aggregate.
[S.A. Ghonaim, H.B.G. Ghazal, and M.F. Abadir. Effect of the Type of Aggregate on the Properties of Alumina Refractory Concrete. Journal of American Science 2010;6(12):673-684]. (ISSN: 1545-1003).

Key Words: Refractory concrete – Alumina – Grog – Sodium citrate – Bauxite

1. Introduction:

The analysis of the composition, the structure, and the properties of conventional refractory concretes shows that their refractory properties are governed by the filler contained in them. The binder component (bonding agent) of the concretes imparts the strength required during transportation and erection; this strength is attained after setting and drying. During subsequent heating up to the temperatures preceding sintering, irreversible destructive processes occur, as a rule, in the binder. In view of the fact that the binder (along with the finely milled additives or aggregates) forms a continuous matrix phase in the structure of the concrete, the thermo–mechanical characteristics of the material are adversely affected. Therefore, in order to improve the existing refractory concretes and to create new concretes, it is necessary to decrease the content of the conventional binders (e.g., high–alumina cements) in them to the minimum possible extent or to produce them without introducing any conventional binders [1, 2, 3, 4].

Thermally stable aggregates combined with a bonding agent are the principal ingredients of a monolithic refractory. These raw materials are available both naturally and artificially. Raw materials available in nature unavoidably vary slightly in their compositions. However it is important to take advantage of the characteristics of these natural minerals that cannot be developed artificially rather than to avoid their use due to variations of chemical composition.

Unlike natural raw materials, artificial raw materials allow adjustment of chemical composition as well as their mineral constituents, and it is possible to get a uniform quality.

One common type of aggregate is bauxite, a raw material for alumina containing about 60% alumina. When calcined, the alumina level is usually raised to above 85%. Bauxite for refractories is calcined in a rotary kiln to make a stable product. Calcined bauxite contains corundum as its principal component, mullite and a small glassy phase.

On the other hand, grog is an artificial aggregate usually obtained from crushed defective refractory bricks. Its alumina content depends on that of the original bricks. It usually ranges from 40 to 80%.

Other types of aggregate include diaspore ($A1_2O_3.\ H_2O$), corundum ($A1_2O_3$), magnesia (MgO), zirconia (ZrO_2), etc…

In the present paper, the physico–mechanical properties of refractory concrete samples prepared from bauxite and grog with varying amounts of cement and varying particle size of aggregate have been studied.

2. Experimental

2.1 Raw Materials:

The raw materials used are:

1- Refractory cement having 50% alumina was obtained from Lafarge Cement Company.

2- Calcined bauxite was obtained from the Alexandria Company for Refractories with an alumina content exceeding 80%.
3- Grog was obtained from previously fired defective bricks that were crushed, ground and screened.

2.2 X–Ray Fluorescence Analysis (XRF):

X–ray fluorescence spectrometry (XRF) was employed for the elemental analysis of the starting materials. The analysis was run on a AXIOS, panalytical 2005, Wave length Dispersive (WD–XRF) Sequential Spectrometer.

2.3 X–Ray Diffraction (XRD):

X–Ray diffraction was used for the qualitative analysis of the phases present in the tested samples.

For X–Ray diffraction study of bauxite and grog analysis, the aliquots for bulk mineral analysis were finely ground (–200 mesh), and analyzed by a BRUKUR D8 ADVANCE COMPUTERIZED X–Ray Diffractometer apparatus with mono – chromatized Cu Kα radiation, operated at 40 kV and 40 mA.

2.4 Particle Size Distribution of Aggregate:

In order to determine the grain size distribution, the procedure described by ASTM D 422/2007[5] was used. The standard sieves method was applied using screen apertures ranging from 6.68 mm (3 mesh) down to 74 μm (200 mesh).

2.5 Preparation of Specimens:

Forty dry mixtures of different formulations for both bauxite and grog at various percentages cement (20%, 17.5%, 15%, 12.5%, 10%) by weight were kneaded with an adequate amount of water, which was determined for each batch according to the standard "good ball in hand test [6]". The mixed batches were then cast into cubes of 50 mm side length using a vibrating table at a frequency of 50 Hz for 4 minutes. The cast samples were left in their moulds for 24 hours in a 100% relative humidity cabinet. The hydrated samples were then demolded. The specimens were left in an open air until their moisture content reaches 3–6%, then put in the drying oven at (110 ± 5) ºC until reached a constant weight. They were then tested for water absorption, bulk density, apparent porosity and cold crushing strength.

2.6 Apparent Porosity, Water Absorption, and Bulk Density:

These properties were determined according to the ASTM Standards C 20/2007 [7]. For each test, the average measurements of five specimens at least were considered.

The five specimens for each test were weighed for their dry weight (D). The specimens were then immersed in water and boiled for 2 h without contact with the heated bottom of the container. They were cooled down to the room temperature while still completely immersed in water. The weight (S) of each specimen was determined after boiling and while suspended in water. The saturated weight (W) was also determined.

Apparent porosity (P) was calculated from the following formula:

$$P,\% = \frac{W - D}{V} \times 100 \quad (1)$$

Water absorption (A) was calculated from the following formula:

$$A,\% = \frac{W - D}{D} \times 100 \quad (2)$$

While bulk density (ρ_B) was calculated from the following formula**:**

$$\rho_B = \frac{D}{V} \times 100 \quad (3)$$

Where:
P = apparent porosity, (%);
W = weight of the specimen as saturated with water, (g);
D = dry weight, (g);
S = weight of the specimen as suspended in water, (g);
V = volume of specimen = W –S, (cm^3);
A = water absorption, (%);
ρ_B = bulk density, (g/cm^3).

2.7 Cold Crushing Strength:

This was carried out on three specimens representing each mix composition after curing for 28 days. Each specimen was placed between two plates of the compression strength tester. This was followed by the application of an axial uniform load. The load at which a crack appears on the sample was noted. The strength was calculated according to BS EN Standards 993–5/2000 [8]:

$$C.C.S\,(\sigma_c) = \frac{W}{a} \quad (4)$$

Where:

σ_c = cold crushing strength, (MPa);

W = total maximum load at visible failure, (N);

a = average of gross area of the two faces, (mm^2).

3. Results and Discussion:

the elemental chemical analysis of the employed refractory cement, bauxite and grog samples.

3.1 Chemical Analysis of Raw Materials:

Table (1) shows the XRF results related to

3.2 XRD of Raw Materials:

Figures (1) and (2) show the XRD patterns of bauxite and grog, respectively. Calcined bauxite consisted exclusively of corundum (Al_2O_3) and mullite ($3Al_2O_3.2SiO_2$). This is expected from the phase equilibrium diagram: Al_2O_3 – SiO_2 for compositions containing > 80% alumina [9]. On the other hand, the XRD pattern of grog (Fig. 3) shows beside the expected phases of mullite and quartz, some non–equilibrium phases of corundum and cristobalite. Halite is also present as an impurity.

Grog and Bauxite were screened to the required size fractions using standard sieves ranging from 3 mesh (6.680 mm) down to 200 mesh (0.074 mm). The mean particle size of a fraction passing through a certain sieve and retained over the next was

taken as the arithmetic average of the two openings. This way, the following mean sizes were used: 4.699 mm, 2.794 mm, 1.651 mm, 1.168mm, 0.991mm, 0.295 mm, 0.175 mm, 0.147 mm, and 0.074 mm.

Figure (3) shows the cumulative screen analyses for grog and bauxite used in the present investigation.

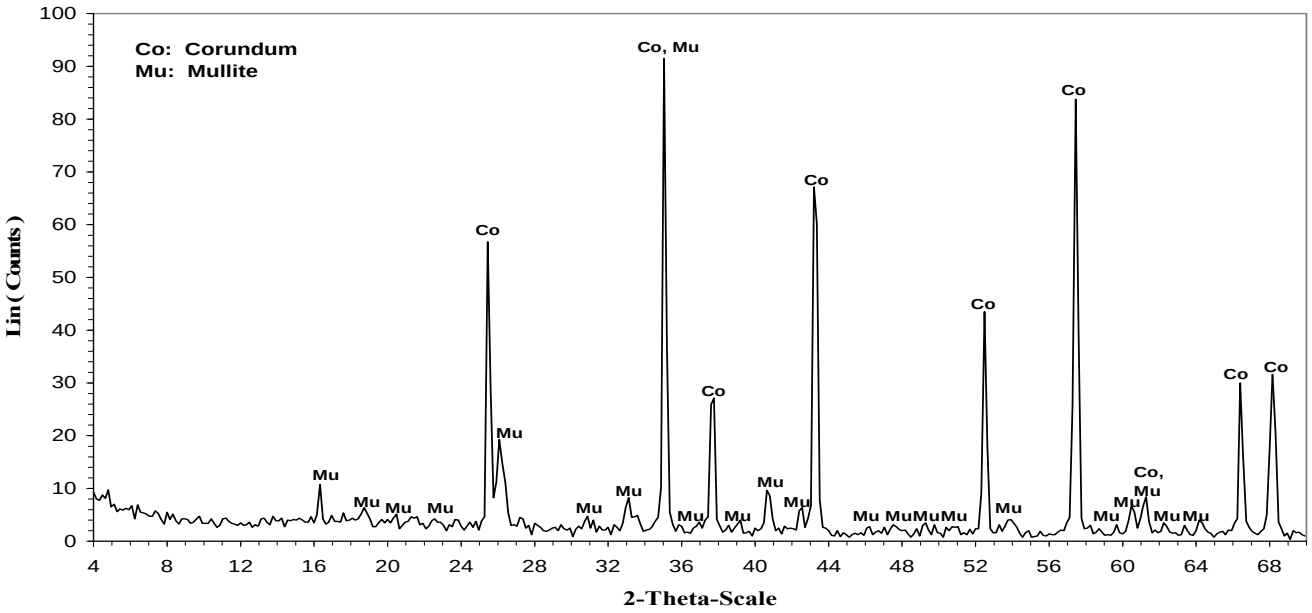

Fig. (1): XRD Pattern of Calcined Bauxite

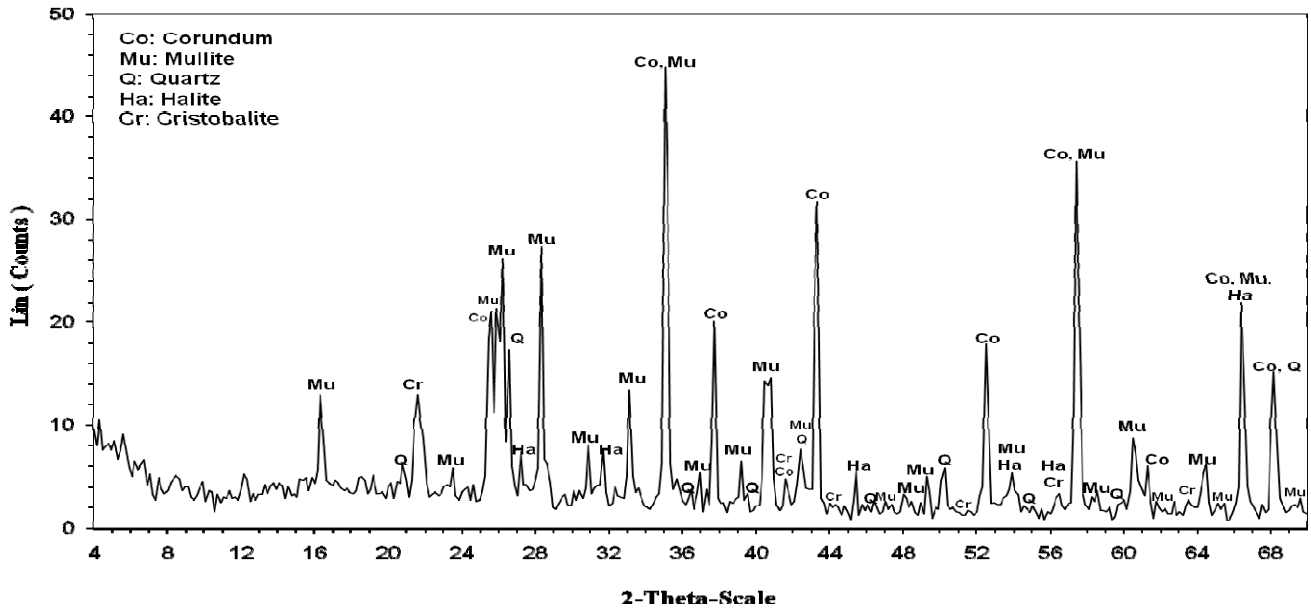

Fig. (2): XRD Pattern of Grog

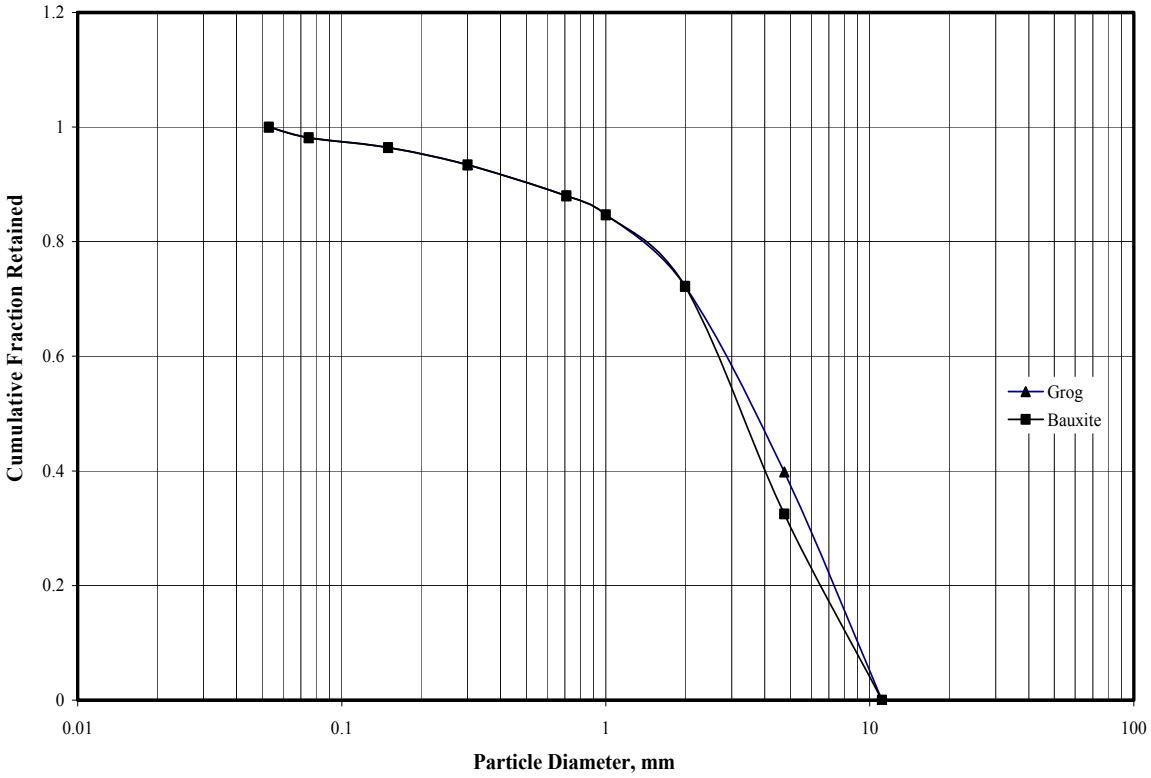

Fig. (3): Particle Size Distribution of Aggregates

3.4 Mean Particle Size of Aggregates:

In order to assess the effect of particle size of the aggregates employed (bauxite and grog,) on the workability, physical and mechanical properties of refractory concrete paste, four different particle size mixes were used. Each is a combination of three different particle size ranges in order to maximize compactness of samples. Table (2) shows the four mixes together with the average particle diameter of each as calculated using the method suggested by McCabe et al [10].

Table (2): Mean Particle Size of Aggregate Formulation Used

	% Weight			
	0–1 mm	**1–3 mm**	**3–5 mm**	**Mean Particle Size (mm)**
A	10	75	15	1.63
B	25	60	15	1.19
C	40	45	15	0.94
D	55	30	15	0.78

3.5 Effect of Mean Particle Size on Water Consumption:

During mixing, the ratio of water added certainly affects technological properties of the final product considerably [2]. Also, when the amount of coarse particles in the particle size distributions increases, the surface area of the particles decreases and less water is required. The amount of consumed water as function of the mean particle size of bauxite and grog are shown in figures (4) and (5), respectively.

The results show that the amount of water added increases with the decrease of both particle size in the aggregate mixture and with the amount of cement. It is also seen that water consumption for samples containing grog is higher than for those containing bauxite. These values range from 7.5 to 9.1% in case of bauxite based formulations against 9.5 to 10.9% for grog–based formulations. This is presumably due to the presence of much more open pores in grog than in bauxite particles. To assess this, the apparent porosity of samples of both types of particles was determined. And found to be 6.7% and 16.5% for bauxite and grog particles, respectively.

Using the excel DATA ANALYSIS module, it was possible to establish correlation tables in both cases to show the relative influence of both cement percent and particle size on the percent of required water. The results are given in tables (3) and (4).

The results given in tables (3) and (4) suggest the following:

First, the relation between the percent water added and percent cement used is an increasing relation. On the other hand the negative sign

associated with the effect of particle size means an inverse relation between the percent water added and particle size.

Second, in the case of using bauxite, the effect of varying particle size on the percent water added is higher than that of varying the cement ratio. On the other hand, on using grog, the two variables have comparable effects.

Table (3): Correlation Table for Water Added in Bauxite Based Mixes

	% Cement	Particle Size	% Water
% Cement	1		
Particle Size	0	1	
% Water	0.642372	− 0.7489	1

Table (4): Correlation Table for Water Added in Grog Based Mixes

	% Cement	Particle Size	% Water
% Cement	1		
Particle Size	0	1	
% Water	0.696767	− 0.68928	1

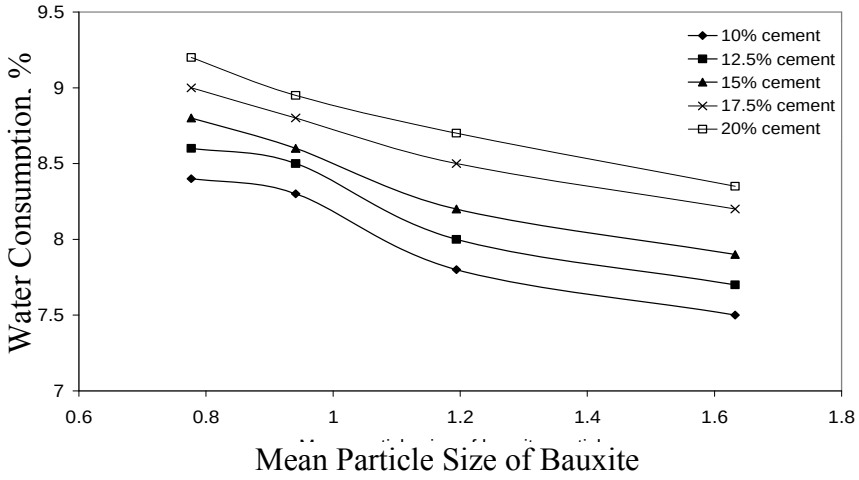

Fig. (4): Effect of Mean Particle Size of Bauxite Aggregates Containing Different Cement Percents on Water Consumption for Mixes

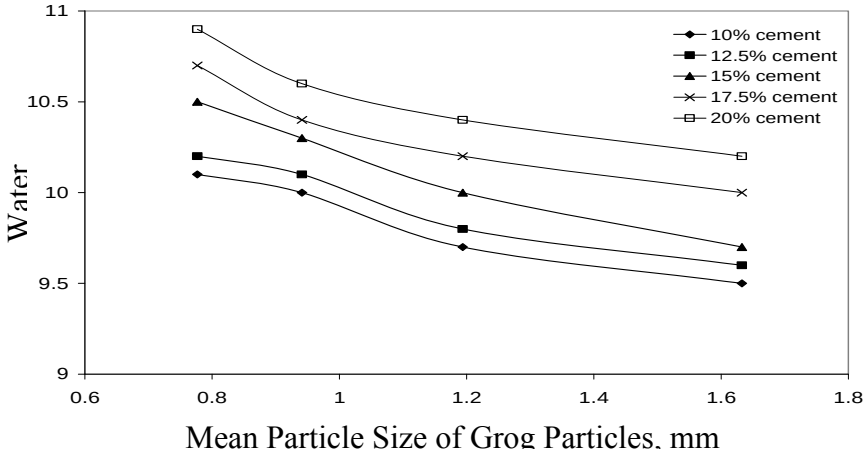

Fig. (5): Effect of Mean Particle Size of Grog Aggregates Containing Different Cement Percents on Water Consumption for Mixes

3.6 Effect of Mean Particle Size on Water Absorption:

Figures (6) and (7) show the relations between the percent water absorption of cast cubes and the mean particle size of either bauxite or grog, respectively.

The results suggest that the percent water absorption appreciably decreases with the increase of cement content. However, as the cement content exceeds 15%, its effect on water absorption diminished. This is expected since higher cement content enhances the closure of available pores.

Of interest is the difference between the water absorption values observed in either cases. It is clear from Fig. (6) that the values of water absorption in case of bauxite based formulations range from about 4.8% to 9.5% depending on the cement level and particle size. In case of using grog, the range of water absorption is 5.3 – 10.5% showing that the use of grog has lead to higher water absorption presumably due to increased open porosity of such samples.

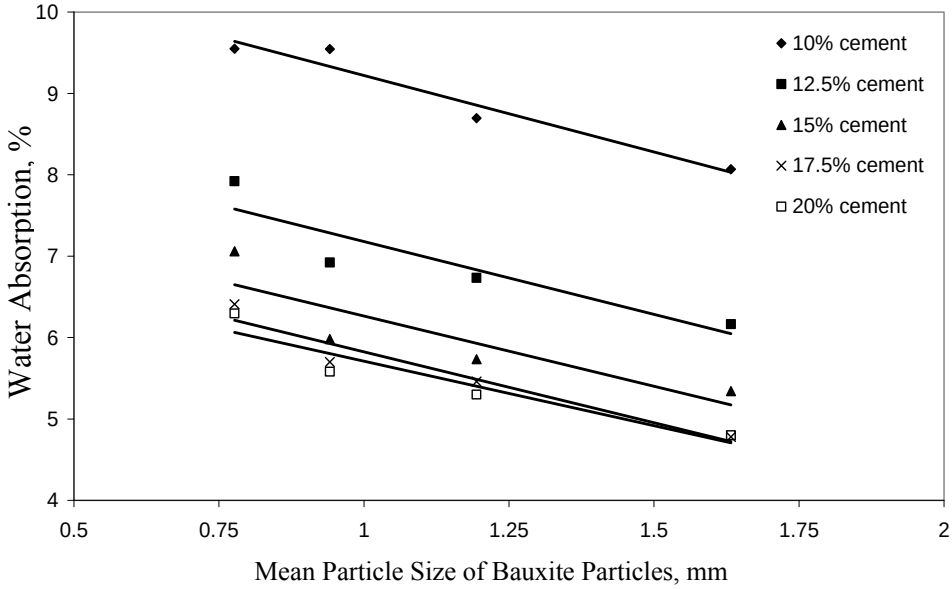

Fig. (6): Effect of Mean Particle Size of Bauxite Aggregates Containing Different Cement Percents on Percent Water Absorption for Mixes

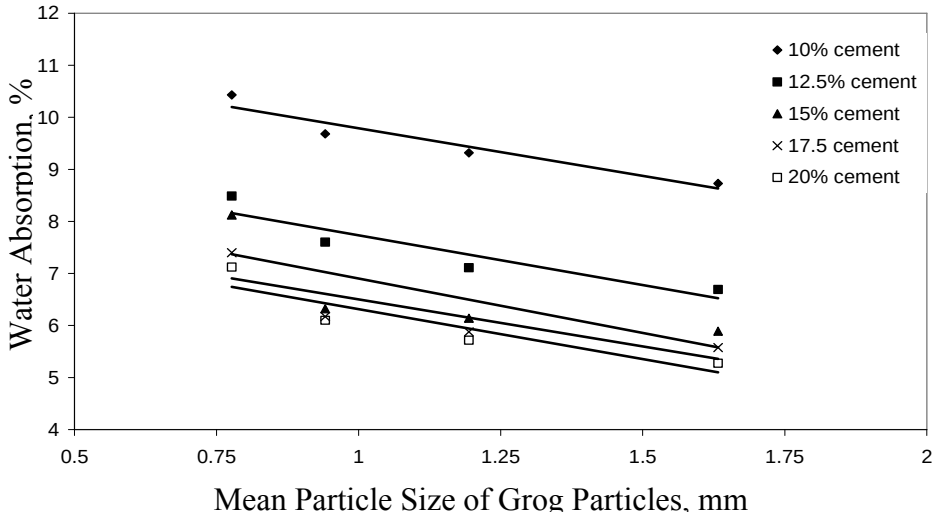

Fig. (7): Effect of Mean Particle Size of Grog Aggregates Containing Different Cement Percents on Percent Water Absorption for Mixes

Also these figures indicate that the percent water absorption is only slightly affected by the increase in particle size. To assess this, the excel DATA ANALYSIS module was used to establish correlation tables which show the relative influence of percent cement and particle size on the percent water absorption in both cases. The results are listed in tables (5) and (6).

Table (5): Correlation Table for Percent Water Absorption for Bauxite Based Mixes

	% Cement	Particle Size	% W.A.
% Cement	1		
Particle Size	0	1	
% W.A.	− 0.82455	− 0.39599	1

Table (6): Correlation Table for Percent Water Absorption for Grog Based Mixes

	% Cement	Particle Size	% W.A.
% Cement	1		
Particle Size	0	1	
% W.A.	− 0.79392	− 0.42302	1

Tables (5) and (6) show that both variables affect negatively the percent water absorption whereas the effect of the variation of percent cement is almost as twice as that of fineness.

3.7 Effect of mean particle Size on Apparent Porosity:

Figures (8) and (9) show the relations between apparent porosity and the mean particle size for formulations containing bauxite and grog. It can be seen that the apparent porosity decreases with the increase of cement content. This is expected since higher cement content enhances the closure of available pores. Also these figures show that the apparent porosity is negatively affected by the increase of particle size.

Using the excel DATA ANALYSIS module, it is possible to establish correlation tables in both cases to show the relative influence of percent cement and particle size on the apparent porosity. Although such tables are not shown, their result indicates that both variables affect negatively the apparent porosity whereas the effect of the variation of percent cement on porosity is almost as twice as that of fineness.

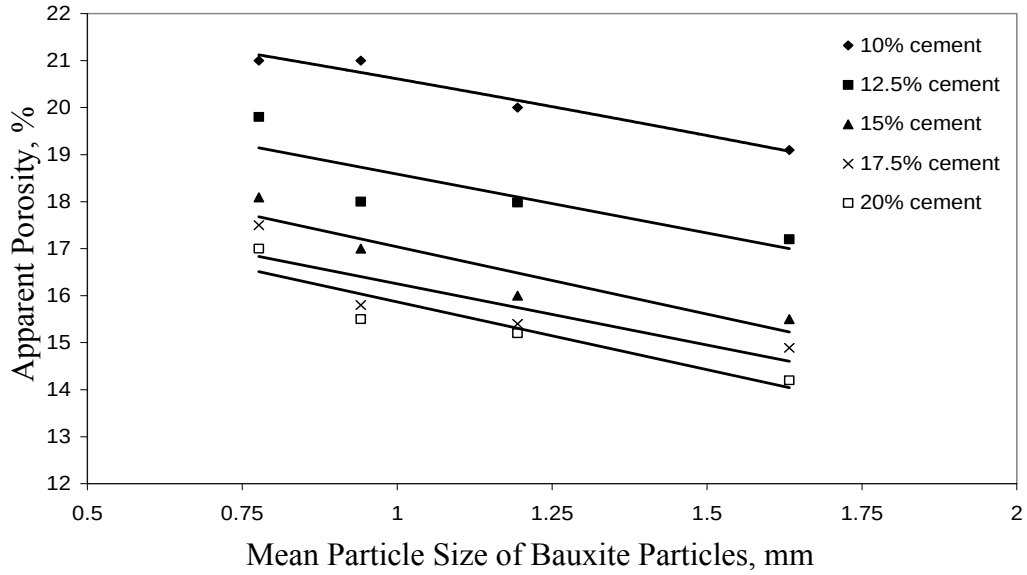

Fig. (8): Effect Mean Particle Size of Bauxite Aggregates Containing Different Cement Percents on Percent Apparent Porosity for Mixes

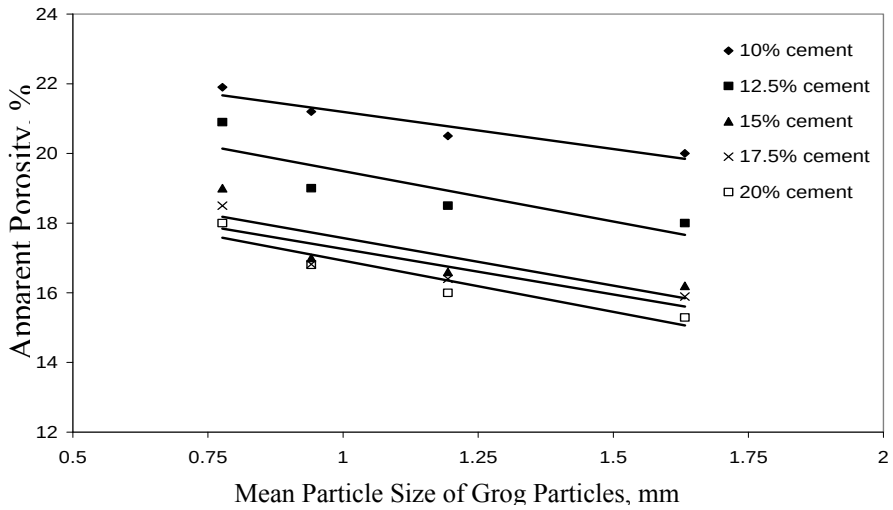

Fig. (9): Effect Mean Particle Size of Grog Aggregates Containing Different Cement Percents on Percent Apparent Porosity for Mixes

3.8 Effect of Particle Size Distribution on Bulk Density:

Figures (10) and (11) show the relations between bulk density and the mean particle size for formulations containing bauxite and grog.

The results indicate that the bulk density increases with the increase in cement content. This is expected since higher cement contents decrease the porosity. Also these figures show that the bulk density is slightly increased with the increase of particle size.

On the other hand, for the same particle size formulation, the values of bulk density of the samples containing bauxite are higher than of those containing grog. For example, at mean particle size = 1.63 mm, the bulk density of samples containing bauxite ranged from 2.37 to 2.96 g/cm^3, depending on the amount of cement added compared with 2.3 to 2.9 g/cm^3 for grog containing samples.

Also, due to the irregular shape of the grog particles , the packing efficiency of a body containing grog is less than that of bauxite. This assists the increased density in the case of using bauxite.

Correlation tables were established to show the relative effect of variations in cement content and particle size for the samples containing either bauxite or grog. These tables show that both cement content and higher particle size favour higher bulk density although the effect of cement variation on bulk density is more pronounced than that of particle size.

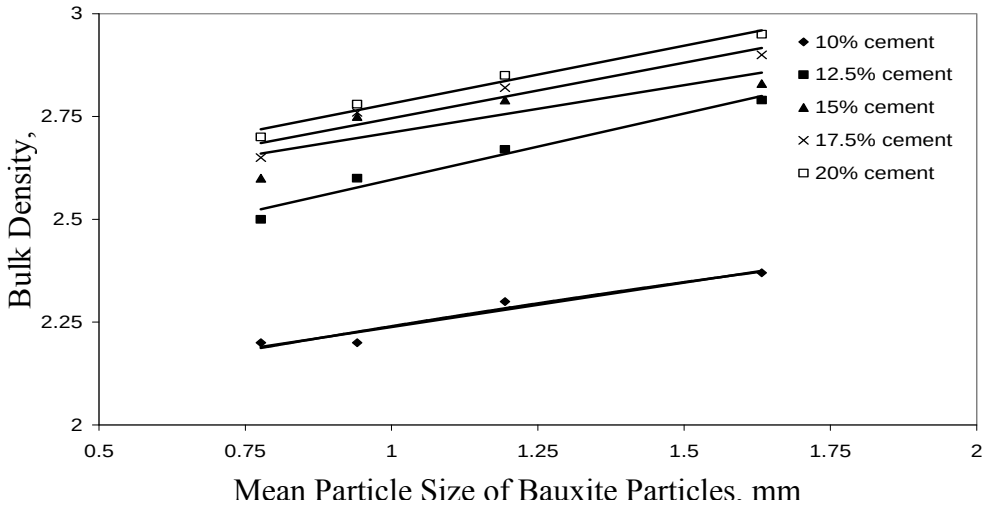

Fig. (10): Effect of Mean Particle Size of Bauxite Aggregates Containing Different Cement Percents on the Bulk Density for Mixes

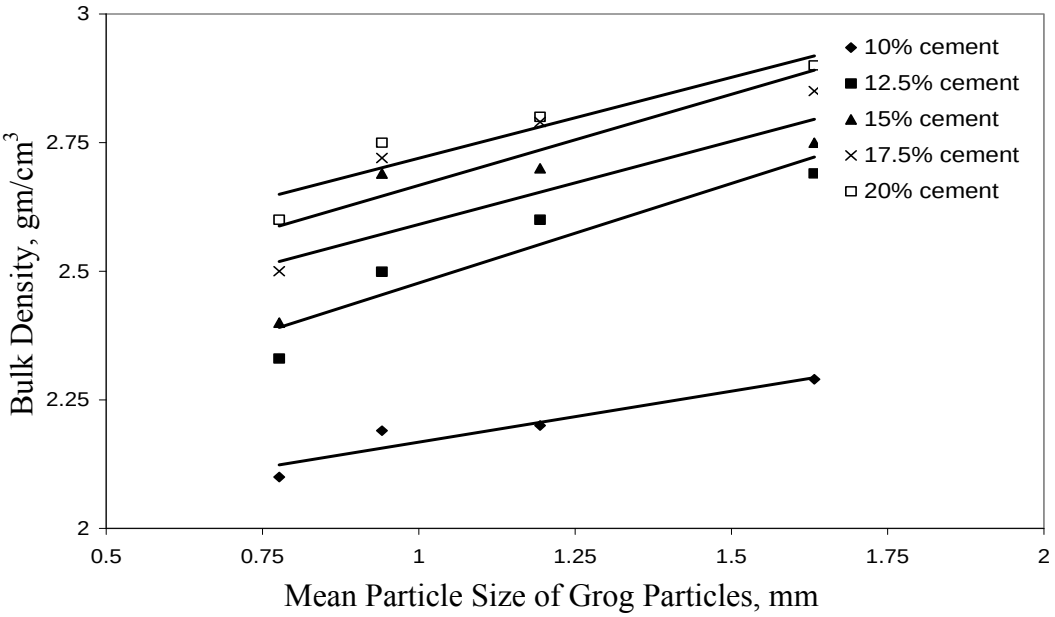

Fig. (11): Effect of Mean Particle Size of Grog Aggregates Containing Different Cement Percents on the Bulk Density for Mixes

3.9 Effect of Particle Size Distribution on Cold Crushing Strength:

Figures (12) and (13) show the relations between the 28 days – cold crushing strength and the mean particle used for different cement contents (bauxite and grog).

It could be seen that the compressive strength increases with the increase in cement content. The effect of mean particle size is more complicated. All curves seem to follow the same pattern: First, the cold crushing strength increases up to a mean particle size of about 0.95 mm then degreases with further increase in particle size. This mean particle size corresponds to formulation C in which the fine particles (D < 1 mm) constitute 40% of the mix whereas the coarse portion represents the remaining 60% (Table 2). Such recipe approaches a state of a minimum total porosity [11] and maximum compaction of the mix leading to a maximum value in C.C.S.

The values of crushing strength were higher for the mixes containing bauxite than for those containing grog: In the former the C.C.S. ranged between 34 and 39 MPa, compared with 32 to 37 MPa in the latter case.

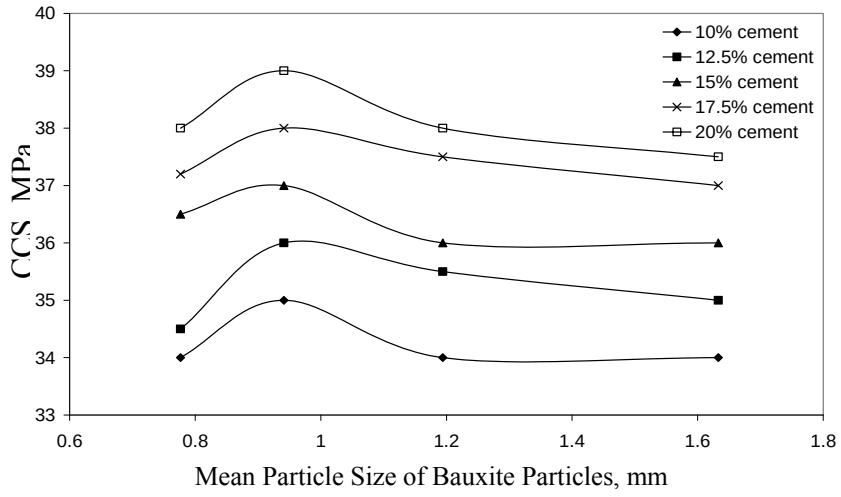

Fig. (12): Effect of Mean Particle Size of Bauxite Aggregates Containing Different Cement Percents on the Cold Crushing Strength of Mixes

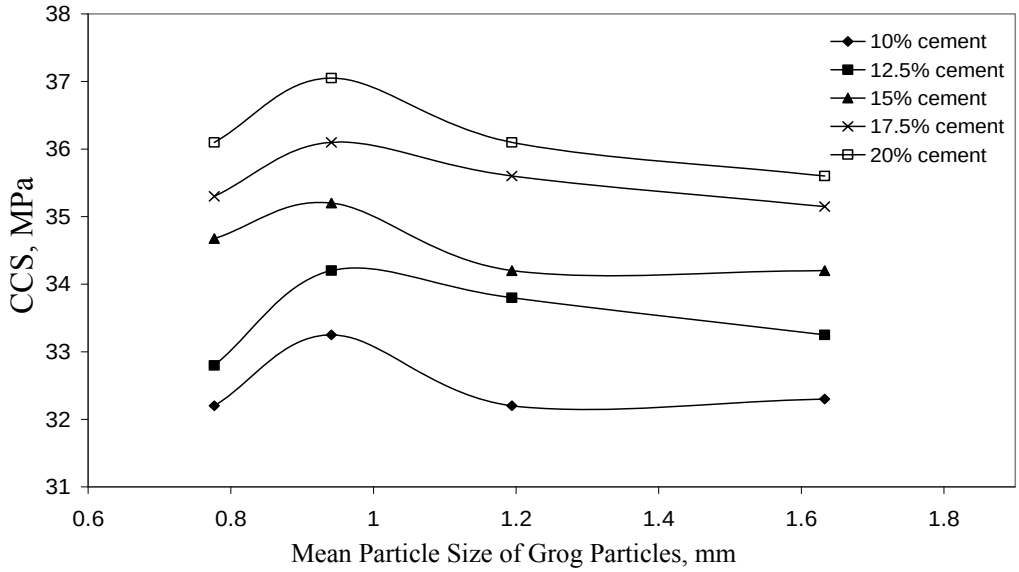

Fig. (13): Effect of Mean Particle Size of Grog Aggregates Containing Different Cement Percents on the Cold Crushing Strength of Mixes

Tables (7) and (8) describe the relative effect of the variation in cement content and mean particle size on the variation in CCS for both types of samples. These tables show that, in both cases, the variation of cement content plays a much higher role than that of particle size in assessing variations in CCS.

Table (7): Correlation Table for CCS for Bauxite Based Mixes

	% Cement	Particle Size	CCS
% Cement	1		
Particle Size	0	1	
CCS	0.945608	− 0.12905	1

Table (8): Correlation Table for CCS for Grog Based Mixes

	% Cement	Particle Size	CCS
% Cement	1		
Particle Size	0	1	
CCS	0.943331	− 0.12633	1

4. Conclusions:

Samples of refractory concrete wereprepared using between 10 to 20% of cement containing 50% alumina and two types of aggregates: calcined bauxite (~ 81% Al_2O_3) and grog containing 52% alumina. These were graded to yield four portions of different mean particle size.

The following results could be deduced:

- Increasing the amount of cement added lead to higher water / solid ratio, lower water absorption lower porosity and higher bulk density.
-
-
- Using coarser aggregate resulted in a reduction in water used for mixing, lower water absorption, lower porosity and a higher bulk density.
- The effect of variation in cement content on the aforementioned properties is generally higher than that of variation of particle size.
- A higher cement content favored higher cold crushing strength and a maximum value was obtained at a mean aggregate particle size of about 0.95 mm corresponding to a state of maximum compactness.
- Better results were generally obtained on using bauxite aggregate rather than grog presumably due to their lower intrinsic porosity.

Abstract: Background: Osteoporosis is a disease characterized by low bone mass and deterioration of bone structure that causes bone fragility and increases the risk of fracture. . Children and adolescents with type 1 (insulin-dependent) diabetes mellitus (T1DM) show several impairment of bone metabolism and structure, resulting in a higher risk of decreased bone mass and its related complications later in life. Objective: to analyze whether bone mineral density (BMD) with bone status are influenced in children with T1DM and evaluate their relationships with clinical status, age and duration. Patients and Methods: Forty cases (age 7.5 $\pm$ 3.4 and duration of disease 3.7 $\pm$ 2.5 years) were studied. BMD expressed as Z-score was measured at neck of femur and Lumbar spines ($L_2 - L_4$) using dual energy x-ray absorptiometry (DEXA) for 15 cases. Urinary excretion of deoxypyridinoline (DPD) was measured by radio immunoassay and was corrected by creatinine (Cr). Serum levels of osteocalcin, osteoprotegrin, procollagen and rankle – markers of bone formation and resorption were measured. They were matched by age and sex for another 40 normal children as control. Results: there was a significant decrease in serum level of osteocalcin in 12 of our patients,all cases showed significant increase in serum rankle with significant difference $P < 0.05$ compared to control. Mean values of procollagen showed no significant difference compared to controls. As regard DPD mean values of cases showed a significant increase compared to control. BMD – expressed as Z-score-by DEXA revealed 10 cases with mild degree osteopenia, while the other 5 cases showed moderate degree. Conclusion: pediatric patients with T1DM appear to constitute a population at risk of developing osteopenia. Age-optimizing of metabolic control in growing diabetic children may prevent osteoporosis in later life.

Keywords: Osteoporosis- Type 1 Diabetes Mellitus-Dual energy x-ray absorptiometry (DEXA), Bone Mass density – Osteopenia.

1. Introduction:

There are several different forms of idiopathic osteoporosis that can affect both children and adolescents (Sone,.2010). Juvenile osteoporosis affects previously healthy children between the ages of 8-14 (Heap et al., 2004).

The disease almost always goes into remission around the time of puberty with a resumption of normal bone growth at that time, (Ingberg et al., 2004). Patient with mild or moderate forms of the disease may be left with a curvature of the spine and short stature, but those with a more severe form may be incapacitated for life (Alonso et al,2010 and Gooch et al., 2000).

Diabetic osteoporosis is increasingly recognized as a significant comorbidity of type 1 diabetes mellitus (Saha et al, 2009 and Galluzzi et al,2005). . Alterations of the nuclear factor-kappa B ligand (RANKL)/osteoprotegerin (OPG) system have been implicated in several metabolic bone diseases characterized by increased osteoclast differentiation and activation and enhanced bone resorption (Carnevale et al,2004) Data uniformly support the concept that new bone formation as well as bone microarchitectural integrity are altered in the diabetic state, leading to an increased risk for fragility fracture and inadequate bone regeneration following injury, (Stagi et al,2010 and He et al., 2004).

The osteopenia associated with diabetes appears to be associated with a decreased bone turnover associated with impaired osteoclastic maturation and function (Brandao et al,2007) . This is reflected in a decrease in serum markers of bone formation, such as osteocalcin. Bone resorption and formation are usually tightly coupled, (Heilman et al,2009 and Gunczler et al., 2001).

Insulinopenia as occurs in type 1 diabetes is associated with several deleterious consequences for skeletal health. Skeletal defects that are observed in conjunction with T1DM include : 1) diminished linear bone growth during the pubertal growth spurt, 2) decreased adult bone density, 3) an increased risk for adult osteoporosis, 4) increased risk of fragility fracture, and 5) poor bone healing and regeneration characteristics,(Saha et al,2009 and Campos et al., 2000).

Aim of the study : To analyze whether bone mineral density (BMD) with bone status are

influenced in children with type 1 diabetes mellitus (T1DM) and evaluate their relationships with clinical status, age and duration.

2. Subjects and Methods:

Forty patients with type 1 Diabetes Mellitus – from endocrinology clinic, Children Hospital, Cairo University – were included in this study. Mean age was (7.5 ± 3.4 years) and mean duration of the disease (3.7 ± 2.5 years). They were matched by age and sex for another 40 normal children as control.

All the above cases were subjected to:

Full history taking for the clinical status, all investigations were done for diagnosis and full details about scheme of treatment.

Special clinical files were done for all the studied cases with all their clinical data.*Blood samples were collected. Separated sea was froozen at –20.

Serum levels of osteocalcin were measured by host-ELISA kit prepared by Bio Source Europe S.A. Serum procollagen Type 1 was detected by Enzyme Immunoassay. Osteoprotegrin was measured by Biovendor Human Osteoprotegrin, while serum level of RANKL was detected by Biomedica Gruppe

Enzyme Immunoassay.

BMD was done by DEXA manifested on the femur bone and Lumbar spines (L_2- L_4) expressed as Z-score.

Statistical methods:

All the above data were collected and statistically tested by analysis of variance or students t-test. Correlations were studied by simple pearsons coefficient. Significance was defined as $P < 0.05$.

3. Results

Our study revealed significant decrease in osteocalcin level (range 2.1 – 5 ng/ml) in 28 of our T1DM cases compared to 12 cases showed normal range of (5-25), with mean values of osteocalcion 5.7 ± 6 for cases against 9.5 ± 7 ng/ml for control with statistical significant difference $P < 0.05$ (Table 1 and Fig. 1).

Positive correlation ($r = 0.6$) was recorded between osteocalcin level and age of the patients in years (Table 2 and Fig. 2).

Forty cases of the study, showed increase in procollagen type 1 level (mean 352.4 ±18.3) compared to control (mean 339.2 ± 19.2) but without significant differene $P > 0.05$. Table (1).

Levels of osteoprotegnin were markedly decreased in all the cases (3.1 ± 6.9) against (7.9 ± 5.4) for controls with $P < 0.05$ (Table 1 and Fig.1). A positive correlation ($r = 0.5$) was detected between osteoprotegrin level and duration of the disease (Table 3 and Fig. 3).

As regard Rankl levels, the cases record significant increase in all the cases (mean 78420.9 ± 16.2) compared to control (15977.2 ± 25.1) with $P < 0.05$ Table (1).

Urinary levels of DPD, revealed marked increase in all the cases (mean 68.65 ± 8.2) compared to control (36.11 ± 1.2) with statistical significant difference $P < 0.05$ Table (1).

The BMD- expressed as Z score – was measured in 15 cases only at the femur and lumbar spines (L_2 – L_4). Our results showed 10 cases with mild form of osteopenia (-1: -1.5) and the other 5 cases with moderate form of osteopenia (-1.5: -2).

Table (1) : Mean Values of some Laboratory Finding of Patients Versus control:

	Osteocalcin ng/ml	Procollagen ng/ml	Rankl Pmol/L	Osteoprotegrin Pmol/L	Deoxypyridin (DPD) n mol DPD/ n mol Cr
Patient (n=40) mean ± SD	5.7 ± 6	352.4 ± 18.3	78420.9 ± 16.2	3.1 ± 6.9	68.65 ± 8.2
Control (n=40) mean ± SD	9.5 ± 7	339.2 ± 19.2	15977.2 ± 25.1	7.9 ± 5.4	36.11 ± 1.2
P-value	P < 0.05	P > 0.05	P < 0.05	P < 0.05	P < 0.05

Statistical sig. difference p<0.0

Table 2 : Relation between Osteocalcin and age of the patients.

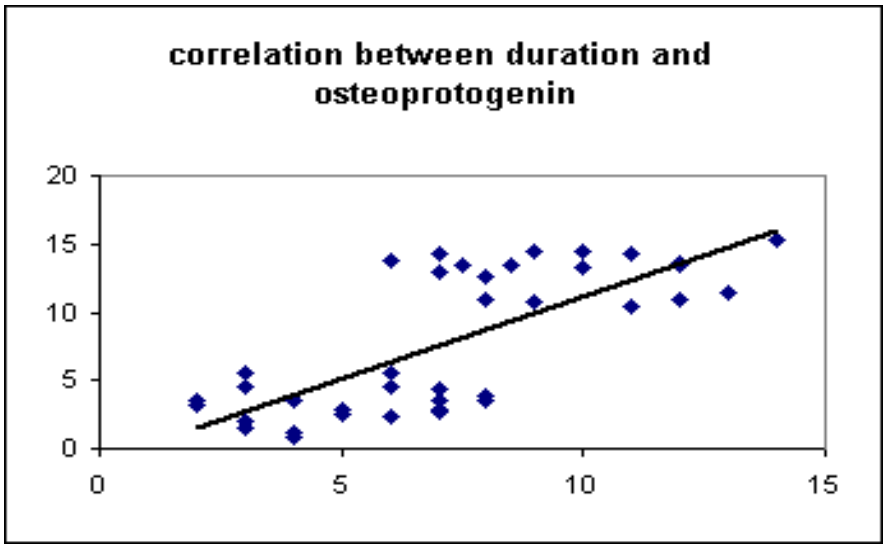

Fig.3 Correlation between osteoprotegrin and duration of disease.

4. Discussion:

Osteoporosis can vary broadly and may involve more than one disorder. Some young patients with osteoporosis may have a primary defect in the regulation of bone cell function, resulting in depressed bone formation, increased bone resorption or both,(Alonso et al,2010 and Heap et al., 2004).

The result of this study on T1DM patients revealed significant decrease in serum values of osteocalcin and osteoprotegrin, (2.1 – 5 ng/mL, 62 ng/ml, 3.1 – 6.9 pmol/L respectively). These findings indicate active depression of bone formation during diabetic illness.

Mean while, our data showed increase mean values of serum Rankl (0.3 – 0.4 pmol/L) and urine values of DPD (600-852 pmol/L). Both indicate increase bone resorption.

These finding indicate that, early onset of diabetes, in particular, is associated with reduced bone density, and patients with type 1 diabetes show evidence of low bone mass following adolescence. Our data fit the same founded by, Geurs, et al., in (2003)and Heilman et al., (2009) who stated that, osteopenia with diabetes appears to be associated with a decrease bone turnover and impaired osteoblastic maturation and function. This is reflected in a decrease in serum markers of bone formation. Bone resorption and formation are usually tightly coupled, (Melhus et al., 2003).

Positive correlation between osteoprotegrin and duration of the disease (r = 0.5), could be explained by the fact that, all bone metabolic changes which occure in early childhood of type 1 diabetic patients will be gradually corrected with long duration of the disease, these results fit the same of Ingberg et al., (2004) and Gilluzzi et al., (2oo5) who suggested that the impact of T1DM on skeletal health may by especially pertinent during adolescence.

The patients in the study were all between age of 5 and 16 and had been receiving treatment for diabetes for at least five years in the endocrinology clinic at Abu-reach hospital. Bone mineral density and bone mineral content measurements were taken for neck of femur and lumbar spine (L_2-L_4) by dual energy X-ray absorptiometry (DEXA). Our result revealed ten cases with mild form of osteopenia (Z-score - 1: -1.5) while only 5 cases were of moderate osteopenia (Z score - 1.5: -2). Careful clinical history taking revealed that, those 15 cases of T1DM were with uncontrolled diabetes with in adequate doses of insulin. This can be explained by findings of, Hou et al.,(1993) vankuijk,(2010)and Kemink et al.(2000), who stated that insulin is an anabolic agent in bone. It can preserve and increase bone density and bone strength, presumably through direct and /or indirect effects on bone formation.

The results of this work demonstrated that osteopenia and osteoporosis are frequent complications of T1DM. This fit the results of Heilman et al, (2009) and Heap et al., (2004). It is relevant therefore, that many studies confirm that T1DM is associated with decreased bone density, (Lopez et al., 2001 and Rozadilla et al., 2003) and a state of low bone turnover, (Thrailkill, 2004).

The osteopenia founded in some of our T1DM population, can be explained by numerous factors which may contribute to the development of osteoporosis over the life time of those diabetic children, 1) insufficient skeletal mineralization during critical periods of bone mass accrual; 2) increased urinary calcium excretion coupled with diminished calcium absorption, leading to chronic clacium deficiency, 3) life long effects of chronic hyperglycemia on osteoblast function; 4) detrimental effects of accumulated glycated end products on bone formation; 5) insulinopenia.

Kemink et al. (2000), suggested that, although insulin as an anabolic agent can preserve and increase bone strength through its effects on bone formation, the persistence of fracture risk in certain hyperinsulinemic states, however, under scores the multifactorial nature of the effects of diabetes on bone and may suggest a threshold for insulin in promoting healthy bone. Multiple confounding variables may have independent negative impacts upon bone mineral acquisition in T1DM and ultimately, on peak bone mass, (Rozadilla et al., 2003).

5. Conclusion:

Pediatric patients with type 1 Diabetes Mellitus appear to constitute a population at risk of osteoporosis in adulthood. Poor metabolic control may expose those patients at adolescents to the risk of osteopenia. So, optimization of metabolic control in growing diabetic children may prevent osteoporosis in later life.

5. Recommendations:

Type 1 diabetes does appear to be a significant risk factor for osteoporosis. Currently we recommend that patients with type 1 diabetes be monitored more carefully than persons without diabetes. Those patients should be encouraged to consume a diet high in both calcium (at least 1200 mg/day) and vitamin D (400-600 Iu/day). It appears that intensive insulin therapy and a stable body weight in patients with type 1 diabetes are important in preventing bone loss.

Studies on Antimicrobial and Antioxidant Efficiency of Some Essential Oils in Minced Beef

Amany, M. Salem*, Reham, A. Amin and Gehan, S. A. Afifi

Food Control Department, Fac. Vet. Med., Benha University, Benha, Egypt
dr_amany40@yahoo.com*

Abstract: In this study, the antioxidant and antibacterial effect of garlic (G), thyme (T) and lemon grass (L) oils were investigated in refrigerated minced beef. It is noticed that, all essential oils used had considerable effectiveness in decreasing aerobic plate count (APC), *Enterobacteriaceae* count, Coliform count and *Staphylococci count*, as well as chemical indices as pH, total volatile nitrogen (TVN) and thiobarbituric acid (TBA). Sensory analysis indicated significant advantages in using lemon grass and thyme oils in refrigerated minced beef. In addition, a highly significant differences ($P<0.05$) between the different oils were noticed. Also, results indicated that the bacterial counts, pH, TVN and TBA values decrease as the concentration of the oil increases since the concentration (1.5%) gives the best effectiveness. The antioxidant and antibacterial activities of the added essential oils followed the order lemon grass oil > thyme oil > garlic oil. The treated minced beef samples extend the shelf life of the treated samples more than the control samples by 6 days. In conclusion, lemon grass, thyme and garlic oils can play an important role as antioxidant and antibacterial agents in refrigerated minced beef, but lemon grass oil is the best one.

Keywords: Antimicrobial; Antioxidant; Efficiency; Oil; Beef

1. Introduction:

Meat and its products have experienced increasing popularity and become widely spread all over the world. The appearance of food is one of the major determinants of its appeal to consumers and consequently, sales of the product. However, during storage, quality attributes of the products deteriorate due to lipid oxidation and bacterial growth which are the main factors that determine food quality loss and shelf life reduction. Lipid oxidation leads to the degradation of lipids and proteins which, in turn, contribute to the reduction in nutritional quality as well as deterioration in flavor, color and texture of displayed meat products (Aguirrezábal *et al.*, 2000), while bacterial contamination can precipitate major public health hazard and economic loss in terms of food poisoning and meat spoilage (Fernández –López *et al.*, 2005).

Although several synthetic food additives have been widely used in the meat industry to extend food shelf life, inhibit lipid oxidation and delay or inhibit the growth of pathogenic microorganisms, the trend is to decrease their use because of the growing concern among consumers about such chemical additives. Consequently, search for natural additives, especially of plant origin, has notably increased in recent years indicating that the application of natural food additives possessing both antioxidant and antimicrobial activities may be useful for maintaining meat quality, extending shelf life and preventing economic loss (Yin and Cheng, 2003 and Mielnik *et al.*, 2008).

Essential oils are regarded as natural alternatives of chemical preservatives and their use in food meets the demands of consumers for mildly processed or natural products, since in modern food industries, mild processes are applied in order to obtain safe products which have a natural or "green" image (Burt, 2004). However, the practical application of essential oils is limited because of flavor considerations, as well as, their effectiveness is moderate due to their interaction with food ingredients and structure (Skandamis *et al.*, 2001). Essential oils of herbs and their components, products from the secondary metabolism of plants, have many applications in ethno-medicine, food flavoring and preservation as well as the fragrance and pharmaceutical industries (Fabian *et al.*, 2006).

Garlic is one of the most commonly used ingredients as a flavor enhancement for sausage. In addition, garlic is appreciated for its medical properties. Garlic has a wide spectrum of actions, not only antibacterial, antifungal and antiprotozoal, but also it has beneficial effects on the cardiovascular and immune systems (Harris *et al.*, 2001). During the last decade, the antimicrobial activity of garlic and garlic derived organosulfur compounds was widely investigated against both food spoilage bacteria and food borne pathogens (Leuschner and Ielsch, 2003).

Thyme is commonly used in foods mainly for its flavor and aroma. Also, thymol, which is found in thyme, has been commercially available as part of mouthwash for more than hundred years. Besides, it is active against *E. coli* and *St. aureus* and spoilage flora in meat products (Solomakos *et al.,* 2008), completely stops the growth of fungi at low concentrations (Soliman and Badeaa, 2002) and inhibits the aflatoxin production (Chiasson *et al.,* 2004), so it has a role as pharmaceutical and preservative (Hammer *et al.,* 1999).

Lemon grass is a rich source of citral, which is used in perfumery and pharmaceutical industries, and bioactive compounds (flavonides and vitamin C). The natural flavonides are also attracting more and more attention not only due to their antioxidant properties, but as anti-carcinogenic and anti-inflammatory agents because of their lipid anti-peroxidation effects (Martin *et al.,* 2002).

Moreover, some researchers reported that there is a relationship between the chemical structures of the most abundant compounds in plants and their above mentioned functional properties (Deans and Svoboda, 1990).

The objective of the present study was to investigate the antioxidant as well as the antimicrobial effectiveness of three essential oils (garlic, thyme & lemon grass oils) at various concentrations on the quality of fresh minced beef during refrigerated storage (4ºC).

2. Materials and methods

A grand total of thirty random samples of fresh minced beef were collected from different butcher shops in Kaluobyia governorate. The samples were taken and transferred directly to the laboratory under complete aseptic conditions without undue delay. The samples were divided into untreated (control) and treated samples. The treated samples were homogenized with garlic, thyme and lemon grass oils in 0.5%, 1% and 1.5% concentrations for each oil. Each sample was packed in polyethylene bag, labeled and stored at 4 ºC. Each sample was analysed promptly at 3 days intervals during storage as follows:

1. Sensory examination:

It was carried out according to Pearson and Tauber (1984).

2. Chemical examination includes:

2.1. PH values were carried out according the technique recommended by ISO (1979).

2.2. Total volatile nitrogen (TVN) was done according the technique recommended by FAO (1980).

2.3. Thiobarbituric acid (TBA) was carried out according the technique recommended by Vyncke (1970).

3. Microbiological examination:

3.1. Determination of aerobic plate count (APC) which was performed according to ICMSF (1996).

3.2. Determination of total coliforms count which was done according to APHA (1985).

3.3 Enumeration and identification of *Enterobacteriaceae* which were carried out according to ICMSF (1996).

3.4. Determination of total *Staphylococci* count which was performed according to Oxoid (1986).

4. Statistical Analysis:

ANOVA was carried out on data of the sensory, chemical and microbiological evaluations. Data are expressed as mean + SE (Gomez and Gomez, 1984).

3. Results and Discussion:

It is obvious from results obtained in table (1) that the sensory properties of different treated minced beef samples during cold storage (4ºC) were enhanced by increasing the concentrations of oils compared to the untreated (control) samples at zero, 3rd and 6th day of the storage period. Generally, samples containing 1.5% lemon grass oil, thyme and garlic oils, respectively demonstrated the highest enhancement of sensory attributes, while the samples treated with 0.5% garlic oil demonstrated the lowest enhancement. The direct addition of essential oils to food may alter the sensory characteristics of food (Seydim and Sarikus, 2006). Nearly similar results were obtained by El-Desouky *et al.,* (2006) and Mielnik *et al.,* (2008).

Lipid oxidation and other degradation reactions lead to the formation of low molecular compounds, which contribute to the sensory profile. Hydroperoxides and secondary oxidation products can react with protein and amino acids during processing and storage period affecting the flavor, odour and texture of meat products (Frankel, 1998).

The differences in pH mean values between different treated and untreated samples were significant during storage at 4ºC (table 3). The results showed a significant ($P<0.05$) increase in pH mean values in different treatments during storage by different rates. The highest incremental rates (pH values) were found in the untreated (control) samples. The samples treated with 1.5% and 1% lemon grass oil, showed the highest significant ($P<0.05$) effect on

pH lowering its values than those of untreated samples, followed by samples treated with 1.5%, 1% and 0.5% thyme oil, respectively, and finally the samples treated with 1.5%, 1% and 0.5% garlic oil, respectively, till the end of the storage period. There was significant ($P<0.05$) increase in pH mean values of all untreated and treated samples with garlic, thyme and lemon grass oils at all concentrations at the 6th day of the storage period. This may be due to the activation effect of microbial load which may cause protein hydrolysis with the appearances of alkyl groups (Yassin - Nessrien, 2003).

The mean values of TVN are summarized in table (3) estimating the degree of meat deterioration during the storage period (zero, 3rd and 6th day). As the storage period at 4^{o}C increased, the TVN values increased as shown in table (3) for all minced meat samples with different rates depending on the nature of treatments. This may be attributed to the breakdown of proteins as a result of activity of microbial strains and proteolytic enzymes (Yassin - Nessrien, 2003). EOS (2005) stated that 20 mg TVN/ 100 gm raw samples indicates the spoilage of minced meat. The highest rate of increase of TVN values was recorded in control samples. The treatments with 1.5% lemon grass, thyme and garlic oils, respectively, were more effective in delaying the rate of TVN increase during the subsequent cold storage. This may be attributed to the role of such oils on microbial population and bacterial growth as antimicrobial agents (Sacchetti *et al.,* 2005).

The evaluation of TBA mean values of control and treated samples during storage at 4^{o}C are shown in table (3). The highest incremental rate was recorded in the untreated (control) samples, while the lowest significant incremental rate was recorded in samples treated with 1.5% lemon grass oil, followed by samples treated with 1% of the same oil. The incremental pattern in TBA values for all the stored samples with advancing the chilling storage time may be due to the auto-oxidation of meat lipids, bacteriological and/or oxidative rancidity. TBA value is routinely used as an index of lipid oxidation in meat products in store (Raharjo and Sofos, 1993) and the rancid flavor is initially detected in meat products between TBA values of 0.5 and 2.0 (Gray and Pearson, 1987).

Thus, it has been reported that thyme oil may act as a high scavenger of radicals involved in lipid peroxidation protecting lipids from oxidation during cold storage as discussed by Kulisic *et al.* (2005) and Bozin *et al.* (2006), while garlic oil posses effective antioxidant activity (Jackson *et al.,* 2002) which is mainly attributed to a variety of sulphur-containing compounds and their precursors (Song *et al.,* 2004). In the same field, Fernández – López *et al.* (2005) found that about 50% of the rancidity of meat products can be controlled by the citrus preparations (e.g. lemon grass oil) with significant advantages in acceptability and aroma in rancidity-susceptible meat products. This antioxidant activity has been mainly attributed to flavonoids and ascorbic acid in citrus fruits (hesperidin, neohesperidin and eriocitrin) (Schwarz *et al.,* 2001). All of these polyphenolic compounds have the ability to act as antioxidants by a free radical scavenging mechanism and also through their known ability to chelate transition metals (inactivation of iron ions) (Martin *et al.,* 2002).

In the past few years, a variety of plant materials containing phenolic compounds have been to be effective antioxidants in model systems. Since ancient times, herbs and spices have been added to food to improve sensory properties and prolong shelf life. Among the main objections against the use of spices as antioxidants, is the characteristic flavor which they give to the meat products. However, this could be turned towards a positive new exciting sensory sensation. The acceptability of the taste of highly spiced food is transmitted both culturally and genetically, and the countries with hotter climate use spices more frequently and at much higher levels than countries with cooler climates. Essential oils rich in polyphenols exhibit antioxidative activities as they scavenge free radicals, similar to synthetic phenolic antioxidants (Cuvelier *et al.,* 1996 and Billing and Sherman, 1998).

The mean values of total aerobic counts (APC) of different untreated and treated minced beef samples during cold storage were shown in table (4). The control samples showed the highest APC counts comparing to others containing lemon grass, thyme or garlic oils with different concentrations (table 4). The relatively high initial counts of control samples may be attributed to the grinding process, which compounds the problem by introducing the pathogens into the interior of the meat and contributes to the increase of total viable counts of meat (Nychas *et al.,* 1991 and Mead and Griffin, 1998). APC counts were gradually increased during cold storage for all samples with different ratios depending on the concentration of oil. The incremental pattern in APC

can be arranged in a descending order as follows: samples treated with garlic, thyme and finally lemon grass oil at 0.5%, 1% & 1.5% concentration levels, respectively. In general, as the concentration of oil decreased, APC increased as discussed by Marino *et al.* (2001).

As shown in table (4), it could be observed that the control samples had the highest counts of *Enterobacteriaceae* and coliform at any time of cold storage compared to other treatments. It is clear that lemon grass, thyme and garlic oils at concentration 1.5% have strong effects against the growth of *Enterobacteriaceae* and coliform, and as the concentration of these essential oils increases, the counts of *Enterobacteriacea*e and coliform reduce especially at the 3rd and 6th days of cold storage.

Data presented in table (5) showed staphylococci counts of different treated and untreated minced beef samples during cold storage. As demonstrated by the different treatments, the treated samples with lemon grass, thyme and garlic oils at concentration 1.5% respectively showed the lowest counts in this parameter at zero, 3rd and 6th days of cold storage.

Table (6) summarized the initial microflora of chilled minced beef samples related to *Enterobacteriaceae*. The contribution of this group to the final flora depends on the type and the concentration of the used essential oil. It needs to be stressed that the rate of growth, lag phase and the final incidence of enteric bacteria were affected by the addition of essential oils (table 6). During the cold storage of minced beef, *Enterobacteriaceae* count reached the highest level with the 6th day of the storage period. *Proteus vulgaris* being the most dominant (66.67%) followed by *Citrobacter freundii* (55.56%) and then *Enterobacter aerogenes* (44.45%) in control samples. The addition of essential oils reduces the growth of *C. diversus, C. freundii, E. aerogenes, K. pneumoniae, P. mirabilis & P. vulagaris* and suppressed the growth of *E. cloacae* & *Serratia liquefaciens* completely. The addition of lemon grass oil showed pronounced inhibition of *C.diversus, E. cloacae, K. pneumoniae, Proteus mirabilis* & *Serratia liquefaciens* and reduced the incidence of *C. freundii* (11.11%), *E. aerogenes* (11.11%) & *P. vulgaris* (22.2%) when compared to the control and the other treated samples with thyme and garlic oils.

Nearly similar results were obtained by Yassin-Nessrien and Abou-Taleb (2007) and Gutierrez *et al.* (2008).

The essential oils will result in immediate reduction of bacterial population (Seydim and Sarikus, 2006) and might be more effective against food borne pathogens and spoilage bacteria when applied directly on foods ready to be used, containing a high protein level at acidic pH, as well as, lower levels of fat or carbohydrates (Gutierrez *et al.*, 2008).

The antimicrobial activity of thyme oil has been thoroughly investigated (Ozcan *et al.*, 2006 and Mielnik *et al.*, 2008) and found to be active against food borne and spoilage flora (Solomakos *et al.*, 2008). This significant rate of antibacterial activities is mostly attributable to the phenolic compounds (cavracrol) and to the hydrocarbons which can be bactericidal or bacteriostatic depending on their effective concentration (Bozin *et al.*, 2006 and Yassin – Nessrien and Abou – Taleb, 2007).

Also garlic oil provides antimicrobial benefits (Sallam *et al.*, 2004), where garlic oil is rich in organosulfur compounds and their precursors (allicin, dially sulfide & diallyl trisulfides) (Ankri and Mirelman, 1999) inhibiting the growth of a lot of pathogens as APC, *E. coli* & *S. aureus* by reacting with their cystine, inactivating the thio-containing enzymes or affecting the metabolism of lipids (Song *et al.*, 2004) and subsequently, extending the shelf life of the product, so the garlic extracts are potentially useful in preserving meat products (Pranoto *et al.*, 2005).

Moreover, lemon grass oil was observed to possess high antimicrobial activity, so it can be used as a way of combating the growth of common causes of food poisoning (Fisher and Phillips, 2006). In the same field, Adegoke and Odesola (1996) added that some bacteria associates with food spoilage / intoxication were inhibited by the essential oil of lemon grass. Lemon grass oil was found to be effective at all concentrations (Chahal *et al.*, 2007), where it is composed of three main components, the alpha and beta-citral components which elicit antibacterial action on Gram-positive and Gram-negative organisms, while the third component is mycrene which provided enhanced activities when mixed with either of the two main previously identified components (Onawunmi *et al.*, 1984)

As an overall conclusion, garlic, thyme and lemon grass oils showed general enhancement in sensory, chemical and microbial attributes due to the

action of these oils in retarding oxidation as well as microbial population in the fresh minced meat during cold storage at 4ºC and the action of these oils is concentration dependent. Also we found that lemon grass oil is the most effective at all concentrations especially at 1.5% than thyme and garlic oils, respectively. The low effectiveness of garlic oil in comparison with thyme & lemon grass oils could be attributed to the losses of volatile sulfur compounds, which have high biological activity, during distillation, and also due to the nature of garlic oil itself, which is volatile and hydrophobic (Sallam *et al.*, 2004).

Therefore, it is suggested that garlic, thyme and lemon grass oils can be used as natural meat preservatives with both antioxidants and antimicrobial activities against food borne pathogens and spoilage organisms, and therefore may be useful in maintaining the meat quality, extending shelf- life of meat products, preventing economic loss and providing the consumer with food containing natural additives, which might be seen more healthful than those of synthetic origin. Further research is necessary to explore the efficiency and palatability of suitable concentrations of natural oils in meat industry.

Table (1): Sensory evaluation of the untreated (control) and treated samples of minced beef during cold storage at 4ºC

Samples	Zero day	3rd day	6th day
Control	Excellent	Very poor	Very very poor
Garlic oil			
0.5%	Excellent	Fair with the presence of garlic odour	Very very poor
1%	Excellent	Fair with the presence of garlic odour	Very poor
1.5 %	Excellent	Fair with the presence of garlic odour	Very poor
Thyme oil			
0.5%	Excellent	Fair with the presence of thyme odour	Very poor
1%	Excellent	Fair with the presence of thyme odour	Very poor
1.5 %	Excellent	Medium with the presence of thyme odour	Fair with the presence of thyme odour
Lemon grass oil			
0.5%	Excellent	Excellent with the presence of lemon odour	Very good with the presence of lemon odour
1%	Excellent	Excellent with the presence of lemon odour	Very good with the presence of lemon odour
1.5 %	Excellent	Excellent with the presence of lemon odour	Very good with the presence of lemon odour

Table (2): Score System for Sensory Evaluation (Pearson and Tauber, 1984)

Score System	
Points	Quality
9	Excellent

Abstract: A total of 152 cows was examined in this study for Staphylococcus species, it was found that 44.3% of cows and were clinically mastitic whereas 14.5% were subclinically mastitic respectively. The identification of Staphylococcus species revealed that *S. aureus, S. epidermidis, S. intermedius* and *S. hyicus* for cows were (17.2%, 7.5%, 3.9% and 1.6%) respectively. *Staphylococcus aureus* isolates were confirmed after biochemical identification by API test. The study of virulence factors of total *S. aureus* isolates from mastitic cows revealed that lipase, fibrinolysin, DNase and protein A production were presented as percentage 67.3, 74.0, 85.6 and 84.6 respectively. The antibiotic sensitivity for *S. aureus* revealed that 96.2% of cow isolates were methicillin sensitive which considered the drug of choice for these isolates. The study also included the identification of *S. aureus* enterotoxins using set-RPLA and multiplex PCR. The incidence of enterotoxins C,A,B and D by set-RPLA were 36.5%, 14.4%, 10.6% and 2.9% respectively. Meanwhile the results of multiplex PCR were 7 isolates as enterotoxin C,4 isolates as enterotoxin E and one isolate for each A,B, and D respectively. The identification of MRSA of cow's isolates using PCR revealed that 3 isolates out of 5 isolates were positive.
[El-Seedy,F.R, El-Shabrawy, M; Hakim, A. S; Dorgham,S.M.m Ata, S. Nagwa; Bakry, M.A and Osman,N.M.N. Recent Techniques used for Isolation and Characterization of *Staphylococcus Aureus* from Mastitic Cows. Journal of American Science 2010;6(12):701-708]. (ISSN: 1545-1003). http://www.americanscience.org.

Key words: *Staphylococcus aureus*; mastitis; methicillin sensitive; set- RPLA, multiplex PCR.

1. Introduction:

Mastitis is the most common infectious disease affecting the dairy cows and remains the most economically important disease of dairy industries around the world. (Khan *et al.,* 1998).

Milk and its products can harbor a variety of microorganisms and can be important sources of food borne pathogens. The presence of food borne pathogens in milk is due to direct contact with contaminated sources in the dairy farm environment or with excretions from the udder of infected animals (Oliver *et al.,* 2005).

A wide variety of bacteria can be involved, but the most common mastitis pathogen is *Staphylococcus aureus*, *S. aureus* is a major pathogen of bovine mastitis worldwide. Despite implementing intensive control measures, it is difficult to eradicate the intramammary infections caused by this pathogen and it remains a substantial economic problem. (Salmon, 2002). *Staphylococcus aureus* produces a broad spectrum of surface components (proteins and capsular polysaccharide) and exotoxins, they are virulence factors involved in the pathogenesis of bovine mastitis as these toxins and products are injurious to milk producing cells of the mammary gland, impair glands and immune defense mechanisms, while they are capable to reside intracellular contributes the ability of *S. aureus* to establish a chronic infection that can persist for the life of the animal(Taverna *et al*., 2007). Enterotoxigenic *S. aureus* in raw milk posses a potential health hazard to consumers and the identification of such strains should be used as a part of analysis of milk and milk products (Zouharova and Rysanek, 2008).

Because of the organisms propensity to acquire antimicrobial resistance, whereas most infections can be treated or prophylacted with antibiotic; antimicrobial resistance of *S. aureus* especially methicillin resistant *S. aureus* (MRSA) continues to be a problem for clinicians worldwide justifies their recognition as a "New Emerging Pathogen" (Shittu and Lin, 2006).

So the present study was conducted to evaluate the recent techniques for isolation and characterization of antibiotic resistant staphylococci (*S. aureus*) from mastitic animals in correlation to its virulent factors.

2. Materials and methods

Samples

Six hundred and eight milk samples were collected from udder quarters of examined cows, 388 were collected from 97 clinically mastitic cows

which had clinical signs of abnormal secretions of mammary glands containing clots or flakes, with udders showing swelling and hardness and 220 from apparently healthy cows detected by palpation of udder and were subjected to California Mastitis Test (CMT) to detect subclinical mastitis.

Isolation of Staphylococci:

The mastitic milk samples were activated by incubation for 18-24 hours at 37°C, then milk samples were centrifuged at 3000 rpm for 20 minutes and the cream and supernatant fluids were discarded, the sediments were streaked onto the surface of the following media: Nutrient agar, Blood agar medium, Mannitol Salt agar, Baird Parker agar and Vogel Johnson agar. The inoculated plates were incubated for 24-48 hours at 37°C, after which they were examined for colony characters, cellular morphology and the purity of the culture. The suspected colonies were identified according to Collee *et al*. (1996) and Quinn *et al*. (2002).

Staphylococci latex agglutination test:

Staphylococci were tested using dry spot kit and colonies from previous media Fresh culture grown overnight 18-36 hours incubation were used. A positive result showed agglutination of the latex particles occurs within 20 seconds. This indicates the presence of *S.aureus*.

Identification of *S. aureus* isolates using API system:

The organism was sub cultured onto Columbia blood agar at 37°C for 18-24 hours. Single well-isolated colony (young culture) from blood agar inoculated into API staph medium to make homogeneous bacterial suspension with a turbidity equivalent to McFarland tube No. 0.5 and this suspension used immediately after preparation. Identification is obtained with the numerical profile on the result sheet, the tests are separated into groups of 3 and a value 1, 2 or 4 is indicated for each. By adding together the values corresponding to positive reactions within each group, a 7-digit profile number is obtained for the 20 tests of API strip.

Antimicrobial sensitivity test of *S. aureus* isolates:

Using disk diffusion method which applied according to (Finegold and Martin, 1982).

Detection of staphylococcal enterotoxins by SET-RPLA kit:

The clear culture supernatant fluids were tested serologically by reversed passive latex agglutination technique using Oxoid SET-RPLA [A Kit for detection of Staphylococcal enterotoxins A, B, C and D] (Shingaki *et al*., 1981).

Extraction of DNA from the Staphylococcal isolates according to Sritharan and Barker (1991):

Extraction of DNA from the Staphylococcal isolates by Hexadechyl trimethyl ammonium bromide (CTAB) according to Sambrook *et al.* (1989):

Multiplex polymerase chain reaction (multiplex PCR) according to Becker *et al*. (1998):

All reactions were carried out in a final volume of 50 µl in micro application tubes (PCR tubes). The reaction mixture consists of 5 µl of the extracted DNA template from the bacterial cultures, 5 µl of 10x PCR buffer, (75 M Tris Hcl PH9.0, 2mM MgCl2, 50 mM Kcl , 20 mM$(NH4)_2So_4$),1 µl dNTPS (40µM),1µl(1U Ampli Taq DNA Polymerase) and 1µl from the forward and reverse primers of (SAEA F-SAEA R), (SAEB F-SAEB R), (GSECR.1-GSECR.2), (GSEDR.1-GSEDR.2) and (GSEER.1-GSEER.2). All primers were used together and volume of the reaction mixture was completed to 50 µl using DDW. 40 µl paraffin oil wax was added and the thermal cycler was adjusted as following program: initial denaturation at 92˚C for 5 minutes followed by 35 cycles of denaturation at 92˚C for 1 minute, annealing step at 52˚C for 1 minute and extension at 72˚C for 1 minute. A final extension step was done at 72˚C for 10 minutes. The PCR products were stored in the thermal cycler at 4˚C until they were collected.

Amplification of mec A gene from DNA of *Staphylococcus aureus* isolates according to Riffon *et al.* (2001):

Each reaction was performed in a final volume of 25 µl in PCR tubes (ependorff). Each reaction contained mixture consists of 3µl of the extracted DNA template from the bacterial cultures plus 20 µl of ready to used master mix and 1 µl from the forward and reverse primer of MecAR1-MecAR2. At the surface of the tube, 40 µl paraffin oil was added to avoid evaporation of the reaction mixture and the thermal cycle was adjusted as following program: initial denaturation at 94˚C for 4 minutes followed by 30 cycles of denaturation at 94˚C for 45 seconds, annealing step at 58˚C for 1 minute and extension at 72˚C for 2 minute. A final extension step was done at 72˚C for 10 minutes. The PCR products were stored in the thermal cycler at 4˚C until they were collected.

The PCR products were electrophoresed in 1.5% agarose gel using Tris-acetate EDTA buffer. The gel containing separated DNA was stained with ethidium bromide. Standard marker containing known fragments of DNA either 100 bp or 250 bp ladders was used.

Table (1): The primers used for PCR

Primer	Sequence(5¯- 3¯)	Product size(bp)

3. Results and Discussion:

From the results presented in table (2) examination of 388 quarter milk samples collected from 97 clinically mastitic cows by bacteriological examination revealed positive results in 232 (44.3%) of them while the examination of 136 quarter milk samples collected from 34 subclinically mastitic cows by CMT revealed positive results in 76 (14.5%) of them as shown in table ().These results are nearly similar to those mentioned by Bakken (1981) and Kossaibat *et al.*, (1998). El –Rashidy *et al.*, (1990) recorded that the incidence of subclinical mastitis was 26.08% and Seddek *et al.*, (1999) 7.1% to 29% among cows.

It is clear from table (3) The affection in two quarters is higher than the other quarter's affection in clinically and subclinically mastitic cows with an incidence of 34.0% and 38.2% respectively. In clinically mastitic cows three quarters affection are 27.8% followed by one quarter affection 21.6% then four quarter affection 16.5% meanwhile in subclinically mastitic cows one quarter affection is 26.5% followed by three quarter affection 20.6 % then four quarter affection 14.7 % . Concerning quarter involvement in mastitic cows, the rate of involvement in one and two quarters were relatively higher in subclinical mastitis (26.5% and 38.2%) than in clinical mastitis (21.6% and 34%) while the affection in the three and four quarters were higher in clinical mastitis (27.8% and 16.5%) than in subclinical mastitis (20.6% and 14.7%), whereas Bansal *et al.*,(1990) found that 64% of the lactating cows were infected in one quarter, 25% in two quarters, 5% in three quarters and 0% in all four quarters respectively, the variation in the quarter involvement maybe due to the differences in the defense reaction among quarters of the same animal (Dopfer *et al.*, 1999).

Table (2): Incidence of mastitis among the examined milk samples of cows.

Healthy state of the udder	Examined cows	Examined quarter	Negative quarter milk samples		Positive quartermilk samples	
			No.	%	No.	%
Clinical mastitis	97	388	156	29.8	232	44.3
Subclinical mastitis	34	136	60	11.5	76	14.5
Total	131	524	216	41.2	308	58.8

Table (3): The distribution of infected quarters in clinically and subclinical mastitic cows:

Number of affected quarters	clinically mastitic cows		subclinically mastitic cows	
	No.	**%**	**No.**	**%**
One quarter	21	21.6	9	26.5
Two quarters	33	34	13	38.2
Three quarters	27	27.8	7	20.6
Four quarters	16	16.5	5	14.7
Total	97	100	34	100

Table (4) illustrated the bacteriological examination of 232 milk samples and 76 milk samples collected from clinical and subclinical mastitis in cows respectively. It was found that only 71 and 22 were positive milk samples for staphylococcal species with an incidence of 30.6% and 28.9% respectively. In clinical mastitis the percentage of *S. aureus* isolates were (17.7%) as major pathogen followed by *S. epidermidis* (6.9%), *S. intermedius* (4.3%) and the lowest incidence was *S. hyicus* (1.7%). On other hand, in subclinical mastitis the incidence of *S. aureus* was (15.8%), *S. epidermidis* was (9.2%), *S. intermedius* was (2.6 %) and *S. hyicus* was (1.3%). These results showed that *Staphylococcus aureus* was the most microorganisms incriminated as cause of clinical and subclinical mastitis, as it represented 17.7% and 15.8% of the total bacterial isolates from examined quarter milk of cows respectively. In agreement with this result Esmat and Bader (1996) and Dego *et al.,* (2002) recorded that *S .aureus* was the most prevalent bacterial agent associated with mastitis in cows.

Table (5) illustrated the tested virulence factors of the *S. aureus* isolates in the present study, 88 out of 104 *S. aureus* isolates (84.6%) showed positive SpA by agglutination test. This observation was in agreement with that mentioned by Rosenberg *et al*, (2000) and Farage (2008). Moreover, the association of virulence genes and clinical mastitis proved the role of spa gene as risk factor (Zecconi *et al.* ,2005). Also the polymorphism of spa gene was confirmed to be scientifically associated with inflammatory response and growth rate (Zecconi *et al.* ,2006). (Kalorey *et al*., 2007).

In the present work all isolates of *S.aureus* were subjected for detection of clumping factor and capsular polysaccharide using dry spot kit (staphtect plus) (Oxoid).It is a latex slide agglutination test for differentiation of *S.aureus* than other staphylococci.
Concerning lipase activity on egg yolk agar medium, only 34 *S. aureus* strains were negative to this test with an incidence of 32.7%. On the other hand 70 strains out of 104 *S. aureus* isolates had lipase activity with percentage of 67.3. These results goes parallel to that recorded by Leung *et al*.,(1993) and Annemuller and Zschock

Table (4): Prevalence of Staphylococcus species isolated from clinically and subclinically mastitic milk samples in cows (1999).

Source of milk samples	No. of examined milk samples	Staphylococcus species								Total number of isolates	%
		S. aureus		*S. epidermidis*		*S. intermedius*		*S. hyicus*			
		No.	%	No.	%	No.	%	No.	%		
Clinical mastitis	232	41	17.7	16	6.9	10	4.3	4	1.7	71	30.6
Subclinical mastitis	76	12	15.8	7	9.2	2	2.6	1	1.3	22	28.9
Total	308	53	17.2	23	7.5	12	3.9	5	1.6	93	30.2

(100%) then subclinically mastitic cows (66.7%).

Table (5): Incidence of virulent factors in *S. aureus* isolates from cows.

Source of isolates	Clinical mastitic cows				Sub Clinical mastitic cows			
No of samples	41				12			
	positive		negative		positive		negative	
	No	%	No	%	No	%	No	%
Lipase activity	29	70.7	12	29.3	7	58.3	5	41.7
Fibrinolysine activity	33	80.5	8	19.5	9	75	3	25
DNase	41	100	-	-	8	66.7	4	33.3
SPA	37	90.2	4	9.8	10	83.3	2	16.7

In the present investigation high sensitivity was recorded to methicillin (96.2%) among the examined *S. aureus* isolates in cows followed by gentamycin (90.6%) and amoxicillin ,clavulinic acid and enrofloxacin (84.9% each) then ciprofloxacin (83.0%) and rifampicin (79.2%). Meanwhile 71.7% of the examined *S. aureus* isolates were resistant to streptomycin, 64.2% to penicillin and 54.7% to oxytetracycline. These results agreed to large extent with the finding of Pengov (1996) and Bhalerao *et al*., (2000).

Table (6): Antibacterial sensitivity test of *S. aureus* isolates from milk samples of cows with clinical and subclinical mastitis.

Antimicrobial agent	µg/disc	Sensitive		intermediate		resistant	
		No.	%	No.	%	No.	%
Ampicillin	10	26	49.0	16	30.2	11	20.8
Amoxycillin	25	32	60.4	9	16.9	12	22.6
Amoxycillin +Clavulinic acid	20+10	45	84.9	2	3.8	6	11.3
Penicillin-G	10 unit	15	28.3	4	7.5	34	64.2
Ciprofloxacin	10	44	83.0	5	9.4	4	7.5
Enrofloxacin	15	45	84.9	3	5.7	5	9.4
Gentamycin	10	48	90.6	3	5.7	2	3.8
Clindamycin	20	35	66.0	5	9.4	13	24.5
Neomycin	30	31	58.5	7	13.2	15	28.3
Streptomycin	10	11	20.8	4	7.5	38	71.7

Cloxacillin	1	36	67.9	5	9.4	12	22.6
Methicilline	5	51	96.2	-	-	2	3.8
Oxytetracycline	30	14	26.4	10	18.9	29	54.7
Sulphamethoxazole-trimethoprim	23.75+ 1.25	20	37.7	12	22.6	21	39.6

The present study detected toxigenic strains in *S. aureus* isolates using commercial available kits, reverse passive latex agglutination test (RPLA). Results obtained showed high incidence of type C enterotoxin followed by type A then type B and type D. These results are in agreement with that mentioned by Jorgensen *et al.*, (2005) who found SEC was the most common enterotoxin detected in *S. aureus* isolates from bovine mastitis. In addition to that mentioned by Soriano *et al.*,(2002) and Badia (2004) who found that obtained results showed high incidence of type C (22 - 41.5%) followed by enterotoxin A, enterotoxin B and enterotoxin D whose numbers of isolates were 7 (13.2%), 5(9.4%) and 3 (5.7%) respectively. Detection of staphylococcal enterotoxins is decisive for confirmation of an outbreak and determination of the enterotoxigenicity of the strains. Since the recognition of their antigenicity, large number of serological methods for detection of enterotoxins in food and culture media has been proposed (Dacunha *et al.*, 2007). From our point of view the distribution of infection in the udder tissues may be related to the role played by toxins, this observation was in accordance to that mentioned by Hillerton and Walton (1991).

Table (7): Prevalence of toxigenic *S. aureus* isolates using RPLA test:

Source of *S. aureus*	No. of *S. aureus* isolates	Toxigenic isolates		Types of toxins							
				A		B		C		D	
		No.	%	No.	%	No.	%	No.	%	No.	%
Cows	53	37	69.8	7	13.2	5	9.4	22	41.5	3	5.7
Buffaloes	51	30	58.8	8	15.7	6	11.8	16	31.4	-	-
Total	104	67	64.4	15	14.4	11	10.6	38	36.5	3	2.9

Detection of toxigenic strains in *S. aureus* isolates using multiplex polymerase chain reaction technique (multiplex PCR). Total number of 12 isolates previously tested by using RPLA and the results were confirmed using multiplex PCR as recent technique. Results obtained showed that 100% agreement between the two tests RPLA and multiplex PCR. Our findings also agree with that of Zouharova and Rysanek(2008) who found that the results of both methods were identical concerning SEB and SED. It was concluded that detection of SEs by multiplex PCR was a useful additional tool to support identification of enterotoxigenic strains. Photo (1) showed the analysis of the results obtained by SET-RPLA method for the productivity of classical enterotoxins A-D and the results obtained by PCR for the presence of sea-sed genes revealed the correlation between each other (Lawrynowicz-Paciorek *et al.*, 2007).

To amplify the mecA gene from the extracted DNA of the previously selected *S. aureus* isolates with MR1-MR2 primers which amplify 1339

bp fragment of mecA gene were used. Results presented in photo (2) revealed that positive amplification of the 1339 bp fragment of mecA gene from the extracted DNA of 3 *S. aureus* isolates out of 5 examined samples. These 5 results of antibiogram of such five isolates were "3 strains methicillin-resistant while 2 strains were sensitive" which indicated that PCR technique could detect the mecA gene in the mecA resistant. This finding was supported by Riffon *et al*., (2001)

Biosynthesis and Characterization of *Aspergillus Niger* AUMC 4301 Tannase.

M. Z. El-Fouly[1]; Z. El-Awamry[2]; Azza A.M. Shahin[1]; Heba A. El-Bialy[1]; E. Naeem[2] and Ghadeer E. El-Saeed[1]*

[1] National Center for Radiation Research and Technology (NCRRT), Radiation Microbiology Department, Atomic Energy Authority, Cairo, Egypt. [2] Faculty of Science, Azhar University, Cairo, Egypt.

Abstract: A study on biosynthesis and characterization of an extracellular tannase from *Aspergillus niger* AUMC 4301 was carried out. *A. niger* AUMC 4301 was selected out of one hundred and thirty fungal isolates have the ability to grow in the presence of tannic acid. Maximum enzyme synthesis under solid state fermentation was attained in the presence of 3% tannic acid and 0.2% ammonium nitrate after five days incubation at 30°C. Effect of different carbon and nitrogen sources on tannase formation was also investigated. Crude tannase had maximum activity at pH 4.8, 60°C and 20 min as a function of reaction time. The catalytic action of biosynthesized tannase was directly proportional to the amount of enzyme in the reaction mixture. Using tannic acid as substrate, the K_m value for tannase was 2.50 mM. Gallic acid was shown to be a competitive inhibitor to tannase and the inhibition constant (K_i) was 1.35 mM. Effect of EDTA and some metal salts on enzyme activity was also studied.
[M. Z. El-Fouly; Z. El-Awamry; Azza A.M. Shahin; Heba A. El-Bialy; E. Naeem and Ghadeer E. El-Saeed. **Biosynthesis and Characterization of *Aspergillus Niger* AUMC 4301 Tannase.** Journal of American Science 2010;6(12):709-721]. (ISSN: 1545-1003). http://www.americanscience.org.

Keywords: *Aspergillus niger*, tannase, tannins, gallic acid, solid state fermentation

1. Introduction:

Tannase (tannin acyl hydrolse, E.C.3.1.1.20) catalyses the hydrolysis of ester and depside bonds of hydrolysable tannins as tannic acid, methygallate, ethylgallate, n-propylgallate and isoamylgallate releasing glucose and gallic acid (Barthomeuf *et al*., 1994). Tannase can be obtained from plant, animal and microbial sources. Industrially, the most important source for tannase production is microbial way because of its stability (Bhat *et al*., 1998). Over the past decade, a few bacterial species have been reported to produce tannase (Ayed and Hamdi, 2002 and Manjit *et al*., 2009) whereas the most reports are fungal origin including *A. aculeatus*, *A. aureus*, *A. flavus*, *A. foetidus*, *A. japonicas*, *A. niger*, *A. oryzae* (Batra and Saxena, 2005 and Purohit *et al*., 2006), *Aureobasidium pullulans* (Banerjee and Pati, 2005), *Paecilomyces variotii* (Mahendran *et al*., 2006), *Penicillium chrysogenum* (Batra and Saxena, 2005), *Penicillium variable*, (Sharma *et al*., 2008) and *Rhizopus oryzae* (Purohit *et al*., 2006).

Nowadays, untraditional fruit juices (pomegranate, cranberry, raspberry, etc.) have been acclaimed for their health benefits, in particular, for its disease-fighting antioxidant potential. The presence of high tannin content in these fruits is responsible for haze results from protein–polyphenol interaction, tannase applied to remove haze and improve color, bitterness, and astringency of the juice upon storage (Rout and Banerjee, 2006). Tannase is extensively used in the production of instant tea by solubilization of tea cream and in the manufacture of coffee-flavored soft drinks (Lu *et al*., 2009). Tannase also participates in the preparation of animal feeding (Nuero and Reyes, 2002) and in leather industry (Orlita, 2004). Tannase can be potentially used for the degradation of tannins present in the effluents of tanneries, which represent serious environmental problems (Van de-Lagemaat and Pyle, 2001). As well as, tannase is used in the treatment of waste water containing polyphenolic compounds such as tannic acids and as an analytical probe for determining the structures of naturally occurring gallic acid esters (Mukherjee and Banerjee, 2006).

Other important application of tannase is the production of gallic acid and propylgallate (Kar *et al*., 2002). Propylgallate is considered as food antioxidant and used in the food industry and some dyestuffs (Sharma and Gupta, 2003). Gallic acid possesses a wide range of biological activities, such as antioxidant, antibacterial, antiviral, analgesic. It also shows cytotoxic activity against cancer cells, without harming normal cells (Beniwal and Chhokar, 2010). Gallic acid is used in the pharmaceutical industry for the synthesis of antibacterial drugs and in the food industry as substrate for the chemical synthesis of food preservatives such as pyrogallol and gallates. It is also used as an ingredient of developer in photography and printing inks.

Since, *Aspergillus niger* is an officially approved microorganism in France for enzyme

production in the food industry and is also classified as 'generally regarded as safe' (GRAS) by the US Food and Drug Administration (Barthomeuf *et al*., 1994), this study will concern on emphasis to produce tannase using local strain of *A. niger* AUMC 4301 through two strategies; optimization of cultivation conditions of *A. niger* AUMC 4301 and optimization of kinetic behavior of produced tannase by optimization of reaction mixture parameters.

2. Materials and methods

2.1. Chemicals

All chemicals used were analytical grades (Adwic, Egypt); Tannic and gallic acids were purchased from Mumbai, India.

2.2. Microorganisms

One hundred and thirty fungal isolates were screened for their ability to grow in the presence of tannic acid in a preliminary experiment. Fungal isolates succeeded to grow in the presence of tannic acid were tested for tannase production individually (data not shown). The most active tannase producer was selected and identified as *Aspergillus niger* AUMC 4301 at Mycological Center, Faculty of Science, Assuit University, Egypt.

2.3. Fermentation process

Aspergillus niger was grown on Czapek-Doxs agar medium for one week at 30°C to enhance spore formation. Spores were collected under aseptic condition using Tween 80 (2.9%). The prepared spore suspension was adjusted to 10^7 spores/ml. Three milliliters of prepared spore suspension were inoculated into 250 ml Erlenmeyer flasks containing 10 g of wheat bran, 3 g tannic acid and supplemented with 10 ml of mineral medium. Mineral medium containing (g/L) K_2HPO_4 1.0, NH_4NO_3 2.0, $MgSO_4.7H_2O$ 2.0 and $CaCl_2.2H_2O$ 0.002 was adjusted at pH 5.7. The inoculated flasks containing media were incubated at 30°C for 5 days.

2.4. Crude extracellular tannase extraction

Tannase was extracted from the fermented medium of the cultures cultivated under SSF conditions by adding 80 of 20 mM acetate buffer (pH 5.0). Flasks were shaken for 1 hr at 200 rpm to extract crude enyme. The buffer containing enzyme was filtered twice through cloth filter and Whatman filter paper. Then, the filtrate was used as crude extracellular tannase.

2.5. Tannase assay

Tannase activity was determined spectrophotometrically using tannic acid as a substrate according to the protocol of Mondal *et al.* (2001a) but with some modifications. The crude extracellular tannase (1ml) was incubated with 1ml of 4µmole standard tannic acid (substrate); in 0.2M acetate buffer (pH 5.4). After 20 min incubation in a water bath at 60°C, the reaction was terminated by icing. Tannase activity was determined spectro-photometrically at 530 nm using 1ml of ferric chloride reagent (0.13M). The enzyme activity was calculated from the difference in absorbance at zero time (beginning of the reaction) and after enzymatic reaction. The unknown amounts of tannic acid were determined from a standard curve prepared by the same procedure (Data not shown). One unit of tannase activity was defined as the amount of tannic acid hydrolyzed by 1ml of enzyme per minute of reaction. The protein concentration of crude extracellular tannase was determined by Lowry *et al*., (1951) after dialyzed against distilled water for 24 hr using dialysis bag (Medicell International Ltd.) to avoid interfered reactions with phenolic compounds. The specific activity of tannase was calculated according to amount of consumed tannic acid and protein content. Specific activity = Activity (U)/Protein concentration (mg).

2.6. Gallic acid assay

Gallic aid was determined spectrophotometrically according to the method of (Pinto *et al*., 2006).

2.7. Factors affecting tannase activity of A. niger AUMC 4301

Tannase was maximized through two stages of optimization; physiological optimization of tannase producer (*A. niger* AUMC 4301**)** and kinetic optimization of tannase itself. All experiments were studied separately by one way experimental design system (ANOVA) and the results were analyzed by Duncan test to detect significant differences among the treatments with a probability of 5% using SAS software package version 6.12.

To achieve physiological optimization; the effect of different incubation periods (2, 3. 4. 5, 6, 7) days, different incubation temperature degrees (5, 20, 30, 40) C° and various tannic acid concentrations (1.5, 3, 6, 9, 12) g/l were investigated on tannase activity of *A. niger*. As well as, the tannase activity of *A. niger* AUMC 4301 was determined at different fermentation states (solid state fermentation and submerged fermentation either under agitated or static conditions). For submerged fermentation, the wheat bran was removed from constituents of cultivation medium. In another experiment, tannic acid was removed from constituents of medium in individual experiment and replaced by different carbon sources (fructose, glucose, glycerol, mannitol,

starch, sucrose and xylose). In addition, ten different nitrogen sources were chosen to determine their efficiency to support tannase activity. They were L-alanine, L-cystein, L-lysine, L-ornithine and L-serine, as organic nitrogen sources and ammonium chloride, ammonium sulfate, potassium nitrate and sodium nitrate as inorganic nitrogen sources as well as ammonium nitrate was served as control. Ammonium nitrate concentration in cultivation medium was increased from 0 to 5 gl^{-1} in order to determine the best nitrogen source concentration that achieved the maximum tannase activity.

To optimize kinetic parameters of tannase itself; the reaction was carried out as a function of time (5-60) min, the reaction mixture was incubated at different temperatures (30, 40, 50, 60, 70, 80)°C and the concentration of tannic acid in the reaction mixture was changed from one to ten micromole. The optimum pH that achieved that maximum tannase activity was estimated using sodium phosphate buffer with different pH values (3.6, 4.2, 4.8, 5.4, 5.6). The ratio between substrate (Tannic acid) and enzyme (Tannase) in the reaction mixture was studied and K_m value of substrate was determined. Thermal stability of crude extracellular tannase at 60 and 70 °C and the effect of gallic acid, inhibitors as EDTA and metal ions such as calcium, cobalt, cupper, iron, magnesium, manganese and zinc addition into reaction mixture were also investigated.

3. 3. Results and Discussion

In general, the degrading enzymes of aromatic compounds are of considerable interest for bioremediation and biodegradation of organic waste products. Tannase hydrolyses ester bond of tannins to produce glucose and gallic acid. It is also utilized in a number of industrial applications including the manufacture of instant tea, beverages and gallic acid.

3.1. Optimization of cultivation conditions

3.1.1. Rate of gallic acid formation from tannic acid by tannase of A. niger AUMC 4301

The present experiment aims to demonstrate the rate of gallic acid formation from tannic acid by tannase of *A. niger* AUMC 4301. Figure (1) illustrated that tannic acid was hydrolyzed by the action of tannase yielding gallic acid and the increase in the amount of formed gallic acid was associated with a decrease in the amount of added tannic acid i.e the amount of consumed tannic acid after 30 minutes was almost equivalent to that of the formed gallic acid on equimolar basis.

3.1.2. Production of tannase by *A. niger* AUMC 4301 using different fermentation states.

Three states of fermentation; solid state, submerged states either shaking or static state were designed to compare their intensifying effect on tannase productivity by *A. niger*. Results recorded in table (1) indicated that tannase activity and accordingly specific activity of *A. niger* AUMC 4301 incubated under solid state fermentation (3.37±0.172 U/mg protein) was higher than those obtained with cultures grown under static (0.014±0.002 U/mg protein) and shaking condition (0.04±0.009 U/mg protein). In this concern, Lekha and Lonsane (1994) reported that titers of extracellular tannase produced by *A. niger* PKL 104 in solid state fermentation (SSF) were 2.5 and 4.8 times higher and required only about half of the fermentation time in comparison with those in the same medium in submerged and liquid surface fermentation, respectively.

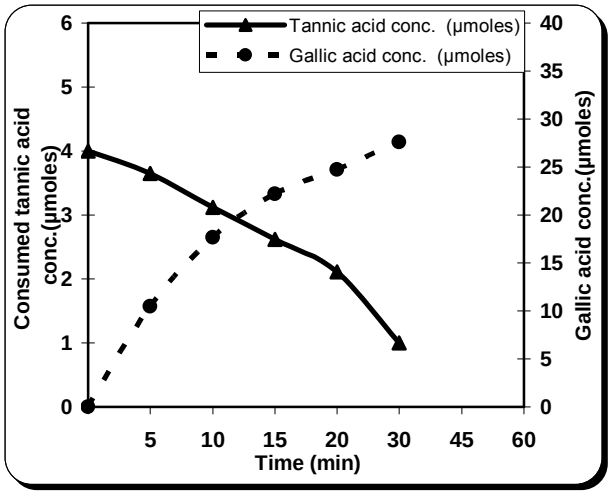

Fig. (1): Rate of gallic acid formation from tannic acid by tannase of *A. niger* AUMC 4301

Other studies were conducted to evaluate tannase production in submerged and solid state cultures (Belmares *et al*., 2004 and Marco *et al*., 2009). These studies proved that tannase yield by *Aspergillus* under SSF conditions was higher than that produced under submerged conditions. On the other hand, Srivastava and Kar (2009) stated that extracellular tannase of *A. niger* ITCC 6514.07 was produced optimally under submerged fermentation conditions. The favorability of tannase production using solid state fermentation in the present study could be explained by the positive effect of SSF on the production process itself and/or on the enzyme producer (*A. niger* AUMC 4301). The presence of support material as rice straw in SSF could be

considerable as additional source of carbon and energy (Sabu *et al*., 2005).

Table (1): Production of tannase by *A. niger* AUMC 4301 using different fermentation states.

Fermentation state	Specific activity (U/mg protein)
Solid state	3.37±0.172[B*]
shaking state	0.038±0.009[B]
Static state	0.014±0.002[A]

*Different symbols means there is a significant difference

3.1.3. Effect of different incubation periods on the production of *A. niger* AUMC 4301

Tannase activity of the fungus under investigation was determined at different incubation periods ranging from 2-7 days. Figure (2) showed that the ability of *A. niger* AUMC 4301 to produce tannase didn't start before 2 days. The lag phase was followed by the exponential phase during third and fourth days where the specific activity of tannase was increased gradually (1.76±0.038 and 2.98±0.082 U/mg protein) and maximized at the fifth day of incubation (3.30±0.11 U/mg protein). Many authors mentioned different incubation periods ranged from (72hr to 120hr) that achieved maximum tannase, this variation depends on the specificity of producers and state of fermentation **(Sabu *et al.*, 2005; Banerjee and Pati, 2007; Rodrigues *et al.*, 2008** and **Enemuor and Odibo, 2009)**. After that, the specific activity of the produced tannase was significantly decreased (R^2=0.994). The decrease in tannase yield with prolonged incubation could be explained by shift in the reaction equilibrium due to accumulation of end product (gallic acid) in the fermentation media **(Kar *et al.*, 1999)** or accumulation of toxic metabolites in the fermentation medium due to fungal metabolism and tannic acid degradation that leads to fungal cell autolysis or enzyme denaturation **(Gautam *et al.*, 2002)**.

3.1.4. Influence of incubation temperatures on the production of *A. niger* AUMC 4301 tannase.

Biological processes generally only occur within a relatively narrow range of temperature (Sabu *et al.*, 2005). The present experiment aims to determine the optimal temperature for tannase formation by *A. niger* AUMC 4301 when grown at various degrees of temperatures ranging from 5 - 40°C. Figure (3) show the optimal temperature for enzyme production was 30°C and a slight decrease in enzyme specific activity was observed at 20 and 40°C where it recorded 2.69±0.062 and 2.34±0.09 U/mg protein in the same order. So, tannase production by local strain of *A. niger* AUMC 4301 can be evaluated at room temperature in our nation without additional efforts or costs. Similar temperature optima was reported for tannases of *A. niger* ATCC 16620 (Sabu *et al*., 2005) and *A. oryzae* (Rodrigues *et al*., 2008) while a somewhat different temperature optimum was recorded for tannase production by *A. fumigates* MA (25°C) (Manjit *et al*., 2008) and for *Trichoderma. viride* tannase (45°C) (Lokeswari *et al*., 2010).

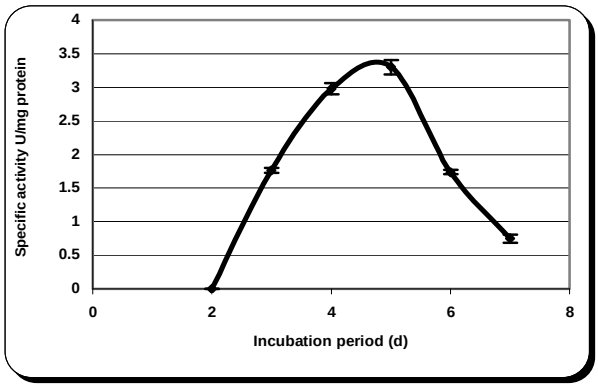

Fig. (2): Effect of different incubation periods on the production of *A. niger* AUMC 4301

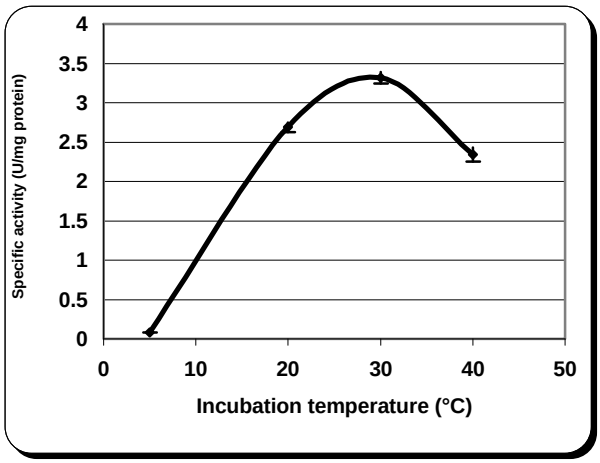

Fig. (3): Influence of different incubation temperatures on the production of *A. niger* AUMC 4301 tannase.

4.1.5. Effect of different carbon sources on the production of *A. niger* AUMC 4301 tannase.

All heterotrophic microorganisms need suitable carbon source to grow and positively react with surrounding environment to produce valuable compounds such as enzymes. Since tannase is an

inducible enzyme, in the following experiment, different carbon sources instead of tannic acid were tested for tannase enhancement by the selected fungal strain *A. niger* AUMC 4301. The tested carbon sources were added to the fermentation medium at the same concentration of tannic acid. Table (2) recorded that none of the tested carbon sources stimulated enzyme formation as compared with tannic acid-grown cultures (control). Glucose caused about 50% repression in enzyme production (Specific activity was 1.68±0.013 U/mg protein), whereas mannitol completely suppressed it. Fructose, glycerol, starch, sucrose and xylose resulted in great decrease in the enzyme activity in comparison with control; they supported specific activity about 0.5 U/mg protein. Comparable studies dealing with the induction of microbial tannase synthesis by tannic acid were recorded by many workers (Banerjee *et al*., 2001, Banerjee *et al*., 2007 and Paranthaman *et al*., 2009). It is worthy to mention that tannase of *A. japonicus* (Bradoo *et al*., 1996) was produced constitutively on simple and complex sugar substrates but activity was doubled in the presence of tannic acid as the sole carbon source. The suppression effect of readily metabolized sugars was also reported by (Lekha and Lonsane, 1997, Mondal *et al*., 2001b and Manjit *et al*. (2009). On the other hand, Van de Lagemaat and Pyle (2005) reported that if carbon source present in the media will be exhausted easily and rapidly, this may lead to the partial induction of tannase. Sabu *et al*. (2005) stated that glucose and other readily metabolized carbon source reduce the lag period required for tannase synthesis and production.

Table (2): Effect of different carbon sources on the production of *A. niger* AUMC 4301 tannase.

Carbon sources	Specific activity (U/mg protein)
Tannic acid(control)	3.35±0.081^{A*}
Fructose	0.56±0.022^{C}
Glucose	1.68±0.134^{B}
Glycerol	0.43±0.058^{CD}
Mannitol	0.03±0.044^{E}
Starch	0.32±0.022^{D}
Sucrose	0.38±0.020^{CD}
Xylose	0.52±0.032^{CD}

*Different symbols means there is a significant difference.

3.1.6. Synthesis of tannase as a function of tannic acid concentration in the culture medium of *A. niger* AUMC 4301.

From the preceding experiment, it is evident that tannic acid was the most suitable carbon source for tannase induction by the experimental fungus. It was then necessary to test the effect of tannic acid concentration (Ranging from 1.5 to 12 %) in the medium on the enzyme yield. The data illustrated in figure (4) show the optimum concentration of tannic acid for *A. niger* AUMC 4301 tannase was 3%, thereafter, the enzyme activity decreased by elevating tannic acid concentration in the medium and almost disappeared at 12%. Banerjee and Pati (2007) noticed the decrease of *A. pullulans* DBS66 tannase at higher tannic acid concentration, they explained this finding on the basis that tannic acid in higher concentration makes an irreversible reaction with surface proteins of the organism, thereby both growth and enzyme production may be reduced. Similarly, Seth and Chand, (2000) found that an over increase in tannic acid concentration induced decrease in tannase activity by deposition of gallic acid on the cell surface.

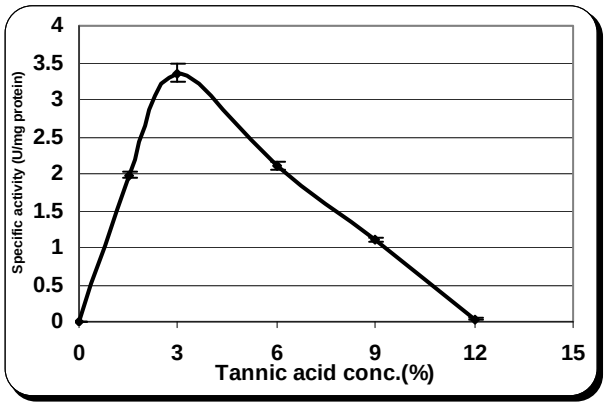

Fig. (4): Effect of different tannic acid concentrations on the production of *A. niger* AUMC 4301 tannase.

3.1.7. Effect of different nitrogen sources on tannase production by *A. niger* AUMC 4301.

Tannase or any other enzyme production depends mainly on the availability of both carbon and nitrogen sources in the medium. Both have regulatory effects on enzyme synthesis (Patel *et al.*, 2005). The nitrogen source (NH_4NO_3 2gm/l) presented in the basal medium was replaced by equivalent amounts of nine different nitrogen sources in dry weight basis. It is obvious from the results cited in table (3) that none of the tested nitrogen sources enhanced the synthesis of *A. niger* AUMC 4301 tannase over that of ammonium nitrate–grown cultures (control). Tannase activity reduced significantly by nearly 90% when L-lysine, L-ornithine or L-serine were used as a nitrogen source

in the culture media (R^2=0.975), whereas ammonium sulfate suppressed it completely. These results suggested the production of tannase enzyme is highly affected by the nature of used nitrogen source. The inhibition of tannase by ammonium sulfate could be due to the toxicity of sulfate ion itself on fungal growth. In addition, organic nitrogen sources can be react with tannic acid forming a complex precipitate, this complex structure inhibit fungal consumption of both carbon and nitrogen source; so it affect greatly on the fungal growth (Kumar *et al*., 2007).

Table (3): Effect of different nitrogen sources on the production of *A. niger* AUMC 4301 tannase.

Nitrogen sources	Specific activity (U/mg protein)
Ammonium nitrate (control)	3.25±0.102^{A*}
L-Alanine	1.22±0.031^{B}
Ammonium chloride	1.25±0.078^{B}
Ammonium sulfate	0.02±0.009^{F}
L-Cysteine	0.70±0.102^{D}
L-Lysine	0.40±0.042^{E}
L-Ornithine	0.34±0.038^{E}
Potassium nitrate	0.99±0.061^{C}
L-Serine	0.28±0.015^{E}
Sodium nitrate	0.83±0.079^{CD}

*Different symbols means there is a significant difference.

3.1.8. Dependence of tannase formation by *A. niger* AUMC 4301 on ammonium nitrate concentration.

As shown in table (3) ammonium nitrate was the most favorable nitrogen source for production of *A. niger* AUMC 4301 tannase. So, it is interesting to study the effect of ammonium nitrate concentration on tannase activity. Data presented in figure (5) demonstrated that the specific activity of *A. niger* AUMC 4301 tannase was increased with increasing ammonium nitrate concentration up to 0.2% in culture medium. After that, tannase activity decreased rapidly with increasing ammonium nitrate concentration, the specific activity of tannase recorded 1.41±0.038, 1.14±0.033 and 0.56±0.035 U/mg protein at ammonium nitrate concentrations 3, 4, and 5 g/l respectively. In spite of ammonium nitrate is readily utilizable nitrogen that stimulates the synthesis of proteins (Djekrif-Dakhmouche *et al*., 2006), high concentration of ammonium nitrate caused tannase denaturation by changing the protein tertiary structure.

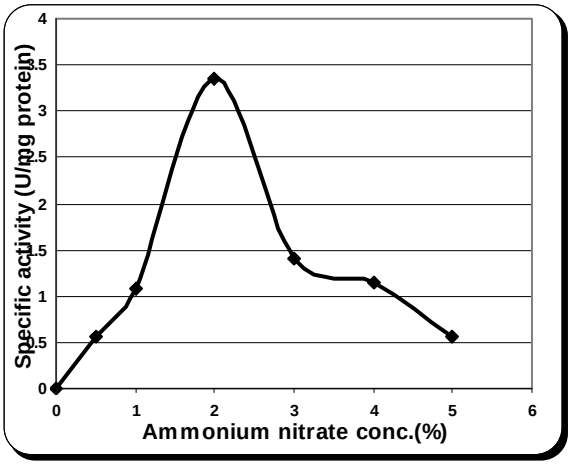

Fig. (5): Effect of different ammonium nitrate concentrations on the production of *A. niger* AUMC 4301 tannase.

3.2. Some kinetics and properties of A. niger AUMC 4301.

Any enzyme is a protein in nature that functions as a catalyst. The role of enzymes is to speed up the rate of chemical reactions without undergoing any permanent changes itself. In our case, extracellular tannase of selected *A. niger* AUMC 4301 strain was mixed with tannic acid (the substrate) and the conditions that maximize tannase activity and consequently tannic acid degradation in the reaction mixture were tested individually. They were reaction time, reaction pH, reaction temperature, enzyme concentration, substrate concentration and addition of metal ions, inhibitors and gallic acid.

3.2.1. Effect of reaction time on the activity of tannase from *A. niger* AUMC 4301.

An experiment was conducted to determine tannase activity as a function of reaction time. The reaction mixture was incubated at 60°C, and samples were withdrawn periodically for a period of 60 min and assayed for tannase activity. Results obtained are graphically presented in figure (6). The reaction was found to be more or less linear with time up to 30 min. Further increase in the reaction time resulted in a sharp decrease in enzyme activity; the percentage of decrease was nearly 70% after 60 min. So, it could be concluded that the rate of the reaction catalyzed by *A. niger* AUMC 4301 tannase couldn't proceed to completion. This may be attributed to the accumulation of gallic acid, one of the products of the reaction, which retard the reaction rate. Similarly,

Sabu *et al.* (2005) reported that the tannase activity by *Aspergillus niger* ATCC16620 (3.9 U/ml) was maximized and stabilized at 15 and 20 min of reaction time and it decreased with further increase in reaction time. **Mukherjee and Banerjee (2006)** reported that an increase up to 5 min was observed in tannase activity of a co-culture of *R. oryzae* and *A. foetidus* followed by a decrease thereafter and the curve started leveling off. The difference in reported reaction time could be attributed to microorganisms employed.

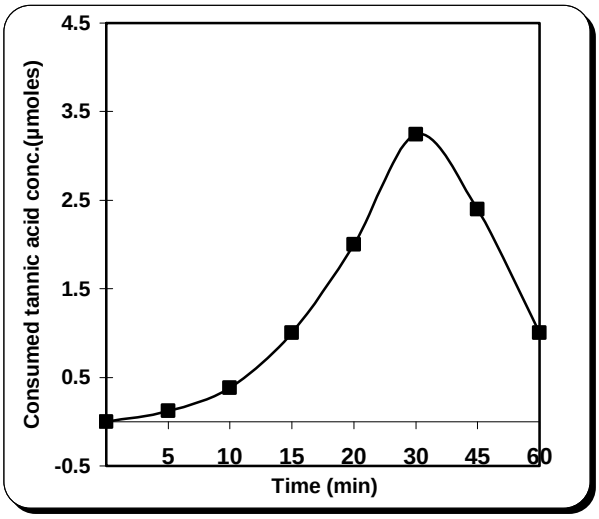

Fig. (6): Effect of reaction time on the activity of *A. niger* AUMC 4301 tannase.

3.2.2. Dependence of tannase activity of *A. niger* AUMC 4301on pH.

Different pH values (3.6, 4.2, 4.8, 5.4 and 5.6) were chosen to investigate the influence of pH on the catalytic activity of tannase. Figure (7) demonstrated the relationship, between pH and activity of *A. niger* AUMC 4301 tannase. Maximal enzyme activity was obtained at pH 4.8 where the amount of consumed tannic acid reached 2.93 µmol. By increasing the pH value above 4.8, a gradual decrease in enzyme activity was recorded. This pH optimum is more or less similar to that reported for the enzyme from *A. aculeatus* DBF6 (Banerjee *et al*., 2001), *A. awamori nakazawa* (Mahapatra *et al*., 2005), *A. foetidus* and *R. oryzae* (Mukherjee and Banerjee, 2006), and *P. variable* (Sharma *et al*., 2008). The pH value for optimal tannase activity of many strains of *A. niger* previously studied was about 6 (Anwar *et al*., 2009; Marco *et al*., 2009 and Srivastava and Kar, 2009). Tannase was active at acidic pH and activity decreased as the pH approached the alkaline range. Any change in pH affects the protein structure and a decline in enzyme activity beyond the optimum pH could be due to enzyme inactivation or its instability (Mahapatra *et al*., 2005).

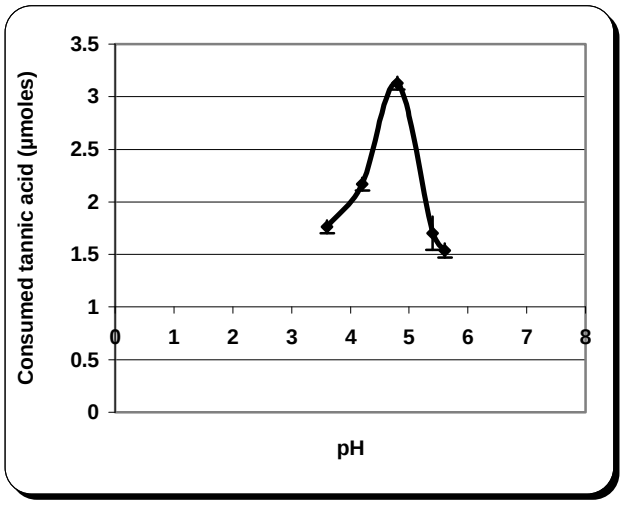

Fig. (7): Effect of reaction pH on the activity of *A. niger* AUMC 4301tannase.

3.2.3. Effect of temperature on tannase activity of *A. niger* AUMC 4301.

An experiment was conducted to find out the degree of temperature at which optimum activity of *A. niger* AUMC 4301 tannase could be achieved. A series of identical reaction mixtures were made and each was incubated at a different temperature. The range of temperatures used was from 30°C to 80°C. Figure (8) showed that maximal enzyme activity was achieved at 60°C (Consumed tannic acid was 3.3 µmol). The *A. niger* AUMC 4301 tannase activity at 70°C was about 50 % of that obtained at 60°C. Presumably the enzyme was denaturated at 70°C, an indication of its thermolability. The amount of consumed tannic acid declined to 1.68±0.13 and 0.98±0.074 at 70°C and 80°C respectively. Our data are in accordance with those reported for the tannase activity of *A. niger* van Teighem (Sharma *et al*., 1999) and *A. niger* GHI (Marco *et al*., 2009) in having an optimal temperature at 60°C whereas the activity of *A. niger* Aa-20 tannase was found to be maximal at 60 to 70°C (Ramirez-Coronel *et al*., 2003). These results indicated that elevating temperature to certain limit has positive effect on tannase activity; this could be attributed to increase in the kinetic energy of the substrate and enzyme molecules or/and increase the reaction rate with elevating temperatures. Beyond the optimum level of temperature, the internal energy of the molecules including translational, vibrational and rotational energy of the molecules increased, some of the weak bonds determining the three-dimensional shape of the active proteins break leading to thermal denaturation

of the tannase protein causing its inactivation. Temperatures above the optimum value also affect the protein ionization state, and the solubility of species in solution, which thus resulted in a reduction in enzyme activity **(Mukherjee and Banerjee, 2006)**.

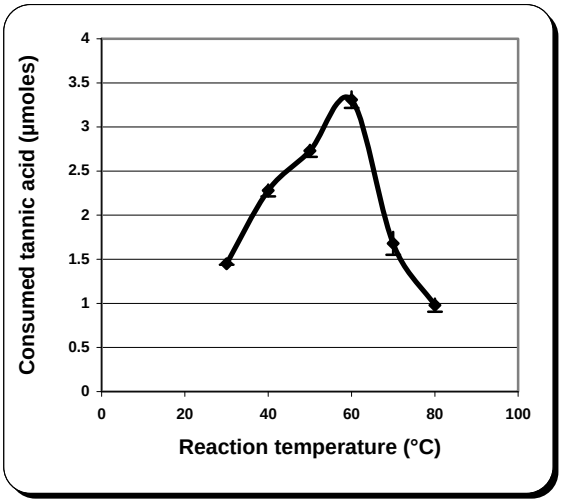

Fig. (8): Effect of reaction temperature on the activity of *A. niger* AUMC 4301tannase.

3.2.4. Heat inactivation kinetics of tannase from *A. niger* AUMC 4301.

Another experiment was designed to test the stability of tannase activity of *A. niger* AUMC 4301 in acetate buffer (pH 4.8) during incubation the enzyme (in absence of tannic acid) at either 60°C or 70°C for different time intervals. It is evident from the results represented in figure (9), a total loss of tannase activity occurred when the enzyme was incubated at 70°C for 5 min. However, exposing the enzyme to 60°C for 5 min and 20 min resulted in about 20% and 60% loss of its activity, respectively. These results indicate that *A. niger* AUMC 4301 tannase is thermolabile. Although the optimum temperature for the tannase activity was 60°C, yet it was inactivated when incubated at the same temperature, in absence of the substrate. This indicates that presence of the substrate in the reaction mixture protects the catalytic site from heat inactivation. Similarly, tannases of *A. niger* LCF8 (Barthomeuf *et al*., 1994) and *A. niger* GHI (Marco *et al*., 2009), were found to be thermolabile. Alternatively, Battestin and Macedo (2007) stated that the crude tannase of *P. variotii* was thermo-stable where it retained 96% and 99% residual activity at 20 and 70°C respectively.

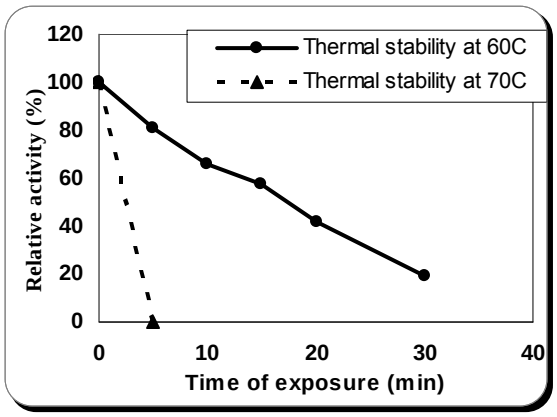

Fig. (9): Heat inactivation kinetics of *A. niger* AUMC 4301tannase.

3.2. 5. Tannase activity as a function of enzyme concentration

An experiment was designed to prove that the rate of catalytic activity of *A. niger* AUMC 4301 tannase is dependent on the amount of enzyme in the reaction mixture. Several reaction mixtures were set up which contained the same amount of tannic acid in acetate buffer at pH 4.8, but had varying amounts of the enzyme. Figure (10) revealed the relationship between tannase activity and protein concentration, the results indicate that the extent of catalytic action is directly proportional to the concentration of the enzyme (R= 0.9961). This could be explained by increasing enzyme concentration to certain limit, increase the availability of more active sites free on the enzyme and increase the incidence of substrate molecules to react with them.

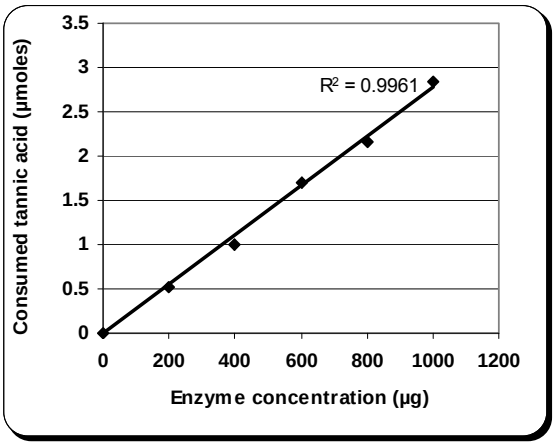

Fig. (10): Tannase activity of *A. niger* AUMC 4301as a function of enzyme concentration.

3.2.6. Determination of the apparent K_m value of *A. niger* AUMC 4301 tannase for tannic acid.

Determination of the apparent K_m (Michaelis constant) value of *A. niger* AUMC 4301 tannase was achieved through a study relating substrate concentration to the velocity of the reaction. Different concentrations of tannic acid were incubated with the same amounts of enzyme protein in acetate buffer (pH 4.8) at 60°C for 20 min. Figure (11) illustrates the effect of tannic acid concentrations on tannase activity of *A. niger* AUMC 4301. Figure (12) represents a Lineweaver Burk plot (Lineweaver and Burk, 1934) of the reciprocal of initial velocities and tannic acid concentrations. From this plot the apparent K_m value of the enzyme was calculated and found to be 2.5 mM. It is clear also from the results seen in Fig. (11) that the enzyme activity was increased with increasing concentrations of tannic acid up to 2.5mM. Further increase in tannic acid concentrations resulted in a significant decrease in enzyme activity ($P>0.0001$). It could be suggested from such finding that gallic acid as a product of the reaction catalyzed by tannase may have an inhibitory effect on enzyme activity. However, tannase of *P. variable* exhibited a much higher K_m value (32 mM) for tannic acid (Sharma *et al*., 2008). On the contrary, lower K_m values for tannic acid were reported for tannases produced by both of *R. oryzae* and *A. foetidus* (Mukherjee and Banerjee, 2006), *A. niger* GHI (Marco *et al*., 2009) and *A. niger* HAYATI (Anwar *et al.,* 2009).

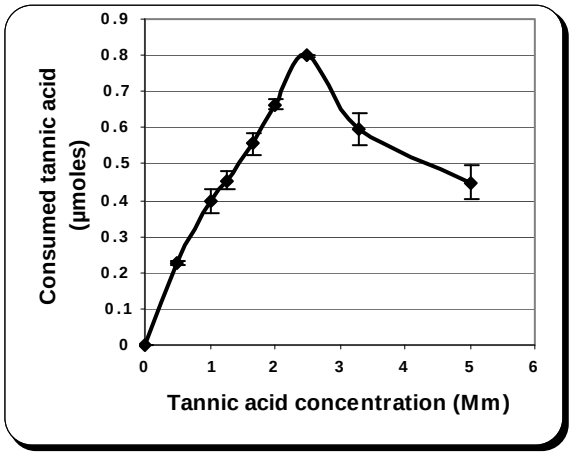

Fig. (11): Determination of the apparent K_m value of *A. niger* AUMC 4301 tannase for tannic acid.

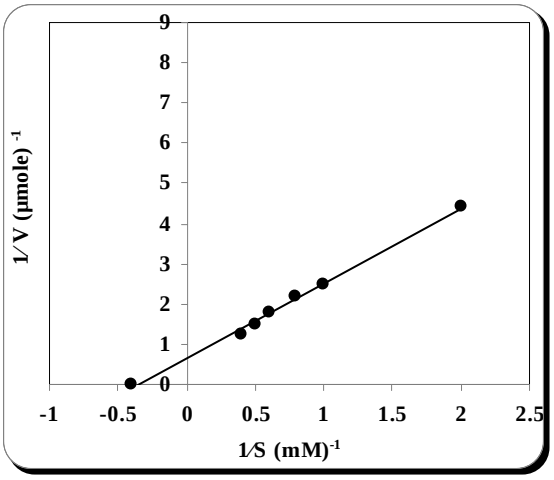

-1/ K_m = - 0.4 mM **K_m value = 2.5 mM**

Fig. (12): Lineweaver-Burk plot of the reciprocals of initial velocities and tannic acid concentration.

3.2.7. Influence of gallic acid on the activity of *A. niger* AUMC 4301 tannase.

Results of tannase activity as function of reaction time and substrate concentration revealed that gallic acid may be an inhibitor to the activity of *A. niger* AUMC 4301 tannase. Thus, another experiment was designed to investigate the effect of gallic acid on the tannase activity. This was carried out by adding gallic acid at a concentration of 5 mM to the reaction mixtures containing increasing concentrations of tannic acid (substrate) and measuring the rates of the reaction catalyzed by the enzyme. This was compared with analogous rates obtained without gallic acid addition. Data obtained are graphically presented in figures (13&14). These results indicated that gallic acid is a competitive inhibitor to *A. niger* AUMC 4301 tannase especially at high substrate concentrations. The K_i (inhibition constant) was calculated and found to be 1.35 mM. Gallic acid itself acts as competitive inhibitor (Kar *et al*., 1999; Kar and Banerjee, 2000). Competitive inhibitors are substances; usually structurally related to substrate; that is able to combine with the enzyme at the same site as the substrate are competitive. Inhibitor and substrate therefore compete for the same site forming enzyme-substrate (ES) and enzyme-inhibitor (EI) complexes, respectively; ESI complexes are not produced. These unfavorable complexes (EI) greatly affect tannase activity. This was clearly appeared by decreasing Michaelis constant (K_i) in the presence of inhibitor compared to absence of it (K_m).

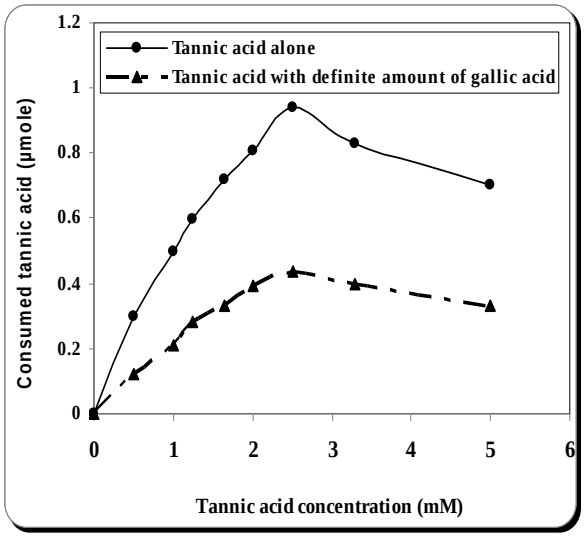

Fig. (13): Influence of gallic acid on the activity of *A. niger* AUMC 4301 tannase.

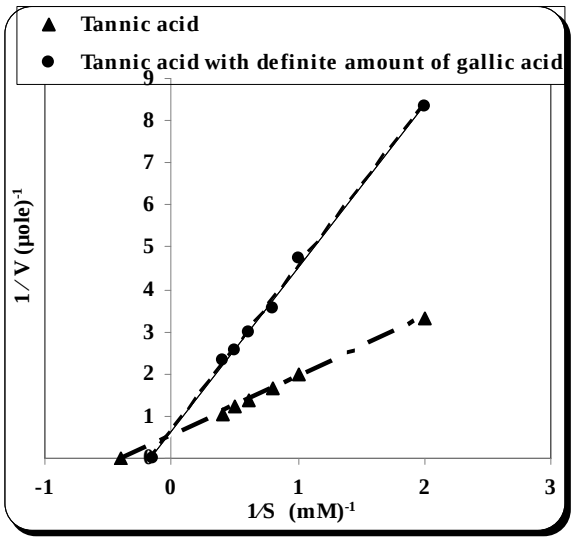

K_m = 2.5 mM. K_p = 1.35 mM .

Fig. (14): Determination of the inhibition type exerted by gallic acid on tannase activity of *A. niger* AUMC 4301.

3.2.9. Effect of EDTA and some metal salts on enzyme activity of *A. niger* AUMC 4301 tannase.

Many enzymes require metal ion activators for expressing their absolute catalytic activity. Since achieving maximum catalytic activity during enzymatic reactions is very important industrially, the effect of metal ion on tannase activity was studied in the following experiment. The results illustrated by figure (15) revealed that all the tested metal ions reduce tannase activity with different degrees. Hence, Fe^{++}, Mn^{++}, Cu^{++}, Zn^{++} and Ca^{++} showed inhibitory effect in a decreasing order on enzyme activity (Ranged from 90% to 20%), Co^{++} and Mn^{++} caused a least decrease in enzyme activity (About 6%). Since inhibition studies provide an insight into the nature of the enzyme and its cofactor requirements, in this experiment the effect of EDTA as a metal chelating agent, on the activity of *A. niger* AUMC 4301 tannase was also investigated. Addition of EDTA to the reaction mixture didn't inhibit tannase activity; this confirmed the negative effect of studied metal ions on the tannase under investigation. The effect of metal ions was studied in many previous reviews, some of them revealed the positive effect of metal ions on tannase activity while others attained the negative effect. Similar to our results, tannase obtained from *A. niger* MTCC 2425 was found to be inhibited by Ca^{+2} (Bhardwaj *et al*., 2003). Sabu *et al*. (2005) also studied effect of metal ions on tannase from *A. niger* ATCC 16620 and found that the addition of metal ions like Zn^{+2}, Mn^{+2}, Cu^{+2}, Ca^{+2}, Mg^{+2}, and Fe^{+2} inhibited the enzyme activity. At the same trend, Kasieczka-Burnecka *et al*. (2007) have reported inhibitory effect of Zn^{+2}, Cu, $^{+2}$ K^{+}, Cd^{+2}, Ag^{+} , Fe^{+3}, Mn^{+2}, Co^{+2}, Hg^{+2}, Pb^{+2}, and Sn^{+2} on tannase from *Verticillium sp*. Decrease in tannase activity in the presence of divalent cations could be due to nonspecific binding or aggregation of the enzyme.

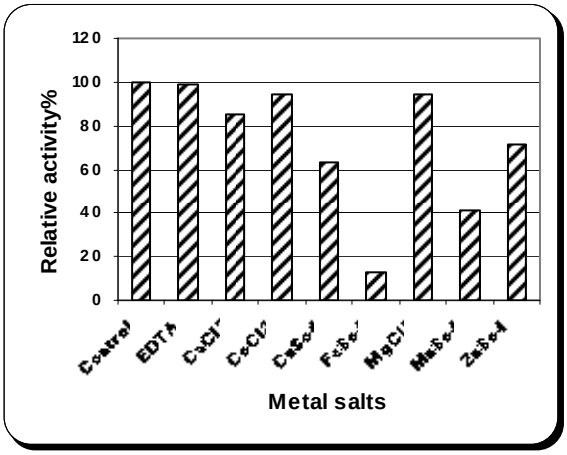

Fig. (15): Effect of some metal salts and ethylene diamine tetra acetate (EDTA) on the activity of *A. niger* AUMC 4301 tannase.

4. Conclusion

The results revealed in this study show that *A. niger* AUMC 4301 represents a valuable source of an economically attractive tannase with potential for application in various industries. The major

physicochemical and kinetic properties of the crude tannase were identified with special emphasis on the effect of substrate concentration, final product (Gallic acid) and metal ions on the enzyme activity. Other research work is in progress toward production of tannase utilizing agricultural wastes instead of tannic acid and improving the tannase productivity by *A. niger* AUMC 4301 using gamma radiation.

Growth, Yield and Fruit Quality of Sweet Pepper Plants (*Capsicum annuum* L.) as Affected by Potassium Fertilization

El-Bassiony, A.M.*; Z.F. Fawzy; E.H. Abd El-Samad and G.S. Riad

Vegetables Crop Research Dept., National Research Centre, Dokki, Cairo, Egypt
*mohsin2eg@yahoo.com

Abstract: Two field experiments were conducted during the two successive summer seasons of 2009 and 2010 at the Experimental Farm of the National Research Centre in El-Nobaria region, Behira Governorate, to investigate the response of sweet pepper plants cv. California wonder to different rates of potassium fertilization (50, 100 and 200 kg/fed.) as potassium sulfate in addition to foliar application by potassium oxide (2 and 4 cm/L) and potassium humate (4 gm/L) as a stimulative dose. Potassium foliar applications were made 3 times in a 15 days interval with the same doses during the growing period (30, 45 and 60 days after transplanting). The highest potassium fertilization rate (200 kg/fed.) gave the tallest sweet pepper plants, the highest number of leaves and branches per plants and the highest fresh and dry weights of leaves as well as the highest total yield. Also, the obtained results reported that the fruit measurements expressed as fruit length, average fruit weight and vitamin C content, as well as leaves chemical composition (N, P, K and total chlorophyll) were increased with increasing potassium fertilization rate. On the other hand, spraying sweet pepper plants with potassium humate at rate of 4 gm/L markedly increased vegetative growth, yield, fruit quality and chemical composition. The favorable effects of the potassium on the growth, total yield and fruit parameters were obtained when sweet pepper plants fertilized with 200 kg/fed. potassium sulfate plus foliar application of potassium humate 4 gm/L followed statistically by 200 Kg/fed. potassium sulfate with foliar application of either 2 or 4 gm/L potassium oxide with no significant differenced between them but both of them were significantly higher than control.

Keywords: Potassium stimulative dose, Potassium humate, Potassium oxide, Foliar spraying, Vegetative growth, Total yield, Fruit quality, Chemical composition.

1. Introduction:

Sweet pepper (*Capsicum annuum* L) is a member of the solanaceous fruity vegetables group. It is one of the most important, popular and favorite vegetable crops cultivated in Egypt for local consumption and exportation, it is commonly called "filfil akhdar", where "filfil" means pepper and "akhdar" means green. It covers a production area of 42,136 ha in year 2007 that yielded 684,640 tons according to Ministry of Agriculture Statistics.

Plant high yields, depend on many factors, the most important factor amongst them is plant nutrition. The nutrients should be provided through suitable sources on adequate amounts and forms in a right time to ensure that plants have adequate amounts of the nutrients required for high yields. There are two ways of application nutrients, first through plant roots and it is the main way and the second through foliar application (additional way). The interest in foliar fertilizers arose due to the multiple advantages of foliar application methods. It is also recognized that supplementary foliar fertilization during crop growth can improve the mineral status of plants and increase the crop yield and quality (Kolota and Osinska, 2001).

Although, potassium is not a constituent of any plant structures or compounds, but it plays a part in many important regulatory roles in the plant, i.e. osmo-regulation process, regulation of plant stomata and water use, translocation of sugars and formation of carbohydrates, energy status of the plant, the regulation of enzyme activities, protein synthesis and many other processes needed to sustain plant growth and reproduction (Hsiao and Läuchli, 1986). It is a highly mobile element in the plant and has a specific phenomenon, it is called luxury consumption. In addition, it plays a very important role in plant tolerance of biotic and abiotic stresses (Marschner, 1995). Potassium is also known as the quality nutrient because of its important effects on quality factors (Imas and Bansal, 1999 and Lester *et al.*, 2006). With the exception of nitrogen, potassium is required by plants in much greater amounts than all the other soil-supplied nutrients (Tisdale *et al.*, 1985).

Nowadays, in Egypt, potassium fertilizers became a highly expensive ones of input factors in

production processes (ton ~ 1250 $), so many farmers minimizing the used amount to the minimum dose. In addition to use any other newly and cheapest potassium sources through foliar application as a stimulative dose to overcome such problem and to maximize their net return to cover the additional cost of this K fertilizer source.

Increasing plant vegetative growth, yield as well as fruit quality and chemical composition due to increasing potassium fertilization levels have been reported by many workers on different crops El-Masry (2000), Nassar *et al.* (2001) and Fawzy *et al.* (2005) on sweet pepper, Chen Zhen De *et al.* (1996) and Fawzy *et al.* (2007) on eggplant, Nanadal *et al.* (1998), Al-Karaki (2000) and Gupta and Sengar (2000) on tomato and Lester *et al.*, (2006) on muskmelon. Potassium humate can be used as a non-expensive source for potassium and it could be used as soil dressing, drenching or foliar applications. It was already subjected to many studies in various areas of agriculture. The mechanism of humate material in promoting plant growth is not completely known. It was reported by many researchers that K-humate application increased the plant growth, nutrient uptake and plant yield and quality as well (Böhme and Thi Lua, 1997; Padem and Ocal, 1999; Hoang and Böhme, 2001; Türkmen *et al.*, 2005; Zaky *et al.*, 2006 and Karakurt *et al.*, 2009).

Soil and/or foliar K-humate applications might successfully be used to obtain higher fruit yield and can significantly enhance pepper fruit quality as demonstrated by Arancon *et al.* (2006). Also, El-Bassiony (2006) and Fawzy *et al.* (2007) found that spraying potassium oxide as a stimulative dose led to the highest plant growth (plant length, number of leaves/plant, and fresh weight of leaves) as well as the highest yield and quality of onion and aubergine plants, respectively. In the same regard, Lester *et al.* (2006) concluded that soil K with foliar K applications during muskmelon fruit development and maturation improved fruit quality by increasing sugar content, ascorbic acid, and ß-carotene levels.

The main objective of this study was to investigate the effect of different potassium fertilization rates in addition to foliar spraying of potassium oxide or K-humate as stimulative doses on the vegetative growth parameters, total fruit yield and its physical and chemical constituents of sweet pepper plants.

2. Materials and methods

Sweet pepper seeds cv. "California wonder" were sown in 209 cell foam trays filled with peat moss:vermiculite (1:1 v/v) media. Afterwards, trays were kept in the greenhouse at the Experimental Station of the National Research Centre in El-Nobaria region, Behira Governorate, and cared by regular practices for seedlings production in greenhouse. After 8 weeks, uniform pepper seedlings were transplanted into the field on the second week of March in both seasons of 2009 and 2010. Seedlings were planted on ridges of 100 cm width, 8 m length on both sides of ridge and 50 cm apart. Each experimental plot included 4 ridges with a net area of 32 m^2. The physical properties and chemical analysis of the experimental soil are presented in Table (1). All agricultural practices were carried out according to the recommendations of Ministry of Agriculture for sweet pepper production in El-Nobaria region.

Potassium sulfate fertilizer (50% K_2O and 18% S, Tessenderlo Co., Belgium) was applied as a fertigation application through drip irrigation system with rates of 50, 100 and 200 kg/fed. Regarding potassium stimulative doses, sweet pepper plants were foliar sprayed for three times in a 15 days interval with the same doses of potassium oxide (2 and 4 ml/L, 37.5% K_2O, Kafr El Zayat Pesticides & Chemicals Co., Egypt), potassium humate (4 gm/L, Power Humus, 12% K_2O, Humintech Co., Germany) and with tap water as control treatment, during the growing period at 30, 45 and 60 days after transplanting. Few drops of wetting agent (Sticky, AGRICO International Co., Egypt) were added to spraying solution.

Experimental design and statistical analysis

The experiment was arranged in a split plot design with four replicates, where potassium fertilization rates were arranged randomly within the main 3 plots, while stimulative doses of potassium foliar spraying treatments plus control treatment were distributed in the sub-plots. The obtained data were statistically analyzed and means separation were done using LSD test according to the method described by Gomez and Gomez (1984).

Table (1): Physical properties and chemical analysis of the experimental soil.

Physical properties					
Sand	Clay	Silt	Texture	F.C.%	W.P.%
90.08	9.26	0.66	Sandy	16.57	5.25

Chemical analysis							
E.C. mmohs/cm	pH	meq./L					
		Ca	Mg	Na	K	HCO_3	Cl
1.7	8.2	7.02	0.527	0.982	0.310	1.3	0.566

Measured parameters:

Five plants were chosen randomly from each sub-plot at 90 days after transplanting date and transferred to laboratory to record the following data:

1- Vegetative growth characters

1- Plant height (cm).
2- Number of leaves/plant.
3- Number of branches/plant.
4- Fresh and dry weights of leaves (gm).

2- Fruit yield and quality

At harvesting time, samples of green pepper fruits were randomly harvested from each sub-plot to measure fruit length, fruit diameter and average fruit weight. In addition, total weight of fruits in each treatment were recorded by harvesting pepper fruits twice weekly and then the total yield as ton/fed. was calculated.

3- Chemical content

Fruit samples were randomly taken at harvesting time to determine vitamin C content in the fruit as mg/100gm fresh weight according to method described by A.O.A.C. (1990). Also, total chlorophyll content in fully expanded leaves was measured as SPAD units using Minolta SPAD-501 chlorophyll Meter (Minolta Co. Ltd., Japan). Leaf samples were oven dried at 68^{o}C for 72 hours, then fine grinded and used to determine ion contents on a dry weight basis. Total nitrogen and phosphorus contents were determined using Kieldahl method and colorimetric method using spectrophotometer (SPECTRONIC 20D, Milton Roy Co. Ltd., USA), respectively, according to the procedure described by Cottenie (1980). Potassium content was measured using flame photometer method (JENWAY, PFP-7, ELE Instrument Co. Ltd., UK) as described by Chapman and Pratt (1982).

3. Results and Discussion:

Vegetative growth characters

There were significant increases of all vegetative growth characters with increasing potassium fertilization rates from 50 to 200 kg/fed. except for number of branches per plant in the second season only, where no significant effect was realized (Table 2). In general, the highest values of plant height, number of leaves, number of branches per plant and fresh and dry weights of leaves of sweet pepper plants were recorded by plants which received 200 kg/fed. potassium sulfate, while the lowest values were recorded by plants received 50 kg/fed. These findings were true in both seasons. These results may be due to the role of potassium element in metabolism and many processes needed to sustain and promotion plant vegetative growth and development. Moreover, many studies proved that K plays a major role in many physiological and biochemical processes such as cell division and elongation and metabolism of carbohydrates and protein compounds (Hsiao and Läuchli, 1986 and Marschner, 1995). The obtained results are in harmony with those of El-Masry (2000), Nassar *et al.* (2001) and Fawzy *et al.* (2005) on sweet pepper, Fawzy *et al.* (2007) on eggplant, Al-Karaki (2000) and Gupta and Sengar (2000) on tomato and Lester *et al.* (2006) on muskmelon.

Concerning the foliar spraying of potassium as a stimulative dose (Table 2), there were significant increases in all vegetative growth parameters with using potassium as foliar application in both seasons, except for number of branches per plant in the second season only. The highest values of plant growth characters expressed as plant height, number of leaves, number of branches per plant and fresh and dry weights of leaves were recorded by using 4 gm/L of K-humate followed by 4 ml/L of potassium oxide when compared with control treatment. The above findings were completely similar in both seasons.

These results are in agreement with those of Hoang and Böhme (2001); Türkmen *et al.* (2005); Zaky *et al.* (2006) and Karakurt *et al.* (2009). They reported that K-humate application led to increasing and improving plant growth parameters. In addition, Böhme and Thi Lua (1997) reported that K-humate had beneficial effects on nutrient uptake by plants and was particularly important for the transport and availability of micro nutrients needed for optimal plant growth and development. In the same respect,

spraying potassium oxide led to the highest values of plant growth characters (plant length, number of leaves/plant and fresh weight of leaves) as reported by El-Bassiony (2006) on onion and Fawzy *et al.* (2007) on eggplant.

Regarding the interaction effect, there were significant differences in all measured vegetative parameters except for number of branches per plant in both seasons. Generally, it could be stated that the highest plant growth characters were recorded by using 200 kg/fed. potassium sulfate with foliar application of K-humate (4 gm/L) followed by using 200 kg/fed. potassium sulfate with foliar application of potassium oxide (4 ml/L) and these findings were true in both experimental seasons.

Fruit yield and quality

Data presented in Table (3) clearly demonstrated that there were significant differences in the total yield and all fruit quality parameters except for the average of fruit diameter. The highest total yield of sweet pepper plants was produced by using 200 kg/fed. potassium sulfate. Concerning, fruit quality measurements (fruit length and average fruit weight), the obtained results concluded that there were significant increases in sweet pepper fruit parameters with increasing potassium levels from 50 to 200 kg/fed. While, potassium sulfate fertilization had no significant effect on pepper fruit diameter. These findings were true in both experimental seasons.

Table (2): Effect of different potassium levels and potassium foliar application on vegetative growth parameters of pepper plant in seasons of 2009 and 2010.

The obtained results might be due to the role of potassium in fruit quality, where it is known as the quality nutrient because of its important effects on fruit quality parameters (Imas and Bansal, 1999 and Lester *et al.*, 2006). Also, the obtained results were in accordance with those obtained by El-Masry (2000), Ni-Wu *et al.* (2001), Ruchi-Sood and Sharma (2004) and Fawzy *et al.* (2005) on pepper plants, Fawzy *et al.* (2007) on eggplant and Al-Karaki (2000) and Gupta and Sengar (2000) on tomato. They concluded that increasing potassium fertilization levels could be used to improve or enhance plant yield and fruit quality as well.

Regarding foliar application of potassium oxide or potassium humate, foliar application treatments had a significant effect on total yield and fruit quality of sweet pepper plants except for fruit diameter in both seasons. The highest values of fruit yield and quality parameters were obtained when sweet pepper plants sprayed with K-humate (4 gm/L) followed by potassium oxide (4 ml/L).

The obtained results are in agreement with Karakurt *et al.* (2009) who showed that humic acid had no significant effect on fruit length or diameter. Also, they demonstrated that humic acid applications might successfully be used to obtain higher fruit yield and can significantly enhance fruit quality in organically grown pepper. Moreover, Arancon *et al.* (2006) reported that pepper plants treated with humic acid significantly produced more fruits and flowers than untreated plants. In addition, Padem and Ocal (1999) demonstrated that increasing K-humate application dose led to a significant increase in fruit weight and total yield. In the same regard, El-Bassiony (2006) and Fawzy *et al.* (2007) summarized that spraying potassium oxide resulted in the highest yield and quality of onion and aubergine plants, respectively.

Concerning factors interaction, there was no significant interaction effect on fruit diameter in both seasons. Whereas, there were significant interaction effects on total yield, fruit weight and fruit length in both seasons. Generally, it could be mentioned that the best results were obtained when potassium sulfate was used at rate of 200 kg/fed. plus K-humate (4 gm/L) followed by using potassium sulfate at rate of 200 kg/fed. plus potassium oxide (4 ml/L) as a foliar application.

Chemical content

Increasing potassium fertilization rates from 50 to 200 kg/fed. significantly increased all chemical composition, i.e. total chlorophyll, N, P and K in leaves and vitamin C content in fruits. In general, the highest and lowest values of measured chemical composition of sweet pepper plants were recorded by plants which received 200 and 50 kg/fed. potassium sulfate, respectively, in both seasons as shown in Table (4). These results may be due to the role of potassium in plant metabolism and many important regulatory processes in the plant. Also, it could be increased mineral uptake by plants (Hsiao and Läuchli, 1986 and Marschner, 1995).

The obtained results are in accordance with Nassar *et al.* (2001) and Fawzy *et al.* (2005) on pepper, Fawzy *et al.* (2007) on eggplant, Al-Karaki (2000) and Gupta and Sengar (2000) on tomato. They proposed that potassium fertilization levels significantly affect fruit quality parameters and plant chemical composition. In the same regard, Lester *et al.* (2006) concluded that potassium fertilization with potassium foliar applications during muskmelon fruit development and maturation improved fruit quality by increasing sugar content, ascorbic acid, and ß-carotene levels.

Potassium not only increased fruit yields but also improved fruit quality by increasing dry matter and vitamin C contents, as well as increasing sugar content and titratable acidity levels of tomato as reported by Economakis and Daskalaki (2003).

Concerning foliar application of potassium oxide with rates of 2 and 4 ml/L or potassium humate with 4 gm/L as stimulative doses, it is of interest to note that they had a positive significant effect on chemical composition of sweet pepper plants except for phosphorus percentage in the second season only. Data presented in Table (4) indicated that the highest values of vitamin C content in fruits and total chlorophyll in leaves, as well as the highest percentages of N, P and K in pepper leaves were recorded when pepper plants sprayed by K-humate (4 gm/L) followed by potassium oxide (4 ml/L) treatments when compared with control treatment in both seasons.

The obtained results are in harmony with Hoang and Böhme (2001), Zaky *et al.* (2006) and Karakurt *et al.* (2009). Also, Böhme and Thi Lua (1997) showed that K-humate had beneficial effects on nutrient uptake and was particularly important for the transport and availability of micro nutrients. In addition, foliar spraying of potassium as a stimulative dose had a significant effect on N and K percentages in dry leaf tissues and significantly increased fruit quality in eggplant as reported by Fawzy *et al.* (2007). Also, Padem and Ocal (1999) and Lester *et al.* (2006) demonstrated that potassium applications can improve fruit quality, i.e. firmness, sugar content and vitamin C content in processing tomato and muskmelon fruits.

The interaction effect between potassium fertilization rates and potassium foliar application had a significant effect on vitamin C content in fruits, total chlorophyll and potassium percentage in leaves. While, no significant effects were realized on nitrogen and phosphorus percentages. These results are similar in both seasons. From data presented in Table (4) it could be clearly summarized that the highest values of vitamin C content in sweet pepper fruits, total chlorophyll and potassium percentage in sweet pepper leaves were recorded when sweet pepper plants received 200 kg/fed. potassium sulfate as fertilization plus 4 gm/L of K-humate as foliar application followed by plants that received 200 kg/fed. potassium sulfate plus 4 gm/L of potassium oxide.

4. Conclusion:

From the above mention results it could be concluded that foliar application of potassium humate (4 gm/L) or potassium oxide (4 ml/L) as a stimulative dose could be successfully used in addition to fertilization application of potassium sulfate with rate of 200 kg/fed. to obtain the highest vegetative growth parameters, total fruit yield, and significantly enhanced fruit quality and chemical composition of sweet pepper plants.

How Do University Students Spend Their Time On Facebook? An Exploratory Study

Alimohammad Aghazamani
Faculty of Technology and Science, Karlstad University, Karlstad, Sweden
Aghazamani99@yahoo.com

Abstract: Despite major productive uses of Internet technology in today's digital world, users prefer to spend much more time on social networking sites (SNSs) like Facebook. The objective of this study is to determine student motives for using Facebook. A close-ended questionnaire was administered to 595 University students who were recognized as users of the site at Karlstad University in Sweden. Male users spend more time on the site than female users during both weekdays (p-value=0.9238) and weekends (p-value=0.9953). The survey showed that undergraduate students login more times per day than graduate students (p-value=0.2138). In addition, friendship was named the most favorite activity among male users (p-value=0.8883) and also among undergraduate students comparing with graduate students (p-value=0.2045). If users were asked to pay a membership fee to use the site, the results showed that male users (p-value=0.9991) and undergraduate students (p-value=0.9884) were more likely to pay the charge than other groups (females and graduate students). It is apparent that using Facebook can be seen as an important part of daily life among University students and its phenomenon spread out inevitably.

Keywords: Internet; Facebook; Global village; Social networking

1. Introduction

Among the variety of online tools now available for communication, social networking sites (SNSs) are one of the most recent and significant tools for connecting people throughout the world. The online world has already proven to impact numerous aspects of the human life including commerce, education, and health (Jalalian M., 2010, Jalalian M. 2008). These virtual spaces, the new building blocks of today's Internet, provide not only the power to access distributed and heterogeneous information, but also interact with millions of people all over the world. SNSs are virtual spaces that allow individuals to create personal profiles - visible to other users- to establish connections and join an online social network. These websites enable computer-mediated communication (CMC) between people. Social networking has been the tool that brings people together in just a click of a mouse (Raskin, 2006).

It seems that SNSs such as Facebook are changing the nature of social relationships (Body & Elisson, 2007). In fact, virtual spaces like Facebook and MySpace (www.myspace.com) offer today's online users a discursive space to experience "communal affiliation around shared experiences" (Mitra, 1997). SNSs users join cyber-communities to overcome geographical distance as well.

Facebook was established in February 2004 by Mark Zuckerberg, a former Harvard University student. The website has more than 500 million active users worldwide while about 70 percent of its users are outside the United States (Facebook, 2010).

Facebook offers its services in more than 75 languages (five times more than its nearest competitor, MySpace) and because of its popularity among Internet users, the number of users has increased considerably. The study on which this research is based examined the amount of time spent on Facebook and factors that persuade university students to fulfill their needs and desires through Facebook. Information was disclosed through paper-based interviews. The investigation assessed gender, education, and age differences in the disclosure of personal preferences and amount of time spent on Facebook. Respondents were students at Karlstad University in Sweden. The survey provided interviews among 595 students during November and December 2009.

The paper begins by discussing our hypothesis and research questions that were asked in the questionnaire. Next, we describe the methodology used to empirically investigate the hypotheses, followed by our analysis and discussion of the results. Finally, we discuss the implications and limitations of this research and suggestions for future research. A major contribution of this study lies in understanding the relationship among individual differences (gender and education), amount of time spent on Facebook, and individual preferences in Facebook usage among university students.

2. Material and Methods

Twelve hypotheses (Hs) regarding the subject of survey were defined and research on the basis of close-ended questions was designed. Investigations were conducted by questionnaire using six questions, with each question offering two to four proposed answers (PA). The questionnaire was developed using a variety of research questionnaires and the results of prior studies. For instance, question No. 4 addresses student motives (gratification) for using Facebook and other questions examine how a student's individual differences in gender and education are related to their use of Facebook. Table 1 illustrates the structure of the questionnaire.

The hypotheses of the survey were defined as follows:

H1: Facebook male users spend more time on Facebook during weekdays than female users.

H2: Undergraduate students use Facebook more during weekdays than graduate students.

H3: Most of Facebook male users spend more time on Facebook during weekends than females.

H4: Undergraduate students use Facebook more than graduate students during weekends.

H5: Most of Facebook male users login more than once a day than female users.

H6: More undergraduate students login to Facebook each day than graduate students.

H7: Friendship is the most favorite activity among male users on Facebook.

H8: Friendship is the most favorite activity among undergraduate users.

H9: Most of Facebook male users like to connect in the morning – more than female users do.

H10: More undergraduate students use Facebook in the morning than graduate students.

H11: Facebook male users are more favorably disposed top paying a fee to connect to the site than females.

H12: Undergraduate Facebook users are more favorably disposed to paying a fee to connect to the site than graduate students.

The city selected for this study is Karlstad, the capital of Värmland County in Sweden. The authors chose Karlstad University, which has approximately 12,000 students with diverse undergraduate and graduate majors. The survey was conducted on the basis of paper interviews that were held in November and December 2009.The data in this study was obtained using a survey questionnaire completed by undergraduate and master's students at Karlstad University. The University was chosen because of its wide range of Swedish and international students in an academic environment where there are many students who are familiar to Facebook. Students were interested in participating in the survey about Facebook. They were asked to comment on readability; understand the questions, and complete the questionnaire in a small period of time. The results indicate that the questions were clear and understandable and required about 15-20 minutes to complete. The goals of these questions were to consider how differences in education and gender are affected by Facebook use among University students.

Table 1. Questionnaire employed in the study

Gender: ( )Male ( ) Female
Do you currently have a Facebook account? ( )Yes ( ) No If you answered ''Yes" to above question, please continue to item No. 1. If No, thank you for your time. If you connect to Facebook every day (Except weekend), answer the question below:
RQ1. How much time do you spend on Facebook during the day? AA1. a. Maximum 5 minutes b. Maximum one hour c. more than one hour
RQ2. How much time do you spend on Facebook during the weekend? AA2. a. Not at all b. Maximum 5 minutes c. Maximum one hour d. more than one hour
RQ3. How many times do you connect to Facebook during the day? AA3. a. Only one time b. more than one time
RQ4. What is your first preference for using Facebook usually? AA4. a. Chat b. Posts and comments c. Friendship d. Other
RQ5. What times do you typically connect to Facebook? AA5. a. 8-12 b. 12-17 c. after 17
RQ6. If you had to pay a charge to login to Facebook, how would you be willing to pay per month? AA6. a. Maximum 50 Kr b. More than 50 Kr c. No charge

To collect the data, we used a questionnaire that was distributed to 750 students and 595 (79.3 percent) answered the research questions regarding their Facebook usage. Responses were voluntary and those who never had a Facebook account did not participate in the survey. We asked students to answer questions and respond to one of the alternatives for each question. After capturing data from students in order to consider our hypothesis, we used Statistical Package for Social Science (SPSS) to analyze the questionnaires. Mean, standard deviation, and coefficient of variance for each question and

group of questions were calculated to determine the order of importance of research factors. ANOVA statistical analysis (t-test) was used to assess the validity of attitudes of male and female students at different education levels toward using Facebook.

3. Results

Table 2 illustrates the frequency distributions of the survey based on gender and education while Table 3 illustrates the separate results. The results showed that 57.6 percent of respondents were male and 42.4 percent were female. Most students were undergraduates. The total results, separated by survey's questionnaire, are presented in Table 2. To consider 12 hypotheses based on p-value test, we used Table 3 to evaluate our hypothesis.

TABLE 2. Frequency Distributions in the study sample

Percentage of the sample (n=595)	
Variable	Frequency (%)
Gender	
Male	342 (57.6)
Female	253 (42.4)
Education	
Undergraduate	434 (72.9)
Graduate	161 (27.1)

Ho is assumed as a null hypothesis. P is the ratio of Facebook users. P has a different meaning with respect to the subject of any hypothesis. For instance, in hypothesis No. 1, P male is the ratio of Facebook male users who spend more time on the site than female users. Results of p-value tests are shown below:

H1. Accepted
H_0: $P_{male} = P_{female}$
H_a: $P_{male} \neq P_{female}$
P-value= 0.9238> 0.05

H2.Accepted
H_0: $P_{Undergraduate} = P_{Graduale}$
H_a: $P_{Undergraduate} \neq P_{Graduale}$
P-value=1 >0.05

H3.Accepted
H_0: $P_{male} \geq P_{female}$
H_a: $P_{male} < P_{female}$
P-value=0.9953 > 0.05

H4.Accepted
H_0: $P_{Undergraduate} = P_{Graduale}$
H_a: $P_{Undergraduate} \neq P_{Graduale}$
P-value=0.3421> 0.05

H5.Accepted
H_0: $P_{male} \geq P_{female}$
H_a: $P_{male} < P_{female}$
P-value=0.9813> 0.05

H6.Rejected
H_0: $P_{Undergraduate} = P_{Graduale}$
H_a: $P_{Undergraduate} \neq P_{Graduale}$
P-value=0.2138> 0.05

H7. Accepted

	50 to 200 Kr.	122	34	93	63
	No charge.	221	65	146	140
How does Facebook affect your social relationships in the real world?	It increases my social relations completely.	94	42	99	37
	It decreases my social relations in completely.	163	49	107	105
	It causes negative and positive effects.	74	40	66	48
	I have never thought about that.	100	28	67	61

4. Discussions

The aim of the study was to examine how university students who deal with SNSs, particularly Facebook.com, spend their time on the site and what their motivations are. In accordance with different gender, education levels, and preferences in using Facebook, results revealed that male Facebook users spend more time on Facebook during the weekday (p-value=0.9238>0.05) than female users. In addition, males spend more time on the site on weekends (p-value=0.9953>0.05) than female users. The number of site logins among graduate students appears to be less than undergraduate students (P-value=0.2138>0.05). Moreover, most male respondents chose friendship as their most favorite activity (p-value=0.8883>0.05) instead of other activities (chat, postings, and comments). Also, friendship was recognized as the most popular activity for undergraduate students compared to graduate students (p-value=0.2045>0.05). One question related to the user's willingness to pay a membership fee to connect the site. The result of p-value test found that male users (p-value=0.9991>0.05) and undergraduate students (p-value=0.9884>0.05) were more interested in paying a charge than other groups (female and graduate students).

The results showed that the vast majority of respondents in our survey use Facebook. One explanation for this popularity is that SNS usage among Internet users has increased dramatically in

today's information-driven societies in Western countries.

Numerous articles outline the significant relationship between SNS and psychological subjects. Some believe that motivations that determine how young people use online social networks are psychological ones, and they are strongly related to the human needs of communication, socialization, being an active part of a group, or maintaining long-distance friendships (Baltaretu & Balaban, 2010). Moreover, there has been significant discussion about the relationship between online media and offline social activities and interpersonal interaction (DiMaggio, Hargittai, Neuman & Robinson, 2001). Thus, the findings show that Facebook usage among Swedish university students seems to be an important part of their everyday life but can present some challenges in their social relationships.

Some researchers have suggested that greater Internet use results in smaller social circles, less communication at home, and loneliness (Kraut et al., 1998). Spending more time on the Internet and particularly in SNSs can create an addiction to the Internet. Internet addiction is a prevalent problem affecting individuals throughout the world and is recognized as an artifact stage of Internet adoption within a society (Zhang & Amos, 2008). The author believes that there are some limitations to this research.

Like any research, the investigation has many limitations that should be considered before generalizing the results to other contexts and recommending future research. First, the survey only sought opinions of students from just one university. However, every university is different. Therefore, norms and preferences of Facebook users and time usage on this SNS might vary from one university to another or from one part of the country to another.

The next limitation of this study involves the lack of facilities and human resources to fully examine the topic of spending time on SNS. Due to these constraints, only 595 students were surveyed. The data comes from students at Karlstad University in Sweden. It is problematic to generalize these findings to the entire worldwide population of SNS members who have diverse backgrounds and different levels of education with different nationalities, attitudes, preferences, and expectations.

Third, the participants were students at one university in Sweden. In this case, the choice of students was appropriate since they are the primary target of one SNS used as a frame of reference in this study. It seems that SNS users are have a wide range of education and interests. Accordingly, to increase the validation of these results and generalize the study's findings, future research should examine other sample groups in different age groups such as high school students, homeowners, and so on.

In addition, the study focused on participants who were studying in Nordic countries. Culture, stage of economic development, and political–economic traditions in Sweden surely influenced the preferences of Facebook users in this country.

The number of Facebook users has increased dramatically in today's global village. Not surprisingly, the site is an important part of daily life among students and its phenomenon has spread out steadily.

Therefore, further investigation is needed to learn if there are specific cultural and nationality differences among Facebook users that could influence generalizability. However, it must be kept in mind that many methodological differences exist among these studies, each of which uses different estimation techniques, question formats, and/or vehicles of payment. Some supplementary issues that should be considered in future research include users' reasons and expectations for using social networking sites such as Facebook. Is it to keep in touch with personal friends or to meet new friends? The content and use of social networking should certainly be a topic of discussion in any managerial aspect such as human resource management (HRM), informal learning within organization, and so on. Consequently, these aspects can be used to either approve or reject our findings.

Abstract: It is becoming increasingly challenging for organizations to obtain qualified and talented staff. Succession planning is often introduced as a way to attract and employ such staff. Succession planning is a process of recruitment and development of employees for vital roles within the organization. Implementation of succession planning is central to certain organizational requirements. This research surveyed organizational requirements in Iranian governmental agencies and their relation to the implementation of succession planning. This study used descriptive methods with correlation. The statistical population consisted of two groups, experts and managers of Iranian governmental agencies, and data was collected using three questionnaires. The findings of this study demonstrated a meaningful relationship between organizational requirements such as managers' commitment, organizational culture, organizational readiness, and managers' competencies with the implementation of succession planning. By considering these organizational requirements in their management practices, managers are more likely to be successful in recruiting, evaluating, training and developing talent as dimensions of the implementation of succession planning.

Keywords: succession planning, requirements, managers' commitment, organizational readiness, competencies

1. Introduction

In the modern, globally-competitive environment, the need for substantial changes and creative work is always felt by organizations. This has forced the modern organizations to consider new working methods when encountering less stability and rapid change in their sectors. However, human resources departments should not only solve specific problems, but also must ensure the success of the organizations in facing potential challenges of the future. One of these challenges is the demand for qualified and talented staff. In order to attract and employ such staff, succession planning (SP) is introduced. SP is vital for day-to-day decision-making in an organization and is considered an important tool for developing individuals (Huang, 2001). This system is also one of the most important mechanisms available for ensuring that an organization can train its employees to provide its future workforce.

SP can be defined as an attempt at proper planning regarding the number and quality of managers and staff with key skills in order to compensate retirement, death, serious illness or promotion, and any new circumstance that may be created in the future plans of the organization (Sambrook, 2005). Likewise, SP is a component of human resource planning that is consistent with the overall strategy of the organization (Beaver and Hutchings, 2004) and is a studied as an intentional program for which the organization and staff must be prepared for future vacant posts (Nuttall, *et al*., 2007). Xavier (2007) shows that it is necessary for managers to venture future managers' development.

Leaders rarely consider the results of their leadership, and after leaving the organization, they realize that the majority of their job was futile, because they were unable to find a qualified successor (Blackaby and Blackaby, 2001), while each post in the organization is required to have an identified successor (Ndwandwe, 2007). Some organizations seek qualified individuals to replace the leadership, but often these eligible employees are replaced for posts which are not related to their skills or career goals (Khurana, 2002). A recent study of Fortune 1000 companies shows that only 64 percent of these companies apply SP processes, and only 50 percent believe in its effectiveness (Wider & Enders, 2004). According to Schramn (2005), the latest forecast by the Society for Human Resources Management (SHRM) shows that few organizations implement management succession plans. Another study shows that, nearly two-thirds of executive managers in the world's largest agencies believe that

they will leave the organization in the next 10 years. Among these managers, 39 percent said they had a substitute for themselves in their mind, and 45 percent of these managers had not set any successor (Jusko, 2005). Alternatively, in some governmental agencies, human resource professionals avoid SP because they worried that the merit system principles of their organization would not be executed (Green, 2000). Although the implementation of SP is simple in theory, in practice it may prove difficult. Besson and Haddadj (2003) believe that implementation of SP processes seems to be difficult for two reasons. First, senior executive do not want to predict successors because choosing a successor means accepting one's resignation. Second, senior executives often prefer to choose his or her own successor from the members of his or her family. Murphy (2006) proposes these administrative problems, as well—underestimating the talent in the organization, failure to create educational opportunities and improvement, lack of managers' sense of responsibility for SP, and attention to SP in high levels of the organization.

Investing in existing staff and improving their skills (Seymour, 2008) through SP can be beneficial for an organization, as SP can increase the ability of the staff to respond to environmental changes (Fairburn, 2008). Additionally it creates incentives in the workforce and considers organizational processes such as recruitment, maintenance, training and development, and the performance management (Hammer, 2004). According to Rothwell (2005) the first step to succession planning is recognition of the organization's problems. However, SP is not considered a serious issue for many organizations. Managers have been reluctant to invest in and support SP because it seems that the workforce of the country is relatively stable and the government feels that any retirement crisis that may occur is in the far future. The most important causes of the failure SP for many organizations can be found in the disability of the program to maintain the necessary support from the organizational culture for example, looking at the program and neglecting the need for comprehensive attitude (Abolala'ei and Ghafari, 2007). Additionally, the findings of Iran's administrators database by the Management and Planning Organization in 2003 show that 52 percent of the country's managers had diploma and associate degree qualifications, and many senior managers have not participated in quality management training. The knowledge and skills of the managers and their managerial experience does not often correspondent with their responsibilities. In government agencies and industrial firms, the number of senior managers who began their career after completing an undergraduate degree and have reached high positions by demonstrating their performance capabilities is very low. Alternatively, the lack of suitable replacements for key organizational posts, i.e. managers and supervisors, at times of emergency such as retirement or promotion of managers is among the many problems faced by organizations in Iran. Most organizations are facing serious problems in filling management posts from among capable and qualified individuals. Lack of a rational and efficient system to promote everyone based on merit and performance and the lack of knowledge among many Iranian directors about the SP system and its implementation results are a main source of difficulties encountered by Iranian governmental organizations (Asmarian, 2004).

Figure 1. A model for SP

The second step is recognition of organizational requirements before the implementation of SP (Rothwell, 2005). Many organizations fail due to a lack of requirements as a main factor. The requirements that any organization must consider before implementing SP include management commitment to SP systems (Rothwell, 2005; Abolala'ei and Ghafari, 2007); participative and supportive organizational culture for the SP systems (Tropiano, 2004; Groves, 2007); preparedness of the organization for the SP system (Rothwell, 2005; Abolala'ei and Ghafari, 2007); capabilities of managers for the SP system (Brooks

and Henderson, 2005; Horton and Duggan, 2005; Lavinga, 2005). After recognition of these organizational requirements, implementation of SP is important. By studying the SP models, it was found that implementation of SP consists of three components—evaluation of present resources (Rothwell, 2005; Wider and Enders, 2004; Brooks & Henderson, 2005); Training and developing talented individuals (Rothwell, 2005; Curlin, 2009; Horton and Duggan, 2005; Groves, 2007; Brooks and Henderson, 2005; Steeves and Ross, 2003), and recruitment of talented individuals (Rothwell, 2006; Groves, 2007). Ultimately, a model for SP is designed (figure 1).

Successful SP in Iranian governmental organizations could be important. For example, SP will lead to the codification of capability models, identification of training needs, promotion of a competence culture, development of staff skills, and improvement of their capabilities. Additionally, providing a management database and detection of management talent within the organization through scientific method can help the organization's authorities to select qualified people for key posts more accurately and avoid common mistakes of manager selection. At the same time, the qualified individuals could reach higher levels of organizational hierarchy outside the normal path of career progress. This research will consider the status of organizational requirements and SP implementation in the public sector. Therefore, seeks to answer the following questions:

1. What is the status of organizational requirements in Iranian governmental agencies?
2. What is the status of SP implementation in Iranian governmental agencies?
3. What is the relationship between organizational requirements and SP implementation in Iranian governmental agencies?

2. Material and Methods

This study was uses the descriptive method with correlation. It uses the Delphi method to design the early model and the questionnaire. The statistical population consists of two groups; the first group consists of 30 experts chosen by selective sampling throughout the country. The second group consists of all managers of executive organizations chosen from five provinces of the 30 provinces in Iran by selective sampling. In each province, there are 72 governmental organizations from which was chosen a senior manager and a middle manager. It is choosing these 720 managers, seven organizations did not cooperate. The sample size is then 65 organizations and 670 managers. Ultimately, 628 managers filled in the questionnaires.

The collection of data is conducted using three questionnaires. The first is used to design an introductory model by experts, which is accepted. The second and third questionnaires evaluate organizational requirements and SP implementation, respectively. The validity of the organizational requirements questionnaire and the SP implementation questionnaire are 0.884 and 0.865, and the reliability of these two questionnaires are 0.881 and 0.884. SPSS is used analyze these data.

3. Results

The demographic characteristics are categorized as follows—626 managers among of 628 marked their ages. 21 managers (3.4 percent) were 30 years old and under; 228 managers (36.4 percent) were between 31 and 40 years old; 377 managers (60.2 percent) were 40 years old or more. Of the 628 managers interviewed, 622 marked their education level. Fifteen managers (2.5 percent) had diploma degree; 318 (51.1 percent) had a Bachelor's degree; 219 managers (35.2 percent) had a Master's degree; and 70 managers (11.3 percent) had a PhD degree.

The Sign Test is used to survey the status of organizational requirements and SP implementation. Managers were asked their opinion of the status of organizational requirements and SP implementation, and the median was evaluated to be more than 3 (rather good). The median of managers' opinions about manager commitment, organizational culture, organizational readiness, managers' competencies (as organizational requirements), evaluation of present resources; training and developing talents; and recruitment of talents (as SP implementation) was evaluated to be more than 3 (rather good).

Table 1. Result of Corelational analysis.

	Variables	Correlation coefficient	P Value
Organizational requirements	SP implementation	0.609	0.000
	Evaluation of individuals	0.515	0.000
	Training and developing talents	0.612	0.000
	Recruitment of talents	0.502	0.000

By using the Spearman Test, the correlation coefficient calculates the P Value with sample size n=628 was less than 0.05; this shows a meaningful

relationship between organizational requirements and SP implementation. Other results show a meaningful relationship between manager commitment, organizational culture, organizational readiness and manager competencies with SP implementation (Table1).

4. Discussions

Results show a meaningful relationship between organizational requirements and SP implementation. Rothwell (2005) emphasizes that the basis of SP implementation is recognition of organizational requirements before implementation. A study of Ibrahim, *et al*. (2004) shows elements that are vital for SP, including management competencies and skills, and successor's commitment to the organization. Many studies such as Rothwell (2005), Horton and Duggan (2005), Tropiano (2004), Murray (2007), and Steeves ajnd Ross (2003) show these relationships. Therefore, organizational requirements are emphasized as an urgent prerequisite in SP implementation. Therefore, it is prospected with the existence of organizational requirements that managers perform better in the evaluation of present resources, and training, development and recruitment of talent. Management commitment as a secondary variable is a force by which a person participate in the activities related to a specific aim (Shahnawaz and Juyal, 2006); so it is needed to have committed individuals for obtaining the success of an organization (Martin, 2008). Many studies confirm the positive effects of manager commitment. Committed individuals can recognize organization goals and values better, and they have stronger tendency for dependency to the organization (Nehmeh, 2009). Huang (2001) shows that SP cannot improve HR performance, but manager commitment to SP is an initial requirement for success. Therefore, it is prospected that manager commitment to SP is caused by desirable SP implementation.

Organizational culture as another variable is a main factor to the success of the leader (Walseth, 2009), and it plays a basic role in SP implementation (Ndubisi, 2008). Tan (2009) also shows how SP processes are influenced by culture. Organizational culture, especially a culture of collaboration and support, are essential for SP implementation (Tropiano, 2004). As a collaboration culture plays a key role in the learning process, a supportive culture can affect continuous commitment (Song and Kim, 2009). A collaboration culture is caused by continuous investment in increasing employees' skills, and persuading cooperation for development. A supportive culture supports talents in new roles. Therefore, a prospected collaboration culture and a supportive culture are influenced by desirable SP implementation. Organizational readiness is another variable that stresses the preparation of all departments of an organization (World Health Organization, 2009). Although there is not any particular frame to SP, a proper starting point for SP implementation is organizational readiness and pursuit of activities. Therefore, organizations should evaluate their readiness (Ritchie, 2005), as it is necessary to ensure plan success. Organizational readiness such as prospecting management needs, an active HR department, a tendency to merit, and retaining organization from politic pressures is needed.

Manager competencies, as a final variable, are employed as basis for all SP activities (Herr, 2007). Additionally, competency models are considered the base of SP implementation. These models provide a plan to make present and future required competencies (Rothwell, 2005). Surveys show that the competency format can be targeted toward different goals in HRM, such as management development, career planning, SP, and performance management (Wickramasinghe and De Zoyza, 2009). Alternatively, competencies provide a common language in HR areas such as selection, development, and SP (Berge, *et al*. 2002). Manager competencies such as conceptual skills, personality factors, decision making skills, and communication skills should be considered in organizations.

Other results show that dimensions like evaluation of human resources; training and developing talents, recruitment of talents to implement SP should be required. In the evaluation of human resources, managers can use performance management and evaluation centers. To develop talent, managers must pay attention to career policies in regards to the necessity of talented forces, to forming partnerships in training plans, and to appointments and promotions in regard to training and growth. Additionally, when training talents, managers should notice training plans and their feedback. When recruiting talents, it is necessary for managers to identify present employees and talents of outside organizations for forming the talent pool. Meanwhile, managers should select young and apt forces for increasing management reserves, and consider recruitment tests for identifying talents in the organization. Ultimately, SP is a strategic plan and a powerful tool not only for reinforcing and developing talent but also for turning a failing organization on a positive path. Identifying organizational requirements and implementing SP are complex tasks that require ongoing attention and sufficient resources. The organizations should spend tremendous resources and time in designing skills

and competencies to recruit, train and evaluate talent. Therefore, the revival and continuous updating of organizational plans is a good start for SP.

It is suggested that organizations' middle managers, senior managers and human resource managers place SP among their main tasks. It is necessary to design a native competencies model to use within governmental organizations. It is important to identify the educational needs of managers at different levels. Iranian organizations should consider activities such as equipping human resource departments, emphasizing the constancy of senior management teams, and utilizing educated and experienced managers to ensure readiness. Organizations should construct data banks for managers to detect management talent within the organization. Investment for developing future managers and establishment of an institute for developing young managers is necessary. It is also suggested to conduct empirical research to examine the realistic results.

Abstract: There has been an increase in the frequency of fungal infections over the past decade. Nosocomial transmission of fungal pathogens and the recognition of resistance to antifungal agents pose a significant problem. This study identified the fungi species prevalent in the labour ward of the general hospital Umuguma and Umezuruike Hospital, Owerri Imo State Nigeria. Fungi are eukaryotic cells and therefore more complex than bacteria. The data available shows that Mucor Species and Rhizopus Species are the predominate species found in both hospitals in decreasing order. Fungal infection are often severe, rapidly progressive and difficult to diagnose or treat, therefore a thorough appreciation and understanding of fungi infections, including diagnostic and therapeutic modalities are needed among clinicians and microbiologists to provide a better patient care.

Key Words: Nosocomial infections, fungi, Mucor, Rhizopus, Penicillin, Hospital, etc.

Introduction

Advances in the medical and surgical therapy over the past two decades have changed the type of patients cared for all over the world. Newer technologies and therapies such a bone marrow or solid-organ transplants and chemotherapeutic agents have become common at many medical centres resulting in many immuno-compromised individuals. Also, care in specialized units and the use of invasive monitoring devices, patient's nutrition, broad-spectrum anti-microbial agents and assisted ventilation have helped to treat patients suffering from previously devastating or fatal diseases and have provided life to premature neonates previously thought to be nonviable.

However, these successes have also resulted in complications in the severely ill and immuno-compromised patients who are highly susceptible to nosocomial infections caused by organisms such as fungi that were previously considered to be of low virulence or "non-pathogenic" (Bodey, 1988). Fungi infections in these patients are often severe, rapidly progressive and difficult to diagnose or treat (Edwards, 1991). In the mid -1980s, many institutions, including cancer research, university and community hospitals reported that fungi were becoming common pathogens in nosocomial infections (Harvey and Myers, 1987). In addition, National Nosocomial Infections Surveillance (NNIS) system reported a steady increase in the rate of nosocomial fungal infections, from 2.0 to 3.8 per 1,000 discharges (Beck-Sague and Jarvis, 1993). The modes of transmission vary and include environmental spread through air, carriage on the hands of hospital personnel and contamination of medical products or devices before (ie intrinsic contamination) or after (ie extrinsic contamination) shipment to hospitals. Understanding the pathophysiology of pathogenic fungi is critical in determining the cause of an outbreak (Benneti *et al*, 1995).

Nosocomial infection could be defined as infections which are as a result of treatment in a hospital or treatment in a healthcare service unit, but secondary to the patient's original condition (Andereoli *et al*, 1997; Nester *et al*, 2004) that is hospital acquired. These infections can also appear within 30 days after discharge, it may be rampant among people who are sick and whose immune systems are in a weakened state, host – flora equilibrium imbalance caused by prolonged intake of antibiotics, the pathogen could be exogenous or endogenous (Andreoli *et al*, 1997). Opportunistic mycoses are equally pressing problems, and occurs primarily in immuno copromised patients (particularly those with malignancies and AIDS) and in patients who have undergone major surgery, bone marrow or solid organ transplantation or who have been severely burned. *Candida albacores*, *Aspergillus* spp. and *zygomycetes* spp. (Bross *et al*, 1989) have been implicated in mycoses infection. *Aspergillus fumigatus*, *A. flavus* and A. *terreus* have become a common cause of nosocomial infection in highly immunocompromised patients such as those with haematologic malignancy undergoing bone marrow or solid organ transplantation or receiving corticosteroid therapy (Anaissie and Bodey, 1989). *Trichosporon bergelii*, *Acremonium* Spp., *Candida* Spp. (*C. albicans* is by far the most common Candida Spp causing infections in humans),

Fusarium Spp., *M. Pachydermatis, Paecilomyces* Spp. have all been implicate in one nosocomila infection or the other (Rowsey *et al*, 1979; Chang *et al*, 2007). Some studies have identified common risk factors for patients developing fungal infections in labour ward, some due to the presence of immunosuppressant or a combination of factors (Karabinis *et al*, 1988). The health care environment can become highly contaminated with nosocomial pathogens that are able to survive for long periods of time like weeks or even months, on bed rails, telephones, call buttons, taps, door handles, mattresses, chairs, floors and on surfaces frequently touched by hand, long enough to be transmitted to cause infection as well as in the air and in dust (Johnson and Conly, 2006). Sometimes health care personnel may be a carrier of a pathogen such as *Candida* Spp. or *Aspergillus* Spp. which they pass on the patient during care providing (Andreoli *et al* 1997; Nester et al, 2004).

Materials And Methods

Preparation Of Media, Chemicals And Reagents

Samples collected were from floor, bed rail, mackintosh, wall and mattress etc. sterilized swab stick moistened with sterile peptone water was used to swab the wall, floor, mackintosh, mattress, bed rail and baby bed in the labour ward while the air was sampled by exposing Sabourand dextrose agar (SDA) plate for 2hrs. The samples collected using the swab stick was inoculated onto the already prepared SDA plates dried in the oven at 40^{o}C and incubated for 72hrs (3 days) at room temperature. Identification using microscopic examination was done by wet preparation using lactophenol cotton blue stain and then examined under the microscope. Cultural and morphological characteristics were also used for the identification. The size, shape, speculation and pigmentation were seen with a magnifying lens, identity of the isolates were further confirmed microscopically with reference to Barnett Hunter (1987). The prominent fungi isolated includes Aspergillus, Mucor, Penicillum, Rhizopus species (yeast) and Candida.

Results: Same sample used for the two hospitals

TABLE 1: *Aspergillus niger*

Sample Code	Colony Code	Gross morphology macroculture	Microscopic Appearance	Most Probable Identity
Uf	Ufi	Black spores with white condiospores. It grows in colonies or clusters	Septate hyphae conidia occur on large radiating heads. condiospores arises from a segment of mycelium called a foot cell.	Aspergillus niger
Um	Um	Black spores with white condiospores.	Aseptate unbranched stipes with swollen vesvlerhizoids are borrn derectly on the vescile.	Aspergillus niger
Gw	Gwi	Black spore with white condiospore in zones. Conidia head radiate and tends to split	Conidiosphores stipes smooth walled; Conidia borne on the stigma	Aspergillis Niger
	GBB_2	Black spores with white condiospores in zones conidia head radiate and tends to split.	Conidiosphores stipes smooth walled, Conidia borne on the stigma.	*Aspergillus niger*

TABLE 2: *Candida* Species

Sample Code	Colony Code	Macroculture	Microscopic Appearance	Most Probable Identity
	GMT_2	2mm whitish colonies with short-hair like spite around the periphery irregular	Large gram positive oval budding yeast cells with short strands of pseudomycellium	Candida species
	UF_2	About 2mm whitish colonies with short hair like spite around the periphery and irregular shape.	Large gram positive oval budding yeast cells with short strands of pseudomycellium	Candida species

TABLE 3: *Penicillium* Species

Sample Code	Colony Code	Macroculture	Microscopic Appearance	Most Probable Identity
	UIR_2	Olive green spores with white periphery.	Septate hyphae conidiophores with smooth stripe and branched.	Penicillium species
	GW_2	Olive green spores with white periphery.	Septate hyphae conidiophores with smooth stripe and branched.	Penicillium species.
	GBR	Olive green spores with white periphery.	Septate hyphae conidiophores with smooth stripe.	Penicillium species.

TABLE 4: *Rhizopus* Species

Sample Code	Colony Code	macroculture	Microscopic Appearance	Most Probable Identity
UBB	UBB	White filamentous hyphae bearing black spores.	Sporangia are globose with slightly rough walled stolen opposite the branched rhizoids.	Rhizopus species
	UMT	White filamentous hyphae bearing black spores.	Sporangia are globose with slightly rough walled stolen opposite the branched rhizoids.	Rhizopus species
	GA_2	White filamentous hyphae bearing black spores.	Sporangia are globose with slightly rough walled stolen opposite the branched rhizoids.	Rhizopus species

TABLE 5: *Mucor* Spp

Sample Code	Colony Code	macroculture	Microscopic Appearance	Most Probable Identity
GF	GF	Black spores with white periphery	Colony composed of both tall and short sporangia which are branched in conopodia fashion.	Species
GBB	GBB_1	Greyish cotton hyphae raised from plates.	Non septate hyphac, sporangiospores symbolically branched with long and short criminate branches	mucor Species
	GA_1	Black spores with white periphery	Colony composed of both tall and short sporangia which are branched in conopodia fashion	mucor Species
UBR	UBR	Greyish green cotton hyphae raised from plates.	Non septate hyphae, sporangiospores symbolically branched with long and short criminate branches	mucor Mucor Ciricinelloides
ULR	ULR_1	woolly like hyphae spreading on the surface of the plate.	Colony composed of both tall and short sporangia which are branched in conopodia fashion.	Species
GMT	GMT	Olive green spores with white periphery	Colony composed of both tall and short sporangia which are branched in conopodia fashion.	Species
	ULW	Olive green spores with white periphery	Colony composed of both tall and short sporangia which are branched in conopodia fashion.	Species

DISCUSSION

The effects of fungi in labour wards cannot be under estimated, the result obtained showed that *Aspergillus* Spp have become a common cause of nosocomial fungal infection in highly immuno compromised patients such as those with rheumatologic malignancy undergoing bone corticosteroid therapy. *A. funigatus* are tolerant at temperature up to 50^{o}C, colonies grow rapidly and are white and velvety at first but soon become green, yellowish or black and powdery as the conidia are formed. *Aspergillus* Spp. infections usually occur in the lungs, people breathing clouds of conidia from the air of granaries, barns and silos, spores simply germinate in the lungs and form fungus balls. In the more invasive form, *Aspergillus* Spp. produces a necrotic pneumonia and disseminates to the brain, heart, skin and a wide range of other organs systemic aspergillosis usually occurs in very ill hospitalized patients with a poor prognosis (Anaissie and Bodey, 1989). Candida Spp the prevailing opportunistic pathogens of humans are the yeasts of Candida which are extremely wide spread yeast, it is the major cause of Candisiasis (also called Candidosis or moniliasis). *Candida albicans* occurs as normal flora in the oral clarity, genitalia, large intestine or skin of 20% humans. Although Candidacies is usually endogenous and not contagious, it can be spread in nurseries or through surgery, child birth, sexual contact and it account for nearly 80% of nosocomial fungal infections and 80% of nosoconial infections, 30% of deaths from nosocomial infections in general; *Candida albicans* causes local infections of the mouth vagina, skin and lungs. It can also disseminate to internal organs. The mucous membranes most frequently involved are the oral cavity and vagina (Bodey, 1988). The rhizopus species are extremely abundant saprobic fungi found in soil, water and food. Their large prolific sporangia release multitudes on humans and usually do little harm beside spoiling foods and rotten of fruits and vegetables. But an increasing number of critically ill patients are contracting a disease called zygomycosis which can cause a patchy infection of the nail bed like tineaungium involved in infection of the lungs of tubercular or highly immunosuppressed patients and occasionally infect the eyes, toe, nails and burned nails. (Rowsey *et al*, 1979). Mucor species can be differentiated from moulds of genera absidia, Rhizomes and Rhizomucor by the shape and insertion of the columnella and the lack of rhizoids. Some mucor species produce chlamydospores. The species have become a common cause of nosocomial fungal infection in imminocompromised patients such as renal failure, diabetes mellitus, receipt of antimicrobial agents, severe underlying disease and exposure to hospital construction activity. Penicillum Spp have been considered as an important causative agents of extrinsic bronchial asthma, they can penetrate the living of the intestine and invade the liver, lungs and skin. Untreated cases with extensive damage to the organs experience a high death rate.

From this study it has become pertinent to note that nosocomial fungal infection are becoming more prominent. There is an increase in the number of immunocompromised patients and patients receiving a broader range of antimicrobial agents in hospitals today compared with previous years. Consequently infections due to previously obscure fungi are being seen more commonly in hospitalized patients. Although diagnostic and therapeutic modalities for some fungi are improving such as those used for Candidiasis or aspergillosis, there is still much to learn about many of the other fungi discussed. Standards for susceptibility testing are currently being developed and should help guide clinicians and hospital epidemiologists in the management of nosocomial fungal infections. Continued epidemiologic and laboratory research is needed to better characterize these pathogens, allowing for improved diagnostic and therapeutic strategies in future. Sensitivity of organisms to antibiotics in use should be checked, needles and sharp objects should be discarded in rigid, puncture proof container without contact using bare hands or replacement of needle caps. Linen and solid reusable items should be placed in protective bags to prevent leaking and further contamination.

A modified Algorithm to Model Highly Nonlinear System

Tharwat O. S. Hanafy

Al_Azhar University,Faculty of Engineering, Systems and Computers Department
s_ewiss@yahoo.com

Abstract: In this paper, the Fusion of neural and fuzzy Systems will be investigated. Membership Function Generation and its mapping to Neural Network are introduced. An adaptive network fuzzy inference system (ANFIS) is introduced, and Multiple Inputs /Outputs Systems (Extended ANFIS Algorithm) is implemented. A Modification algorithm of ANFIS, Coupling of ANFIS called coactive neuro fuzzy system (CANFIS), is introduced and implemented using Matlab. The software of the modified algorithm of MIMO model identification is built. To test the validity of the modified algorithm ANFIS (CANFIS algorithm), an example is simulated from the numerical equation. The result of modified algorithm (CANFIS) showed a conformance with the simulated example and the root mean square (RMSE) is very small.

Keywords: A modified Algorithm to Model Highly Nonlinear System

1. Introduction:

Fuzzy logic was first developed by Zadeh [1] in the mid-1960s for representing uncertain and imprecise knowledge. It provides an approximate but effective means of describing the behavior of systems that are too complex, ill-defined, or not easily analyzed mathematically. Fuzzy variables are processed using a system called a fuzzy logic controller. It involves fuzzification, fuzzy inference, and defuzzification[2]. An adaptive network fuzzy inference system is investigated. In this paper we will introduce two different learning algorithms. Also, Multiple Inputs /Outputs Systems (Extended ANFIS Algorithm) is implemented using two methods. Modification algorithm, Coupling of ANFIS is called coactive neuro fuzzy system (CANFIS), is introduced and implemented using Matlab. Also, software for modification algorithm for MIMO is built. To test the validity of the modified algorithm ANFIS (CANFIS) algorithm, an example is simulated from the numerical equation[3]. This paper organized seven sections. The first section is introduction. The structure of neuro fuzzy systems is introduced in section 2. The generating fuzzy rules are investigated in section three. Two different ANFIS learning algorithm presented in section four. The modified algorithm (CANFIS) is introduced in section five. Section six introduced conclusion.

2. Neural Fuzzy Systems

In order to process fuzzy rules by neural networks, it is necessary to modify the standard neural network structure appropriately [2]. Since fuzzy systems are universal approximators, it is expected that their equivalent neural network representations will posses the same property. The reason to represent a fuzzy system in terms of neural network is to utilize the learning capability of neural networks to improve performance, such as adaptation of fuzzy systems. Thus, the training algorithm in the modified neural networks should be examined.

2.1 Membership Function Generation

A generalized bell membership function, commonly referred to as bell MF, is characterized by three parameters namely a, b, c.

$$\mu_{Ai}(x_1) = \exp\{-[(\frac{x - c_i}{a_i})^2]^{b_i}\}, \qquad (1)$$

A desired, generalized bell membership function can be obtained with the proper selection of the parameters a, b, c. The parameters a and c represent the width and the center of the bell function, and b represents the slopes at the crossover points. Various other membership functions such as triangular, trapezoidal, Gaussian, and sigmoidal can be used in the formulation of membership functions [3]. The triangular and trapezoidal membership functions, due to their simplicity and computational efficiency, are used extensively in the formulation of membership functions (MF) consist. The Gaussian, the generalized bell function, and the sigmoidal membership functions are smooth and nonlinear functions and are increasingly popular for specifying fuzzy sets. The generalized bell function has one parameter more than the Gaussian membership functions, resulting in an extra degree of freedom to adjust the steepness at the crossover points [4].

The reason to represent a fuzzy system in terms of a neural network is to utilize the learning

capability of neural networks to improve performance, such as adaptation of fuzzy systems. To convert Membership Function from FIS structure to construct the same membership using NN layer. The parameter of membership equals to weights and bias in neural network. Fig. (2) Shows the representation of parameters for membership function using NN. Let the bell MF from eq. (1)

Where $a(n) = e^{-n^2}$ Transfer Function (TF) (2)

Let

$$b = 1$$

$$n = \frac{x-c}{a} = \frac{1}{a}x - \frac{c}{a}, \quad \because n = wx + bias \qquad (3)$$

$$w = \frac{1}{a}, \quad b\text{ias} = -\frac{c}{a}$$

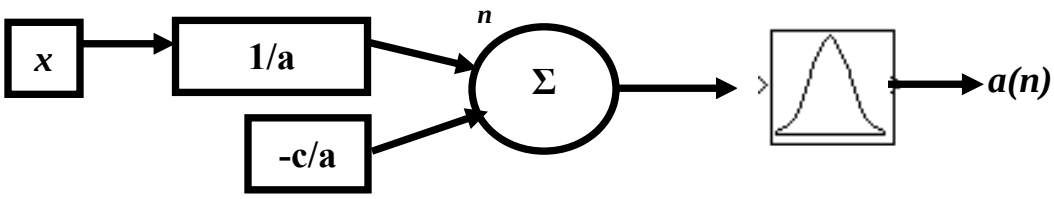

Fig. (2) Representations of membership function using NN

2.2 Adaptive network fuzzy inference systems

To illustrate the use of neural networks for fuzzy inference, we present some successful adaptive neural network fuzzy inference systems, along with training algorithm known as ANFIS. These structures, also known as adaptive neuro fuzzy inference systems, were proposed by Jang [6]. It should be noted that similar structures were also proposed independently by Jang [6]. These structures are useful for control and for many other applications. To fix the ideas, consider the problem of graphically representing the way fuzzy control is achieved in the Sugeno-Takagi model. For a simple example, consider a fuzzy rule base consisting of only two rules [7]:

R_1: if x_1 is A_1 and x_2 is B_1 then $y=f_1(x)$
R_2: if x_1 is A_2 and x_2 is B_2 then $y=f_2(x)$
(4)

where A_i and B_i are fuzzy sets and

$$f_1(x) = a_0^1 + a_1^1 x_1 + a_2^1 x_2$$

$$f_2(x) = a_0^2 + a_1^2 x_1 + a_2^2 x_2$$

Recall that when numerical input x= (x_1, x_2) is presented, the inference mechanism will produce the numerical output [8]

$$y^* = \frac{A_1(x_1)B_1(x_2)f_1(x) + A_2(x_1)B_2(x_2)f_2(x)}{A_1(x_1)B_1(x_2) + A_2(x_1)B_2(x_2)} \quad \textbf{(5)}$$

The ANFIS model suggested by Takagi and Sugeno represents a mathematical tool, which is used to build an ANFIS model of a system. ANFIS model of a non-linear system implication rule contains fuzzy variables with unimodal membership functions. Since such membership functions are linguistically understandable, the fuzzy variables are also called linguistic variables. Takagi and Sugeno's fuzzy model approximates a nonlinear system with a combination of several linear systems by decomposing the input space into several subspaces and representing the input/output relationship, in each subspace, with a linear equation.

3 Generating Fuzzy Rules

Linguistic labels in our natural language convey useful information in human control strategies as well as in other cognitive decision processes. The fuzzy set theory approach to modelling this type of information is based on this thesis that each linguistic label can be represented as a fuzzy subset of an appropriate set U, expressing the semantics of the label. While this seems quit reasonable from a modelling point of view, the concern in applications is determining the membership function of a label. This is related to the more general and more difficult problem of determining rules. There are several approaches to answer this concern. Rules and membership functions can be given by experts, either in a subjective manner or by using some statistical sampling methods. When experts are not available, but instead, numerical experimental data are at hand, it is possible to use neural networks as a solution to the problem of rule and membership function determination. With ANFIS, the structure of the rules and the types of the membership functions are specified in advance, and the parameters of the membership functions are learned from the data [11]. However, rules and membership functions can also be determined by using methods that do not presuppose a rule structure. Both the extraction of rules and the determination of membership functions can be implemented by some

kid of clustering. Clustering using neural networks belongs to the domain of unsupervised learning that relies on input data and no corresponding outputs. As in conventional clustering, the goal is to group data points that are similar to each other in some way- that is forming clusters. Given a set of crisp input-output tuples, or training data (x_i, y_i), $i=1,\ldots n$, fuzzy clustering techniques are applied to the input data to determine a collection of fuzzy clusters. Each fuzzy cluster represents one fuzzy "IF….then…"rule, where the fuzzy membership functions in the rule are obtained by projecting the cluster to input and output spaces [2, 6, 9].

In the forward pass of the hybrid learning algorithm, node outputs go forward until layer 4 and the consequent parameters are identified by the least squares method outlined above. In backward pass, the signals that propagate backwards are the error signals and the premise parameters are updated by the gradient descent method.

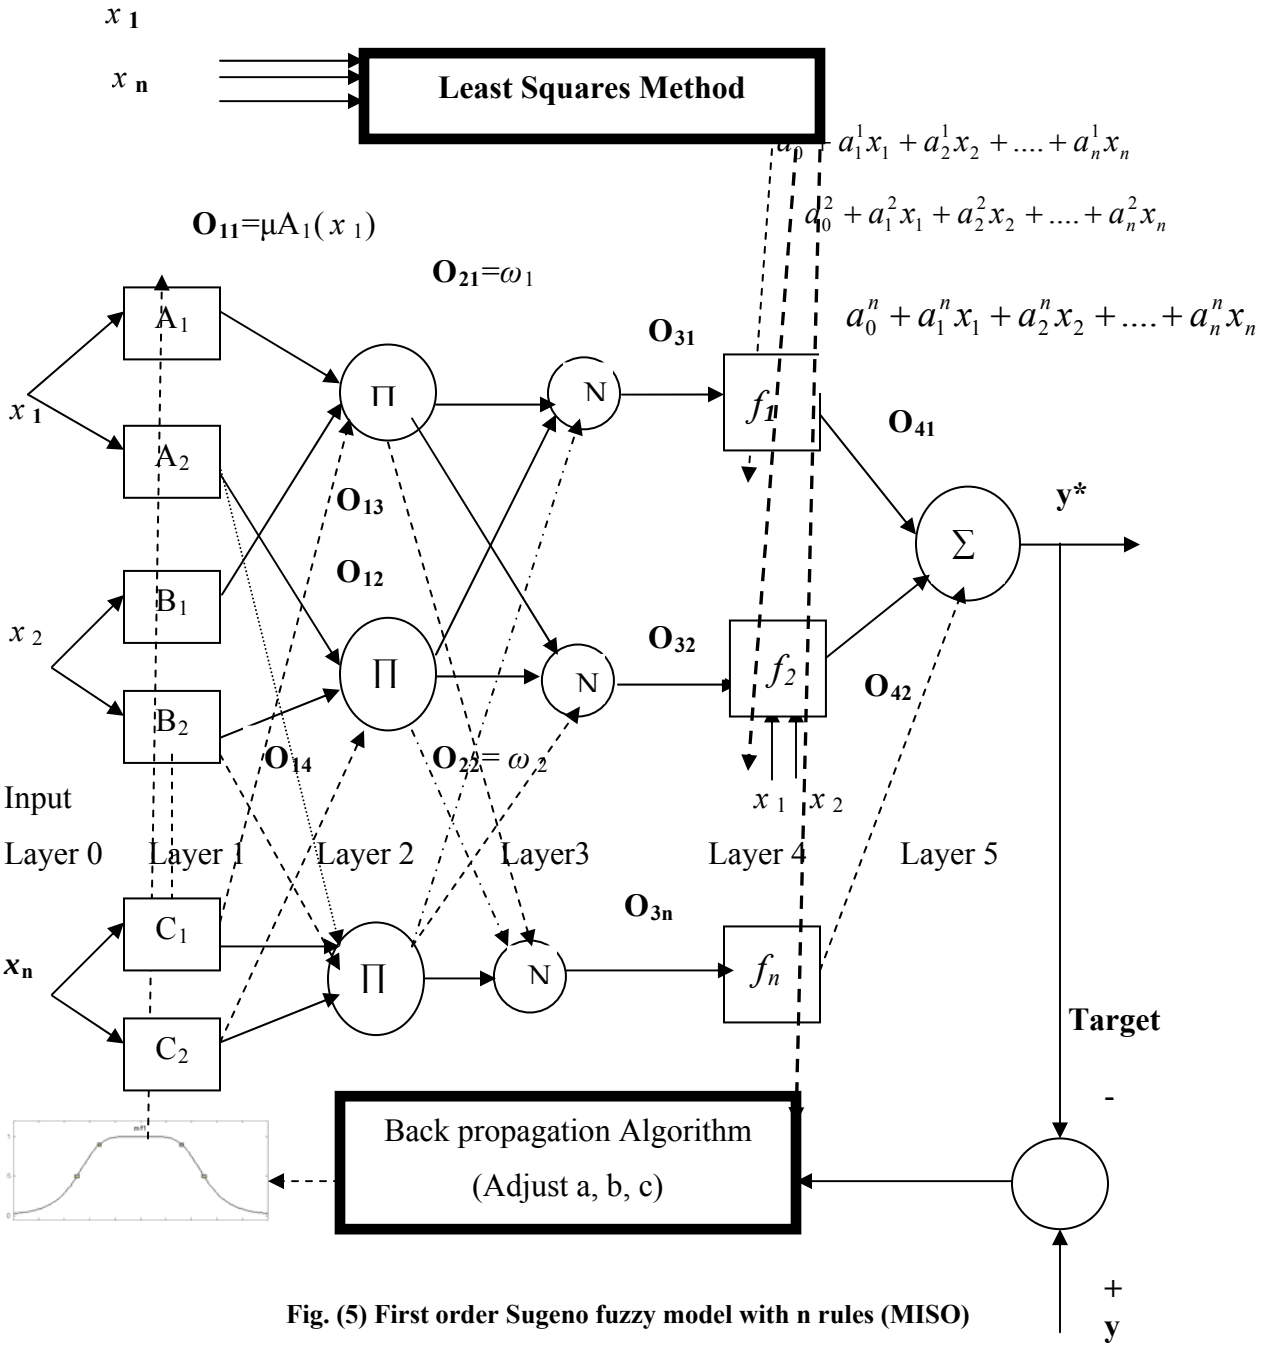

Fig. (5) First order Sugeno fuzzy model with n rules (MISO)

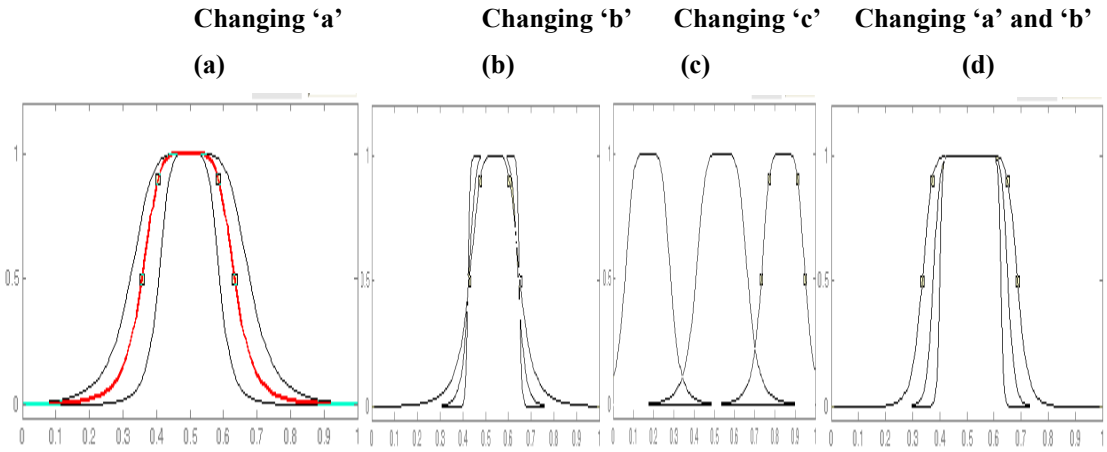

Fig.(6) The effects of changing parameters in Bell MFs: (a)Changing 'a' (b)Changing 'b' (c) Changing 'c' (d) Changing 'a' and 'b'

3.1 Input Space Partitioning

Now it should be clear that the spirit of fuzzy inference systems resembles that of "divide and conquer"- the antecedent of fuzzy rule defines local fuzzy region, while the consequent describes the behavior within the region via various constituents [24]. The consequent constituent can be a consequent MF, a constant value (Zero-order Sugeno Model), or a linear equation (first order Sugeno Model). Different consequent constituents result in different fuzzy inference systems, but their antecedents are always the same. Therefore, the following discussion of methods of partitioning input spaces to form the antecedent of fuzzy rules is applicable to all three types of fuzzy inferences [24].

1- Grid partitioning 2- Tree partitioning3- Scatter partitioning

3.2 Data Clustering Algorithms

Clustering algorithms are used extensively not only to organize and categorize data, but are also useful for data compression and model construction. Two different clustering algorithms are introduced [14]. The first algorithm introduces the most representative of line clustering techniques frequently used in conjunction with radial basis function networks and fuzzy modeling: subtractive clustering. Second, introduces the most representative on line clustering techniques frequently called evolving clustering methods (ECM). The advantages of this method are

1-Creating new cluster through training.

2-New fuzzy rules are created and updated during the operation of the system (through learning). Clustering partitions a data set into several groups such that the similarity within a group is larger than the among groups [15].

Clustering techniques are used in conjunction with radial basis function networks or fuzzy modeling primarily to determine initial locations for radial basis functions or fuzzy if-then rules. For this purpose, clustering techniques are validated on the basis of the following assumptions [16]:

Assumption 1:- States that the target system to be modeled is a smooth input outputs; mapping this is generally true for real world systems.

Assumption 2:- requires the data set to conform to some specific type of distribution; however, this is not always true. Therefore, clustering techniques used for structure identification in neural or fuzzy modeling are highly heuristic, and finding a data set to which clustering techniques cannot be applied is not uncommon.

4 ANFIS learning algorithm

In this section we introduce two different learning algorithms [26].

4.1 The First Learning Algorithm (Hybrid – Learning Algorithm)

From the ANFIS architecture in Fig. (5) We observe that when the values of the premise parameters are fixed, the overall output can be expressed as a linear combination of the consequent parameters [1].. Therefore, the formulas are usually referred to as kalman filter algorithm. In the forward pass of the hybrid learning algorithm, node outputs go forward until layer 4 and the consequent parameters are identified by the least squares method outlined above. In backward pass, the signals that propagate backwards are the error signals and the premise parameters are updated by the gradient descent method [16]**.** Table 3.2 parameters update during the forward and backward passes in the hybrid

learning procedure for ANFIS [12].

Table 2. Two passes in the hybrid learning procedure for ANFIS

Signal flow direction	forward pass	backward pass
Consequent parameters	Least-Squares estimator	Fixed
Premise Parameters	Fixed	Gradient descent method
Signals	Node outputs	Error signals

4.2 The Second Learning Algorithm (ANFIS)

The representation in the preceding section of a neural network is simply a graphical display of the computation steps in the sugeno-Tackagi procedure. In order for this representation to be more useful in implementing the model, one needs to equip it with an efficient learning algorithm [16]. In conventional neural networks, the back propagation algorithm is used to learn, or adjust, weights, on connecting arrows between neurons from input-output training samples. In the ANFIS structure, the parameters of the premises and consequents play the role of weights. Specifically, that is, the shape is specified and the function is determined by a finite number of parameters, these parameters are called **premise parameters**, whereas the parameters a_i, b_i, c_i, i=1, 2 in the "then" part of the rules are referred to as **consequent parameters**. The ANFIS learning algorithm consists of adjusting the above set of parameters from sample data $((x_1^k, x_2^k), y^k)$, k=1,…,N.

It is important to keep in mind that when we develop a set of prototype fuzzy rules, we are in fact representing possibly nonlinear input-output relationships [16]. The effectiveness of fuzzy models representing nonlinear input-output relationships depends on the membership functions, is an important issue in fuzzy modelling [16]. This tuning task can be viewed as an optimization problem; neural network offer a possibility to solve this problem [3]. In order to train a fuzzy neural network, we need a set of training data in the form of input – output tuples, and a specification of the rules, including a preliminary definition of the corresponding membership functions [4]. A standard approach is to assume a certain shape for the membership functions depend on parameters that can be learned by the neural network. We describe one method for learning membership functions of the antecedent and consequent parts of fuzzy "If….then…" rules. Suppose an unknown function, to be realized by a fuzzy inference system is known only through the training set [16]

$\{(x^1, y^1),\ldots,(x^k, y^k)\}$ (22)

where $x^k = ((x_1^k,\ldots,x_n^k) \in R.$ and, $y^k \in R$. To model the unknown function, we use fuzzy "If….then…" rules R_i, $i=1,\ldots., m,$ of the following type

R_i : If x_1^k *is* A_i^1 and … and x_n^k is A_i^n then

$$y = \sum_{j=1}^{n} z_i^j x_j^k + z_i \quad (23)$$

where A_i^j are fuzzy membership functions and z_i^j are real numbers.

5 Multiple Input /Output Systems (Extended ANFIS Algorithm)

One way to get multiple outputs is to place, as many ANFIS models side by side as there are required outputs. In this MANFIS (multiple ANFIS) no modifiable parameters set of fuzzy a rule, which makes it difficult to realize possible certain correlation between outputs [24]. An additional concern resides in the number of adjustable parameters, which drastically increases as outputs increase. This approach is represented in Fig. (7) and Fig. (8). another way of generating multiple outputs is to maintain the same antecedents of fuzzy rules among multiple CANFIS models. In short, fuzzy rules are constructed with shared membership values to express correlations between outputs. In this thesis we investigate the Second approach CANFIS to produce multiple outputs. This model is illustrated in Fig.(9).

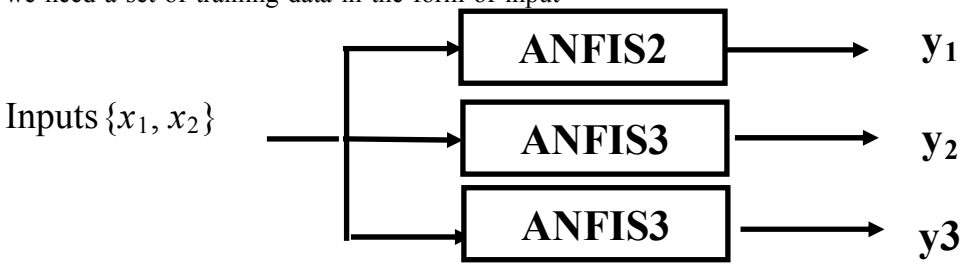

Fig (7). MANFIS Structure Decoupling MANFIS Structure

In this work we convert Fuzzy inference system structure to neural network structure, such as, membership functions for input variables, membership functions for outputs variables, Rules base.

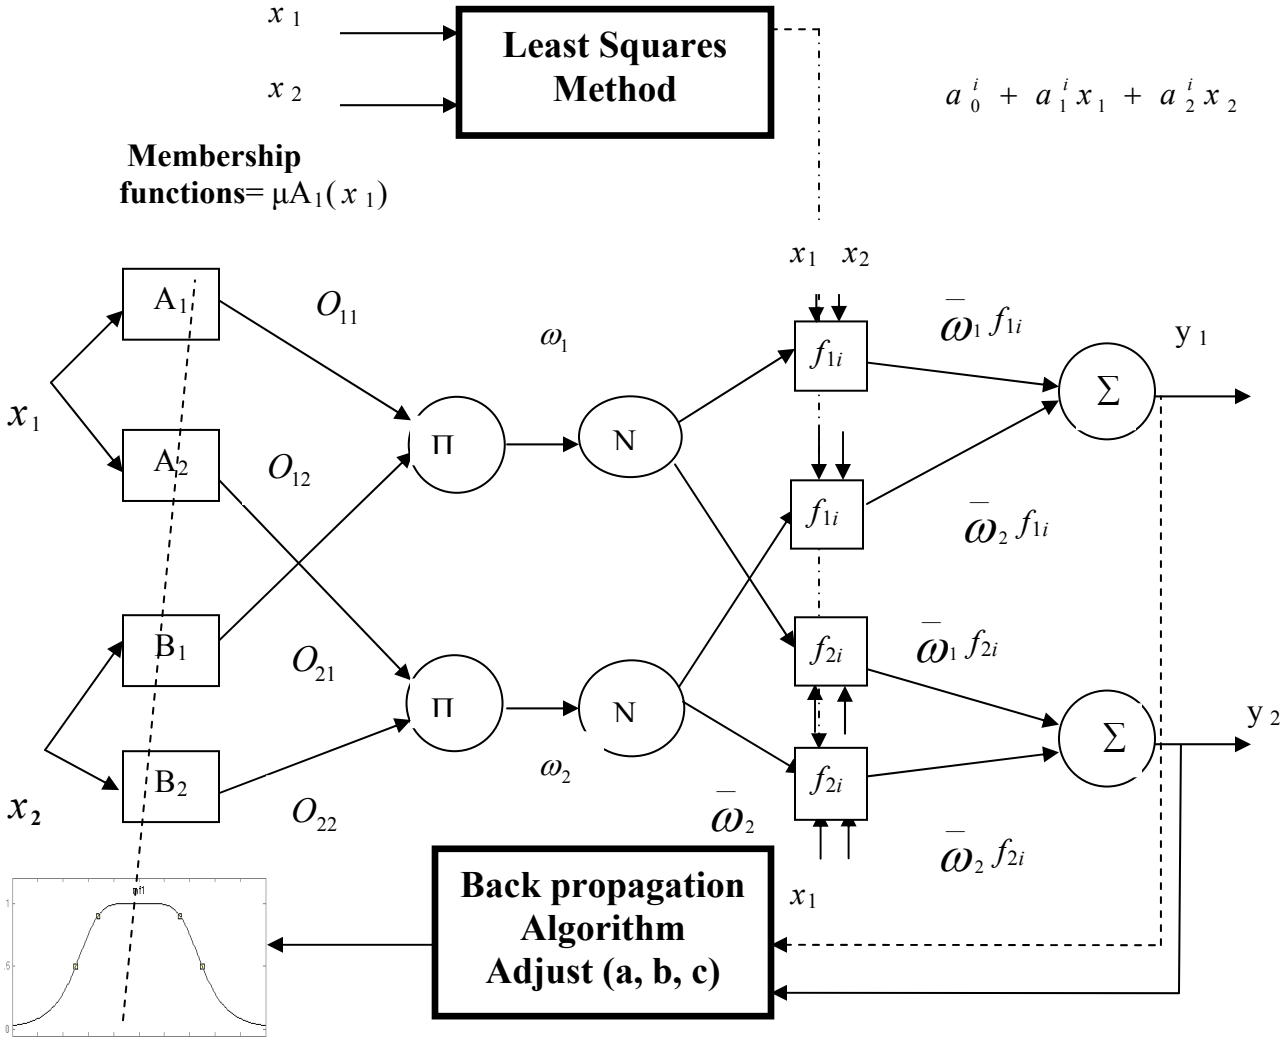

Fig. (8) Two outputs CANFIS Architecture with two rules per outputs

After conversion of FIS structure to NN, we train fuzzy neural network (FNN) and compute weights of each layer, weights of inputs, and weights of outputs to generate model. Then the weights are transformed to membership function parameters to construct FIS structure. The layer structure of CANFIS is defined as follows [2, 24, 26].

Layer 1: Every node *i* in this layer is a square node with a node function

$$O_{1,i} = \mu_{Ai}(x_1), \quad \text{For } i=1, 2, \quad \text{or}$$

$$O_{1,i} = \mu_{B\,i-2}(x_2) \quad \text{For } i=3, 4 \qquad (33)$$

where x_1 (or x_2) is the input to node i, and A_i or(B_{i-2})is a linguistic label, such as (small, large, etc.) associated with this node. In other words, O_i^1 is the membership grade of a fuzzy set A=(=A_1, A_2, B_1 or B_2) and it specifies the degree to which the given x_1 or x_2 satisfies the quantifier A. Here the membership function for A can be any appropriate parameterized membership function such as the generalized bell function:

$$\mu A_i(x_1) = \frac{1}{1+\left|\frac{x-c_i}{a_i}\right|^{2b}} \quad (34)$$

Or

$$\mu A_i(x_1) = \exp\{-[(\frac{x-c_i}{a_i})^2]^{b_i}\}, \quad (35)$$

where $\{a_i, b_i, c_i\}$ is the parameter set. As the values of these parameters change, the bell shaped functions vary accordingly, thus exhibiting various forms of membership functions for fuzzy set A. In fact, any continuous and piecewise differentiable functions, such as commonly used trapezoidal or triangular-shaped membership functions, are also qualified candidates for node functions in this layer. In this thesis we convert equation (35) to NN structure. Parameters in this layer are referred as premise parameters.

Layer 2: Every node in this layer is a circle node labeled π, which multiplies the incoming, signals and sends the product out. For instance,

$$\omega_i = \mu A_i(x_1) \times \mu B_i(x_2) \qquad i = 1,2. \quad (36)$$

Each node output represents the firing strength of a rule. (In fact, other T-norm operator that performs generalized AND can be used as the node function in this layer).

Layer 3: Every node in this layer is a circle node labeled N. the *i*-th node calculates the ratio of the *i*-th rule's firing strength to the sum of all rules' firing strengths:

$$\varpi_i = \frac{\omega_i}{\omega_1+\omega_2}, \quad i=1, 2 \quad (37)$$

For convenience, outputs of this layer will be called normalized firing strengths.

Layer 4: Every node *i* in this layer is a square node with a node function

$$o_i^4 = \varpi_i f_i = \varpi_i(a_0^1 + a_1^1 x_1 + a_2^1), \quad (38)$$

Where ϖ_i is the output of layer 3, and (a_{0i}, a_{1i}, a_{2i}) is the parameter set. Parameters in this layer will be referred to as consequent parameters. $f_{ji} = a_0^i + a_1^i x_1 + a_2^i x_2$, *i=1,2,..n* where *n* is number of rule, *j* number of *output*

Layer 5: The single node in this layer is a circle node labeled $\sum$ that computes the overall output as the summation of all incoming signals, i.e.,

$$o_j^5 = overall\text{output}j = \sum_i \varpi_i f_{ji} = \frac{\sum \omega_i f_{ji}}{\sum_i \omega_i}$$

where *j=1, 2, 3* (39)

Thus we have constructed an adaptive network, which is functionally equivalent to a type-3 fuzzy inference system as shown in Fig. (5) from chapter 2. Fig. (10) Shows the NN layers corresponding to FIS of multiple inputs three outputs system.

The structure of NN layer for MIMO (2 i/p-3 o/p) Simulink Model of Fuzzy Neural Network is introduced. We add layer 1 for distribution. We use layer 1 to distribute inputs; one input per one membership function. Also, we add sub layer in the consequent parameter for layer 5 to compute multiple outputs. Layer 6 is the overall outputs. Table 3.2 Present the comparison between ANFIS and CANFIS

Table 3. Comparison between ANFIS and CANFIS

	Layer 1	Layer 2	Layer 3	Layer 4	Layer 5	Layer 6

CANFIS	Distribution	Convert Crisp To membership value	Product	Normalization	Add sub Layer for rule sharing	Over all outputs

6 Procedure of Neuro fuzzy System Identification

In this section we introduce the procedure to construct Neuro fuzzy model. Fig. (13) Presents the preprocessing data Using Subtractive clustering Data. The Flow chart of learning ANFIS model is introduced in Fig. (12).

7- Testing of the Modified Algorithm (CANFIS**)**

To test the validity of the modified algorithm ANFIS (CANFIS) algorithm, an example is simulated from the numerical equation. The result of modified algorithm (CANFIS) showed a conformance with the simulated example and the root mean square (RMSE) is in the range of 0.00248735. This section presents the simulation results of the proposed CANFIS with off line learning. In this example, CANFIS is used to model highly nonlinear functions and the result is discussed as follows. Modeling (2) two inputs (3) three outputs nonlinear functions, in this example we consider using CANFIS to model a nonlinear sin-cos equations.

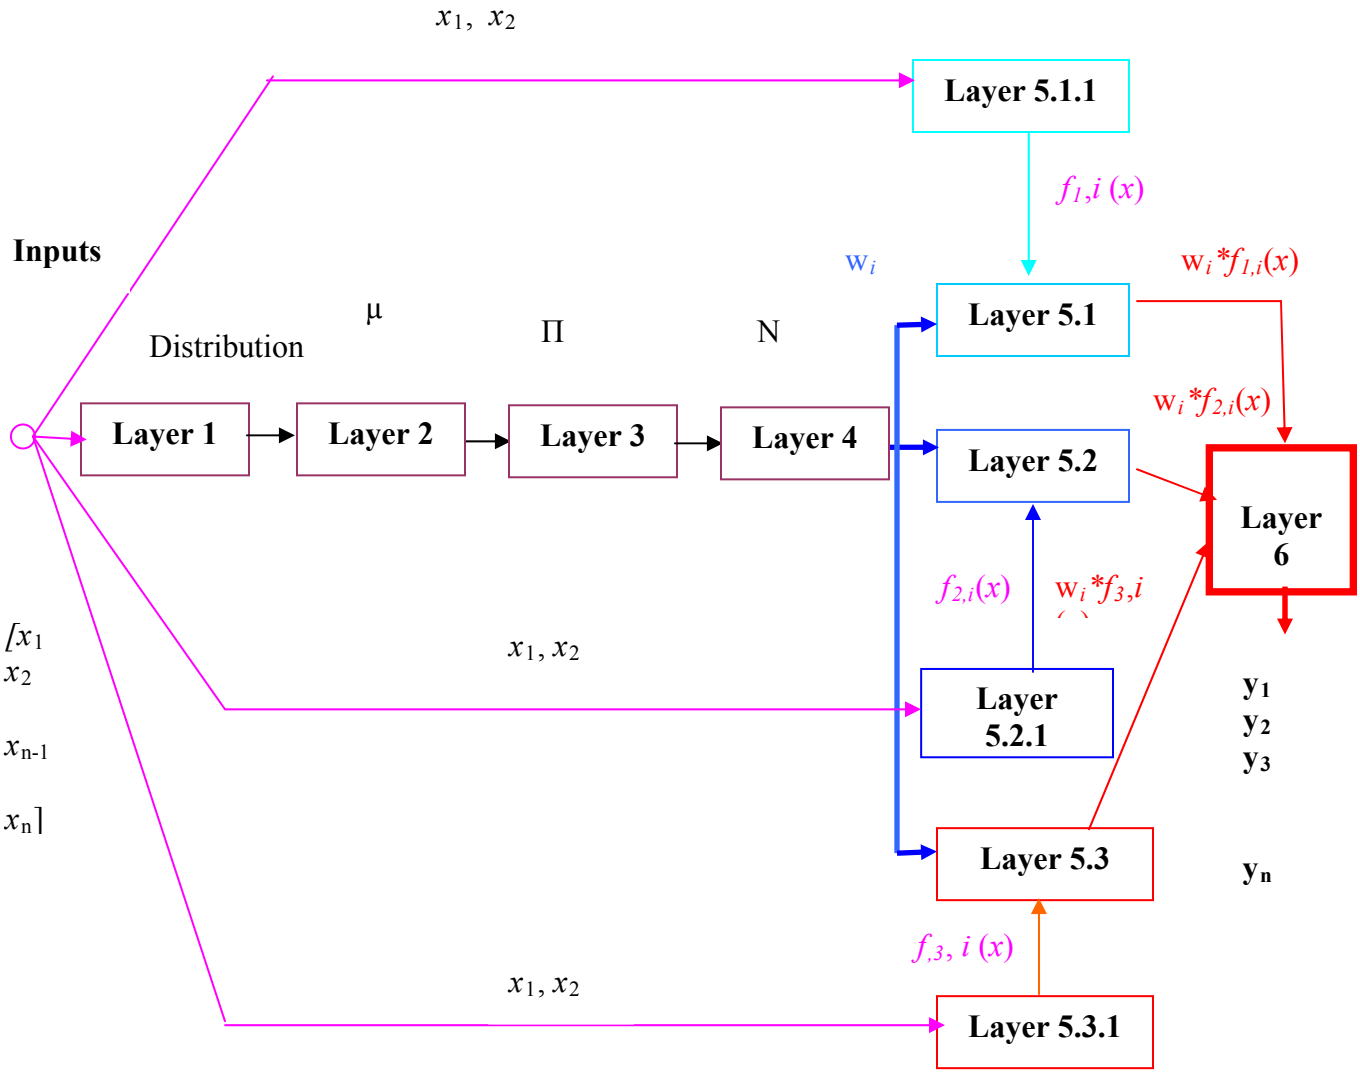

Fig. (10) NN Implementation to FIS

The following three equations are presented to model 2 two inputs (3) three outputs using CANFIS. Fig. (14) Shows the relationship between inputs and outputs before training (above figure) after training (below figure) for first output. Fig. (15) Shows the relationship between inputs and outputs before training (above figure) after training (below figure) for second output. Fig. (16) Shows the relationship between inputs and outputs before training (above figure) after training (below figure) for third output where x_1, x_2=sample number, period time=0.01 second.

$$y_1 = (\sin(\frac{x_1 * \pi}{180}))' * \sin(\frac{x_2 * \pi}{180}); \qquad (40)$$

$$y_2 = (\cos(\frac{x_1 * \pi}{180}))' * \cos(\frac{x_2 * \pi}{180}); \qquad (41)$$

$$y_3 = (\sin(\frac{x_1 * \pi}{180}))' * \cos(\frac{x_2 * \pi}{180}); \qquad (42)$$

$e_i = y_j - \hat{y}_j$, The root mean square error for model is given by

$$\text{RMSE} = (\frac{1}{N}\sum_{1}^{n} e_i^{\,2})^{\frac{1}{2}} \qquad i=1,2,.....N,\ j=1,\ 2,\ 3 \quad (43)$$

Where N is number of samples, y_j is the output of numerical equation; $\hat{y}_j$ is the actual output of CANFIS Model. Mean square error of modified algorithm is equal to (MSE) =0.00248735, after execution of program (TestFIS) which is found in the CD of programs. The RMSE is computed from equation (43). This result shows very good performance of the modified algorithm.

8 Conclusions

In this paper, the principles of neuro fuzzy Systems have been investigated. Membership Function Generation and its mapping to Neural Network are introduced. An adaptive network fuzzy inference system (ANFIS) is introduced, and Multiple Inputs /Outputs Systems (Extended ANFIS Algorithm) is implemented. A Modification algorithm of ANFIS, Coupling of ANFIS called coactive neuro fuzzy system (CANFIS), is introduced and implemented using Matlab. The software of the modified algorithm of MIMO model identification is built.

To test the validity of the modified algorithm ANFIS (CANFIS algorithm), an example is simulated from the numerical equation. The result of modified algorithm (CANFIS) showed a conformance with the simulated example and the root mean square (RMSE) is in the range of 0.00248735.

Abstract: The diabetic foot syndrome is clearly one of the most important complications of diabetes and is the most common cause of hospitalization among diabetic patients. *Staphylococcus aureus* is found to be the commonest pathogen present in diabetic foot infections. The aim of the present study is to determine activities of three kinds of antibiotics against Staphylococcal biofilm and planktonic cultures *in vitro*, and to indicate the difference in wound healing between staphylococcal planktonic and biofilm stage of colonization *in vivo* by using diabetic rat models. Biofilm forming staphylococci were identified by using the modified microtiter plate method. And the effect of different concentrations of several antibiotics (including ciprofloxacin, gentamycin and amoxicillin-clavulanic acid) on eight isolates was determined. The result showed that out of 86 Staphylococcal isolates, eight strains were found to be strong biofilm forming. It was found that the preformed biofilm was very difficult to remove with most isolates even with multiples of the MIC and that the biofilm MBC reached 46 times the planktonic MBC in some isolates. This was also noticed in case of the diabetic foot infection of the rat model, as the treatment was more efficient when it started immediately after infection, before the formation of the biofilm, as the bacterial infection was eliminated within 3-4 days, while it could not be completely eliminated when treatment started after the biofilm formation. This was also observed from the rate of healing and confirmed by histological examination.

Keywords: *In vitro- in vivo-* diabetic foot- staphylococcus- biofilm

1. Introduction:

The diabetic foot syndrome is clearly one of the most important complications of diabetes and is the most common cause of hospitalization among diabetic patients (Wrobel *et al.*, 2001), people with diabetes are 25 times more likely to have a leg amputated than those without the condition, according to the International Diabetes Federation (Lau *et al*., 2008). The combination of peripheral neuropathy, peripheral arterial disease and infections would result in unhealing ulcers, gangrene and amputation (Aulivola *et al*., 2004). Kandemir *et al*. (2007) found that the most frequent etiological agent for diabetic foot infections was staphylococci. In tissues removed from patients with recurrent staphylococcal infections, the cells are frequently organized in confluent colonies with a biofilm-like appearance. The pathogenesis of staphylococcal infection begins with primary bacterial adhesion and colonization of the host tissues (Morikawa *et al*., 2005). Once a biofilm has been established, it is a major concern for clinicians in the treatment of infectious disease because of the resistance to a wide range of antibiotics (Amorena *et al*., 1999). Therefore, a better understanding of bacterial biofilms is needed, and this may ultimately result in development of novel therapeutics for the prevention and treatment of wound infections (Davis *et al*., 2006).

Biofilm formation occurs upon initial rapid attachment of staphylococci to the surface, followed by multilayered cellular proliferation and intercellular adhesion in an extracellular polysaccharide matrix excreted by the bacteria (Gotz, 2002). Cell adhesion between staphylococci is mediated by polysaccharide intercellular adhesin (PIA), a linear homopolymer of ß-1,6-linked *N*-acetylglucosamine residues (Arciola *et al*., 2001).

Biofilm infections are difficult to treat due to their inherent antibiotic resistance. Once staphylococcal biofilm has formed on damaged tissue, it is difficult to disrupt. Most antimicrobial therapies for biofilms have largely proven unsuccessful. The mechanism of biofilm-associated

antibiotic resistance is uncertain and likely multifactorial. A number of factors have been postulated, including binding of antibiotic to the slime, poor penetration of antibiotic into the biofilm, slow growth rate of organisms in the biofilm, high bacterial density, and changes in gene expression in biofilm bacteria. Bacteria released from biofilms retain susceptibility to antibiotics characteristic of free-growing bacteria rather than biofilms, implying that the mechanism of resistance is not genetic change (Saginur *et al*., 2006).

The objective of this study was to determine the effect of different antibiotics on biofilm removal, also to compare the planktonic and biofilm MBC of staphylococcal isolates retrieved from diabetic ulcers to these antibiotics, and then to study the effect of planktonic and biofilm stage of colonization on an *in vivo* diabetic rat model.

2. Materials and methods

Bacterial strains: In this study 140 clinical swab form foot ulcers of diabetic inpatients in the university hospital (Alexandria, Egypt) were collected. Out of 197 isolate 86 isolates were identified as Gram positive bacteria (Staphylococi). Identification of the staphylococcal strains was done by Gram staining, catalase, coagulase tests, and cultivation on mannitol salt agar, further confirmation was carried out by using the API Staph system. Out of the 86 staphylococci isolated 62 (70.4%) were *Staphylococcus aureus* and 25 (29.6%) were Coagulase negative staphylococci (CONS).

Quantification of biofilm formation: This was done by using the modified microtiter plate method (Stepanovic *et al*., 2000), where the strains were grown in TSB supplemented with 2.5% glucose (Christensen *et al*., 1985). All strains were categorized as non, weakly, moderately, or strongly adherent, based upon the ODs of bacterial films as described by Stepanovic *et al*. (2000).

Antimicrobial agents used: Gentamycin (CN) (Alexandria Co., Egypt), Ciprofloxacin (CIP) (Amriya, Egypt), and Amoxicillin-Clavulanic acid (AMC) (GlaxoWellcome) were used.

MIC and MBC determination: Susceptibility testing to each drug was performed on planktonic cultures using the two-fold dilution method according to Clinical and Laboratory Standards Institute guidelines (CLSI, 2003). MICs were performed in 96-well microplates (Greiner, Wemmel, Belgium) and results were recorded after incubation at 35 °C for 18 h. For MBC determination, 10µl aliquots were removed from the wells after incubation and spread onto Mueller–Hinton agar in Petri dishes and incubated overnight at 35 °C (Tre-Hardy *et al*., 2008).

Effect of antimicrobial drugs on pre-formed biofilms:

Biofilms were allowed to form as described above. The content of the wells was then aspirated and the wells were washed and fresh TSB containing two fold serial dilution of the antimicrobial agent was added to the wells as described above. The plate was then incubated at 35^{o}C for 24h. The content of the wells was aspirated then washed and stained by using crystal violet as described above. The optical densities were determined after elution as before. Biofilm persistence in the presence of antimicrobial agents was calculated using the following formula (Tre-Hardy *et al.*, 2008).

Percentage of biofilm persistence = $[(A_{590x} - A_{590\text{negative control}})/ (A_{590\text{ positive control}} - A_{590\text{negative control}})] \times 100$, where x corresponds to the antimicrobial agent used.

Animal model

Alloxan-induced diabetes model:

Diabetes was induced by a single intraperitoneal injection of 130 mg/kg monohydrated alloxan (Sigma, St. Louis, MO, USA) dissolved in sterile 0.9% saline. Rats were made to fast prior to alloxan administration. After 12 h, a 10% glucose solution was offered to the animals to prevent hypoglycemia (Diniz *et al*., 2008). After 72 h, blood samples were collected from the eye of the animals for evaluation of plasma glucose levels by the glucose-oxidase enzymatic colorimetric method (Biomedical Systems, Spain). Animals presenting glucose levels above 300 mg/dL were included in the diabetic group.

Diabetic foot ulcer study:

The adult diabetic rats (>300 mg/dl) were used for wound induction. On the day of wound induction (defined as day 0) each rat was anesthetized with an intraperitoneal injection of 50 mg/kg thiopental sodium. A rectangular pattern was marked on the dorsal surface of the foot using a flexible transparent plastic template, and then a layer of skin in full thickness with standard area of 2 mm × 5 mm was removed as shown in Figure 1. The initial wound size was measured on day 1 (Lau *et al*., 2009).

Treatment groups:

A total of 16 rats were used in this study, they were divided into control and treatment groups, each group was composed of three rats and one rat was sacrificed on day 2 for the histological studies to confirm the formation of the bacterial biofilm within the wound bed. The treatment groups included two groups, the first received ciprofloxacin and the second received amoxicillin clavulanic acid. Half the

number of rats in each group started the treatment 15 minutes after inoculation (representing the planktonic stage), the other half started the treatment after 48 hours (representing the colonized bacteria forming the biofilm). Antimicrobial agents were administered orally by gavages. This experiment was made once with the *S. aureus* isolate (25S), and another time with the *S. epidermides* (78S).

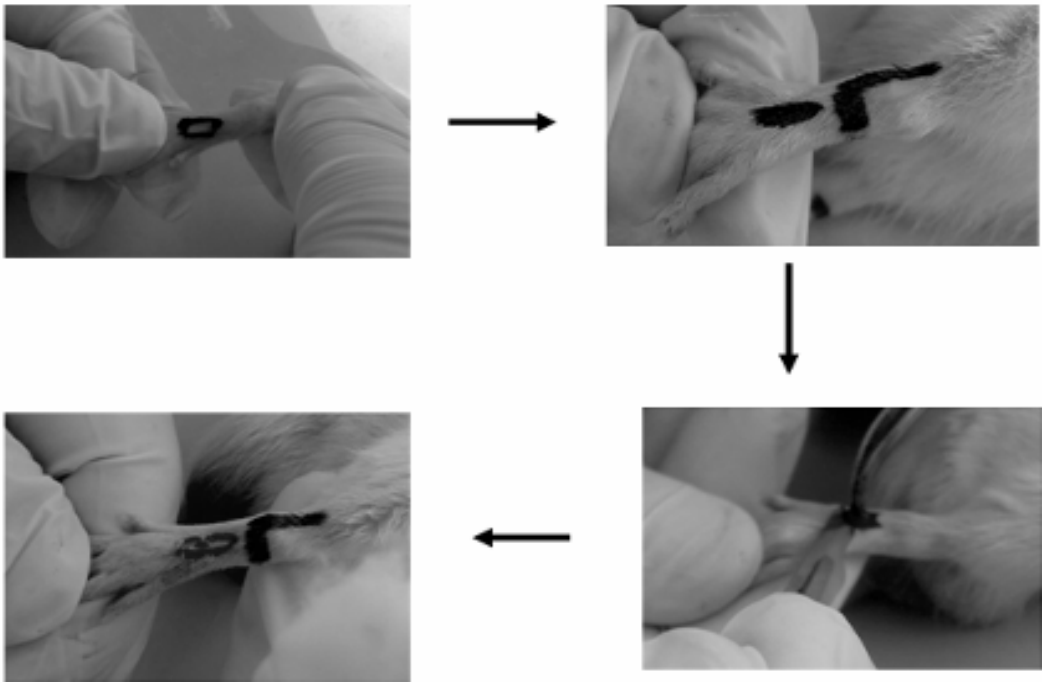

Figure 1: Wound formation in the dorsal surface of the rat hind paw.

Preparation of bacterial inoculums:

Overnight cultures of the staphylococcal isolate were used to inoculate the wounds. The wounds representing the planktonic stage of bacterial colonization started the antimicrobial treatment 15min. after inoculation, while the wounds representing the biofilm-associated cells were inoculated with the initial inoculum and left for 48 hours to allow wounds to be colonized (Davis *et al.,* 2008a)

Sampling and Wound area measurement:

In this study we selected the one-point sampling method because of the relatively small size of wounds that can be induced in rats and to better avoid contamination with peri-wound flora. In this method the swab cultures were taken from the center of each surgical wound by rotating the swab three times clockwise. Ulcer digital photographs and swabs were taken on days 1, 3, 5 and 9. Ulcer area measurement were made by using the digital photographs of the wounds perpendicular to a metric reference scale (Sullivan *et al.,* 2004), which allowed us to enlarge the photograph in order to increase the accuracy of wound area measurement and the photographs were processed by using Microsoft Word where the wound area was traced and measured on the scale present in the same photograph as shown in Figure 2.

Antimicrobial therapy:

Antimicrobial doses were chosen to approximate, in the rat, the serum or tissue AUCs achieved in humans. The doses were 350/87.5 mg/kg and 200 mg/kg for amoxicillin/clavulanic acid and ciprofloxacin respectively (Berry *et al*., 2000). Rats receive the antimicrobial treatment twice daily for 7 days (Cagni *et al*., 1995).

Histological examination:

Biopsy specimens were obtained 48 hours after inoculation and colonization and at the end of the treatment for evaluation with light microscope. Specimens were placed in 10% formaldehyde and stained with hematoxylin and eosin and with Gram crystal violet (Kugelberg *etal.,* 2005)

3. Results

Quantification of biofilm formation:

The experiment performed was carried out to measure the degree of adherence and subsequent biofilm formation of all staphylococcal isolates. Out of the 86 staphylococcal isolates 4 (4.65%) were non-adherent, 35 (40.7%) were weakly adherent, 39 (45.35%) were moderately adherent and 8(9.3%) were strongly adherent. The eight strong biofilm forming strains (16S, 17S, 18S, 25S, 45S, 78S, 90S and 108S) were selected for further investigations. Three of which (16S, 25S and 45S) were *S. aureus*, while 17S, 18S, 78S, 90S and 108S were CONS.

MIC and MBC determination: MICs and MBCs recorded for the tested antimicrobial agents against the eight staphylococcal isolates are summarised in Table1.The biofilm MBCs were found to be much higher than the planktonic MBCs. These results are shown in Figure 3.

In case of ciprofloxacin, the biofilm MBC was 2 to 512 times higher than the planktonic MBC. Also, the biofilm MBC for gentamycin was 2 to 256 times higher than that of the planktonic culture. Whereas, the biofilm MBC in case of amoxicillin-clavulanic acid was 4 to 64 times higher than that of the planktonic culture.

Variable behavior in biofilm formation for the 8 staphylococcal isolates was observed in biofilm and planktonic cultures; no fixed increase was noticed for all strains with the different antibiotics used.

Detachment of established staphylococcal biofilms after antibiotics exposure:

The effect of MIC and its multiples on the pre-formed biofilm was tested in order to determine the biofilm removing capacity of the studied antibiotics. It was found that ciprofloxacin showed relatively the best results in biofilm detachment as it removed from 40-80% of an already formed biofilm in five (62.5%) of tested isolates. However, amoxicillin-clavulanic acid showed the lowest ability for biofilm detachment. On the other hand, two strains (25S, 45S) showed increase in the biofilm formation by the addition of antibiotics (Figure 4).

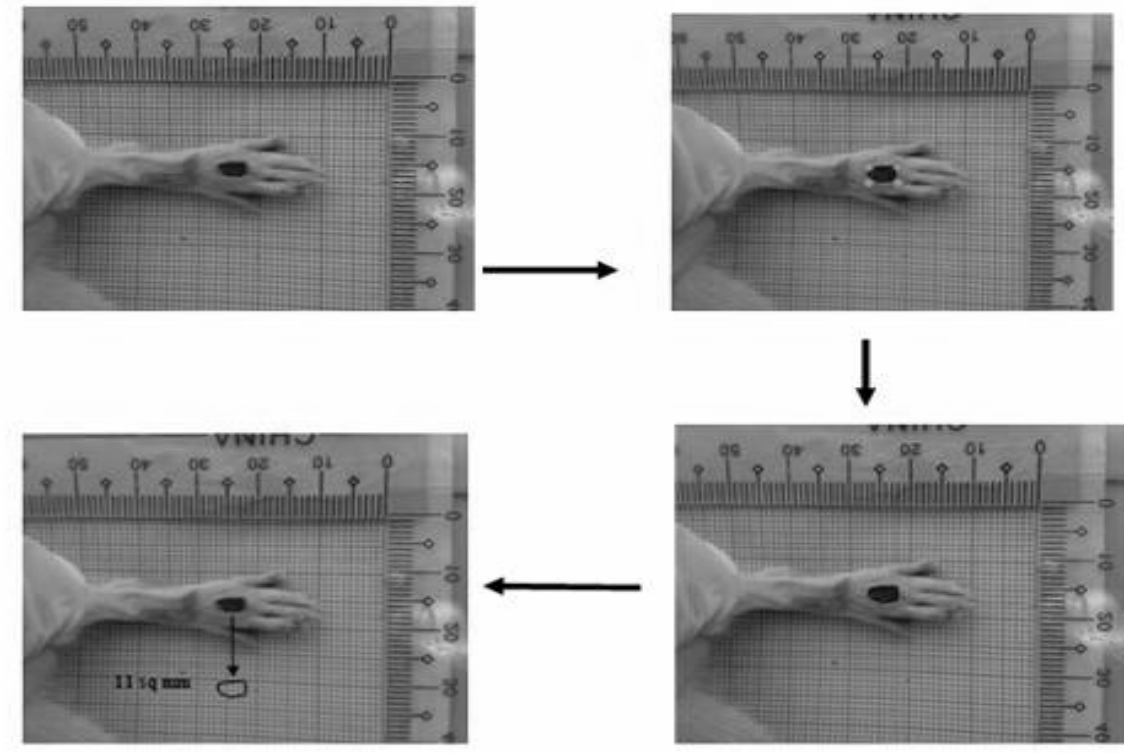

Figure 2: Wound area measurement in the diabetic rat model.

Table 1: MIC and MBC values for the tested antibiotics against the 8 staphylococcal isolates. The equivalent MIC breakpoints for *staphylococcus* spp. (CSLI 2005) were R: ≥4, S:≤ 1 for ciprofloxacin; R: ≥8, S:≤ 4 for gentamycin and R: ≥ 8/4, S: 4/2 for amoxicillin-clavulanic acid.

Strain	Ciprofloxacin		Gentamycin		Amoxicillin-clavulanic acid	
	MIC (µg/ml)	MBC (µg/ml)	MIC (µg/ml)	MBC (µg/ml)	MIC (µg/ml)	MBC (µg/ml)
16S	0.5	1	2	4	8	32
25S	0.5	1	4	8	8	32
45S	128	512	128	256	64	256
18S	32	128	128	256	32	32
17S	8	8	64	128	8	8
78S	0.5	0.5	0.25	0.5	0.25	0.25
108S	0.125	0.5	1	2	0.25	1
90S	8	16	128	128	8	32

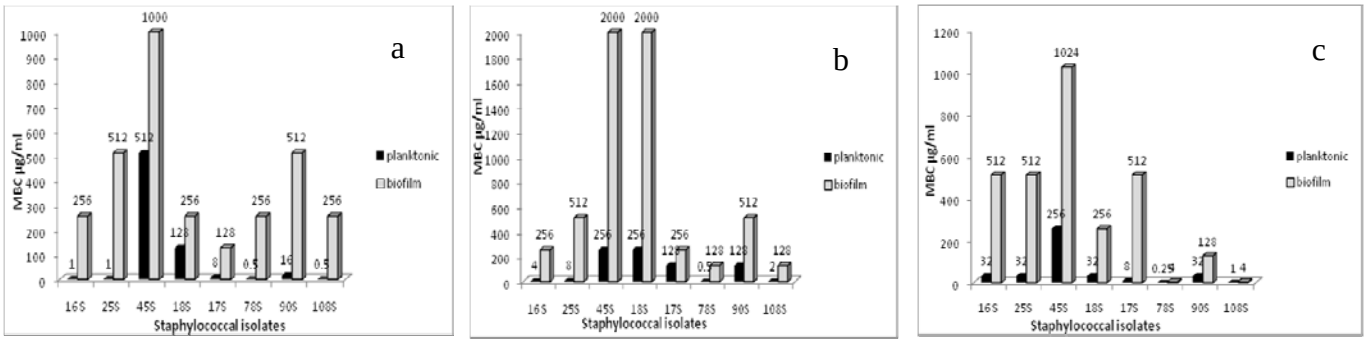

Figure 3: Comparison between planktonic and biofilm MBC of ciprofloxacin (a), gentamycin (b), and amoxicillin-clavulanic acid (c) for the 8 staphylococcal isolates.

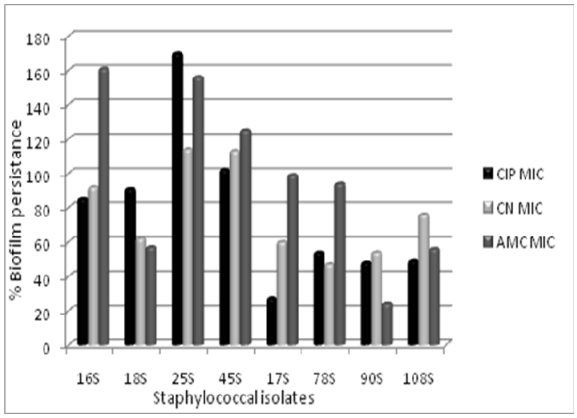

Figure 4: Effect of the MIC of each antibiotic on the removal of a pre-formed biofilm

Animal model:

Wound area measurement:

The wound healing effect of ciprofloxacin and amoxicillin clavulanic acid in case of planktonic stage of bacterial infection was compared with that after biofilm formation on days 1, 3, 5 and 9 in the diabetic rat foot infection model.

In case of the *S. aureus* isolate 25S, a trend of greater reduction of the ulcer area was observed in case of planktonic bacterial colonization treated with the antibiotic than that after the biofilm formation, where the average ulcer area in the control untreated groups decreased from 9mm^2 (100%) on day 1 to 3 mm^2 (33.33%) on day 9, whereas that treated with ciprofloxacin decreased from 13 mm^2 (100%) on day 1 to complete healing on day 9 (Figure 9), and that of the group treated with amoxicillin-clavulanic acid decreased from 14 mm^2 (100%) on day 1 to 1 mm^2 (7%) on day 9 .

Similar results were obtained in case of the wound inoculation with the isolate 78S, where the wound area started with 9, 18and 17 mm^2 (100%) on day 1 and was reduced to 3 mm^2 (33.33%), 1 mm^2 (5%) and 1 mm^2 (5.8%) in case of the control, ciprofloxacin and amoxicillin clavulanic acid treatment groups respectively.

It was noticed from the wound swab samples taken that complete eradication of the staphylococcal infection was achieved after four days in case of the isolate 25S when treated with either of the antibiotics, and three days for the isolate 78S in case of both

antibiotics. Whereas, after the formation of a biofilm it was difficult to completely eradicate the bacterial infection throughout the nine days of the experiment.

Histopathological studies:

Histopathological examination of rat skin sections of different treatment groups was made. Figures 6, 7 shows a wound made 48 hours before the examination, with the bacteria forming biofilm, this section was stained with H&E (Figure 6), and with Gram Stain (Figure 7) to visualize the Gram positive bacteria. Figure 8 showed complete healing and recovery from bacteria which was achieved with the ciprofloxacin treatment in case of the planktonic cells infection with the *S. aureus* isolate 25S. Whereas treatment after the biofilm formation with amoxicillin-clavulanic acid showed the persistence of bacterial infection with bacteria found around the hair follicles (Figure 9).

4. Discussion:

Biofilms, products of bacterial adherence, are structured communities of bacterial cells enclosed in a self-produced exopolysaccharide matrix and adherent to an inert or living surface. Establishment of a biofilm is the prelude to the development of various chronic, intractable infections, such as biomaterial-associated infections and pulmonary infection in patients with cystic fibrosis (Bonaventura *et al.*, 2004). Despite various efforts, treatment of an infection after biofilm is established is frequently futile because of the reduced susceptibility of biofilm to antibiotics. At least three mechanisms have been proposed to account for recalcitrance of biofilms to antimicrobial agents: (i) failure of the antimicrobial to penetrate the biofilm, (ii) slow growth and the stress response, and (iii) induction of a biofilm phenotype (Bonaventura *et al.*, 2004).

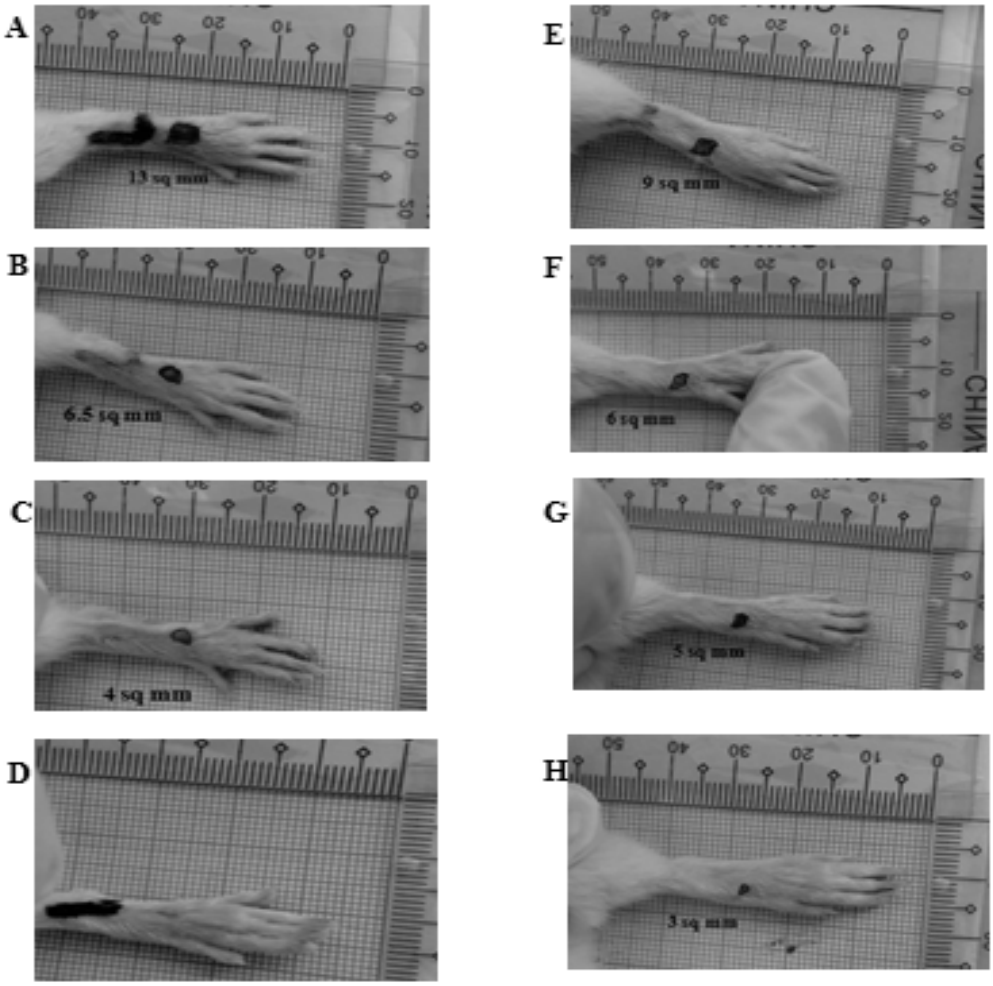

Figure 5: Effect of the treatment with ciprofloxacin on planktonic infection (on the left), compared to the control (untreated) (on the right) on wound healing of diabetic rat foot infection with *S. aureus* 25S.

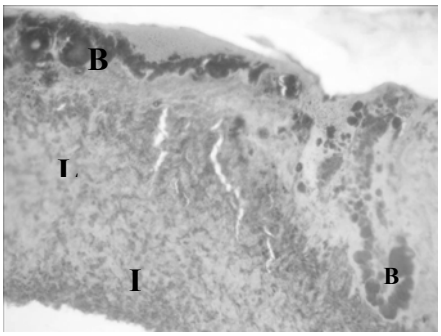

Figure 6: H & E stained section in diabetic rat skin 48 hours after wound formation and infection at X400 magnification using light microscopy. In the wound bed there are circular basophilic granular structures, which are multiple bacteria joined together living in biofilm-like structure (B) in the wound bed in the epidermis while the dermis shows lytic necrosis (L) and mononuclear cellular infiltrate (I). There is also hyalinizatrion and vaculation of the epithelial cells, and pathological changes in the epidermal cells was observed with mononuclear cellular infiltrate, hemorrhagic areas.

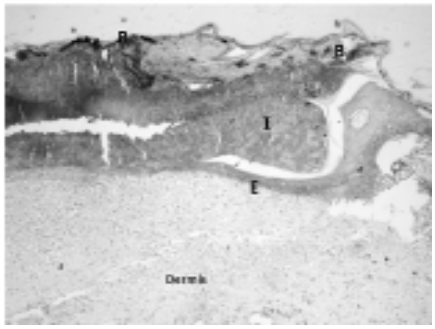

Figure 7: Section of 48 hours untreated wound stained with Gram stain showing Gram positive bacteria (B), cellular infiltrate (I), and reduced epidermis (E) (X100).

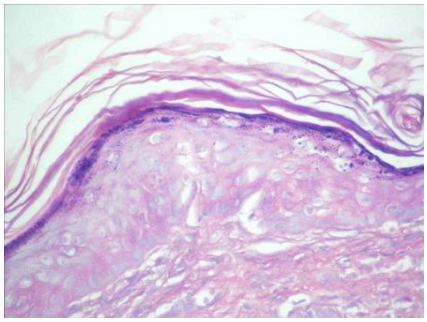

Figure 8: High power view of the epithelium showing normal skin, where complete healing was achieved in case of treatment of *S. aureus* 25S infection as planktonic cells with ciprofloxacin. (H&E stain X400)

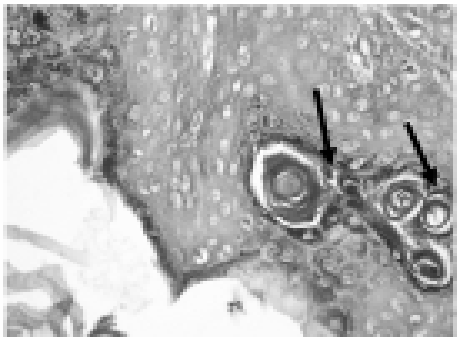

Figure 9: Another section in rat skin showing bacteria around transversely cut hair follicles with mononuclear inflammatory infiltrate. (H&E stain X400)

Microtiter plate systems for quantifying adherence and biofilm formation were used in this study, these techniques have been investigated with many different organisms and stains (Christensen *et al*., 1985) and they have been widely used because they are simple, reproducible, and quantitative methods. However, the staining measurements reflect the total amount of biofilm (sessile cells plus exopolysaccharide matrix) but do not give any information about its viability (Griffis *et al*., 2009). Thus, in this study, cell viability was also measured by determination of biofilm MBC, which was found to be very high (512 × planktonic MBC) in case of the isolates 25S, 78S and 108S when tested with ciprofloxacin. However, in other cases the difference between biofilm and planktonic MBC is much less (2 × planktonic MBC) in case of the isolate 18S when tested with ciprofloxacin also. These results was also noticed by other investigators who found that 4× MBC of the antibiotics used is not sufficient for killing *S. aureus* in biofilm (Amorena, *et al*., 1999). Also *Pseudomonas aeruginosa* in biofilm showed a 4-fold greater resistance against ciprofloxacin and gentamycin compared with free-living forms (Agarwal *et al*., 2005).

In the present study, the effects of several antibiotics on Staphylococcal adherence were tested. The studied antibiotics were chosen for several reasons. Amoxicillin-clavulanic acid was tested because it is frequently used in the therapy of Staphylococcal infections. Quinolone (ciprofloxacin) was chosen because of their interesting activity against gram-negative (Baskin *et al*., 2002) and gram-positive (Wilcox *et al*., 1991) bacterial biofilms. Currently there are no antibiotics on the market specifically indicated for the prevention of diabetic foot infections. Furthermore, diabetic ulcers are often associated with vascular disease and restricted peripheral blood flow, which may render

systemically acting antibiotics less effective. By achieving very high localized concentrations of antibiotic, gentamycin may be used to overcome these concerns if used locally**.**

In case of the preformed biofilm, ciprofloxacin showed the best results in biofilm removal. Concentrations ranging from 0.5-2 MIC caused removal of 50% of an already formed biofilm in five (62.5 %) of the tested isolates, followed by gentamycin where the MIC caused the removal of 50% of an already formed biofilm in only four (50%) of the tested isolates. However, amoxicillin-clavulanic acid showed the least results in biofilm removal (Figure 4). In addition, the effect of MIC of the tested antibiotics on a preformed biofilm showed that there is no fixed pattern for the effect of antibiotics on this preformed biofilm but it was noticed that the bacterial behavior in response to the different antibiotics applied is strain dependant, which requires further investigations. These results suggest that ciprofloxacin is able to penetrate staphylococcal biofilm with a strain-specific efficiency, as suggested by the high strain-to-strain variation, probably due to chemical and physical heterogeneity of staphylococcal biofilms. This difficulty in biofim removal with antibiotics alone led Krespi YP *et al*. (2010) to use ciprofloxacin in combination with different types of lasers to remove more than 80% of Staphylococcal biofilm cells. Other investigators used other approaches to treat biofilm-associated staphylococcal infections such as cell-wall degrading enzymes (Son J *et al*. 2009).

From this study we can conclude that once biofilms are formed they are very difficult to be removed even by applying multiples of the MIC of the tested antibiotics. And it was found that there is a high strain-to-strain variation in the behavior towards the tested antibiotics, so it is advised to study each strain separately.

The majority of skin pathogenic and non pathogenic biofilm research is performed *in vitro*. Although *in vitro* assays have several advantages, including lower cost, and the ability to control the number of bacteria, they do not take into consideration the effect of wound fluid, growth factors, proteases, and antimicrobial peptides (Davis *et al.*, 2008a). In this study the rat model used was anticipated to help clarify the role of bacterial biofilms in diabetic wound infection and healing.

In *in vivo* studies of ulcer healing, surgical ulcers were usually induced on the chest or back of a rat or a mouse. With the aim of mimicking more closely the clinical condition of diabetic foot ulcers, the ulcers were created on the feet of alloxan-diabetic rats. The animal model was probably suitable for *in vivo* studies of ulcers in response to different medications. In this study, the diabetic rat foot ulcer model was created by removal of full-thickness skin. This artificially created ulcer is different from the ulcer in the human diabetic foot which usually results from local pressure. Human diabetic foot ulcers usually extend beyond the surface boundaries and this subcutaneous extension does not occur in this animal model (Lau *et al*., 2008).

The authors previously demonstrated that pathogenic wound bacteria *in vitro* can form a mature biofilm within 10 hours. Results of an *in vivo* study have shown that occluding wounds following inoculation with pathogenic bacteria facilitates the development of biofilms after 24 hours. The authors believe that biofilms are likely to be present in chronic wounds and additional strategies to disturb or eliminate them are sorely needed (Davis *et al*., 2008b).

Studies made by Dr. Akiyama's group demonstrate biofilm-like structures in a mouse wound model and one in human skin. Using confocal laser scanning microscopy they showed colonies of bacteria surrounded by glycocalyx. These studies firmly established that biofilm-like structures are present in the murine wound infection model (Akiyama *et al*., 2004)

The management of chronic wounds such as those found in diabetic feet or leg ulcers is placing an increasing burden on health service systems (Krouskop, 2002). Chronic wounds, however, have an unfortunate tendency of healing very slowly. Any measurement technique used for the purpose of establishing healing progress therefore has to be very precise in order to capture small changes in a wound's dimensions.

The 'gold standard' for area measurement is the practice of tracing the perimeter of a wound through a double layer of a flexible transparent sheet material (Keast, 2004). While the layer in contact with the wounds is discarded, the upper layer with the tracing is then measured by either placing it on metric graph paper, planimeters or by a second round of tracing using a digitizing tablet (Thawer, 2002). This contact making method can be painful to the patient and may risk infection. In practice the use of unsuitably thick or exhausted marker pens and the high degree of dexterity required by the clinician performing the tracing significantly reduce the theoretical precision of the method and errors up to 25% have been reported (Lagan, 2000).

Photography has the advantage of avoiding contact with the patient (Smith, 1992; Stacey, 1991). Wound pictures are usually measured on a computer screen where they can also be enlarged so that the tracing process is freed from time restrictions and physical demands. Although area measurements

produced this way tend to be more precise than those obtained by transparency tracings the method depends on the photography skills of the clinician who has to combine a frame-filling wound picture together with a reference scale in a single image taken perpendicular to the wound site (Solomon, 1995).

Digital photography was the way used in the wound area measurement in this study, where the wound and the metric reference scale were included in the same picture as shown in Figure (2). This gave us the advantage of avoiding direct contact with the wound and allowed us to enlarge the wound picture together with scale on the computer screen in order to increase the accuracy of wound area measurement.

In this study bacterial biofilm colonization in an animal model was obtained, where the wounds were inoculated with the selected isolate and left untreated, swabs were taken to ensure the presence of the bacteria in the wound of the control group through out the study period. This was also made by Davis *et al*. (2008a) who observed colonies of bacteria firmly attached to and on the wound surface, encased in an amorphous substance; they also observed the polymorphnuclear cells on the surface of the biofilm, but not within the biofilm. Histologically, bacterial biofilms are tissue-like structures resembling multicellular eukaryotic tissues. According to the histology text book edited by Leon Weiss (1988) a tissue is a multicellular aggregate of similar cells. In line with this definition bacterial biofilm can be described as a "bacterial tissue" within the host tissue.

In order to show a physiological difference between the planktonic and biofilm bacteria *in vivo*, we studied the efficacy of two antibiotics on two bacterial isolates in the rat model. The treatment with ciprofloxacin or amoxicillin-clavulanic acid was extremely effective in eradicating the organisms that were not attached to the wound surface (3-4 days). However, after allowing the biofilm formation, this treatment was not able to eradicate the staphylococcal infection at such a short time because the biofilm bacteria were more persistent, fulfilling one of the criteria for biofilm-associated diseases, which is reduced susceptibility. These results were also demonstrated by Davis *et al*. (2008a) who studied the effect of two topical antibiotics on *S. aureus* infected wound healing, where the antibiotics were not able to eradicate bacteria that were allowed to form biofilm.

The concordance of *in vitro* and *in vivo* findings observed in the staphylococcal isolates tested using this biofilm test methodology is encouraging. This concordance suggests that the test could be useful in clinical practice and extensive studies especially needed to eradicate the increasingly frequent chronic staphylococcal infections and in particular those associated with the diabetic foot ulcers.

The use of an *in vivo* model in this study supports the hypothesis that staphylococcal biofilm are more difficult to eradicate and may play an important role in acute and chronic diabetic foot infections. We have provided evidence that biofilms play a role in diabetic foot infections. A new paradigm has arisen; it is not sufficient to think of bacteria in infections as unicellular independent pathogens, rather it is now important to understand that they form multicellular tissue like structures (Davis *et al.*, 2008a).

Women Participation in Agro-allied Small and Medium Scale Enterprise and Its Impact on Poverty Alleviation in Oyo State Nigeria

Fajimi F.O and Omonona B.T

Department of Agricultural Economics, University of Ibadan, Ibadan, Nigeria
ffovivid@yahoo.com

Abstract: This study examined the impact of women participation in agro-allied small and medium scale enterprises (SME) on poverty alleviation. Data were collected using the multistage sampling technique from 119 respondents in the study area made up of 59 participants and 60 non-participants. Data generated were analysed using descriptive statistics, FGT – weighted poverty measures and Probit regression analysis. Results from the study showed that the non-participants have the highest poverty level (51%), while the participants have poverty level of (17%) and the non-participants contribute greatly to whole group poverty. The estimated probit regression analysis showed that marital status, household size and women status in the family are poverty enhancing while educational status participation in Small and Medium Enterprises, income and monogamous family type are poverty reducing. Hence participation in agro-allied Small and Medium Enterprises is antidote to reducing poverty among women.

1. Introduction

Poverty in Nigeria has been described as "widespread and severe" (World Bank, 1996). In spite of the country's vast resources it is known with low GDP per capita, high unemployment rate, low industrial utilization capacity, high birth rate and agricultural dependent (Jhingan, 2005). Poverty is basically a situation of deprivation experienced by human beings. Burkey (1993) defined poverty in terms of the absence of basic needs which includes clean air and water, adequate food and balanced diet, emotional and physical security and culturally and climatically, appropriate clothing and shelter. Poverty is often described as a threat to economic and social stability and is defined as a condition of being in want of something. It is also characterized by malnutrition, illiteracy, disease, high infant mortality and low life expectancy at birth. Poverty is not only a state of existence but also a process with many dimensions and complexities (Khan, 2000). Table 1 shows the trends in poverty level in Nigeria between 1980 and 1996. The incidence of poverty increased sharply both between 1980 and 1985 and between 1992 and 1996. The 27.2% for 1980 translated to 17.7 million persons whereas there were 34.7 million poor persons in 1985. As at 1996, two out of every three Nigerians were below the poverty line (Yusuf, 2002).

Table 1: Trends in poverty level: 1980-1996 (in %)

Year	Poverty Level (%)	Estimated population (million)	Population in poverty (million)
1980	28.1	65	18.3
1985	46.3	75	34.7
1992	42.7	91.5	39.1
1996	65.6	102.3	67.1

Source: FOS, 1999

In an attempt to deal with the problem of poverty through poverty alleviation programme in an agrarian country like Nigeria, knowledge of poverty profile is essential. It has been empirically established that low productivity in agriculture is the cause of high incidence of poverty in Nigeria (World bank, 1996). This is obvious as agriculture is the mainstay of Nigeria's economy contributing about 42% to total GDP and employing about 77% of the working population. It therefore imperative that any policy measure aimed at alleviating poverty must take agriculture and rural development into consideration.

The Federal Office Statistic/World Bank in their analysis of the poverty trend in Nigeria noted that poor families are in higher proportion in farming household that are mainly in the rural areas (Adeolu & Taiwo, 2004). Poverty has been described to have a predominant 'female face' in both developing and industrialized countries (Odejide, 1997). Neo Leen (1996) reports that more than 564 million women live in absolute poverty and revealed the following about the state of women in the world.

1. Women own ten percent of the world poverty and hold one percent of chief executive position worldwide.
2. Women comprise two-thirds of people who cannot read or write.
3. Women are 70 percent of the world's absolute poor.
4. Women and children comprise 75 percent of the displaced people in ecologically fragile zones.

Women are regarded as the world's poor because the majority of the 1.5 billion people living on 1 dollar a day or less are women and earn an average slightly more than 50 percent of what men earn (UNDP, 2000). Women understand poverty in different ways such as; a situation of deprivation, inability to measure up to certain expectations related to basic needs and inability to create resources for recreation and holidays also, Nigerian women are affected with poverty and have long duration in poverty because they often have too many children spaced too closed together to the detriment of their health and productivity (Ijaiya, 2000, Adepoju, 2001). The incidence of poverty among Nigerian women has been progressively increasing. It has increase from 26.9% in 1980 to 58.5% in 1996 and in the past two decades women have constantly been put under the pressure of retrenchment, belt-tightening fiscal policies to boost the deteriorating economic activities/conditions more than men and has forced them to share the preserved role of the provider with men or in some cases assume the entire responsibility (FOS, 1999, Adepoju, 2001). The core source of the entire gender differential in poverty is that women relative to men are more vulnerable because of the socio-cultural framework of human society. The socio-cultural beliefs are the limiting factors, which limits the opportunities and capabilities of women, and make them resource less and powerless individuals (Ijaiya, 2000). Poverty reduction is the supreme goal of development policy. The incidence, depth, and severity of poverty should be known by the policy makers so as to reduce poverty. The paper estimates poverty measures using the gap and squared gap poverty measures as well as the headcount ratio; Easterly (2000) and Ravallion (1997) limit their analysis to the headcount measure. The uses of depth and severity measures of poverty is important as these two additional measures of poverty and, hence complement the poverty– spread picture painted by the headcount ratio. Given the importance of small and medium scale enterprises as discussed, the main objective of this study is to determine the impact of women participation on the poverty status of women. This becomes imperative in Nigeria due to dearth of literature on women's participation in small and medium scale enterprises on women poverty status. The working hypothesis is that women's participation in agro-allied small and medium scale enterprises will significantly affect the poverty status of the women.

2. CONCEPTUAL FRAMEWORK

The definition of small and medium scale enterprises differ from one country to another. It has been defined against various parameters such as the number of workers employed, volume of output or sales, the value of assets or capital employed, and the type of energy used. Some definitions are based on whether the owner of the enterprises works alongside with the workers, the degree of sophistication in management, and whether or not an enterprises lies in the "formal" section. SMIES and NERFUND (2004) define SMES as an enterprise with an asset base not exceeding N200,000,000.00 excluding land and working capital with staff strength of not less than 10 and not more than 300. A cursory glance at the structure of SMES in Nigeria reveals that 50% are engage in distributive trade, 10% in manufacturing, 30% in agriculture and the rest 10% in services. Obitayo (2000) stated that globally, the small and medium scale enterprises are noted for their immense contributions to development process and as engine of economic growth. They are promoted as a critical segment of the manufacturing sub-sector, effective strategy for tackling unemployment, diversifying output and achieving trade and balance of payment, given their nature and characteristics with respect to quick adaptation of technologies, manageable number of workers and reduced capital intensiveness. Nnanna (2001) stated that small and medium scale enterprises needs funds to bring together the other factors of production- land, labour and capital for production to take place. Sule (1986) stated that, it is evidence around the world that small and medium scale enterprises provide an effective means of stimulating indigenous entrepreneurship, enhancing greater employment opportunities per unit of capital invested and aiding the development of local technology. Nnanna (2003) acknowledged that, small and medium scale enterprises are considered generally as the bedrock of the industrial

development of any country. The small and medium scale enterprises (SMES) have been generally acknowledged as the bedrock of the industrial development of any country (Yerima et.al, 2007).

The dynamic role of small and medium scale enterprises in developing countries have been highly emphasized. These enterprises have been identified as the means through which the rapid industrialization, job creation, poverty alleviation and other development goals of these countries can be realized. The changing role of small and medium scale enterprises in developing countries as an engine through which the growth objectives of developing countries can be achieved has long been recognized. It is estimated that SMEs employ 22% of the adult population in developing countries. These enterprises have been recognized as the engines through which the growth objectives of developing countries can be achieved. They are potential sources of employment and income in many developing countries. (Daniels and Ngirira, 1992; Daniels and Fisseha, 1992). Women's participation in small scale enterprises are alternative systems of production operating on the principle of human economy, in that their goal is to contribute to the education and health of the family with minimum emphasis on profit. This is based on the rationale that a greater proportion of women's income compared to that of men goes to meet family needs. The micro-enterprise activities provide opportunities for women to develop the skills in decision-making, problem solving and information-seeking. According to Jariah and Laily (1999), a rural enterprise project has the potential of providing an avenue for the rural women not only to improve their socio-economic wellbeing, but more so to increase their entrepreneurial abilities and personal empowerment. Over the past twenty years there has been a due recognition of women's potential contribution which has resulted in a major shift towards women as a key target group for programmes using small and medium scale enterprises development as a way to achieve wider poverty reduction (ILO, Gender Briefs Series No.3). Tanko (1995) observed that women play a pivotal role in alleviating poverty through productive work that they are engaged in outside their home. Although increasing women's participation in small and medium scale enterprise is among the developmental goals and targets to reduce poverty, improved family health and empower women's economic status. Therefore, this concept is very important in the study of women participation in agro-allied small and medium scale enterprises and its impact on poverty.

Hence, women participation in small and medium scale enterprises is expected to be positively associated with reduced poverty through increased cash income and opportunities for women to develop their entrepreneurial skills. The rest of the paper is divided into three: section three discusses the methodology while section four is on results and discussion. The last section concludes the paper.

3. Research Methodology

Area of Study

The study was conducted in Oyo state of Nigeria, the state is located in the southwest region of Nigeria and lies between latitude 7^0 and 9^0 30' North of the equator and between longitude 2.5^0 and 5^0 east of the prime meridian. The state is made up of 33 Local Government Areas. 5 Local Government Area were chosen for the study.

Sampling Procedure

Multistage sampling technique was employed for selecting the representative women. The first stage was random selection of five local government areas from the Ibadan/Ibarapa zone of the state. The second stage was sampling of villages/areas based on the list of community development project of the State Ministry of Women Affairs and University Village Association (UNIVA). The third stage involved the use of systematic random sampling to obtain the required women, by choosing every fifth housing unit in which four women were randomly selected for the interview. A total of 150 women were sampled but only 119 were used for the final analysis. Table 2 shows the distribution 119 women whose questionnaires were used for the analysis, while table 3 shows the distribution of Small and Medium Scale Enterprises engaged in by the women as obtained from the study.

Table 2: Distribution of Sampled Women

Location/LGA	SME Participant	SME Non-participant

Tie and dye	8	13.6
Soap making	6	10.2
Livestock management	3	5.1
Total	59	100

Source: Field Survey, 2005.

Analytical Techniques

The analytical techniques used in the analysis of the data include Foster, Greer and Thorbecke's (FGT) weighted poverty index and the Probit Regression Model.

The FGT weighted poverty measure, otherwise called the Pα measure is used to obtain the incidence, depth and severity of poverty. The FGT measure is mathematically given as:

$$P_\alpha = \frac{1}{n_i}\sum_{i=1}^{q_i}\left[\frac{z - Y_{ij}}{z}\right]^\alpha \qquad 1$$

where Pαi is the weighted poverty index for the ith subgroup; ni is the total number of households in subgroup i, qi is the number of the ith subgroup households in poverty; Yi is the per capita expenditure (PCE) of women j in sub group i; Z is the poverty line and α is the degree of aversion.

When α = 0, it gives the incidence of poverty; α = 1 gives the depth of poverty and α = 2 gives the severity of poverty.

The contribution (Ci) of each sub-group's weighted poverty measure to the whole group's poverty measure was determined as follows:

$$C_i = \frac{n_i P_{\alpha i}}{n P_\alpha} \qquad 2$$

Where ni is the total number of women in the subgroup i, Pαi is weighted poverty for the subgroup i, pα is the whole group poverty index.

The poverty line for the study was obtained by converting the nationally determined poverty line of ₦395/annum in 1985 constant prices to the 2005 prices. This was done by multiplying the derived raising factor of 66.2361 by the nationally obtained poverty line of ₦395 per annum at constant 1985 prices by FOS (1999). This value indicate by how much 1985 poverty line must be raised to give 2005 poverty line and this was then divided by 12 to obtain the monthly poverty line per capita for the study.

The correlates of poverty are isolated using a Probit model in which a dichotomous variable representing whether or not a household is poor is regressed on a set of supposedly exogenous explanatory variables.

The probit regression model hypothesizing the determinants of poverty and ascertaining the effects of certain factors (especially SME participation among women) is stated below as:

$$Y = \beta_0 + \sum_{i=1}^{n}\beta_i X_i \qquad 3$$

The dependent variable Y is of a binary nature (poverty status of women), which takes 1 and 0, 1 if poor, 0 if non-poor. The independent variables (X) are as follows:

X_1 - Age of the respondents (in years)

X_2 - Marital status (Dummy D = 1, if married, 0 if otherwise)

X_3 - Household type (Dummy, D =1 if monogamous, 0 if otherwise)

X_4 - Household size

X_5 - Educational status (Number of years spent in school)

X_6 - Women status in family (Dummy, D =1 if household head, 0 if otherwise)

X_7 - Participation Dummy (D = 1 if participant, 0 if non-participation).

X_8 - Income (Naira)

4. Results and Discussion

The results in table 1 shows the average age for the participants stood at 48 years while that of the non-participants is 43 years, also the two groups has higher proportion of married women of 76% and 66% respectively. The mean year of schooling for the two groups is very close of about 6 years and 7 years while the average number of family size of about 5 persons is common to the two groups. The participants has a higher proportion of women who have polygamous household type of 61% and 50% for the non-participants also the status of women within the family also follow the same manner of 34% for the participants and 18% for the non-participants.

Table 4: Socio-Economic Variables of the Representative Women.

Variables	Participants (P)	Non-Participants (NP)
Age of representative women(mean)	48.28	43.10
Marital status (% married)	66	76
Educational Status (mean)	5.9	6.9
Household size (mean)	5	5
Household Type (% polygamous)	61	50
Women status (%household head)	34	18.3
Income(mean monthly)	11,912.44	6,500.00

Source: Field survey, 2005

Poverty Profile of Sampled Women

The poverty status of the sampled women was decomposed based on factors such as age, marital status and educational status of the women. Others are household size, household type, women status within the family and household expenditure.

Women's Household expenditure

Table 5 below shows that the non-participants have higher poverty incidence, depth, and severity than the participants and contributes about (75%) to the whole group. Therefore from the table, one can conclude that poverty is more prevalent among the non – participants than the participants judging from the poverty incidence, depth and severity. This may be due to the higher mean per capita expenditure than the non-participants.

Table 5: Poverty Profile by Women Household Expenditure

Participants index	P_0	P_1	P_2	Contribution to		
				P_0	P_1	P_2
Participants	0.169	0.021	0.002	0.243	0.142	0.066
Non-participants	0.516	0.124	0.030	0.755	0.856	1.008
All	0.3445	0.64	0.012			

Source: Field survey, 2005.

Marital Status of Sampled Women

Table 6 showed that the married women are poorer for the participants and non – participants and also contributes higher proportion to the whole group poverty level. The higher poverty level among the married may be due to the joint effect of increased household size and dependency ratio.

Table 6: Poverty Profile by Marital Status of Women

Participants marital status	P_0	P_1	P_2	Contribution to P_0	Contribution to P_1	Contribution to P_2
Married	0.118	0.049	0.021	0.169	0.337	0.694
Single	0.051	0.021	0.008	0.073	0.142	0.264
Non–participants						
Married	0.400	0.096	0.023	0.585	0.663	0.773

Source: Field Survey, 2005

Four age groups were used to profile poverty among the women. These are 26 – 35 years, 36 – 45 years, 46 – 55 years and 56 – 65 years. The table below shows that poverty incidence is higher for ages 36 – 45 (21%) and 46 - 55 years (18%) in the non-participants group than the participant that has 3% and 6% respectively. For the participant there was non-poor in ages between 26 – 35 years while 5% were poor for the non – participant in this age group. For ages between 56 – 65 years the participants and non – participants have the same proportion of 6% poor, the respective contribution follows the same pattern. The participants belonging to poor while the non-participants are poorer so also the other age groups such as 36-45, 46-55 and 50-65.

Household Size of Women

The level of poverty experienced by any household is directly related to the number of the members of the household.

Table 8: Poverty Profile by Household Size

Participants Household size	P_0	P_1	P_2	Contribution to P_0	Contribution to P_1	Contribution to P_2
4-6	0.016	0.006	0.002	0.023	0.041	0.066
7-9	0.152	0.063	0.026	0.218	0.427	6.859
Non-participants						
4-6	0.35	0.084	0.02	0.023	0.041	0.066
7-9	0.16	0.040	0.002	0.241	0.278	0.324

Source: Field survey, 2005.

The table above shows that while 2 percent of those households with 4-6 members are poor, 15 percent is poor in households with between 7 and 9 members for the participants while for the non-participants 35 percent of those households with 4-6 members are poor, 16 percent is poor in households with between 7 and 9 members, though non participants have large family size but are less poor than those with smaller household size, this may be due to the dependency ratio.

Household Type of Sampled Women

Table 9: Poverty Profile by Household Type

Participants	P_0	P_1	P_2	Contribution		
				P_0	P_1	P_2
Monogamous	0.067	0.028	0.011	0.096	0.190	0.388
Polygamous	0.101	0.043	0.017	0.145	0.292	0.586
Non-participants						
Monogamous	0.333	0.080	0.019	0.487	0.552	0.638
Polygamous	0.183	0.044	0.011	0.267	0.303	0.369

Source: Field survey, 2005.

Table 9 revealed that (33%) of women from a monogamous household are poor and poorer than their counterparts in polygamous household for the non-participants while it is vice-versa for the participants in which the polygamous households are poorer than the monogamous household.
From their respective contribution to poverty, monogamous household contributes more than the polygamous household for the non-participants and polygamous contributes more than monogamous household for the participants.

Educational Status of Sampled Women

Table 10 below shows that participants across the four education groups have less than 10% poverty incidence no formal education (5%) primary school (6%), secondary school (3%) and tertiary (1%) while for the non – participants have more than (10%) poverty incidence with the secondary school (18%) the poorest among the groups no formal education (16%), primary school (15%) and tertiary (1%). Therefore, the women in the non-participants group are poorer in terms of education than the participants and contribute more to poverty of whole group.

Table 10: Poverty Profile by Educational Status.

Participants Educational status	P_0	P_1	P_2	Contribution to		
				P_0	P_1	P_2
Non-formal education	0.050	0.021	0.008	0.072	0.142	0.264
Primary school	0.067	0.028	0.011	0.169	0.190	0.388
Secondary school	0.034	0.014	0.005	0.048	0.095	0.165
Tertiary	0.016	0.006	0.002	0.023	0.040	0.066
Non-Participants						
No formal education	0.166	0.040	0.009	0.242	0.278	0.324
Primary school	0.150	0.036	0.008	0.219	0.248	0.292
Secondary school	0.183	0.044	0.011	0.267	0.303	0.369
Tertiary	0.016	0.004	0.001	0.025	0.002	0.033

Source: Field survey, 2005.

Women Status within the Family

Table 11 showed both the participants and non-participant women who are not the household heads are poorer than their counterparts, who are the household heads in their respective household for the participants and non-participants, so also their contribution to poverty.

Table 11: Poverty Profile by Women Status

Participants Women status	P_0	P_1	P_2	Contribution to P_0	 P_1	 P_2
Household head Non-household head	0.067 0.101	0.028 0.043	0.011 0.017	0.169 0.145	0.190 0.292	0.388 0.56
Non-participants						
Household head Non-household head	0.116 0.40	0.027 0.096	0.006 0.023	0.169 0.585	0.186 0.663	.0201 0.773

Determinants of Poverty and Impact of SMEs on Poverty

As indicated in the methodology, the determinants of poverty among women and effect of participation of women in agro-allied SMEs were examined. The results are indicated in Table 12. The correlation coefficient (Bo) is estimated at 5.3133 and it represents the independent poverty depth among the women in the study area, the model is statistically significant at the 1% critical level, this show that the model has a good fit to the data. Only 1 of the explanatory variables was not statistically significant of all the 8 variables. The variables that are significant includes marital status, household type (polygamous), household size, educational status (number of years spent in school) status of the woman in the family (household head or non-household head), participation in SME (yes or no) and income. The coefficient of each variable is related to the independent poverty depth as follows: The coefficient of the intercept of dummy of the marital status of the women is 0.774. This indicates that the autonomous poverty level of the women will be increased by 0.774 to become 6.089 while that of unmarried women will remain as 5.3133. This may be connected to the fact that married women have a larger household size than the unmarried which will decrease the per capita income.

Household type also has a significant effect on the poverty level of the sampled women. The coefficient of the variable is –0.628. Therefore woman with a monogamous household have a reduced poverty level by 0.628 to 4.685 while that of a polygamous household is 5.313. This is so because polygamous household have a larger household size. For the household size which has a coefficient of 2.119. This means that a unit increase in household size will increase the poverty of the household by 2.119 because larger household size will reduces per capita income. For educational status the poverty level of the women will be decreased by 0.3823, while for the status of women as either household head or not the poverty level of women will be increased by 2.2319 if there is a unit change in the status. Participation of women in SMEs has a coefficient of –3.199. This indicate that the poverty depth of the women will be reduced by –3.199 to 2.114 if there is unit increase in participation by women so also the income will reduce the poverty depth by 0.0004528 if there is a unit increase in income. Therefore variables which are positively correlated with the poverty level indicates that a unit increase in such will increase the poverty depth of women household and are poverty enhancing variables or determinants, while those variables that are negatively associated indicates that a unit decrease in such variable will decrease the poverty depth of the women household and are poverty reducing variables.

Table 12: Results of Regression Analysis

Variables	Coefficients	Standard Error	t-Value
Constant	5.3133	1.8287	2.9050

Household size	2.1189*	0.4215	5.0270
Educational status	-0.3829***	0.2177	-1.7590
Women status in family	2.2320***	0.8592	2.5980
Participation index	-3.1992***	1.1475	-2.7880
Income	-0.0005*	0.00002	-1.7270

*** Denotes significance at 1%, ** at 5% and * at 1%

5. Policy Recommendations

1. Education has been seen as a major tool for human capital development which transcends into national development. Therefore the process of acquiring good education should be made available because participation of women will be limited to their level of education also with the adoption of new technology for the expansion of the small and medium scale enterprise activities. Also poverty decreases as the level of education increases therefore women should be given the opportunities to education.
2. Women should be sensitized the more on the awareness of birth control, because poverty increases with the number of people in the households. If this is done, it will reduce the ratio of child depending on the parents.
3. Participation in the agro-allied small and medium scale enterprise should be encouraged among the women folk either as a full time or part-time employment because income generated from the agro-allied small and medium scale enterprises serves as empowering tool. There should be enlightenment campaigns and programmes on the benefits and importance of women participation in SMEs as a poverty alleviation strategy.

ABSTRACT: The coag-flocculation behavior of MOC in respect of pH variation in brewery effluent has been investigated at room temperature using various dosages of unblended MOC. Coag-flocculation parameters such as order of reaction α, rate constants (K and K_s), coagulation period $\tau_{1/2}$ e.t.c were determined. Turbidity measurement was carried out using the single angle (90°) nephelometric standard jar test while MOC processing was based on work reported by Ghebremichael. Microsoft excel package was employed in the evaluation of simulated parameter K_s. The maximum MOC performance are recorded at K of 6.6667 x $10^{-4}m^3$/kg.s, dosage of 0.4kg/m^3, pH of 4 and $\tau_{1/2}$ of 289.2614s while the minimum are recorded at K of 1.3333 x $10^{-4}m^3$/kg.s, dosage of 0.5kg/m^3, pH of 2 and $\tau_{1/2}$of 1446.6419s. The least value of E (%) recorded after 30 minutes is > 78%, thus confirming MOC as effective coag-flocculant. In general, the parameter obtained lie within the range of previous works, confirming that the theory of perikinetics holds for coag-flocculation of brewery effluent using MOC at the conditions of the experiment.

Keywords: *Moringa oleifera;* coag-flocculation; coal effluent; kinetics; coagulation

INTRODUCTION

The use of renewable resources of plant origin in local community for the removal of colloidal and non colloidal turbidity in waste water is not a new phenomenon. This phenomenon highlights the concept of coagulation / flocculation (cog-flocculation),a routine water treatment procedure that stimulate the formation of flocs arising from the destabilization of charged colloids(Ma et al,2001; Diterlizzi, 1994; Edzwald, 1987; O Melia, 1978). Among the factors that can influence the aggregation process are temperature, pH, effluent quality, stirring time e.t.c (Jin,2005).

Readily, coag-flocculation has been achieved via inorganic and organic synthetic substances such as alum, $FeCl_3$, polyamine e.t.c. However, the coag-flocculation performance of these aggregating agents are well researched and documented with inadequate attention especially in the aspect of kinetics given to the study of coag-flocculation behavior of the plant and animal derivatives. To this end, focus is hereby given to the study of coag-flocculation performance of plant origin, *Moringa oleifera* seed.

Moringa oleifera is a small, fast growing drought deciduous tree commonly found in the tropics such as Eastern Nigeria. The seed kernels of *Moringa olifera* contain significant quantities of positively charged water soluble protein which bind with the negatively charged particles in water to promote floc formation (Schwarz, 2000). *Moringa oleifera* are edible, non toxic, biodegradable and biocompatible substances. Previous results from its coagulation performance highlight prospects for renewable organic aggregating agent with extensive application in large scale water treatment technology.

Against this backdrop, this work embraces coag-flocculation kinetics and performance of MOC under varying pH of brewery effluent and MOC dosages, using single angle (90°) and simulated multi angle light scattering (nephelometry) techniques. Thus if well harnessed and developed, MOC can be an alternative to or be used in conjunction with the conventional coagulants. Ultimately, the post usage handling and health challenges posed by the inorganic coagulant can be reduced.

THEORETICAL PRINCIPLES AND MODEL DEVELOPMENT

For a uniformly coag-flocculating equilibrium phase with negligible influence of external force (Hunter, 1993):

$$\mu_i = \overline{G}_i = \left[\frac{\partial G}{\partial n_i}\right]_{P,T,n} = \text{a constant} \quad \ldots.1$$

And

$$f_d = \frac{-K_B T}{C_i}\frac{dC_i}{dx} \quad \ldots2$$

Where G is the total Gibbs free energy

n_i is the number of moles of component i

μ_i *is* chemical potential

C_i is concentration

x is diffusion distance

f_d is viscous drag force.

But from Ficks law

$$D' = \frac{-f_d}{B}\frac{C}{\left(dC/dx\right)} \quad \ldots3$$

Where D' is diffusion coefficient

B is friction factor

Comparing equation 2 and 3 generates Einstein's equation:

$$D' = \frac{K_B T}{B} \quad \ldots4$$

For similar phase, the rate of successful collision between particles sizes i and j (mass concentration/Time) to form particle of size k is (Thomas et al, 1999):

$N_{ij} = \varepsilon_p \beta (i,j) n_i n_j$ …5

where

ε_p = collision efficiency

β (i, j) = collision factor between particles of size i and j

$n_i n_j$ = particle concentration for particles of size i and j, respectively.

Assuming monodisperse, no break up and bi particle collision, the general model for perikinetic coag-flocculation is given as (Swift and Friedlander, 1964; Von Smoluchowski, 1917):

$$\frac{dn_k}{dt} = \frac{1}{2}\sum_{i+j=k}\beta(i,j)n_i n_j - \sum_{i=1}^{\infty}\beta(i,k)n_i n_k \quad \ldots6$$

where $\frac{dn_k}{dt}$ is the rate of change of concentration of particle of size k (concentration / time).

β is a function of the coag-flocculation transport mechanism.

The appropriate value of β for Brownian transport is given as(Von Smoluchowski,1917):

$$\beta_{BR} = \frac{8}{3}\varepsilon_p \frac{k_B T}{\eta} \quad \ldots7$$

Where K_B is Boltzmann's constant (J/K)

T is Absolute temperature (K)

The generic aggregation rate of particles (during coagulation / flocculation) can be derived by the combination of equations 6 and 7 to yield:

$$-\frac{dN_t}{dt} = KN_t^{\alpha} \quad \ldots8$$

Where N_t is total particle concentration at time t, $N_t = \sum n_k$ (mass / volume)

Meanwhile $K = \frac{1}{2}\beta_{BR}$ …9

K is the menkonu coag-flocculation rate constant

α is the order of coag-flocculation process

Also, $\beta_{BR} = 2\varepsilon_p K_R$ …10

Combining equations 8, 9 and 10 produce:

$$-\frac{dN_t}{dt} = \varepsilon_p K_R N_t^{\alpha} \quad \text{….11}$$

Where K_R is the Von smoluchowski rate constant for rapid coagulation (Van Zanten, 1992)

However $K_R = 8\pi a D'$ ….12

$$R_p = 2a \quad \text{….13}$$

Where a is particle radius.

From Einstein's equation: $D' = K_B T / B$

From Stoke's equation : $B = 6\pi\eta a$ ….14

where η is the viscosity of the coag-flocculating fluid

Combining equations 11 to14 gives:

$$-\frac{dN_t}{dt} = \frac{4}{3}\varepsilon_p \frac{K_B T}{\eta} N_t^{\alpha} \quad \text{…15}$$

Comparing equations 8 and 15 show:

$$K = \frac{4}{3}\varepsilon_p \frac{K_B T}{\eta} \quad \text{...16}$$

For perikinetic aggregation, α theoretically equals 2 as would be shown below (Fridkhsberg,1984; Hunter,1993):

From Fick's law,

$$J_f = D' 4\pi R_p^{\,2} \frac{dN_t}{dR_p} \quad \text{..17}$$

Integrating equation 17 at initial conditions $N_t = 0$, $R = 2a$:

$$\frac{J_f}{D' 4\pi} \int_0^{R_p} \frac{dR_p}{R_p^{\,2}} = \int_{N_0}^{N_t} dN_t \quad \text{...18}$$

Thus $J_f = 8\pi D' a N_0$ …19

For central particle of same size undergoing Brownian motion, the initial rate of rapid coag-flocculation is:

$$-\frac{dN_t}{dt} = J_f \cdot \varepsilon_p \cdot N_0 \quad \text{…20}$$

$$= \frac{4}{3}\varepsilon_p \frac{K_B T}{\eta} \cdot N_0^2 \quad \text{...21}$$

$$\equiv \frac{4}{3}\varepsilon_p \frac{K_B T}{\eta} N_t^2 \text{ at } t > 0$$

Hence, from equation 21, $\alpha = 2$

For $\alpha = 2$; equivalence of equation 8 yields:

$$\frac{dN}{dt} = -KN^2$$

Hence:

$$\int_{N_0}^{N} \frac{dN}{N^2} = -K \int_0^t dt \quad \text{…22}$$

Thus $\frac{1}{N} = Kt + {}^{1}\!/_{N_0}$ ...23

Plot of $\left({}^{1}\!/_{N}\right)$ Vs t produces a slope of K and intercept of ${}^{1}\!/_{N_0}$.

For the evaluation of coagulation period ($\tau_{1/2}$), from Equation 23:

$$N = \frac{N_0}{\left[1 + \frac{t}{\left({}^{1}\!/_{N_0 K}\right)}\right]} \quad \ldots 24$$

Where $\tau = \left[{}^{1}\!/_{N_0 K}\right]$ …25

Hence:

$$N = \frac{N_0}{1 + (t/\tau)} \quad \ldots 26$$

When $t = \tau$, equation 26 becomes

$$N = {}^{N_0}\!/_{2} \quad \ldots 27$$

Therefore as $N_0 \rightarrow 0.5N_0; \tau \rightarrow \tau_{1/2}$

Hence $\tau_{1/2} = {}^{1}\!/_{(0.5N_0 K)}$ ...28

For Brownian (perikinetic) aggregation at early stages (t≤30 minutes), equation 6 can be solved exactly, resulting in the generic expression

$$\frac{N_{m(t)}}{N_0} = \frac{\left[{}^{t}\!/_{\tau'}\right]^{m-1}}{\left[1 + {}^{t}\!/_{\tau'}\right]^{m+1}} \quad \ldots 29$$

Where $\tau' = 2\tau$

Hence, for singlets *(m=1)*

$$N_1 = N_0\left[\frac{1}{\left(1 + {}^{t}\!/_{\tau'}\right)^2}\right] \quad \ldots 30$$

For doublets *(m=2)*

$$N_2 = N_0\left[\frac{\left({}^{t}\!/_{\tau'}\right)}{\left(1 + {}^{t}\!/_{\tau'}\right)^3}\right] \quad \ldots 31$$

For triplets *(m=3)*

$$N_3 = N_0\left[\frac{\left({}^{t}\!/_{\tau'}\right)^2}{\left(1 + {}^{t}\!/_{\tau'}\right)^4}\right] \quad \ldots 32$$

Also for the coag-flocculating phase and multi angle nephelometry, the intensity of light scattered from suspension of monodispersed phase is described as (Van Zanten,1992):

$$I(q,\mathrm{T}) = I(q,0)\left[1+2\sum_{m=2}^{\infty} C_m(\mathrm{T})A_m(q)\right] \quad \ldots.33$$

Where I (q, *T*) is the intensity of light scattered by the initially unaggregated suspension ;
$T = \mathrm{t}/\tau'$ (dimensionless time)
q is the scattering wave vector

$$q = \left(\frac{4\pi}{\lambda_0}\right) n_0 \sin(0.5\theta) \quad \ldots34$$

Where λ_0 is the wave length of the laser incident light in Vacuum, *($\lambda_0 = 2\pi a / 6$)*
n_0 is the refractive index of the suspending medium
θ is the scattering angle
A_m is the form factor for an aggregate consisting of m primary particles.
a is radius of particles sphere.
If the coagulating medium obeys the Rayleigh-Gans-Debye (RGD) approximations, then

$$A_m(q) = \sum_{i}^{m}\sum_{j>1}^{m} \frac{\sin qr_i}{qr_{ij}} \quad \ldots35$$

Where r_{ij} is the centre-to-centre separation of primary particles *i* and *j* in the given m-fold aggregate. The summation accounts for all pairs of particle centers in the aggregate.

The expression for the scattered intensity in view of many possible configurations arising from larger aggregates is:

$$I(q,\mathrm{T}) = I(q,0)\left[1+2\frac{\sin qd_0}{qd_0}\frac{\mathrm{T}}{(1+\mathrm{T})^3}+2\sum_{m=3}^{\infty} C_m(\mathrm{T})A_m(q)\right] \quad \ldots36$$

The form factors are given by an average of all contributing structures where d_0 is hard core interaction diameter of singlets. Differentiating equation 36 as t→0 yields:

$$\frac{I}{I(q,0)}\left(\frac{dI(q,t)}{dt}\right)_{t\to 0} = \frac{d}{dt}\left[1+2\frac{\sin qd_0}{qd_0}\frac{\mathrm{T}}{(1+\mathrm{T})^3}+2\sum_{m=3}^{\infty} C_m(\mathrm{T})A_m(q)\right] \quad \ldots37$$

$$\frac{I}{I(q,0)}\left(\frac{dI(q,t)}{dt}\right)_{t\to 0} = \left[\beta_{BR}N_0\frac{\sin qd_0}{qd_0}\right] \quad \ldots38$$

Using simulated version of equation 38, K_S (simulated *K*) can easily be determined at several scattering angles. A plot of $\frac{I}{I(q,0)}\left(\frac{dI(q,t)}{dt}\right)_{t\to 0} Vs \frac{\sin qd_0}{qd_0}$ gives a slope of $N_0\beta_{BR}$ from where $(K_S)_{t\to 0}$ could be determined.

MATERIALS AND METHOD

The sample of *Moringa olifera* seeds was sourced from Agulu Town, Anambra state Nigeria and processed to MOC based on the work reported by Ghebremichael (2004).

The jar test was conducted based on standard Bench scale Nephelometric method (single angle procedure) for the examination of water and waste water (WST,2005; AWWA,2005) using model WZS-185 MC Turbidimeter, APPNo 688644A Gulenhamp magnetic stirrer and mettler Toledo Delta 320 pH meter. For the simulation of multi angle nephelometry, excel package was used while d_0 = 0.8875μm and n_o were sourced from ENSWC (2008) and simple refractometric measurment respectively.

RESULTS AND DISCUSSION

Coag-flocculation parameters

The values of coag-flocculation parameters are presented in tables 1 to 6.At a general level, the values of R^2 for the results presented are quite satisfactory, confirming the theory of perikinetics that shown α=2 .Meanwhile, it is evident that α relates inversely with K.Thus, for a higher α to be obtained, a lower K is a necessary condition (Fridkhsberg, 1984). This is readily amplified in tables 1 to 5.For K (=0.5β_{BR}), there is no regular observed trend, as the pH increases from 2 to 10 for tables 1 to 5.However, it should be observed that the highest values if K are recorded at pH of 4.This explains why lowest $\tau_{1/2}$are also recorded at pH of 4.This is amply demonstrated in figs 5 to 9 where best coag-flocculation were

recorded for pH of 4.Also,observations from tables 1 to 5 indicate that the values of K experiences minimal variation for 0.1kg/m^3 to 0.5kg/m^3 at a given pH. This clearly emphasizes that coag-flocculation is more sensitive to changes in pH than that of dosages. It can be argued that at given pH, a similar mechanism controls the process. This can account for the little variation in K at a given pH.

In theoretical bases, $\tau_{1/2}$,ε_p , and K_R are coagulation effectiveness factors, understood to be accounting for the coagulation efficiency, before flocculation sets in. In view of the particle distribution plots (Figs 17 and 18); the values of $\tau_{1/2}$ obtained are satisfactory, though millisecond has been reported in system where minimal Zeta potential exists (Hunter, 1993). For a case of minimal variation in K_R, ε_p relates directly to $2K=\beta_{BR}$. Hence ,high ε_p results in high kinetic energy to overcome the Zeta potential either by double layer compression or colloid destabilization.

Meanwhile, K_S, the simulated version of K for varying pH and dosages are presented in table 6.It is an attempt to assess the variation between K (from single angle) and K_S (from simulated multi angle) in view of the angular dependence of K_S .The agreement between K and K_S is satisfactory. Note that K and K_S were obtained from equations 23 and 38 respectively where the slope of equation 38 is $\beta_{BR}N_0$.Representative results are presented in (figs 1 and 2) and (Figs 3 and 4) for equation 23 and 38 respectively.

The discrepancies observed in the results presented in tables 1 to 6 are due to unattainable assumption that mixing of particles and MOC throughout the dispersion is 100% efficient before any aggregation occurs (Yates etal,2001). Another account is the interplay between Van der waal forces and the hydrodynamic interactions which alters the theoretically predicted parameter values by a factor ±2 .Other additional short range forces do also contribute (Holthof,etal,1997; Holthof, etal,1996).

SP (=N in kg/m^3) vs. time plots.

Plots of SP vs. time are presented in figs 5 to 9; with initial SP of 10.3691kg/m^3 .Generally, for the plots, the SP decreases with time. This is expected because during coag-flocculation, particles aggregate into large flocs, settling under gravity and progressively decreasing the intensity of light scattered. The rapid settling of SP is very apparent in figs 5 to 9 in view of the initial value of SP. This is in consonance with the theory of rapid coag-flocculation. The best coag-flocculation was recorded at pH of 4 supporting lowest and highest values of $\tau_{1/2}$ and K respectively recorded in the study.

However, the least $\tau_{1/2}$ recorded is = 289.2614 at pH of 4.This is high in view that milliseconds have been recorded. This can be adduced to low initial SP present in the brew effluent. Secondly, the resulting flocs may be of less density such that there may exist disproportionality between the rate of coagulation and rate of settling of the flocs formed.

Efficiency E (%) vs. time

E (%) vs. time plots are presented in figs 10 to 14 .The E (%) indicates the effectiveness of ABC to remove SP from the effluent. The least E (%) recorded after 30 minutes of coag-flocculation is > 78% in spite of low value of initial SP .This confirms MOC as a plant derived aggregating agent. This collaborates with the general real life experience where in some cases, 90% particle removal are routinely achieved in minutes during water treatments. Observed that in general, the best efficiency is recorded at pH of 4.

Plots of E (%) vs. pH

This is presented in fig 15.it indicates the performance of various doses of MOC at varying pH. Maximum efficiency are recorded at pH of 4 followed by pH of 10.Low doses of 0.1kg/m^3 and 0.2kg/m^3 exhibit high E (%) at pH of 2 while high doses of 0.4kg/m^3 and 0.5kg/m^3 perform maximally at pH of 4 and 10.

Plot of E (%) vs. Dosages (kg/m^3)

This is presented in fig 16.The optimum dosages are recorded for pH of 4 at 0.4kg/m^3 though performances for pH of 10 at 0.4kg/m^3 are satisfactory. It confirms the earlier observation that pH of 4 provides optimum coag-flocculation properties for MOC .The minimum performance was recorded for pH of 2 at 0.5kg/m^3 and 0.4kg/m^3

Time evolution of the cluster size distribution

These are graphically presented in figs 17 and 18.They represent the time evolution for singlets , doublets and triplets obtained for $\tau_{1/2}$ = 289.2614s and $\tau_{1/2}$ = 1446.642s .Both figs 17 and 18 exhibit similar trend , an indication of a process controlled by similar mechanism. The curves represent a case in which the values of N_3 and $\sum N_i$ are close such that their variation with time is near same. Also, similar trend with respect to N_2 and N_1 is obtained .The curves indicate that there exists a wide margin of difference in concentration of SP between the pair of (N_3 and $\sum N_i$) and (N_2 and N_1).The implication is the existence of high shear force and resistance to collision .This is clearly demonstrated by the values of $\tau_{1/2}$ which are high. This is an indication of high Zeta potential associated with the process.

CONCLUSION

The potential of MOC as an effective natural organic coag-flocculants applicable in large scale water treatment has been confirmed. The conformity

of the values of the obtained parameters with perikinetics theory in conjunction with the establishment of common parameter β_{BR} for both single (90°) and multi angle light scattering theories present a novelty in this work. These indicate a step further in what had already be developed in the coag-flocculation study.

The optimum dosage, pH and $\tau_{1/2}$ recorded are 0.4kg/m^3, 4 and 289.2614s respectively. The degree of agreement between K and K_S emphasizes that both single and multi angle light scattering techniques can be used to study coag-flocculation .This authenticates the validity of Von Smoluchowski theory. Overall, the results obtained are in line with previous works (Jin,2005; Van Zanten and Elimelech,1992;Holthof *et al*,1996;Menkiti *et al*,2009; Menkiti *et al*,2010).

NOMENCLATURE

K :α^{th} order coag-flocculation constant
β_{BR}: Collision factor for Brownian Transport
ε_p: Collision Efficiency
$\tau_{1/2}$: Coagulation Period / Half life
E: Coag-flocculation Efficiency
R^2: Coefficient of Determination
α: Coag-flocculation reaction order
$-r$: Coag-flocculation reaction rate
$(SP)_0^c$: Computed initial suspended particle (kg/m^3)
J_f:Flux
f_d: Drag force
K_S : K value obtained from simulation.
MOC: *Moringa olifera* coagulant
d_o : Hard core interaction diameter of the primary particle.
a: Radius of the primary particle

Abstract: The aim of the present study was to determine changes in inflammatory markers, lipid profile and vascular wall integrity, (monitored as nitric oxide levels) in the male rats with experimental atherosclerosis. Also, to evaluate the role of two olive oils (virgin and refined) in these changes. Experimental atherosclerosis was induced by feeding rats normolipidemic diet (NLD) supplemented with (4% cholesterol, 1% cholic acid and 0.5% thiouracil, w/w) for three months. Feeding atherogenic diet (AD) exhibited marked elevation in serum total cholesterol (TC), low density lipoprotein cholesterol (LDL-C), very low density lipoprotein cholesterol (VLDL) and triglycerides (TG), along with decreased high density lipoprotein cholesterol (HDL-C). Besides, an elevation in serum level of the two inflammatory markers, tumor necrosis factor-α (TNF-α) and fibrinogen was demonstrated with a lowered nitric oxide (NO) levels in both aorta and cardiac tissues, indicating impaired vessel wall integrity and development of cardiovascular disorders in response to hyperlipidemia and enhanced inflammation. Subsequently, marked elevations in total leucocytes and other inflammatory mediators, including monocytes and lymphocytes have been recorded in the atherogenic diet fed rats. In addition, a significant reduction in erythrocytes count, hemoglobin (Hb) content and other hematologic indices was demonstrated, indicating further signs of inflammation. However, administration of olive oil (OO) [(in particular virgin olive oil (VOO)] to atherogenic rats exhibited improved inflammatory status, lipid profile and NO levels. Therefore, VOO might be a good candidate to replace other fats in the functional food for retarding atherosclerosis and risk of cardiovascular disorders.

Key words: Atherogenic diet, inflammatory markers, nitric oxide, vascular wall injury

1. Introduction:

Atherosclerosis is a slow and complex disease that represents one of the most prevalent causes of death world wide (Jaffer *et al.,* 2006). It is an arterial disease in which fatty substances, cellular wastes, and other elements build up in the inner lining of the artery. This build is called plaque that can grow large enough to significantly reduce blood flow throw the vessel (Earnest e*t al.,* 2005). Within the arterial wall, many processes act in a seemingly concerted manner to initiate the formation of lesions that result in occlusion of blood flow (Ross 1999). These processes include injury to the endothelium and retention of lipoproteins within the arterial wall, (Brown *et al.,* 2004) which, in turn leads to the formation of foam cells and the development of atherosclerosis (Hansson, 2009).

In broad outline, atherosclerosis can be considered to be a form of chronic inflammation resulting from interaction between lipoproteins, monocyte-derived macrophages, T cells, inflammatory cytokines and the normal cellular elements of the arterial wall. This inflammatory process can ultimately lead to the development of complex lesions, or plaques, that protrude into the arterial lumen (Glass and Witztum, 2001). It is now recognized that atherosclerosis is an inflammatory disease of the arterial wall that underlies many of the common causes of cardiovascular diseases (CVD) (Zhang, 2009).

Dietary, oils may affect vascular wall integrity and consequently the process of atherosclerosis and its related cardiac complications (Sekalska *et al.,* 2007). Among edible oils, olive oil (OO) is the only one produced from a fresh fruit and can be consumed just as obtained from the olive, like fruit juices. It is a pure natural product requiring and is becoming increasingly present in food as the healthiest alternative to other oils (Perona *et al.,* 2005). Olive oil is extensively used by people in the

Mediterranean region that has been associated with reduced incidence of CVD in these people (Nagaraju & Belur, 2008). This may be the result of its high content of monounsaturated fatty acids (MUFAs) mainly oleic acid and minor biologically active components, such as phenolic compounds (PhCs) (Miles *et al.,* 2005).

The present study was carried out to evaluate the effect of prolonged intake of OO on the risk of cardiovascular disorders in male rats with experimental atherosclerosis, in terms of selected inflammatory markers and lipid parameters, as well as NO levels. Two olive oils; refined olive oil (ROO) and VOO (identical in their fatty acids composition, but different in phenolics content) were used to compare their effects.

2. Materials and methods

Experimental animals:

This study was performed on male albino rats of Wistar strain, initially weighing 105±5 g. Rats were obtained from the Institute of Ophthalmic Disease Research, Cairo. They were housed in stainless steel cages at a well ventilated animal house. Rats were permitted adequate standard diet and given water *ad libitum* for one week of adaptation period prior to the experimental work.

Research design:

Rats were randomly divided into six groups of five animals each. The first one was the control group received NLD without any supplementation (The Nutrient Requirements of Laboratory Animals, 1995). The second and third groups were fed NLD supplemented with 10% ROO or VOO, respectively (El-Seweidy *et al.,* 2005). The fourth group received AD (NLD supplemented with 4% cholesterol, 1% cholic acid and 0.5% thiouracil, w/w) (Parmer and Kar, 2007), while the fifth and sixth groups received AD supplemented with ROO (10%) or VOO (10%), as described in 2nd and 3rd groups. All animal groups were maintained on their respective diets for duration of three months.

Samples collection:

At the end of the study period, overnight fasted rats were sacrificed under ether anesthesia. From each rat, two blood samples were collected. The first blood sample was taken on EDTA as anticoagulant for determination of hematological parameters. The second blood sample was collected with no additives to obtain serum by centrifugation at 3000 r.p.m for 10 minutes for biochemical analysis. Immediately after collecting blood, the heart and aorta from each rat were removed, and placed into clean and dry tubes. The tissues were then homogenized using a homogenizer surrounded with an ice jacket and the homogenate was kept frozen at $-20C^0$ until being analyzed.

Biochemical analysis:

Serum concentrations of glucose, TC, HDL, and TG were determined calorimetrically using Spectrophotometer with Kits from Spinreact Co., according to the manufacture instructions, as described by McCleary and Codd (1991); Zoppi and Fellini (1976); Wahlefeld (1974); Naito (1984), respectively. LDL-C and VLDL:-C, as well as atherogenic index (AI) was calculated according the following equation:

LDL-C = TC – HDL-C – TG/5 (Ahmedi *et al;* 2008). VLDL-C = TG/5 (Satheesh and Pari, 2008).

AI = (VLDL-C + LDL-C) / HDL-C (Pandya *et al.,* 2006).

The concentration of nitric oxide (NO) was measured by determination of total nitrate and nitrite concentrations according to the method of Green *et al.* (1982).

Inflammatory and hematologic analysis:

Serum TNF-α was measured, using ELIZA technique, that is a solid phase enzyme amplified sensitivity immunoassay, according to Aggarwal (1985). Quantitative determination of fibrinogen in serum was carried out using Multifibren – U – Kit, as described by Cooper and Douglas (1991).

Red blood cells (RBCs), platelets (Plts) and total white blood cells (WBCs) count was measured by hemocytometer neubauer slide, while differential count of WBCs was determined by Leishman's stained blood film (Harvey, 2001). Whole blood Hb was measured colorimetrically by Randox kits according to Haemat (1967). Hematocrit (Hct) value was determined using hematocrit capillary tubes. The percent of Hct was determined by the use of microscopically reader (Alwan *et al.,* 2009). Mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH) and mean corpuscular hemoglobin concentration (MCHC) were calculated using the formulae mentioned by Dacie and Lewis (2001).

Statistical analysis:

All data are represented as means ± SE. One-way analysis of variance ANOVA was used to analyze the results. The level of statistical significance at $P < 0.05$ was performed by Least Significant Difference (LSD) test (SPSS Inc. 1999).

3. Results

The present study investigates the impact of two types of olive oil (OO) [(refined olive oil (ROO)

and virgin olive oil (VOO)] on biochemical, inflammatory and hematological changes developed in male rats with experimentally induced atherosclerosis. The statistical evaluation of obtained data were calculated for the atherogenic group according to the normolipidemic diet (NLD) group and for OO+AD treated groups according to both the atherogenic and the NLD groups (no comparison between the two groups OO+AD and ROO, VOO groups were carried out).

In the present study, administration of ROO or VOO to normal rats did not produce significant changes in all measured parameters if compared to NLD group (Table 1, 2, 3, 4). On the other hand, administration of atherogenic diet exhibited elevated serum lipids (TC, TG and LDL-C), along with decreased HDL-C concentrations. Besides, serum glucose level was increased in the atherogenic animals, if compared to NLD group (Table 1). Meanwhile, the levels of NO in both aorta and cardiac tissues showed significant reduction (Table 2), along with marked elevation in the serum levels of the two inflammatory markers, TNF-α and fibrinogen (Table 3). Additionally, Table 4 showed elevations of Plts count, as well as WBCs, monocytes and lymphocytes, concomitantly with a reduction in RBCs count, Hb content and other indices (Hct%, MCV, MCH and MCHC) in the atherogenic rats, in comparison with NLD group. On the other hand, feeding rats an atherogenic diet supplemented with ROO or VOO caused an ameliorative effect on all these parameters, as evidenced by restoration of the changed lipid profile, inflammatory markers, NO level and hematologic indices near to normal values. However, the greatest effect was recorded with VOO administration.

4. Discussion

Atherosclerosis is generally assumed to develop following prolonged exposure of the vascular wall to elevated levels of cholesterol and glucose and also to several inflammatory and hematological changes. However, due to special anatomical position of the vascular endothelium (between circulation and vascular wall) it is a primary target for these risk factors, which in turn causes endothelial dysfunction. Dysfunction of vascular endothelium appears to be a key event in initiating, progression and complications of atherosclerosis (Vallance & Chan, 2001). One of the principal mechanisms underlying endothelial dysfunction is through increased generation of reactive oxygen species (ROS) with consequent oxidative stress (OS) (Hassanabad *et al.,* 2010). Lipid metabolic abnormalities are considered the main cause for increased OS under atherogenic state (Rizzo *et al.,* 2009). However, hyperglycemia (occurred as a result of insulin resistance) associated with lipid abnormalities seemed to be also responsible (Ferroni *et al.,* 2006). In this regard, the present study has shown that feeding rats an atherogenic diet induced elevations in serum levels of glucose and lipids (TC, LDL-C and TG), which may reflect increased generation of ROS that contribute to atherosclerosis development.

Increased ROS is suggested to play a role in atherosclerosis by inducing endothelial dysfunction characterized by impaired production of NO (Balakumar *et al.,* 2009). ROS including O_2^- can react with NO to form peroxynitrite ($OONO^-$), thus inactivating NO and directly decreased endothelium synthesis of NO (Perona *et al.,* 2006). Consistent with this, it was reported that patients with developing atherosclerosis have reduced NO bioavailability in both coronary and peripheral vasculature (Barbato & Tzeng, 2004). Additionally, functional NO has been demonstrated to decrease in plasma and tissues of experimental atherogenic conditions (Deepa and Varalakshmi, 2004). In the

present study, observed finding of decreased aorta and cardiac NO levels following atherogenic diet feeding could therefore indicate development of atherosclerosis with increased risk of CVD.

Nitric oxide normally functions to maintain vascular homeostasis through a number of physiologic processes. One prevalent action involves the activation of soluble guanyl cyclase, which then produces cyclic guanisine monophosphate (cGMP), being responsible for vasorelaxation (Dhir and Kulkarni, 2007). Nitric oxide can also act directly on calcium dependent potassium channels, leading to relaxation of vascular smooth muscles (SMCs) (Costa & Assreuy, 2005). Moreover, the vasoprotective effect of NO includes promotion of endothelial proliferation and protection of endothelial cells (ECs) from apoptosis and adherence of inflammatory cells (Hengartner, 2000) thus serves to limit endothelial inflammation. Based on this, the reduction in NO, as in case of atherosclerosis has suggested to promote pro-inflammatory endothelial response (Napoli *et al.,* 2006). It involves enhanced vulnerability of vascular wall to circulating leukocytes and other inflammatory mediators, leading to atherosclerotic vascular injury (Naseem, 2005). It is now clear that inflammatory mediators are intimately involved in atherogenic process (Libby, 2002), thereby demonstrating atherosclerosis as an inflammatory disease (Burger-Kentischer *et al.,* 2006).

Excessive inflammation leads to patho-logical situation that including leucocytes migration into the inflammatory site. During vascular atherosclerosis, leucocytes and ECs are the major cellular players of the inflammatory reactions, while numerous mediators are involved in augmenting the inflammatory process (Zakynthinos & Pappa, 2009). It was explained that ECs coordinate the recruitment of inflammatory leucocytes to sites of vascular injury that consequently result in production and release of inflammatory cytokines, which are large family of small chemoattractant proteins (Reape & Groot, 1999). Among these, TNF-α is recognized to have a major role in inflammation, apoptosis, cell proliferation and stimulating synthesis of other cytokines, which further augment expression of cell adhesion molecules, such as intracellular adhesion molecule-1 (ICAM-1), vascular cell adhesion molecule-1 (VCAM-1) and E-selectin (Hennig & Toborek, 2001). Circulating leucocytes (in particular monocytes) are attracted by these molecules and adhered to endothelium, from which they migrate to the subendothelial space. Once within the vascular wall, monocytes differentiate into macrophages, which express scavenger receptors, allowing them to scavenge oxidized LDL-C (Ox-LDL-C) (Fuhrman *et al.,* 2008). LDL-C can be oxidized by ECs, SMCs and macrophages present in the arterial wall and the formed Ox-LDL-C may directly damage the endothelium and contribute to atheroma plaque formation, through increased adherence and migration of monocytes and lymphocytes (predominantly T-lymphocytes) into the vascular wall (Quehenberger, 2005). T lymphocytes recognize specially antigens that are produced in plaques including Ox-LDL-C (McLaren and Ramji, 2008). In this regard, the study of Kentischer *et al.* (2002) demonstrated that monocytes, macrophages and T-lymphocytes are critical cells characterizing all stages of atherosclerosis. Once stimulated they increase production of several pro-inflammatory cytokines, such as TNF-α, which are important in initiating the expression of variety of genes that in turn promote cell adhesion and other processes required for progression of atherosclerosis (Zhang *et al.,* 2007). Further evidence that atherosclerosis is linked to inflammation is provided by the present observation that feeding rats on atherogenic diet induced marked elevation in several inflammatory markers, including total leucocytes, monocytes and lymphocytes, as well as serum level of the pro-inflammatory and pro-atherogenic TNF-α. In other studies, the interactions between these inflammatory mediators promote SMCs migration and proliferation which in turn leads to atheroma plaque rupture with subsequent adherence and aggregation of platelets, leading to progression of atherosclerotic injury (Chon *et al.,* 2006).

Platelets are circulating cells that play a key role in hemostasis system (Ni & Freedman, 2003). By adhering to damaged blood vessels PLts become activated, which in turn release PLts derived growth factor that promote plaque growth contributing to progression of atherosclerotic disease (Crowther, 2005). Besides, activated PLts play a role in atherosclerosis through providing other hemostatic factors, including fibrinogen (Ni and Freedman, 2003). This latter effect has already been demonstrated in the present study, as evidenced from the raised fibrinogen levels in parallel to the increased PLts count following atherogenic diet feeding. Raised plasma fibrinogen is associated with development of atherosclerosis and is considered a risk factor for CVD (Sato *et al.,* 2000). Several reasons for the association between fibrinogen and the risk of CVD have been suggested. They include the effect on plasma viscosity, coagulation, fibrinolysis (Junker *et al.,* 1998), promotion of vascular SMCs proliferation (Rauch *et al.,* 2007) and also the induction of PLts aggregation (Willoughby *et al.,* 2002). In addition, recent studies indicated that fibrinogen accumulation in the vessel wall may

contribute to the early vascular inflammation (Heffron *et al.,* 2009). Other studies showed that fibrinogen induced production of the systemic inflammatory marker C-reactive protein (CRP) in SMCs, both in messenger ribonucleic acid (m-RNA) and protein levels (Guo *et al.,* 2009), suggesting that fibrinogen possesses a pro-inflammatory properties which is related to atherosclerosis development. In support, Guo *et al.,* (2009) reported that macrophages accumulation in the arterial wall may be associated with increased plasma concentrations of both fibrinogen and CRP, two markers of inflammation thought to be early signs of atherosclerosis and CVD. Therefore, increased fibrinogen level as detected in this study may indicate enhanced inflammatory status under present atherogenic condition.

Apart from the role of the two hemostatic factors, fibrinogen and PLts in atherosclerosis there is evidence that RBCs may also serve as a potential partner in this process, through activation of the vascular endothelium leading to vascular inflammation and atherosclerosis (Blum, 2009). A number of changes can affect RBCs and thereby lead to development and progression of atherosclerosis. Researchers have indicated that RBCs are particularly exposed to oxidative hazards because of their specific role as oxygen carriers (Manna *et al.,* 1999). Under normal physiologic conditions, there is a steady state balance between the production of ROS and their destruction by the endogenous antioxidant defense system (Takenaka *et al.,* 1991). However, if ROS are over produced, as in atherosclerosis, this can damage both plasma membrane and cytosolic components, leading to oxidative hemolysis of RBCs and decreased survival of oxidized RBCs in circulation (Manna *et al.,* 1999). Therefore, the possibility of RBCs oxidative modification appears to be an explanation for the reduction in RBCs count and other hematologic indices (Hb, Hct, MCV, MCH and MCHC) observed under present atherogenic condition.

As a consequence of oxidative modification, drastic changes in RBCs morphology occur, causing RBCs activation thereby, microvesicles of RBCs are formed (Leopold & Loscalzo, 2009). Formation of membrane vesicles is associated with loss of plasma membrane asymmetry, consequently, RBCs shed microvesicles from their main body, and circulating levels of microvesicles are augmented, as in case of most CVD (Blum, 2009). Microvesicles activate ECs, attract leucocytes and enhance their adherence to ECs, as well as induce production of pro-inflammatory cytokines and upregulation of ICAM-1 involved in the recruitment of monocytes into the arterial wall, thereby promoting the whole cascade of inflammatory events, leading to evolution of atherosclerosis with increased risk of CVD (Kaperonis *et al.,* 2006).

In contrast to these multiple atherogenic events, there is compelling evidence that nutrition can affect genesis of atherosclerosis by modulating functional properties of vascular ECs. In particular the lipid environment of the vascular endothelium may profoundly influence the inflammatory response during atherosclerosis and thereby confer an overall beneficial effect (Ringseis & Eder, 2010). With the discovery of the relationship between dietary fat and atherosclerosis; olive oil rich diets have been acclaimed for its protective effects on several of changes associated with atherosclerosis and heart disease (Acın *et al.,* 2007). This was in accordance with the present observations, where feeding rats on atherogenic diet supplemented with VOO or ROO has shown lowered atherogenic hazards. This effect was observed mainly in terms of modulating a number of inflammatory markers. Besides, a reduction in the hyperlipidemic status, concomitant with increased NO levels were recorded. The present data showed also that VOO was more effective than refined ROO, where the maximal protection was observed with VOO administration.

Evidence from other studies indicated that each of VOO or ROO consists mainly of monounsaturated fatty acids (MUFAs), with minor constituents, like phenolic compounds (PhCs) that contribute to the stability of the oil and exhibit wide range of biological activities (Ruano *et al.* 2005). From previous studies, it was indicated that PhCs are influenced by procedures of OO extraction and that PhCs are lost when OO is refined (Mir´o-Casas *et al.,* 2001). Therefore, VOO obtained by physical procedures has high amounts of PhCs. Actually, both VOO and ROO contain similar proportions of MUFAs; however the total PhCs concentration is greater in VOO, which may contribute to the more beneficial properties of VOO compared to ROO, as observed in this study.

In some studies the healthy effects of OO on cardiovascular risk factors have been attributed to its high content of MUFAs, such as oleic acid (Massimo *et al.,* 2009). In fact, MUFAs are suggested to be effective in improving serum lipid profile, through a decrease in TC, LDL-C and TGs and increase in HDL-C (Moreno & Mitjavila, 2003). Besides, OO has been shown to lower blood glucose levels (Tahvonen *et al.,* 2005), which together with improved blood lipids (as shown in this study) may reflect some protection against development of atherosclerosis.

Other studies suggested that nutrients, including MUFAs may modulate atherosclerosis by

affecting vascular endothelium (Covas, 2007), through increasing the amount of oleic acid in the arterial wall and displacing saturated fatty acids (SFAs), while leaving polyunsaturated fatty acid (PUFAs). This change in vessel wall composition is favorable for three reasons: (1) Saturated fatty acids are atherogenic and favor platelet aggregation through decreasing prostacyclin and increasing thromboxan production. They can thus be considered prothrombotic substances. (2) Polyunsaturated fatty acids reduce platelet activity and prothrombotic capacity of the arterial wall. (3) The accumulation of MUFAs in the arterial wall decreases the expression of several endothelial adhesion molecules involved in the selective monocytes recruitment in the arterial wall (Perona *et al.,* 2006). Thus, oleic acid may contribute to prevention of atherosclerosis, mainly through a protective effect against atherogenic vascular wall lesions.

Despite the beneficial effects attributed to oleic acid, it is very likely that other minor components with antioxidant and anti-inflammatory properties, such as PhCs could be responsible for OO effects observed in this study and in other experimental trials. Oleuropin and its derivative hydroxytyrosol have the strongest radical scavenging properties among all olive oil PhCs (Oram *et al.,* 2004). Massaro *et al.* (2002) hypothesized that these components may exert direct vascular athero-protective effects by inhibiting endothelial dysfunction through quenching ROS and reversing the imbalance between increased OS and impaired antioxidant status. Association between OS and impaired endothelial function, characterized by reduced NO bioavailability have been demonstrated in humans and experimental animal models of atherosclerosis (Moraes *et al.,* 2007). Endothelial dysfunction could be reversed in atherogenic patients by administration of agents capable of scavenging ROS (Jackson *et al.,* 1998), such as OO and its PhCs (Covas, 2007). In this regard, it was reported that oleuropein and hydroxytyrosol are potent scavengers of ROS and O_2^- in neutrophils, which might prevent formation of the powerful oxidant peroxynitite ($OONO^-$) leading to an increase in NO levels, being linked to endothelial improvement and inhibition of atherosclerosis (Briante *et al.,* 2001). In support, the present data showed increased NO levels in both aorta and cardiac tissues in rats fed atherogenic diet supplemented with OO.

Other mechanisms have been suggested to explain beneficial effects of olive oil PhCs. They include: (1) Antioxidant protection of LDL-C from oxidative modification, either directly or with interaction with endogenous antioxidants likes vitamin E (Rajasekhar *et al.,* 2004). (2) Reduction of microphage uptake of Ox-LDL-C (Rosenblat *et al.,* 2008). (3) Increase in size of LDL-C particles that become less pro-atherogenic (Perona *et al.,* 2006). Apart from protecting LDL-C from oxidation, PhCs exhibited also some beneficial effects on PLts (Singh *et al*., 2006), fibrinogen and erythrocytes, as consequence of its antioxidant properties (Covas, 2007). PhCs from olive leaf extract significantly inhibited PLts aggregation *in vitro,* possibly through their H_2O_2 scavenging properties, which may offer a degree of protection from thrombosis and other CVD risk factors (Singh *et al.*, 2006). Moreover, OO with different phenolic contents were found to reduce fibrinogen levels, but increase RBCs count (Huang & Sumpio 2009), as well as Hb concentration, MCHC and Hct (Ashour *et al.,* 2007). Similar observations were also demonstrated with the present study, where feeding rats an atherogenic diet supplemented with OO showed a lowering effect on both PLts and fibrinogen levels, concomitant with elevations in RBCs count and other hematological indices (Hb, Hct, MCV, MCH, and MCHC), thereby suggesting a potent antiatherogenic role of OO.

Other studies in humans and animals evidenced that PhCs from OO have demonstrated anti-inflammatory effects, through inhibiting a number of inflammatory mediators released by endothelial cells (Ros *et al.,* 2004). De La Puerta *et al.* (1999) studied a range of VOO phenolics (oleuropein glycoside, caffiec acid and tyrosol) in rat peritoneal leucocytes, indicating inhibited production of leukotriene B_4 (LTB_4), which is a chemoattractant and activator of neutrophiles. Moreover, Miles *et al.* (2005) found a very strong effect of oleuropein glycocide on production of cytokines, IL-6 and TNF-α. Also, monocyte adhesion to ECs can be modulated by VOO- PhCs, through inhibiting mRNA expression of several adhesion molecules, including VCAM-1 (Carluccio *et al.,* 2003). This occurs as a result of interfering with activation of the most important transcription factor controlling endothelial activation, nuclear factor kB (NFkB) (Perona *et al.,* 2007). In this respect the present study showed marked reduction in total leucocytes, monocytes and lymphocytes, as well as the pro-inflammatory marker TNF-α in rats fed atherogenic diet supplemented with OO. The out come of these effects in all, is indicative of lowered inflammatory tendency in response to OO intake, which in turn may decrease the risk of atherosclerosis and cardiovascular disorders.

In conclusion, the results of this study illustrated the role of inflammatory changes as an etiology of atherosclerosis and further indicated the ability of OO (in particular VOO) to favorably influence these changes. Therefore, VOO may be

useful in designing dietary strategies to minimize development of atherosclerosis and related cardiovascular disorders in humans.

Response of Wheat to Magnesium and Copper Foliar Feeding under Sandy Soil Condition

EL-Metwally, A.E.[1]; F.E. Abdalla[2]; A.M. El-Saady[2]; S.A. Safina[1] and Sara S. EI-Sawy[2]

[1.] Agronomy Dept., Fac. of Agric., Cairo University, Cairo Egypt
[2]. Fertilization Technology Dept., National Research Centre (NRC), Dokki – Cairo Egypt

Abstract: Two field experiments were conducted during the winter seasons of 2007/2008 and 2008/2009 at Ismailia Experimental Station, Agriculture Research Center, Ismailia Governorate, to study the influence of foliar feeding with magnesium (Mg), copper (Cu) either as single nutrient or in combination on growth of wheat (*Triticum aestivum* L.) cv. Sakha 94. Nine treatments were applied: two levels of Mg, two levels of Cu and four combined treatment (Mg + Cu), in addition to control treatment. Results showed that the highest positive significant effect on flag leaf area, chlorophyll contents and dry matter/m^2 were achieved by spraying the highest Mg level + the highest Cu level (6.72 kg Mg + 1.68 kg Cu/fed.) Results also, showed that most of both macro and micronutrients content increased markedly due to the same previous treatment.

Keywords: Wheat, *Triticum aestivum* L., Magnesium, Copper and Sandy soil.

1. Introduction:

Wheat (*Triticum aestivum L.*) is the most important cereal crop in the world. Wheat ranks as the first among all cultivated cereals in Egypt. Its cultivated area reached to about 1.2 million hectare in year 2008, produced about 7.9 million tons (FAO, 2008). However, this production did not meet consumption party due to crop leakage for other misused and as well as the over growing population and hence, consumption. It is clear that there is a great shortage in the production of wheat in Egypt. This reflects the size of the problem that shows the need of increasing both of vertical and horizontal expansion in old alluvial soils and new desert area. Sandy soils predominate in most newly cultivated area. These soils suffer from very low soil fertility level and as well very low water holding and nutrients retention capacity.

Nutrients play a very important role in chemical, biochemical, physiological, metabolic, geochemical, biogeochemical, and enzymatic processes. Magnesium has major physiological and molecular roles in plants, such as being a component of the chlorophyll molecule, a cofactor for many enzymatic processes associated with phosphorylation, dephosphorylation, and the hydrolysis of various compounds, and as a structural stabilizer for various nucleotides. Studies indicate that 15 to 30% of the total magnesium in plants is associated with the chlorophyll molecule (Marschner 1995).

Copper is an essential micronutrient that requires for the functioning of more than 30 enzymes, all of which are either redox catalysts (e.g., cytochrome oxidase and nitrate reductase) or dioxygen carriers (e.g., haemocyanin). El-Magid *et al*. (2000) recorded that, spraying wheat plant with Fe, Zn, Mn or B increased shoot height, while Cu had little effect on this parameter. Spraying such nutrients increased the number of tillers per plant and shoot weight. It was found also that spraying Cu and B reduced N content, while spraying Zn, Mn, B, Fe and Cu increased wheat plant P and K contents. Ziaeian and Malakouti (2001) reported that copper as well as the other micronutrient application led to significantly increase in their concentration and uptake in grain and flag leaf. Such nutrient application increased significantly grain protein content. Shaaban (2002) showed that foliar fertilizer feeding containing 5.2 % Mn, 0.65 % Zn and 0.65 % Cu increased the concentration of Mg, Ca, Fe, Mn, Zn and Cu in the leaves of wheat.

El-Maghraby (2004) found that the soaking of wheat grains in $FeSO_4$, $MnSO_4$, $ZnSO_4$ and $CuSO_4$ had highly significant effects on the uptake of N, K, Fe, Mn, Zn and Cu in straw. The treatments had highly significant effects on the uptake of N, P, K, Fe, Mn and Zn by grains**.** Korzeniowska (2008) found that wheat plants after Cu application showed higher N concentration than control plants. Moreover, high correlation between Cu and N concentration in wheat shoots were obtained.

The purpose of this work is to study the response of wheat cultivar Sakha 94 to magnesium and copper levels either alone or in combination to induce the highest values of growth parameters as well as nutritional status of plants under sandy soil condition.

2. Materials and methods

Two field experiments were carried out at Ismailia Experimental Station, Agric. Res. Center, Ismailia Governorate, during 2007/2008 and 2008/2009 winter seasons to study the influence of magnesium, copper and either alone or in combinations on growth and nutritional of wheat cv. Sakha 94. The experimental design was randomize complete block with six replicates nine treatments.

Treatments:

The experiment contained nine foliar spray treatments as follows:

1- Control (water spray) 2- 3.36 kg Mg/feddan
3- 6.72 kg Mg/feddan 4- 0.84 kg Cu/feddan
4- 68 kg Cu/feddan
5- .36 kg Mg + 0.84 kg Cu/feddan
6- 3.36 kg Mg + 1.68 kg Cu/feddan
7- 6.72 kg Mg + 0.84 kg Cu/feddan
8- .72 kg Mg + 1.68 kg Cu/feddan

Wheat plants were sprayed with the aforementioned treatment two times, the first was 45 and the second was 60 days after planting. The sprayed solution volume was 350 and 400 L/fed. in the first and second spray, respectively. Soil was ploughed using a chisel plough and divided into experimental units, 2.0 m long and 3.0 m wide. Every plot contained 15 rows each of 20 cm width. Wheat grains were sown on November 22 th and 13th in 2007/2008 and 2008/2009 seasons; respectively at the rate of 60 kg/feddan by hand drilling in rows.

Soil Analysis:

Representative soil samples were taken after soil preparation and before fertilization from the experimental sites (0-30 cm depth) for physico-chemical characteristics (Table 1).

The samples were air-dried and passed through 2mm sieve pores. Soil fractions were determined using the hydrometer method (Bauyoucos, 1954). E.C. and pH were determined in soil/water extract (1:2.5) according to Jackson (1973). $CaCO_3$ was determined using the calcimeter method according to Black (1965). Organic matter was determined using the potassium dichromate method according to Walkely and Black (1934). Soil phosphorus was extracted using sodium bicarbonate (Olsen *et al*., 1954). Potassium, sodium and magnesium were extracted using ammonium acetate (Jackson, 1973). Iron, manganese, zinc and copper were extracted using DTPA-solution (Lindsay and Norvell, 1978).

Table (1): Soil Physico-chemical characteristics (0 – 30 cm) in 2007/2008 and 2008/2009 seasons.

Characteristics	2007/2008	2008/2009
Physical Properties		
Sand (%)	88.4	90
Silt (%)	4.0	3.2
Clay (%)	7.6	6.8
Texture	Sand	Sand
E.C dS/m	0.20	0.35
pH	8.95	9.15
Chemical Properties		
$CaCO_3$ %	1.20	1.84
Organic Matter %	0.54	0.09
Exchangeable macronutrients (mg/100g soil)		
P	0.36	0.62
K	7.6	4.24
Na	18.0	41.4
Ca	240	308
Mg	9.0	3.64
Determined micronutrients (ppm)		
Fe	3.7	3.83
Mn	2.8	1.13
Zn	0.22	0.15
Cu	0.1	0.25

Nitrogen, phosphorus and potassium were added at rate of 106 kg N/fed, 37 kg P_2O_5/fed., and 24 kg K_2O/fed., respectively. Nitrogen was applied as ammonium sulfate (20.6 % N) in three equal splits (at planting, 30 and 50 days after sowing) in both seasons. Phosphorus was applied as a single super phosphate (15.5 % P_2O_5) during soil preparation. Potassium was applied as Potassium sulphate (50 % K_2O) at 30 days after sowing. The whole experimental plots were also sprayed with mixed iron, manganese and zinc in EDTA form two times (45 and 60 days after planting) at rate of 0.5 g/L. from each nutrient.

Plants were irrigated at 6 days interval using sprinkler system. Weeds were controlled by hoeing.

Plant samples:

Wheat shoots at 75 days after the second spray, were taken to determine the dry weight (g/m^2). The samples were washed with tap water (0.01 N HCl) and bi-distilled water, then oven dried at 70º C for 24 hours and ground. The ground material was dry-ashed in a muffle furnace at 550º C for 6 hours. The residue then suspended in 0.3 N HCl.

Recorded Data:

A sample of 25 x 25 cm2/plot was randomly taken at 75 days after sowing to determine dry weight

per plant, shoot macro and micronutrients concentration. Flag leaf area (cm^2) per plant was also calculated using formula (Length x maximum width x 0.79) according to Voldeng and Simpson (1967).

Nutrients Determination:

Total nitrogen was determined in the dried plant shoots based on Micro-Kjeldahl method (Ma and Zauzage, 1942). Phosphorus was photometrical determined using the molybdate-vanadate (Jackson, 1973). Potassium, Ca, Fe, Mn, Zn and Cu were determined according to Chapman and Pratt (1978). Dr. Lang -M8D Flame-photometer was used for K and Ca, while Atomic Absorption Spectrophotometer (Perkin-Elmer 100 B) was used for Fe, Mn, Zn and Cu.

Statistical analysis:

Collected data were subjected to the proper statistical analysis with the method described by Snedecor and Cochoran (1967). Since the data in both seasons took similar trends and variances were homogeneous according to Bartllets test, the combined analysis of both seasons' data was done. LSD test at 5 % level was used for comparing the numerical averages according to Waller and Duncan (1969).

3. Results and Discussion:

Experimental soil presentation:

Data in Table (1) showed that the experiment soil was sand in texture, very high alkalinily in reaction, had low content of macro and micronutrients. The soil was poor in organic matter, without any salinity problems. Soil evaluation was according to Ankerman and Large, 1974.

Effect of magnesium and copper foliar application on wheat growth:

Data in Table 2 showed that all magnesium and/or copper foliar application significantly affected wheat growth parameters. (i.e. flag leaf area, chlorophyll and total dry weight /m^2 at 70 days after sowing.

The increment ranged between 19-31% in flag leaf area, 7-29% in chlorophyll content and 22-88% in total dry weight, over control treatment. The highest increment recorded for the aforementioned parameters was due to spraying plants with the treatment contains the high level of both magnesium and copper (i.e. 6.72 kg Mg + 1.68 kg Cu/fed).

Positive effect of magnesium and copper foliar application on studied wheat growth parameters can be attributed to the important function of copper in plant metabolism since copper participates in photosynthesis and chloroplast development (Amberger, 1974). Since, magnesium is the central atom in the chlorophyll molecule. This makes it essential for photosynthesis. It also plays other critical roles in plant growth (Marschner, 1995). The same trend was found with Mg application on twelve sorghum genotypes (Tan *et al.*, 1992). El-Magid (2000) reported that application of Cu at 0.1% with other micronutrients increased the shoot wheat plants. Kumar *et al.* (2009) found in a pot experiment that production of wheat dry matter enhanced with increasing Cu levels and reached to the maximum at 1.5 mg kg^{-1}.

Table (2): Effect of magnesium and copper on growth characteristics of wheat plants at 70 days after sowing (combined of 2007/2008 and 2008/2009 seasons).

Treatment	Growth characteristic		
	Flag leaf area (cm^2)	Chlorophyll (mg/g)	Total dry weight(g/m^2) (gm / m^2)
0 Cu + 0 Mg	19.23	2.22	463.4
3.36 kg Mg /fed.	22.85	2.38	567.3
6.72 kg Mg /fed.	24.00	2.52	604.6
0.84 kg Cu /fed.	23.25	2.55	577.3
1.68 kg Cu /fed.	24.23	2.60	632.0
3.36 kg Mg + 0.84 kg Cu /fed.	24.42	2.57	686.4
3.36 kg Mg + 1.68 kg Cu /fed.	24.53	2.70	766.8
6.72 kg Mg + 0.84 kg Cu /fed.	24.07	2.78	810.4
6.72 kg Mg + 1.68 kg Cu /fed.	25.13	2.85	871.8
LSD at 0.05	1.78	0.15	40. 5

Macronutrients Status:

Concentration of macronutrients in wheat shoots as affected by different treatments of magnesium and/or copper are shown in Table 4. It is obvious that nitrogen concentration was significantly increased as a response to application of magnesium and copperas compared with control.

Table (3): Effect of magnesium and copper on macronutrient contents (%) of wheat shoots at 70 days after sowing (combined of 2007/2008 and 2008/2009 seasons).

Treatment	Macronutrient (%)				
	(N)	(P)	(K)	(Mg)	(Ca)
0 Cu + 0 Mg	1.73	0.21	2.70	0.14	0.32
3.36 kg Mg /fed.	2.49	0.24	3.32	0.15	0.35
6.72 kg Mg /fed.	2.70	0.28	3.94	0.17	0.44
0.84 kg Cu /fed.	2.55	0.26	3.67	0.14	0.41
1.68 kg Cu /fed.	2.71	0.26	3.95	0.14	0.45
3.36 kg Mg + 0.84 kg Cu /fed.	2.40	0.29	3.26	0.16	0.50
3.36 kg Mg + 1.68 kg Cu /fed.	2.68	0.29	3.57	0.16	0.50
6.72 kg Mg + 0.84 kg Cu /fed.	2.85	0.29	3.47	0.18	0.51
6.72 kg Mg + 1.68 kg Cu /fed.	3.06	0.30	3.84	0.18	0.51
LSD at 0.05	0.07	0.01	0.35	0.01	0.06

Phosphorus concentration determined in wheat shoots significantly increased with foliar application of 6.72 kg Mg + 1.68 kg Cu/fed.

Concerning potassium content, it was found that either spraying plants with the highest level of magnesium or the highest level of copper or their combination gave the highest content, 3.94, 3.95, and 3.84, respectively. Magnesium has major physiological and molecular roles in plants, such as being a component of the chlorophyll molecule, a cofactor for many enzymatic processes associated with phosphorylation, dephosphorylation, and the hydrolysis of various compounds, and as a structural stabilizer for various nucleotides. Studies indicated that 15 to 30% of the total magnesium in plants is associated with the chlorophyll molecule (Marschner 1995). These results are in agreement with the results of El-Magid (2000), Brohi *et al*. (2000), Shaaban (2002), El-Maghraby (2004) and Korzeniowska (2008).

Micronutrients Status:

Micronutrient concentrations in wheat shoots were differed significantly with different treatments (Table 4).

Table (4): Effect of magnesium and copper on micronutrient contents (%) of wheat shoots at 70 days after sowing (combined of 2007/2008 and 2008/2009 seasons).

Treatment	Micronutrient (ppm)			
	(Fe)	(Zn)	(Mn)	(Cu)
Control (0 Cu+0 Mg)	114.0	31.2	18.0	5.2
3.36 kg Mg /fed.	139.6	38.4	21.2	6.0
6.72 kg Mg /fed.	153.0	40.4	25.3	6.3
0.84 kg Cu /fed.	135.4	38.6	23.5	10.6
1.68 kg Cu /fed.	155.7	40.8	24.8	17.1
3.36 kg Mg + 0.84 kg Cu /fed.	156.9	41.9	25.2	12.1
3.36 kg Mg + 1.68 kg Cu /fed.	163.8	48.2	25.7	19.3
6.72 kg Mg + 0.84 kg Cu /fed.	164.5	48.0	26.3	12.5
6.72 kg Mg + 1.68 kg Cu /fed.	176.5	50.0	27.0	18.9
LSD at 0.05	7.6	6.7	2.4	1.5

It is obvious that the highest Fe, Mn, Zn and Cu concentrations were obtained by spraying wheat plants with 6.72 kg Mg + 1.68 kg Cu/fed. Sicene, the fertilizer contains relatively higher concentrations of nutrients than other treatments which mostly absorbed by the plant shoots and raise their concentrations in the shoot tissues (Kassab et al. 2004). The same trend was found by Brohi et al. (2000) who determined the effect of Mg fertilization on the rice yield grown on artificial siltation soil and N, P, K, Fe, Cu, Zn and Mn contents. The uptake of all nutrients in straw was increased with Mg

treatment. El-Maghraby (2004) found that the soaking of wheat grains in Fe (FeSO4), Mn (MnSO4), Zn (ZnSO4) and Cu (CuSO4) had highly significant effects on the uptake of micronutrients (Fe, Mn, Zn and Cu) by straw.

4. Conclusions

It could be concluded that:

1. Magnesium and copper fertilization is very important for the growth of winter wheat plants under sandy soil condition.
2. Combined treatments (Mg + Cu) under experiment conditions could improve growth and nutritional status of wheat.
3. Spraying wheat plants with 6.72 kg Mg + 1.68 kg Cu/fed. Is highly recommended to achieve maximum growth and nutritional status value.

Abstract: The present investigation was designed to evaluate the role of yeast, *Saccharomyces cerevisiae* (SC) in the reduction of aflatoxicosis induced by aflatoxin B_1 (AFB_1) in Japanese quail. Sixty male quail were used and distributed into six groups. The first group received basal diet. The other five groups received the basal diet plus 0.5 mg AFB_1/kg diet. Four of them received increasing levels of SC (0.5, 1.0, 2.0 and 2.5 gm/kg diet, respectively). All groups received their prospective diets for 35 days. The birds were weighed weekly to determine body weight (BW) and body weight gain (BWG). The results showed that addition of the SC to AFB_1-containing diet significantly reduced the adverse affect of AFB_1 on quail BW and BWG. The concentrations of AFB_1 had been lowered in the breast muscle and liver samples of quail fed diet containing AFB_1 plus SC than those found in such quail organs of AFB_1 group. The expression levels of neural and gonadal genes were significantly up-regulated in quail fed diet containing AFB_1 plus high levels of SC compared to those of AFB_1 group. It could be concluded that SC supplementation to quail diets suppressed the aflatoxicosis in quail tissues leading to improvement of growth performances and enhancement of expression levels of neural and gonadal genes. Thus, the use of HPLC and gene expression analysis might contribute in detecting aflatoxin contamination in the poultry industry in Egypt.

1. Introduction:

Aflatoxins are a group of closely related, biologically active mycotoxins which are produced by storage fungi during growth on a number of foods and feed materials (Abo *et al.*, 1995 and Oliveria *et al.*, 2002). Aspergilla are the most common fungal species that can produce aflatoxins (AFs) in food and feedstuffs (Oliveria *et al.*, 2002 and Abousadi *et al.*, 2007). Among the different types of AFs produced, AFB_1 is the most prevalent and potent and is often found in high concentrations in cereal grains and peanut meal, which comprises between 50 and 60 percent of many poultry diets (Stanley *et al.*, 1993; Miazzo *et al.*, 2000; Parlat *et al.*, 2001 and Gowda *et al.*, 2004). Aflatoxicosis due to AFB_1 in poultry, causes listlessness, anorexia with lowered growth rate, immunosupression, decreased body weight gain, poor feed utilization, reduced egg production and increased mortality (Oguz and Kurtoglu, 2000; Oliveria *et al.*, 2002 and Abousadi *et al.*, 2007).

Removing AF from contaminated food and feedstuffs remains a major problem and there is a great demand for effective decontamination technology. These procedures have focused on degrading, destroying, inactivating or removing AF by physical (heat, irradiation), chemical (ammoniation, sulphites, hypochlorides, ozone), nutritional (vitamins, minerals) or biological (bacteria, yeast) methods (Stanley *et al.*, 1993; El-Nezami *et al.*, 2000; Raju and Devegowda, 2000; Galvano *et al.*, 2001; Abousadi *et al.*, 2007 and Tovar-Ramirez *et al.*, 2010). A successful detoxification process must be economically capable of eliminating all traces of a toxin without having harmful residues and must not impair the nutritional quality of the commodity (Leeson *et al.*, 1995 and Kubena *et al.*, 1998). One approach of many to this problem is the use of the yeast *Saccharomyces cerevisiae* (SC) and its cell wall component (manner oligosaccharide) for minimizing the adverse effects of AF in poultry on the basis of biological

degradation (Parlat *et al.*, 2001).This approach will not only benefit human health but also result in increased profit and productivity of poultry (Galvano *et al.*, 2001). The inclusion of SC (1gm/kg) to the AFB_1-containing diet provided significant improvements on the adverse effects of AFB_1 (5 mg/kg) in broiler chicks fed for 28 days (Stanely *et al.*, 1993). Also, Raju and Devegowda (2000) extracted mannan oligosccharide, which was believed to be responsible for the beneficial effect against AFB_1 from the wall of SC. They added (1gm/kg) to AFB_1-containnated feed and reported significant amelioration on the adverse effect of AFB_1 (0.3mg/kg) in broiler fed for 35 days. Moreover, Abousadi *et al.* (2007) observed that the addition of SC (0.2%) to AFB_1-containing diet significantly improved the adverse effect of AFB_1 (125 ppb) on growth performances in broiler chicks fed for 21 days. In quail, Parlat *et al.*, (2001) reported that the supplementation of SC (1gm/kg) to the AF-containing diet significantly reduced the deleterious effect of AFB_1 (2.5mg/kg diet) on body weight and body weight gain in birds fed for 35 days (Parlat *et al.*, 2001)

The present study was designed to investigate the role of SC in reducing aflatoxicosis caused by AFB_1 in Japanese quail. Therefore, the measurements of growth performances and the concentrations of AFB_1 in some quail organs were determined. Moreover, the expression levels of some neural(Glycerinaldehyde-3-phosphate ehydrogenase, GAPDH, neural cell adhesion molecule, NCAM, and Cadherin-2, CDH2) and gonadal (Cytochrome P450 cholesterol side chain cleavage, P450scc) genes were studied.

2. Materials and Methods

Birds and diet:

Sixty unvaccinated 14 days old male Japanese quail chicks were obtained from the quail project, Faculty of Agriculture, Cairo University. The quail were divided into six groups. Each group of 10 quail, were weighted and placed in a heated wooden brooder (battery cage). The birds received 24 h of light per day (continues light) for the duration of the experiment. They also received *ad lib*., water and a commercial growing quail ration (basal diet) containing 24% protein and 2,900 Kcal ME/Kg diet. The diet also contained all the required amino acids, vitamins and minerals according to the recommendations of the National Research Council (NRC, 1994), without adding antibiotics, coccidiostats or growth promoters. All animals received humane care in compliance with the guidelines of the Animal Care and Use Committee of Faculty of Agriculture, Cairo University, Egypt.

Aflatoxin B_1 (AFB_1):

AFB_1 used in this experiment was purchased from Sigma (Buchs, Switzerland). Twenty five milligrams of pure crystalline of AFB_1 were dissolved in chloroform. The chloroform solution was placed in a flask, and kept in a water bath at 60°C until complete evaporation of the solvent. Then AFB_1 was dissolved in 500 ml sterile maize oil. This solution was then added to 50 kg basal diet and homogenized to obtain the required final levels of AFB_1 which was 0.5mg of AFB_1/kg diet according to procedure of Soares and Rodrigues-Amaya (1989).

The appropriate experimental doses of AFB_1 that affect quail organs were determined previously by Sinsek *et al.* (2007). These appropriate doses ranged from 0.5 to 6.0 mg of AFB_1/kg diet.

Saccharomyces cerevisiae (SC):

SC was obtained from Microbial Chemistry Department, National Research Centre, Giza, Egypt. The SC culture was supplied at four rates, 0.5 gm, 1.0 gm, 2.0 gm and 2.5 gm/kg of feed. The live yeast was added to the appropriate diets mixed in cooking grade soybean oil. The soybean oil-SC suspension was added to the feed in the final mix as the last step in mixing, such as would occur commercially according to the procedure of Parlat *et al.* (2001). The AFB_1 was incorporated into the mixed feed before SC was added.

Experimental design:

Six groups of quail were supplemented with six dietary treatments as follows; (1) control, basal diet; (2) basal diet plus 0.5 mg of AFB_1/kg diet; (3) basal diet plus 0.5 mg of AFB_1 plus 0.5 gm of SC/kg diet; (4) basal diet plus 0.5 mg of AFB_1 plus 1.0 gm of SC /kg diet (5) basal diet plus 0.5 mg of AFB_1 and 2.0 gm of SC/kg diet (6) basal diet plus 0.5 mg of AFB_1 plus 2.5 gm of SC /kg diet.

Performance parameters:

a) Growth performance

The trial period was carried out for 5 weeks. During the experiment, the birds were weighed weekly to determine their body weight (BW) and body weight gain (BWG) at 14, 21, 28, 35, 42 and 49 days of age after fasting for 8 hours, to the nearest gram using a digital scale. The cumulative body weight gains were calculated by subtracting W2-W1.

After the end of the experiment, all birds were euthanized. Liver, brain, testis and breast muscle were collected, in order to (i) determine the aflatoxin concentrations in breast muscle and liver

samples by using HPLC analysis and (ii) to evaluate the expression levels of some neural and gonadal genes by using sqRT-PCR method.

b) Analysis of toxin residues in quail organs:

Samples of liver and breast muscle were collected, squashed, homogenized and extracted by using acetonitrile-water solution (85/15) (v/v). The sample extraction was filtered and diluted (5ml) with 95 ml of phosphate buffer saline (PBS). The filtrated solution was applied onto the immuno-affinity column (Alfa BG. 1003, VICAM). The column was rinsed twice with 10 ml of deionized water and the toxin was eluted from the column with 1.0 ml of acetonitrile-methanol mixture (3+2). The column was subsequently washed with 1ml of deionized water and the washing was combined with the acetonitrile-methanol elute. AFB_1 in the acetonitrile-methanol-water mixture was determined by an HPLC method using a Lich rospher 100 PR-18 ECO Pack column (5µm, 25 x 4.6 mm i.d., Merek, Portugal), with post-column derivatization involving bromination with pyridinum hydrobroide perbromide (PBPB, Sigma P-3179, Quimica S.A., Spain) and fluorescence detection (Merck Hitachi, excitation and emission wavelengths were 360 nm and 420 nm, respectively). The mobile phase was water-acetonitrile-methanol solution (6/2/3) (v/v/v) and flow rates were 1.00 ml/min for mobile phase and 0.30 ml/min for the PBPB reagent (Martins *et al.*, 2008).

c) Gene expression Analysis:

1. Extraction of total RNA

Liver, brain and testis tissues of quail of all groups were used individually to extract total RNA using TRIzol® Reagent (cat#15596-026, Invitrogen, Germany). Total RNA of each tissue was treated individually with 1 U of RQ1 RNAse-free DNAse (Invitrogen, Germany) to digest DNA residues, re-suspended in DEPC-treated water and photospectrometrically quantified at A_{260}. Purity of total RNA was assessed by the 260/280 nm ratio (between 1.8 and 2.1). Additionally, integrity was assured with ethidium bromide-stain analysis of 28S and 18S bands by formaldehyde-containing agarose gel electrophoresis. Aliquots were used immediately for reverse transcription (RT), otherwise stored at -80°C.

2. Synthesis of the cDNA using reverse transcription (RT) reaction

The complete Poly(A)$^+$ RNA isolated from quail tissues was reverse transcribed into cDNA in a total volume of 20 µl using RevertAid^{TM} First Strand cDNA Synthesis Kit (MBI Fermentas, Germany). An amount of total RNA (5µg) was used with a reaction mixture, termed as master mix (MM). The MM was consisted of 50 mM $MgCl_2$, 5x reverse transcription (RT) buffer (50 mM KCl; 10 mM Tris-HCl; pH 8.3), 10 mM of each dNTP, 50 µM oligo-dT primer, 20 U ribonuclease inhibitor (50 kDa recombinant enzyme to inhibit RNase activity) and 50 U M-MuLV reverse transcriptase. The mixture of each sample was centrifuged for 30 sec at 1000 g and transferred to the thermocycler (Biometra GmbH, Göttingen, Germany). The RT reaction was carried out at 25°C for 10 min, followed by 1 h at 42°C, and finished with a denaturation step at 99°C for 5 min (Khalil *et al.*, 2008a,b). Afterwards the reaction tubes containing RT preparations were flash-cooled in an ice chamber until being used for DNA amplification through sqRT-PCR.

3. Semi Quantitative Real Time-Polymerase Chain Reaction (sqRT-PCR)

An iQ5-BIO-RAD Cycler (Cepheid. USA) was used to determine the quail cDNA copy number. PCR reactions were set up in 25 µL reaction mixtures containing 12.5 µL 1× SYBR® Premix Ex TaqTM (TaKaRa, Biotech. Co. Ltd.), 0.5 µL 0.2 µM sense primer, 0.5 µL 0.2 µM antisense primer, 6.5 µL distilled water, and 5 µL of cDNA template. The reaction program was allocated to 3 steps. First step was at 95.0°C for 3 min. Second step consisted of 40 cycles in which each cycle divided to 3 steps: (a) at 95.0°C for 15 sec; (b) at 55.0°C for 30 sec; and (c) at 72.0°C for 30 sec. The third step consisted of 71 cycles which started at 60.0°C and then increased about 0.5°C every 10 sec up to 95.0°C. At the end of each sqRT-PCR a melting curve analysis was performed at 95.0°C to check the quality of the used primers. Each experiment included a distilled water control.

The quantitative values of RT-PCR of Glyceraldehyde Phosphate dehydrogenase (GAPDH-F: 5′-GGT GAA AGT CGG AGT CCA-3′, GAPDH-R: 5′-TTC TGT GTG GCT GTG ATG -3′, (SQUITTI *et al.*, 1999); N-cadherin (N-cadherin-F: 5′-GAT GTC AAT GAC AAT CCT CC-3′, N-cadherin-R: 5′-CAT CCT AGT TGC GTC TTC AAA G -3′, (Squitti *et al.*, 1999); Neural cell adhesion molecule (NCAM-F: 5′-GCC TGA AAC CTG AGA CAA C-3′, NCAM -R: 5′- CTT ACG AAC TGG CTG TGT TC -3′, (Squitti *et al.*, 1999); and Cytochrome P450 cholesterol side chain cleavage (P450scc-F: 5′- ACA GCA GTT CAT CGA CGC CG -3′, P450scc-R: 5′-AAG GAG GCT GAA GAG GAT G -3′, (KANDA *et al.*, 2000) genes were normalized on the bases of β-actin (β-actin-F: 5′- TGT GAT GGT GGG AAT GGG TCA G -3′, B-actin-R: 5′- TTT GAT GTC

ACG CAC GAT TTC C -3′, (Hwang *et al.*, 2009) expression.

The selected genes are responsible for different functions during cell differentiations. Where, GAPDH is a gene coding an enzyme that catalyzes the sixth step of glycolysis and thus serves to break down glucose for energy and carbon molecules. NCAD is a gene coding a protein that has been implicated as having a role in cluster of differentiations. Also, NCAM is a gene coding a hemophilic binding glycoprotein expressed on the surface of neurons, ganglia, skeletal muscle and natural killer cells. P450scc is a gene coding a mitochondrial enzyme associated with the conversion of cholesterol to pregnenolone.

At the end of each sqRT-PCR a melting curve analysis was performed at 95.0°C to check the quality of the used primers.

4. Calculation of Gene Expression

First the amplification efficiency (Ef) was calculated from the slope of the standard curve using the following formulae (BIO-RAD, 2006):

$Ef = 10^{-1/slope}$

Efficiency (%) = (Ef – 1) x 100

The relative quantification of the target to the reference was determined by using the ΔC_T method if E for the target (GH, IGF-1) and the reference primers (β-Actin) are the same (Bio-Rad, 2006)

$Ratio_{(reference/\ target\ gene)} = Ef^{C_T(reference)} - {}^{C_T(target)}$

Statistical analysis:

Body weight (BW), body weight gain (BWG) and gene expression data were analyzed as a one-way analysis of variance using the General Linear Model, SAS software (SAS INSTITUTE, 2004). Weight data were reported as least square means (LSM) ± standard errors (SEM). Gene expression data are expressed as means ± SEM. Mean values were separated, when significance is present, using Duncan′s Multiple Range Test (Duncan, 1955). Significance level was set at 5%.

3. Results

Effect of AFB_1 and yeast on growth performances:

Data presented in Table (1) showed the effect of dietary treatments on body weight (BW). Feeding AFB_1 alone suppressed the BW from the 3rd week (BW3) to week 7th week (BW7) compared to control. This deleterious effect of AFB_1 on BW was significant ($P \leq 0.05$) in the 6th week and the 7th week. The addition of (SC) at levels of 0.5-2.5 gm/kg to AFB_1-containing diets had ameliorated the adverse effect on BW. However, it was only significant during the 6th and 7th week of age.

Feeding AFB_1 alone also suppressed the BWG (Table 2) from the first week onwards and increased progressively until the end of the experimental period compared to controls. This suppression in weight gain was significant ($P \leq 0.05$) from the 6th to the 7th week of age and highly significant ($P \leq 0.01$) from 2nd to the 7th week of age (overall). The addition of SC to AFB_1 -containing diets improved the adverse effect of AFB_1 on BWG. This improvement was significant ($P \leq 0.05$) in group fed diet containing AFB_1 plus SC at 2.5 gm/kg diet level for the overall period.

Toxin analysis in some quail organs by using HPLC method:

As shown in Table (3), the concentrations of AFB_1 were higher in breast muscle (Figure 1[a-f]) and liver (Figure 2[a-f]) samples of quail fed diet containing AFB_1 than those found in samples of quail fed basal diet alone (control). The liver samples had the highest concentration of AFB_1. On the other hand, the amount of AFB_1 were reduced in breast muscle and liver samples that were collected from quail fed diets containing AFB_1 plus SC compared to those observed in samples of quail fed diets containing AFB_1 alone. The concentrations of AFB_1 in breast muscle and liver samples of quail fed diets containing AFB_1 plus high levels of SC (2.5 gm/kg) had the lowest amount of AFB_1 followed by the group that was fed diet containing AFB_1 plus 2.0 gm SC/kg diet.

Gene expression analysis:

Determination of the linear range of PCR amplification

The optimum values for the oligonucleotide primer concentrations were performed by using quail first strand cDNA as a template. The relationship between the CT value and the logarithm of the dilution factor of cDNA was evaluated under conditions that optimized the amplification of the target genes (GAPDH, N-cadherin, NCAM and P450scc). This evaluation was shown to be linear with a correlation coefficient > 0.99.

Gene expression of GAPDH, N-cadherin, NCAM and P450scc genes

The present results (Figures 3-5) revealed a significant ($p \leq 0.01$) decrease of gene expression levels of GAPDH, N-cadherin and NCAM genes in quail fed diet containing AFB_1 compared with those of the control group.

In contrary, the expression levels of GAPDH, N- cadherin and NCAM genes in quail fed diet containing AFB_1 plus low levels of SC (0.5 gm or 1.0 gm SC/kg diet) were higher than those found in quail fed diet containing AFB_1 alone. However,

these differences were not statistically significant. On the other hand, the expression levels of GAPDH, N-cadherin and NCAM genes in the brain and liver samples collected from quail fed diet containing AFB_1 plus high levels of SC (2.0 gm or 2.5 gm SC/kg diet) were significantly ($p \leq 0.01$) higher than those observed in quail fed diet containing AFB_1 alone.

Means with different letters, within tissue, differ significantly ($p \leq 0.05$).

4. Discussion:

Regarding to P450scc gene, the present results (Figure 6) revealed that the expression level of this gene in testis and liver samples of quail fed diet containing AFB_1 was significantly ($p \leq 0.05$) low compared to those of the control group.

The expression level of P450scc gene in quail fed diet containing AFB_1 plus low level of SC (0.5 gm or 1.0 gm SC/kg diet) were higher than those detected in quail fed diet containing AFB_1 alone. However, these increases were not statistically significant. On the other hand, the gene expression level of P450scc in quail fed diet containing AFB_1 plus high levels of SC (2.0 gm or 2.5 gm SC/kg diet) were significantly higher ($p \leq 0.05$) compared with those found in quail fed diet containing AFB_1 alone.

In the present study, the quail consumed AFB_1 (0.5 mg/kg) containing diet showed poor body weight (BW) and body weight gain (BWG). These deleterious effects of AFB_1 on BW were statistically significant at 6 weeks ($P \leq 0.05$) and 7 weeks ($P \leq 0.01$) of age compared to control. Also the suppression of BWG was statistically significant ($P \leq 0.05$) from 6 to 7 weeks of age and highly significant ($P \leq 0.01$) from 2 to 7 weeks of age (overall). These results agree with other research on experimental aflatoxicosis in quail (Parlat *et al.*, 1999; Celik *et al.*, 2001 and Denli *et al.*, 2003); in broiler (Kubena *et al.*, 1998 and Celik *et al.*, 2001); and other poultry species (Kubena *et al.*, 1991 and Stewart *et al.*, 1998). These adverse effects of AFB_1 on BW and BWG may be due to anorexia, listlessness, inhibition of protein synthesis and lipogenesis (Campbell *et al.*, 1983; Oguz and Kurtoglu, 2000; Oguz *et al.*, 2000a,b and Parlat *et al.*, 2001). Moreover, Campbell *et al.* (1983) reported that the AF- contaminated feed decreased the activities of several enzymes, which are important to the digestion of carbohydrates, proteins, lipids and nucleic acid in broiler chicks. Also, Boden and Jensen (1985) stated that toxic effect induced by AF could have disrupted the activity of the digestive enzymes and the absorption of essential nutrients.

On the other hand, the present results showed that the addition of SC to AFB_1–containing diet significantly improved the adverse effect of AFB_1 on BW and BWG in quail. These findings were similar to that reported in quail by Parlat *et al.* (2001). They found that the addition of SC (1.0 gm/kg) to the AFB_1-containing diet, significantly elevated the adverse effects of AFB_1 (2.5 mg/kg diet) on BW and BWG in quail fed for 35 days. Our results were also supported by the study of Stanley *et al.* (1993) on broiler chicks, who observed significant amelioration of the adverse effects of AFB_1 (0.5 mg /kg) on performance in broilers fed for 28 days. Moreover, Abousadi *et al.* (2007) reported that the addition of SC (0.2%) to AFB_1-containing diet significantly decreased the adverse effect of AFB_1 (125 ppb) on BW and BWG in broiler chicks fed for 21 days.

The role of SC on the detoxification were attributed to its ability to produce biological enzymes that interacts with the AF molecules (Stanley *et al.*, 1993) and other growth promoting effects (Raju and Devegowda, 2000). It was also reported that yeast has been known to alter stress in animals by providing a source of vitamins, enzymes and growth protein for reducing stress, to enhance the biological value of nitrogen compounds along the digestive tract (Stanley *et al.*, 1993). Moreover the additional benefits of SC which were observed in the present study may be due to stimulation of the immune response (Savage *et al.*, 1996), alteration of intestinal microbial environment (Newman, 1994) and producing enzymes for gut micro flora to enhance the nutrients bioavailability (Stanley *et al.*, 1993; Raju and Devegowda, 2000; Parlat *et al.*, 2001 and Abousadi *et al.*, 2007).

The mode of action of yeast or its constituents (antioxidant compounds) against mutagenic or toxic effect of AFB_1 in animal cells (*in vivo*) may be due to binding with the mutagens or inhibition of activation of enzymes of cytochrome system-mediated N-hydroxylation with consequently enhancement of liver and kidney functions and reduction of abnormalities of genetic materials (Wang *et al.*, 2004 and Devaraj *et al.*, 2008).

As known, the liver is considered the principal target organ for Aflatoxins (Heathcote and Hibbert, 1978 and Phillips *et al.*, 1995). From the present results it was observed that the concentrations of AFB_1 were higher in liver samples than those found in breast muscle samples. These results are similar to those reported by Bintvihok *et al.* (2002) who found that the levels of AFB_1 and its metabolites, including acid-hydrolysable metabolites, were much higher (about 10-fold) in liver than those observed in muscle cells in all species of treated domestic fowls, with such toxin. Our findings were also supported by those results reported by Howard and Eaton (1990); Eaton and Groopman (1994); Cullen and Newberne (1994) and Smele and Curier (2001) who observed that the liver is considered the main organ in which the AFB_1 are metabolized by enzymes of cytochrome P450 group and converted to many metabolic product such aflatoxins Q_1, P_1 and M_1 and also Aflatoxin 8, 9 epoxide.

The present results showed that the concentrations of AFB_1 have been reduced in liver and breast muscle samples that were obtained from quail groups receiving AFB_1+SC than those found in

the liver and breast muscle samples from quail receiving AFB_1 alone. As discussed above, the SC or its constituents (some of the carotenoids and vitamins) have the ability for detoxification of AFB_1 through interacting or binding with AFB_1 molecule (Stanley *et al.*, 1993 and Raju and Devegowda, 2000). Also, Gradelet *et al.* (1998) reported that carotenoids exert their protective effect through the deviation of AFB_1 metabolism towards detoxification pathways in rats. In quail, Denli *et al.* (2003) observed that the dietary vitamin A reduced the toxic effects of AFB_1 so yeast addition caused less toxicity in the liver and kidney than the AFB_1 group.

The present results revealed that the gene expression of neural cell adhesion molecule (GAPDH, N-cadherin- and NCAM) genes were down-regulated in the quail fed diet containing AFB_1. Such changes of gene expression of neural genes are characteristic due to the AFB_1 according to Kreutzberg (1995). The present findings are in agreement with those reported by Ahmed and Singh (1984) in chickens and by Ibegwuonu (1983) and Llewellyna *et al.* (1988) in rats. Those authors found that the concentrations of RNA in the nervous tissues were depressed by AFB_1 treatment. The breakdown of gene expression of neural genes which was observed in the present study may be due to retrograde signals from the nervous terminal as a result of AFB_1 treatment (Pershon *et al.*, 1989; Pahl and Baeuerle, 1996 and O′Neill and Kaltschmidt, 1998).

The present results also showed that the expression level of P450scc gene was down-regulated in quail fed diet containing AFB_1. These findings are supported by Macé *et al.* (1997) who found that treatment with AFB_1 induced DNA adduct formation and P^{53} mutations in CYP450 in human liver cell lines. Epidemiological studies by Bressac *et al.* (1991); Harris (1996) and Soini *et al.* (1996) showed a positive association between AFB_1 intake and a hot-spot guanine to thymine transversion mutation at the third base in the codon 249 of the P^{53} tumor suppressor gene. Moreover, some *in vitro* studies have provided indirect evidence for a mutative role of aflatoxin exposure in p^{53} mutagenesis by showing that AFB_1 causes primarily G-T transversions in bacteria (Foster *et al.*, 1993) or human cells (Trottier *et al.*, 1992 and Cariello *et al.*, 1994). Aflatoxins have been found to be a potent mutagenic food component (Hall *et al.*, 1988). This component is metabolized by the mixed function oxidase system to a number of hydroxylated metabolites and to aflatoxin 8, 9 epoxide which binds to DNA forming covalent adducts (Bushy and Wogan, 1984). The DNA adduct formation causes genomic instability including gene expression of animal genes (Soini *et al.*, 1996; Harris, 1996; Macé *et al.*, 1997; Huang and Kolodner, 2005 and Guardiola *et al.*, 2008).

On the other hand, the present results showed that SC was able to prevent the genetic alterations induced by AFB_1 in the quail tissues. Where, the mRNA concentrations were significantly increased in AFB_1 + SC groups compared to AFB_1 group in quail brain, liver and testis. To our knowledge, there is no available information about the use of SC as protective agents on gene expression of animal genes against the toxic effect of mycotoxins. However, some studies reported that the yeast cells contain high amounts of carotenoids, vitamins, minerals, and essential amino acids as well as the presence of B-D glucans on the cell wall of yeasts (Hussein *et al.*, 1996; Vetvicka, 2001; Brown and Gordon, 2003). These constituents are considered as antioxidant agents, that interrupts the free radical-initial chain reaction of oxidation or scavenge and disable free radicals (ROS) and reduced DNA-oxidative damage (Vasankari *et al.*, 1997; Sener *et al.*, 2007 and Oliveria, *et al.*, 2009) leading to genomic stability including gene expression of animal genes (Vetvicka, 2001; Brown and Gordon, 2003 and Van Breda *et al.*, 2005).

Furthermore, in a previous study, Park *et al.* (2000) identified five peroxiredoxins in the SC that were named Tsa1 (CTPX1), Tas2, AhP1, Dot5 and Prx1, of which Tsa1 possesses the most potent ability to scavenge H_2 O_2. Also, Huang and Koshland, (2003) reported that the Tsa1 is the most potent protector of genomic stability and prevents a broad spectrum of mutations.

In Conclusion; *Sccharomyces cerevisiae* yeast has the ability to reduce the toxic effect of AFB_1 in quail. It was also apparent that the higher the inclusion rates of SC in the diet of quail (2.5 mg/kg) the more the effective it is. This was apparent from the BW, BWG data and the level of AFB_1 in the different quail tissues and the gene expression data.

aminah@ace.upm.edu.my

Abstract: The objective of this research is to examine the role of perceived family-supportive work culture in reducing turnover intention of employees and the mediating role of affective commitment in the relationship between perceived family-supportive work culture and turnover intention. The subjects in this study constituted 693 employees from 20 private service organizations in the Klang Valley, Malaysia. Results of multiple regression analyses indicate that perceived family-supportive work culture is positively related to turnover intention of employees and employees' affective commitment mediate the relationship between perceived family-supportive work culture and turnover intention. The results imply the need for employers to understand how employees view the family-friendly programs in terms of the support provided and the values they place on the programs as captured in perceived family-supportive work culture. Positive perceptions would help reduce turnover intention as well the affective commitment of employees.

Keywords: Perceived family-supportive work culture; turnover intention; affective commitment

1. Introduction

Employee turnover is a persistent problem in organizations since organizations have to deal with costs due to termination, advertising, recruitment, selection, and hiring (Abbasi and Hollman, 2008). Employee turnover may jeopardize an organization's strategic plans to achieve its objectives (Abasi and Hollman, 2008). When an organization loses its critical employees, there might be several outcomes including a reduction in the overall level of innovation and quality of customer service (Denvir and McMahon, 2002; Miller, 2010). According to Garino and Martin (2005), organizations suffer the loss of job-specific skills and disruption in production, and incur the costs of hiring and training new workers when employees leave the organization.

For many years, researchers have tried to understand the major determinants of turnover intention and some managerial implications (Tuzun, 2007) especially with the rapidly changing demography of the workforce including the increase of women workers. Such a change results in more couples having to juggle work and family roles (Aminah and Zoharah, 2008; Perrewe´, Treadway and Hall, 2003) and hence it is expected that organizations be more sensitive to employees' family responsibilities and needs outside the workplace.

Consequently, contemporary public and private organizations are increasingly seeking initiatives to help employees balance their work and family responsibilities that may lead to positive organizational outcomes. One of the initiatives is to offer benefits that are family-supportive. Thompson, Beauvais, and Lyness (1999) introduced the concept of work-family culture which refers to the shared assumptions, beliefs, and values regarding the extent to which an organization supports and values the work-family integration of employees. This concept includes three dimensions namely, managerial support for work-family balance, career consequences associated with utilizing work-family benefits, and organizational time expectations that may interfere with family responsibilities. A supportive work–family culture increases the likelihood that employees will feel comfortable using family-friendly benefits like flextime, as they are less likely to worry about possible negative career consequences (Thompson et al., 1999). Another similar concept, organizational family support, refers to the organization's interest in helping employees achieve work-life balance and it encompasses work-family policies and practices offered by an organization (Allen, 2001).

Previous research have shown that employees who find that their organizations are less responsive to their family needs would be less committed to organizations and hence may leave the organizations (Haar and Spell, 2004; Rothbard, Phillips and Dumas, 2005; Wang and Walumbwa, 2007). In addition, research have also shown that affective organizational commitment, which refers to employee's emotional attachment to, identification with, and involvement in the organization (Meyer and Allen, 1991), is the strongest predictor of organizationally desired outcomes such as employee retention (Allen et al., 2003; Meyer and Smith, 2000; Rhoades et al., 2001) as compared to other forms of commitment, namely normative and continuance commitment. An employee who is affectively committed strongly identifies with the goals of the organization and desires to remain as part of the organization (Meyer and Allen, 1993) and are least likely to leave the organization (Thompson and Prottas, 2005; Gaan, 2008).

Despite the acknowledgement of the importance of workplace culture and studies examining employees' perceptions towards family-supportive culture, there is a need to examine the role of perceived workplace culture in reducing negative outcomes such as turnover intention and increasing organizational commitment since previous studies, with the exception of the work discussed earlier, have focused more on benefits offered rather than how comfortable employees feel using the family-friendly benefits and the values they place on the benefits as captured in perceived family-supportive work culture. The purpose of this study is to examine the role of perceived family-supportive work culture in reducing turnover intention and the mediating role of affective commitment. This study draws upon the social exchange theory (Blau, 1964) to examine relationships between these variables. The social exchange theory recognizes conditions under which individuals feel obligated to reciprocate when they personally benefit from another's actions (Lambert, 2000). The social exchange theory can be used to explain the relationships between family-supportive work culture and employees' commitment to organization and turnover intention. Besides this theory, the results of previous research also offer the bases for the formulation of hypotheses.

2. Literature Review

2.1 Perceived family-supportive work culture and affective organizational commitment

Thompson et al. (2004) found that employees who perceive that their supervisors and organization are family-supportive are more committed affectively to their organization. According to Gibson and Tremble (2006), employees' affective organizational commitment is derived from their perceptions of the extent to which the employer is committed to and supportive of them. Assistance in balancing the demands of work and family life is a promising intervention for improving employee experiences and increasing retention in the organization. Haar and Spell (2004) examined the relationship between the perceived value of work-family practices among employees and their affective commitment and found a significant relationship. Similar findings were obtained by Muse et al. (2008). Thus empirical evidence seems to support the relationship between perceived family-supportive work culture and affective commitment, and the following hypothesis was tested.

H1: There is a positive relationship between perceived family-supportive work culture and affective commitment.

2.2 Perceived family-supportive work culture and turnover intention

Availability of organizational family support (family benefits and alternative schedules) and informal organizational support (work-family culture, supervisor support, and coworker support) have been suggested as a means to reduce employees turnover intention (Gaan, 2008). Previous research indicates that employees who perceive that their organization support them in integrating between work and family responsibilities will have less intention to leave the organization (Allen, 2001).

According Pasewark and Viator (2006), flexible work arrangement, which is part of the work-family support, seem to be effective in reducing turnover intention. Earlier, Thompson and Prottas (2005) investigated the relationships among informal organizational support (work–family culture, supervisor support, and coworker support) and turnover intention. They found that the informal organizational support was associated with reduced turnover intention. Recently, Yanadoria and Katob (2010) examined the effects of work-family support at the workplace in Japanese firms and found statistically significant associations between work-family support and female employee turnover in Japan. Previous research findings seem to support the relationship between work-family support at work place and turnover intention and the following hypothesis was tested.

H2: There is a negative correlation between family-supportive work culture and turnover intention

2.3 Affective commitment and turnover intention

Affective organizational commitment refers to employee's emotional attachment to, identification with, and involvement in the organization (Meyer and Allen, 1991). Lack of organizational affective commitment has detrimental effects including increase in turnover rate and turnover intention (Baotham et al., 2010). As evident by several studies, affective commitment is negatively correlated with employee turnover intention (Ali and Baloch, 2009; Addae and Parboteeah, 2008; Yeoh et al., 2010). In other words, employees who are more committed to their organizations are less likely to leave the organization. Since employees' affective commitment could be a predictor of turnover intention, the following hypothesis was tested:

H3: There is a negative correlation between affective commitment and turnover intention.

2.4 Affective commitment as a mediator in the relationship between family supportive work culture and turnover intention

Besides examining the magnitude of the perceived family-supportive work culture and turnover linkage, this present study also examined the mediating role played by affective commitment in this relationship. Based on the literature review as has been discussed earlier, perceived family-supportive work culture is related to affective commitment and the latter is also related to turnover intention. Drawing upon the social exchange theory (Blau, 1964) positive employee outcomes (e.g. organizational commitment and employee retention) could be achieved in response to benefits provided by organizations. Based on previous findings and the social exchange theory, the following hypothesis is formulated:

H4: Affective commitment mediates the relationship between perceived family-supportive work culture and turnover intention

3. Materials and methods

3.1 Sample

A total of 693 employees from 20 private service organizations in the Klang Valley, Malaysia, participated in this study. Only organizations with a minimum of 100 employees were included in this study since larger organizations are more likely to provide support in the form of family-friendly policies such as flexible work and child care arrangements than smaller organizations, while smaller organizations will adhere to basic requirements such as leave arrangement and medical coverage (Wood et al., 2003; Dulk et al., 2005). According to Poelmans et al. (2003), the provision of such support depends on several factors including organizational size. Forty employees from three categories, namely (1) managerial and executive, (2) supervisory and technical and (3) clerical and other support staff from each organization, 10 from the first category, 10 from the second category and 20 from the third category.

3.2 Measurement

3.2.1 Perceived Family-supportive work culture

Perceived family-supportive work culture was measured using 18 items from the work-family culture scale developed by Thompson et al. (1999). Three dimensions of work-family culture were measured, namely managerial support, career consequences and organizational time demand. For each support scale, items were measured on a 5-point Likert scale that ranged from (1) strongly disagree to (5) strongly agree; high scores represented more managerial support, career consequences and organizational time demand. Examples of items are: "The higher management in this organization encourages supervisors to be sensitive to employees' family and personal needs" and "In this organization, employees are encouraged to strike a balance between their work and family lives". The reliability coefficient of the scale was. 92.

3.2.2 Affective organizational commitment

Affective organizational commitment was measured using 8 items from Allen and Meyer (1990). The employees were requested to respond using five-point scaled response options ranging from strongly disagree (1) to strongly agree (5). Examples of items include "I feel a strong sense of belonging to my organization" and "I feel emotionally attached to this company". The reliability coefficient of the scale was .87.

3.2.3 Turnover intention

Turnover intention was measured using 6 items, two items were adopted from the instrument developed by Scott, Bishop and Chen (2003), three by Lee and Mowday (1987) and one from Seashore, Lawler, Mirvis, and Cammann (1983). The subjects of this study were requested to respond using five-point scaled response options ranging from very unlikely (1) to very likely (5). Examples of items are: "I often think of quitting my current job" and "I am actively looking for a job with another company". The reliability coefficient (alpha) of this scale was 0.92.

3.3 Statistical analysis

Descriptive statistics were calculated to describe the main characteristic of the respondents. Correlation coefficients were computed to examine the relationships among family-supportive work culture, affective commitment and turnover intention. A series of regression analyses was employed to test the hypotheses of the study. Baron and Kenny (1986) recommended the use of a series of regression models to test mediational hypotheses. First, regressing the mediator on the independent variable; second, regressing the dependent variable on the mediator; third, regressing the independent variables on the dependent variables and fourth, regressing the dependent variable on both the independent variable and the mediator. The following are the four conditions for establishing mediation: (1) The independent variable significantly affects the dependent variable; (2) The independent variable significantly affects the mediator; (3) The mediator significantly affects the dependent variable; (4) The effect of the independent variable on the dependent variable shrinks upon the addition of the mediator to the model. If the independent variable does not affect the dependent variable upon regressing the dependent variable on both the independent variable and the mediator, then full mediation is established. If otherwise, the test supports partial mediation.

4. Results

The respondents' age ranged from 18-57 years (M = 32.35, SD = 8.56). About two-fifths of respondent belonged to the 26-33 age group. There were about equal proportions of females (50.5%) and males (49.5%). Managerial and executive staff constituted 32.2% of the total respondents, supervisors and technical 16.2%, and clerical and other support staff 51.6% (Table 1).

The mean score for perceived family-supportive work culture was 3.25 (SD = 0.43), affective commitment 3.57 (SD = 0.70) and turnover intention 2.60 (SD = 0.82) (Table 2). Correlational analyses results revealed that perceived family-supportive work culture was positively related to affective commitment ($r = 0.31$, $p<0.01$) and negatively related to turnover intention ($r = -0.28$, $p<0.01$) (Table 2). Affective commitment was negatively related to turnover intention ($r = -0.49$, $p<0.01$) (Table 2). The results show that an increase in employees' scores of perceived family-supportive work culture leads to an increase in affective commitment and a decrease in turnover intention. An increase in affective commitment leads to a decrease in turnover intention. These results support H1, H2 and H3.

Table 1. Characteristics of respondents

Characteristics	Frequency	%	Mean	SD
Age (years) (n = 680)			32.35	8.56
≤25 years old	154	22.2		
26 - 33 years old	281	40.5		
34 - 41 years old	131	18.9		
42 - 49 years old	75	10.8		
≥ 55 years old	39	5.6		
Gender (n = 693)				
Male	343	49.5		
Female	350	50.5		
Job category (n = 684)				
Managerial and executive	220	32.2		
Supervisory and technical	111	16.2		
Clerical and other support staff	353	51.6		

Table 2. Means, standard deviations and intercorrelations of the variables

	Variable	1	2	3	Mean	SD
1	Turnover intention	1.00			2.60	0.82
2	Affective Commitment	-0.49**	1.00		3.57	0.70
3	Perceived family-supportive culture	-0.28**	0.31**	1.00	3.25	0.43

** <0.01

Table 3 presents the results of the regression analyses (N = 693) testing whether the relationship between perceived family-supportive work culture and turnover intention is mediated by affective commitment.

Step 1: Effect of perceived family-supportive work culture and turnover intention (Fig.1a) is statistically significant ($\beta=-0.28$, $p<.01$), satisfying step 1 of Baron and Kenny's method.

Step 2: Statistically significant effect of perceived family-supportive work culture on affective commitment ($\beta = 0.31$, $p<0.01$) (Fig. 1b), meets the stipulation of this step.

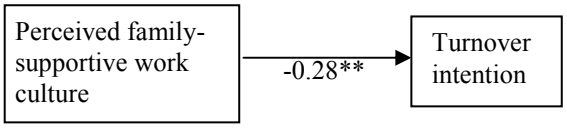
Step 3: The effect of affective commitment on turnover intention is statistically significant (β=-0.44, p<0.01). This relationship is independent of the association between perceived family-supportive work culture and turnover intention.

Step 4: The effect of perceived family-supportive work culture on turnover intention shrinks upon the addition of affective commitment (the mediator) to the model (bottom of Fig. 1b), (β=-0.15, p<0.01) and this is consistent with mediation. Since the perceived family-supportive work culture does affect the turnover intention upon regressing the turnover intention on both perceived family-supportive work culture and on affective commitment, then partial mediation is established. Hence, the results support H4.

Table 3. Regression Analysis

Step	Independent Variable	Dependent Variable	β	R2
1	Perceived family-supportive culture	Affective commitment	.31**	
2	Affective commitment	Turnover intention	-.49**	
3	Perceived family-supportive culture	Turnover intention	-.28**	
4	Perceived family-supportive culture Affective commitment	Turnover intention	-.15** -.44**	.26

(1a)



(1b)

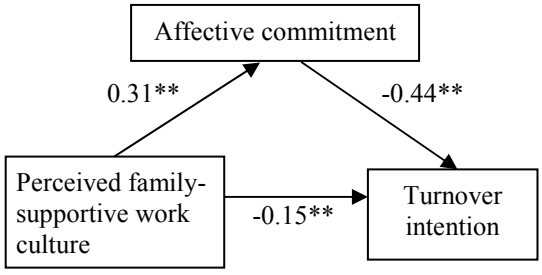


Figure 1.Regression analysis results.
(1a) portrays the simple model of perceived family-supportive work culture, affective commitment and turnover intention.
1(b) depicts the full model that includes affective commitment as the mediator.

Table 3 shows the results of regression analyses. The regression analysis between perceived family-supportive work culture and turnover intention has an R^2 of 0.08. Adding affective commitment to the model increases the value of R^2 to 0.26. Thus the change in R^2 associated with adding affective commitment is 0.18. The inclusion of affective commitment in the model accounts for an additional 18% of the variance in turnover intention.

5. Discussion

The findings that perceived family-supportive work culture is a significant and negative predictor of turnover intention have also been reported by Thompson and Prottas (2005) and the social support-commitment relationship has also been reported by other researchers (Gaan, 2008; Pasewark and Viator, 2006). The findings of this study show that employees who perceive that their organizations are supportive of their family needs are less likely to leave the organizations. With regard to perceived family-supportive work culture and its association with affective commitment, this study found that an increase in perceived support by managers or organizations led to an increase in affective commitment. These findings are consistent with the findings of Allen (2001) and Haar and Spell (2004). Similar findings have also been reported by O'Neill et al. (2009). In other words, employees who receive support to manage their work and family lives are more committed to their organizations and are more likely to stay in their organizations.

The significant relationship between affective commitment and turnover intention is consistent with the results reported by Baotham et al. (2010) whereby individuals with higher levels of affective commitment tended to report lower levels of intention to leave. Similar findings have been reported by Addae and Parboteeah (2008), Ali and Baloch (2009) and Yeoh et al. (2010).

With regard to the mediating effect of affective commitment in the relationship between perceived family-supportive work culture and turnover intention, the results show that employees with more positive perceptions of organizational support tend to experience higher levels of affective commitment and this would in turn decrease their levels of intention to leave the organization. Theoretically, the findings have shown that the social exchange theory (Blau, 1964) offer a theoretical guide to understanding the outcomes of perceived family–supportive work culture whereby positive employee outcomes (e.g. organizational commitment and employee retention) could be achieved in response to benefits provided by organizations.

The findings of this study have important implications for organizations. The findings demonstrate that employees' perception of organizations' family-supportive culture is an important factor that is related to employees' affective organizational commitment and turnover intention. Given that turnover is a serious problem since it involves costs due to termination, advertising, recruitment, selection, and hiring (Abbasi and Hollman, 2008), identifying factors that that could further explain turnover is an important attempt. Employers should also look into the possibility of developing family-friendly practices that are sensitive to employee family needs to assist employees in managing work and family roles such that employees will not be hesitant in associating themselves with such practices since employers will be perceived as supportive. With this supportive perception there is a greater tendency for employees to be more committed to the organization and an increased likelihood to remain in the organization.

The implication for future research is that, when exploring the influence of family-supportive work-life programs or practices on attitudes (e.g. commitment and turnover), it is meaningful to explore how employees view the work-life programs or practices besides examining the practices or the offering of programs. Simply offering work-life programs does not necessarily mean that employees find the organization supportive of their work-life needs (Thompson et al., 1999).

Several limitations of this study should be noted. First, a significant limitation of the present investigation is the sample size that was utilized. The results reported here may only be generalized to employees working in private service organizations located in Klang Valley, Malaysia. Caution must be exercised in generalizing the findings from this sample to employees in other organizations such as manufacturing organizations. There is also a need for future researchers to examine the work culture perceptions and its effects on employees' organizational commitment and turnover intention in other industries such as the manufacturing industry which is another important industry in Malaysia. Second, the inferences drawn from this study are limited by self-report data and cross-sectional characteristics of the data.

6. Conclusion

We could conclude that perception of family-supportive work culture is an important antecedent of turnover intention and affective commitment is a mediator in this supportive culture-turnover relationship. An employee who perceives that there exists family-supportive culture in an organization, characterized by high responsiveness to work-family issues, seems to be more likely to remain in the organization and have a greater sense of affective commitment to the organization.

Abstract: In the present study formulated synbiotic tarhana (Turkish fermented cereal food) was produced as a functional food from the fermentation of wheat flour, some spices [salt, pepper, dill and sweet marjoram (Organum majorana)], some vegetables [tomato (Lycoprsicum esculentum), pepper (Capsicum annum) and onion (Allium cepa)], and synbiotic yoghurt which prepared with prebiotic (inulin and lactose each 3%) and different concentrations of the probiotic culture (0.5, 1.5, 3, 4.5% DVS-ABT2 containing Streptococcus thermophilus, Lactobacillus acidophilus and Bifidobacterium bifidum). After fermentation (3 days), tarhana dough was dried in the sun. The effect of the fermentation (0, 1, 2 and 3 days) and the probiotic culture concentration on the chemical composition and the probiotic population of the wet tarhana were evaluated. The effect of the probiotic culture concentration on the chemical composition, the probiotic population and the sensory attribute of dried tarhana were evaluated. Also the effect of dried tarhana (prepared from yoghurt which was fermented by 4.5% probiotic culture) on the plasma lipid profile of human subjects was studied. The results showed that the pH value decreased while the acidity increased, acetaldehyde and diacetyl values increased during the fermentation period and by increasing the probiotic culture concentration of the wet and the dried tarhana. Neither the fermentation nor the concentration of the probiotic culture of wet and dried tarhana affected the crude protein, ether extract, crude fibre, and ash values. The numbers of probiotic bacteria increased until the second day of fermentation. However, in the following day, with an increase of the acid content their number decreased. Generally the increasing of the probiotic culture concentration increased the numbers of probiotic bacteria of the wet and dried tarhana. Also the concentration of the probiotic culture didn't affect the sensory attributes of dried tarhana. Subjects supplemented with dried tarhana showed significant reduction in total plasma cholesterol, low density lipoproteins (LDL-C) and triglycerides, while high density lipoprotein (HDL-C) increased.

Key words: Tarhana, functional food, fermented food, probiotic, synbiotic yoghurt, serum lipids.

1. Introduction

Fermentation as an old and economical method of producing and preserving food, it is carried out to enhance flavor, aroma, shelf-life, texture, nutritional value and other pleasant and appealing properties of foods (Steinkraus, 2002). It is possible to obtain probiotic foods from several matrices, including both fermented and non-fermented products (Rivera-Espinoza and Gallardo-Navarro 2010). Tarhana is a traditional fermented milk-cereal mixture containing lactic acid bacteria with probiotic properties. Tarhana has been considered as one of the oldest probiotic foods (Ozdemir *et al*. 2007).

Tarhana is a popular traditional Turkish fermented wheat food produced both commercially and in homes. It is mainly used in the form of a thick and creamy soup consumed at lunch or dinner and is easily digested (Bilgicli and Elgun 2005). Tarhana is prepared by mixing wheat flour, yoghurt, yeast and a variety of cooked vegetables and spices (tomatoes, onions, salt, mint, paprika) followed by fermentation for one to seven days (Daglioglu 2000). Lactic acid bacteria and the yeast are responsible for the acid formation during fermentation and the leavening effect. The dough at fermentation is called as wet tarhana. Afterwards, the dough is dried in the sun or by dryer as a lamp, nugget or thin layers to obtain dry tarhana. Also the tarhana is locally consumed as snack after being dried as thin layer or nugget, not to be ground. Since there is no standard production method, nutritional properties of tarhana strictly depend on ingredients and their ratios in the recipe (Erbas *et al*. 2006).

Tarhana is a good source of minerals, organic acids and free amino acids which make it healthy for children, the elderly and medical patients. In addition, it is a good source of vitamins such as

thiamine, riboflavin and vitamin B12 (Ibanoglu *et al*. 1995). Ascorbic acid, niacin, pantothenic and folic acid are also present (Ekinci, 2005, Ekinci and Kadakal 2005). Lacticacid bacteria (LAB) from yoghurt also aid in absorption of nutrients, which would otherwise, be indigestible or poorly digestible. (Farnworth, 2003).

Fermentation of tarhana dough is generally carried out using yoghurt bacteria, such as Lactobacillus bulgaricus, Streptococcus thermophilus and Baker's yeast (Saccharomyces cerevisiae) (Bilgicli and Ibanoglu 2007). This is similar to other natural systems (e.g. Kefir grains) in which associations of LAB and yeasts are used in food fermentation (Gobbetti 1998). The fermentations occur simultaneously during this aspect of production (Bilgicli et al. 2006). Yeast fermentation proceeds through the Embden-Meyerhof pathway (EMP), in which glucose is transformed into ethanol (via piruvate and acetaldehyde), carbon dioxide, and traces of other acids and carbonyl compounds (Gobbetti 1998, Gelinas and McKinnon 2000). According to Mugula et al. (2003) a combined culture of yeasts and lactobacilli cause a more significant decrease in pH (increase in acidity), than with the use of single cultures in the fermented millet.

The present study was initiated to produce synbiotic tarhana and evaluate it as a functional food. The effect of fermentation time (0, 1, 2 and 3 days) and starter concentrations (0.5, 1.5, 3 and 4.5%) on the chemical composition and the probiotic bacterial counts of wet tarhana were evaluated. Also the effect of starter concentrations (0.5, 1.5, 3 and 4.5%) on the sensory attributes, chemical composition and the probiotic bacterial counts of dried tarhana were evaluated. The hypocholesterolemic effect of dried tarhana on human subjects was studied.

2. Material and Methods

Tarhana ingredients: Vegetables [Tomato (Lycopersicum Esculentum), Green Pepper (Capsicum Annum), Chicory (Cicohorium Intybus) and Onion (Allium Cepa)], Cereals [Wheat (Triticum oestivum)], Spices [salt, pepper, dill and sweet marjoram (Origanum majorana)], Yeast (Saccharomyces cervisiae, press form) were purchased from the local market, Cairo, Egypt. Lactulose syrup (52.40% lactulose, 4.3% lactulose and 2.5 galactose) was obtained from the Egyptian International Industries Company (EIPICO), Cairo, Egypt and Spray dried skim milk (low heat) was obtained from Dina for Agriculture Investments, Egypt.

Probiotic Culture: DVS-ABT2 (containing Streptococcus thermophilus, Lactobacillus acidophilus and Bifidobacterium bifidum) were obtained from Chr. Hansen's Lab., Copenhagen Denmark. M17 agar, MRS-Salccin agar, violet red bile agar (VRBA), potato dextrose agar, and MRS agar. All media were purchased from Oxoid LTD, London.

Preparation of Chicory Water-Soluble Extract

Chicory Water-Soluble Extract was prepared according to the methods described by Kim and Shin (1998) as follows: 10g dried chicory plant was dissolved into 200 ml distillated water, soaked for 24 hours under refrigeration, heated at 70^{o}C for 15 min, then filtered. Chicory extract was then added to the synbiotic yoghurt.

Preparation of synbiotic yoghurt

Milk samples were standardized by adding skim milk powder to achieve 16% total solids content, pasteurized (15 min. at 85^{o}C) and cooled to 40^{o}C. Chicory extract and lactulose syrup (3% each) were individually added to milk samples, then inoculated with different concentrations (0.5, 1.5, 3, 4.5%) of the DVS-ABT2 culture, then milk was dispensed into pasteurized plastic cups (100 ml), capped, incubated (5 hours at 44^{o}C) cooled and stored in the refrigerator at 5^{o}C to prepare synbiotic tarhana.

Preparation of synbiotic tarhana

The ingredients of tarhana are presented in Table (1). Production method of tarhana is presented in fig. (1). All ingredients were prepared (cleaned, peeled and cut), then mixed, blended, pasteurized (30 min. at 65^{o}C) and cooled at 25^{o}C, whole flour, salt, synbiotic yoghurt (with different concentrations of the probiotic culture) and Baker's yeast were added to the mixture, then kneaded to form tarhana dough. The dough was fermented (3 days at 25^{o}C) in an incubator. The samples were withdrawn at time intervals (0, 1, 2 and 3 days) for chemical analysis and microbial analysis. Also tarhana samples (fermented for 3 days) were dried in the sun, filled in small packages and stored. The dried tarhana were subject to chemical, microbial and sensory evaluation and it was also used in human studies to evaluate its hypolipidemic effect.

Chemical analysis

pH value, total acidity, crude proteins, ether extract, crude fiber and ash were determined according to AOAC (2000). Acetaldehyde was estimated as described by Lees and Jaco (1969). Diacetyl was determined according to Lees and Jaco (1970).

Microbial analysis

Bifidobacterium bifidum was enumerated according to Dave and Shah (1969) using the modified MRS agar supplemented with 0.05% L. cysteine-HCl. The plates were anaerobically incubated at 37°C for 48 hours using anaerogen sheets.

Lactobacillus acidophilus count was estimated according to Dave and Shah (1969) on MRS-salccin agar. Incubation was carried out at 37°C for 48 hours.

Streptococcus thermophilus count was estimated according to Terzaghi and Sandine, (1975) using M17 agar. Incubation was carried out at 25°C for 48 hours.

Moulds were enumerated according to standard methods for examination of dairy products (APHA, 1994). Incubation was carried out at 25°C for 4 – 5 days.

Coliform group bacteria were enumerated according to standard methods for examination of dairy products (APHA, 1994) using violet red bile agar (VRBA). Incubation was carried out at 37°C for 48 hours.

Sensory evaluations

Synbiotic tarhana samples were organoleptically evaluated by 10 panelists from the staff members of food science and nutrition department of the National Research Center, Dokki, Cairo, Egypt. The panelists evaluated the samples using a five point Hedonic scale (5 = Liked Extremely to 1 = Unacceptable) adopted from (Iwe, 2000). All samples were evaluated for appearance, taste and general acceptability. The samples were filled in small white porcelain bowl (150 ml) and they were coded with numbers and served to the panelists at random.

Human experiment

Fifteen hyperlipidemic volunteers aged between 40 and 55 years old were studied, all were in good general health, with no history of cardiovascular or gallbladder disease, non of the volunteers were taking any medications. They were given their regular diet which was daily supplemented with 200g of synbiotic tarhana (prepared from yoghurt which was inoculated by 4.5% probiotic culture) for 45 days.

Blood sampling

Blood samples were collected from each volunteer, before supplementation and at the end of the experimental period, after overnight fasting and withdrawn through heparinized tubes for serum. The blood was allowed to clot at room temperature for one hour, and then the serum was separated by centrifugation at 3000 rpm for 15 minutes, clear serum was divided into aliquots and stored at 20°C until analyzed.

Biochemical analysis

Blood lipids were estimated according to the following methods, total cholesterol (Allain et al., 1974), total triglycerides (Fossati and Prencipe 1982), high density lipoproteins (Lopes-Virella et al., 1977), and low density lipoproteins (Friedewald et al., 1977).

3. Results

Evaluation of tarhana dough

Changes in some of the chemical components of tarhana dough samples [prepared with yoghurt and inoculated by different concentrations (0.5, 1.5, 3 and 4.5%) of the probiotic culture (DVS-ABT2)] were studied in relation to different fermentation time. Table 2 shows that for all tested tarhana dough samples, fermentation time had no effect on crude fiber, ether extract and ash. However, fermentation time had an effect on pH value and acidity of tarhana dough. The acidity content of all studied tarhana dough samples increased by increasing the fermentation time and consequently the pH values decreased until the end of fermentation course. Also increasing of probiotic culture concentrations from 0.5 to 4.5% decreased the pH values and increased the acidity content of the resultant tarhana dough samples. The pH value decreased from 5.47, 4.89, 4.62 and 4.57 to 4.89, 4.09, 4.08 and 3.92 while the acidity increased from 3.9, 5.0, 6.8 and 7.7 to 7.4, 9.7, 10.2 and 13.6 respectively during the fermentation time when a probiotic culture inoculation of 0.5, 1.5, 3 and 4.5% respectively was added.

Acetaldehyde and diacetyl contents of tarhana dough samples increased during fermentation. Also they increased with increasing of the probiotic culture concentrations in tarhana dough as shown in Figure 2 and 3. The effect on fermentation time on microbial counts of tarhana dough samples are presented in Table 3. Results indicate that the microbial counts numbers increased by increasing the fermentation time reaching the highest level at the second day of fermentation, then these decreases by increasing that period to record the lowest level at the end of fermentation (3 days). It was found that increasing the probiotic culture concentrations 0.5, 1.5, 3 and 4.5% (samples A, B, C and D) increased the numbers of probiotic bacteria as shown in Table 3. The highest population of probiotic bacteria from tarhana dough samples that contained 0.5, 1.5, 3 and 4.5% probiotic culture was recorded at the second day of fermentation being 8.5 x 10^7, 5.9 x

10^9. 9.7 x 10^{10} and 9.9 x 10^{10} (cfu/g) for *L. acidophilus*, 7.2 x 10^7, 6.4 x 10^9, 6.1 x 10^{10} and 7.6 x 10^9 (cfu/g) for *S. thermophilus* and 6.4 x 10^7, 8.6 x 10^8, 8.2 x 10^9 and 9.0 x 10^9 (cfu/g) for *B. bifidum*. Also, the results indicate that all tarhana dough samples were free from coliform and mold during the fermentation period, indicating no contamination occurred from the environment or the row materials.

Sensory characteristics (flavor, body and texture and appearance) of dried tarhana samples (A, B, C and D) prepared with different concentrations of probiotic culture (0.5, 1.5, 3 and 4.5%) were evaluated as shown in Table 4. The obtained results show that the sensory evaluation properties of dried tarhana had good scores and were acceptable for all the samples which contained different concentrations of probiotic culture.

Chemical composition of dried tarhana samples prepared by yoghurt inoculated with different concentrations of probiotic culture (0.5, 1.5, 3 and 4.5%) is presented in Table 5. Results indicate that all dried samples (A, B, C and D) had a protein content that ranged between (19.87-19.88%). All dried samples (A, B, C and D) had a fiber and ash content that ranged between (3.80-3.82%) and (9.93-9.95%) respectively. All dried samples (A, B, C and D) had an ether extract that ranged between (2.90-2.92%). Concerning pH value and acidity content of dried tarhana sample results Table 5 disclose that the acidity increased and pH value decreased by increasing the concentration of the probiotic culture. The highest acidity (13.4) and the lowest pH value (3.9) were recorded for dried tarhana sample D (containing 4.5% probiotic culture). Acetaldehyde and diacetyl contents of the dried tarhana are shown in figure 4. Acetaldehyde and diacetyl contents of the dried tarhana samples increased by increasing probiotic culture concentration. The highest content of Acetaldehyde (0.65 µmol/ml) and diacetyl (0.55 µmol/ml) were obtained for tarhana samples contained 4.5% probiotic culture, while the lowest contents were obtained for sample having 0.5% probiotic culture being 0.46 and 0.31 µmol/ml consecutively.

Effect of sun drying on microbial population of tarhana samples (A, B, C, and D) is shown in Table 6, data presented disclose that all dried tarhana samples recorded a sharp decrease in probiotic bacterial counts after drying compared to the corresponding values at the end of fermentation (day three) as shown in Table 3.

Hypolipidemic effect

Table 7 shows the changes in total cholesterol, total triglycerides, low and high density lipoprotein of the subjects that consumed dried synbiotic tarhana for 45 days (prepared from yoghurt which was inoculated by 4.5% probiotic culture). Results show a significant hypocholesterolemic effect where the mean of the serum cholesterol concentration was (222.0 ± 5.2) at the start of experiment then decreased to (202.6 ± 8.5) at the end of the experiment, triglyceride level showed a highly significant reduction from (179.8 ± 5.4) at the start of experiment to (169.0 ± 5.5) at the end of the experiment, high-density lipoprotein cholesterol was significantly raised from (50.1 ± 1.0) to (57.8 ± 0.9) at the end of the experiment. As for the low-density lipoprotein cholesterol there was no significant change with a value of (92.7 ± 0.7) at the start of experiment to (81.9 ± 0.5) at the end of the experiment.

Table 1: Synbiotic Tarhana Ingredients (% w/w)

4. Discussion:

In the present study, changes in some of the chemical components of tarhana dough samples were studied in relation to different fermentation time. Results show that for all tested tarhana dough samples, fermentation time had no effect on crude fiber, ether extract and ash. This is in the agreement with the results obtained by Erbas *et al*. (2005), who found out that fermentation had no significant effect on dry matter, crude protein, ether extract and ash.

Data obtained revealed that the acidity content of all studied tarhana dough samples increased by increasing the fermentation time and consequently the pH values decreased until the end of fermentation course. The increase in the acidity followed by a decrease in pH value may be due to the formation of organic acids from fermentation of sugars mostly by probiotic bacteria. Such findings coincide with those reported by Ibanoglu *et al*. (1995) and Erbas *et al*. (2005), who demonstrated that the acidity of tarhana dough increased and the pH decreased during fermentation.

Acetaldehyde and diacetyl are two important aromatic compound. Acetaldehyde and diacetyl contents of the tarhana dough samples increased with increasing of the probiotic culture concentrations in tarhana dough. Acetaldehyde content is attributed to probiotic bacteria (Erbas *et al*. 2005).

Results indicate that the microbial counts numbers increased by increasing the fermentation time reaching the highest level at the second day of fermentation, then it decreases by increasing that period to record the lowest level at the end of fermentation (3 days). These results are in accordance with those obtained by Daglioglu *et al*. (2002) using Turkish tarhana. The results of bacterial counts are close to those reported by Capela *et al*. (2006), who, reported that the viability of probiotic organisms in yoghurt that had been inoculated with 4% was more than in yoghurt that had been inoculated with 2% before and after fermentation. Ibanoglu *et al*. (1999) found that the increasing of yoghurt amount from 500g to 1000g in tarhana during the fermentation increased the population of probiotic bacteria of tarhana.

Sun drying is a slower but a more common and economical approach for traditional tarhana production. As for the drying process the critical moisture value is 13 – 15% for the inhibition of undesirable microbial growth in dry recipes produced from wheat flour (Bozkurt and gurbuz, 2008). The moisture content of tarhana is low, that it can be stored for 2 or 3 years without deterioration (Ibanoglu et al. 1999, Tarakc et al. 2004).

The results of the sensory analysis show that the use of yeast in the tarhana formula had a positive effect on the sensory properties. This shows that yoghurt bacteria and yeast together produce lactic acid, ethyl alcohol, carbon dioxide, and other fermentation products, which give tarhana its characteristic taste and flavour (Koca et al. 2002).

The protein content of the dried samples was higher than that obtained by Daglioglu (2000), Kose and Cagndi (2002) who reported that the crude protein content of dried tarhana were between 14.5 – 16 %. The latter author added that dried tarhana is a good source of protein. This can be explained by the differences in the tarhana formulas produced in different regions of Turkey.

The fiber and ash content in the present study were higher than that obtained by Daglioglu (2000), Erbas *et al*. (2006) who reported that the crude fiber and ash content of dried tarhana were 1% and 6.2%. The ether extract content was less than that obtained by Daglioglu (2000), Erbas *et al*. (2006) who reported that the ether extract content of dried tarhana was 5.4%. This can be explained by the

differences in the tarhana formulas produced in different regions of Turkey.

Drying treatments can slightly affect the increase in the pH and the decrease in acidity contents of the tarhana samples. The acetaldehyde and diacetyl contents of the dried tarhana may be due to the formation of aromatic components which is attributed to the presence of probiotic bacteria as reported by Erbas et al. (2005).

The sharp decrease in probiotic bacterial counts after drying coincide with the results reported by Daglioglu et al. (2002) who observed a sharp drop in L.A.B. population of tarhana samples after conventional drying. Also Erbas *et al*. (2005) attributed the decrease of L.A.B. population to the low water content of dried tarhana samples.

In the present study it was found that increasing the probiotic culture concentrations increased the number of probiotic bacteria of dried tarhana. These results are in agreement with those reported by Capela *et al*. (2006) who, disclosed that the viability of probiotic organisms in freeze-dried yoghurt was increased by increasing the inoculums volume from 2 to 4 %.

Hypolipidemic effect

The relationship between atherosclerotic cardiovascular disease and nutrition is very important. Many functional foods have been found to be potentially beneficial in the prevention and treatment of cardiovascular disease. (Anderson 2003).

The hypocholesterolemic effect of dried tarhana may be due to its content of probiotic bacteria and prebiotic inulin because it is soluble in water and not hydrolyzed by human digestive enzymes, it is expected to behave like a soluble fiber and to have a hypolipidemic effect (Kim and Shin 1998), wheat flour which as explained by Illman et al. 1993 lowers plasma cholesterol and increases cecal steroids relative to whole wheat flour, wheat bran and wheat pollard in rats. Also wheat is among cereals containing high concentrations of ß-glucan which is known to have a cholesterol lowering effect (Newman et al. 1989, Mc Intoch et al. 1991). Vegetables such as onion have hypocholesterolemic effect by inhibiting hepatic cholesterol biosynthesis (Gupta and Porter 2001, Singh and Porter, 2006) , Lycopene from tomatoe led to reduction of serum total cholesterol (Agarwal and Rao 1998) and green pepper which prevents arteriosclerosis and lower cholesterol (Mezzetti et al. 1995).

5. Conclusion

Fermentation process is an important stage for the development of sensory profile of tarhana. Fermentation and increasing probiotic culture concentrations decreased the pH values and increased acidity, acetaldehyde and diacetyl values while neither the fermentation nor the concentrations of the probiotic culture affected crude protein, ether extract, crude fibre and ash values of wet and dried tarhana.

The increasing of the probiotic culture concentration from 0.5 to 3% ensured probiotic bacteria population of wet and dried tarhana at satisfactory level while increasing the probiotic culture concentration from 3 to 4.5% slightly increased probiotic bacteria population. Generally drying process decreased the viability of probiotic bacteria as drying decreased the water activity. So it has a poor medium for pathogens and spoilage organisms.

Since tarhana is a good source of B vitamins, minerals, organic acids, and free amino acids, and since it is a product of L.A.B. and yeast fermentation, it may be considered a functional and probiotic food with hypolipidemic effect.

Response of Wheat to Different Rates and Ratios of Organic Residues on Yield and Chemical Composition under Two Types of Soil

Yassen, A.A*; Khaled, S.M and Sahar, M. Zaghloul

Plant nutrition Dept., National Research Centre, Dokki, Giza, Egypt.
*azimyassen@yahoo.com

Abstract: Two field experiments were conducted in two successive seasons (2007-2008 and 2008-2009) at Atta, Giza –Governorate and Nubaria region to study the effect of different rates and ratios of organic residues (Farmyard manure and filter mud) on yield and chemical composition of wheat under two types of soils (sandy and Calcareous soil). Results showed that, application of farmyard manure and filter mud residue gave a significant increase in grain and straw weight, total yield, crop index, harvest index, curd protein, N, P and K compared to the control treatment. Data also, indicated that significant increase grain, straw and total yield in sandy soil compared with calcareous soil under study in all treatments. On the other hand, the addition of organic materials (Farmyard manure and filter mud) were effective either individual or mixed with other. The pronounced increase in grain and straw weight, N, P and K content and uptake was noticed when farmyard manure was combined with filter mud at the rate of 2% compared with 1% of organic residues.

[Yassen, A.A; Khaled, S.M and Sahar, M. Zaghloul. Response of Wheat to Different Rates and Ratios of Organic Residues on Yield and Chemical Composition under Two Types of Soil. Journal of American Science 2010;6(12):858-864]. (ISSN: 1545-1003). http://www.americanscience.org.

Key words: wheat plant - organic residues –yield –N, P, K

1. Introduction:

Wheat is considered one of the most important and strategically crops in Egypt, but its area produced only about 30% of the domestic needs. There are several ways for increasing wheat production; one of them is the appropriate application of organic residues, especially in the newly reclaimed areas. Most of the newly reclaimed areas in the deserts of Egypt are sandy soils, which have certain problems in their cultivation. Sandy soils are very poor in their organic matter contents as well as their primitive fertility. On the other hand, organic materials such as crop residues, farmyard manure, industrial wastes (filter mud), etc., are available in abundance and reach tremendous amounts every day. Organic matter is a key component of the soil because it carries out many functions in agro-ecosystem. Organic manure is commonly applied to the soil to hence improve their physical, chemical and biological properties of many soils (Jimenez *et al.*, 2002 Nardi *et al.*, 2004, Weil and Magdoff, 2004 and Celik, *et al.*, 2004).

Fliessbach *et al.*, (2000) suggested that, organic manure application increased the transfer elements between the solid phase and soil solution in addition to higher microbial activity. They also, reported that organic soil management improved the soil structure by increasing soil aggregate, thus reducing the risk of soil erosion and promoted the development of the earth condition for plant. The activity of soil microorganisms was higher in the organic farming system, which helped the nutrient uptake to be faster.

Thind *et al.*, (2002) found that, significant increase in N uptake by maize and wheat was observed with continuous application of organic manures.

In wheat plant Sing *et al.*, (2002); Sushila and Gajendra (2002); Nehra and Hooda (2002); Thangavel and Prabakaran (2003); Tawfik and Gomaa(2005), and Zeidan *et al.*, (2005), found that farmyard manure application significantly enhanced the yield and N, P and K uptake of wheat. Sieling et *al.*, (2006) found that the former N treatments (pig slurry) enhanced grain yield and total N uptake of wheat compared with the former unfertilized control, Yaduvanshi and Sharma (2008), found that application farmyard manure with chemical amendment increased wheat yield and N, P and K uptake in grain yield.

Gong et al., (2009) and Enke Liu et al., (2010) indicated that, long-term additions of organic manure have the most beneficial effects on grain yield of wheat and maize.

In Egypt, a tremendous mass of filter mud as byproducts obtained from the clarification of cane juice in sugar industries. These waste residues present a problem for disposal; therefore, it was through useful to use residues as an organic source. Sugar can filter mud contain a considerable amount of plant

nutrients, mainly nitrogen (Arafat 1994). Sugar can filter mud is a good source of available N when applied to soil and its application cane reduce the amount of fertilizer nitrogen required for optimum crop yield and play a role in decreasing the pollution effect of excessive N mineral fertilizer in soil (Arafat *et al.,* 1997 and Yassen *et al.,* (2002).

The current investigation was carried out to study the effect of different sources and ratios of organic residues on yield and chemical composition of wheat under two types of soil.

2. Materials and methods

Two field experiments were conducted in two successive seasons (2007-2008 and 2008-2009) at Atta, Giza Governorate and Nubaria, Behaira Governorate to study the effect of different rates and ratios of organic residues on yield and chemical composition of wheat under two types of soil. Some soil physical and chemical characteristics of the studied soil are recorded in table (1).

The experimental design included 12 treatments which were as follows:

1- Control (without fertilizer)
2- NPK (recommended does 100: 50:50 kg /fed)
3 - FY (1 %)
4 - FY (2 %)
5 - FM (1 %)
6 - FM (2 %)
7- FY: FM (1%) 1: 1
8 - FY: FM (1%) 2: 1
9 - FY: FM (1%) 1: 2
10- FY: FM (2%) 1: 1
11 - FY: FM (2%) 2:
12 - FY: FM (2%) 1: 2

Table (1) some characteristics of soil under investigated

Characteristics	Sandy soil	Calcareous soil
pH 1.2.5	8.25	8.09
EC 1:5	0.15	3.99
CaCO3	1.73	18.43
Organic matter %	0.31	0.48
Available N ppm	33.0	24.0
Available P ppm	11.0	9.00
Available K ppm	4.00	2.00
Mechanical analysis		
Sand %	82.52	78.09
Silt %	10.68	3.49
Clay %	6.8	18.42

The design of each experiment was a complete randomized block system in three replicate. The area of the experimental plot was 10 m^2. The organic materials (Farmyard manure and filter mud) were thoroughly mixed with 0 – 30 cm of the surface soil layer before sowing, (Table2).

Table (2) some properties of farmyard manure (FY) and filter mud (FM)

characteristics	pH	EC dSm^{-1}	Organic matter %	Organic carbon %	Total (%)			Available micro.Nutrient (ppm)		
					N	P	K	Fe	Zn	Mn
Farmyard manure	7.97	2.6	66.68	38.76	1.78	0.31	0.89	412	138	281
filter mud	8.82	0.72	69.14	40.20	2.37	1.48	0.49	1854	121	253

Basal dose of 50 kg P_2O_5 fed^{-1} and 50 kg K_2O fed^{-1} in the form of Superphosphate (15.5%) and potassium sulphate (48% P_2O_5) was added before transplanting, the recommended does of nitrogen was 100 kg N/ fed.

Wheat seeds (Triticum *a estivum L,*) c.v Gemaza 9 were sown in the chosen soil on the last of November for both seasons. The grains were broadcasted on the soil at the rate of 60 kg/fed. At the maturity stage, the plants were harvested and separated into grains and straw. Production was recorded and prepared for analysis. Samples were digested with the acid mixture. Total nitrogen, phosphorus and potassium were determined according to the method described Cottonie et al., (1982).

Statistical analysis of all results was conducted using (NLSD) according to Gomez and Gomez (1984) and the combined analysis of the two seasons was calculated according to the method of Steel and Torrie (1980). The physical and chemical properties of the soil were determined according to Chapman and Pratt (1961)

3. Results and Discussion:

Effect of organic residue on wheat production

The data in table (3) represent that, the wheat production under different rates and ratios of organic

residues with the two types of soil of wheat. The addition of farmyard manure and filter mud residue within all tested rates resulted in a significant increase in grain, straw weight and total yield compared to the control treatment, and consequently, the biological yield of wheat plant. These results are in a good harmony with Yassen *et al.,* (2002) and Zeidan *et al.,* (2005), Yaduvanshi and Sharma (2008). They found that the addition of farmyard manure or/and filter mud had a beneficial effect on grain and straw of wheat plant.

Data also, indicated that application of filter mud decreased grain and straw yield compared to farmyard manure with the two types of soil. This phenomenon may be due to high C/N ratio of filter mud (Arafat *et al.,* 1997).

Concerning the effect of farmyard manure and filter mud, data showed that significant increase grain, straw and total yield in sandy soil compared with calcareous soil with all treatments. In the same time, data showed that, applying farmyard manure and filter mud as a soul at a rate of 2% were more effective in producing grain and straw than application farmyard manure and filter mud at a rate of 1% for both soil. It could be concluded that increasing organic matter to wheat plants induced more grain and straw yield. This may be due to the ability of organic manure to support the growth plants with micro and macro nutrients need for their growth. Similar Results were obtained by Barzegar *et al.,* (2002). Results also, indicated that application of the farmyard manure and filter mud ratio at (1: 1); (2: 1) and (1:2) in both rate at 1% and 2% improve grain, straw weight and biological yield compared with application farmyard manure and filter mud alone in both soil. Farmyard manure addition combined with filter mud may correct the final C/N ratio mixture in order to obtain a preferable condition for enhancing the mineralization of the organic N.

It was worthy to mention that data obtained FY: FM (1:2) had a beneficial and pronounced effect on yield production than other treatments. Data also, observed that application FY and FM increased crop index and harvest index compared the control under types of soil. It has been noticed that farmyard manure combined with filter mud at a ratio (1:1) were markedly increased in the crop index and harvest index in sandy soil while increased CI and HI at a ratio (2:1) in calcareous soil at rate 1%.

Table (3) effect of different rates and ratios of organic residue on grain and straw total yield of wheat plant under two types of soil (Average two seasons)

Chemical composition

The N concentration and uptake of nitrogen in wheat plant grown in sandy and calcareous soil treated with different rates and ratios of farmyard manure and filter mud are recorded in table (4). Data indicated that, all treatments tended to increase nitrogen concentration and uptake in grain and straw as compared with the control treatment. The increasing of N concentration and its uptake with organic matter application may be attributed to the mineralization of organic minerals and slow release of minerals in an available form, from organic manure and may be due to the effect of several organic acids, produced during manure decomposition. These results are in a good agreement with that obtained Zeidan *et al.,* (2005)

Sieling et *al.*, (2006) they stated applying farmyard manure to the soil increased content and uptake by grain and straw due to the beneficial effect of organic matter for improving the nutritional statue, particularly nitrogen.

It is interested to mention that, nitrogen concentration in grain and straw yield with respect to a ratio; rate and type of organic residue (FY and FM) were very clear. Taking the nitrogen uptake into consideration, data in the same table showed that, N uptake increased in sandy soil than calcareous soil. This increase seems to be due to the increase in dry matter formation.

With respect to the effect of farmyard manure and filter mud at different rates of 1% and 2 % and ratios (1:1), (2:1), and (1:2) combined with filter mud data declared that, applying the two sources with each other, gave the higher increase in total N content for both grain and straw compared to farmyard manure or filter mud applied alone. The same trend was observed in N uptake. The pronounced increase in N content and uptake was noticed when farmyard manure was combined with filter mud at a rate of 2%.

On the other hand, data in the same table indicated that, protein content increased when the two organic residues combined with each other as compared to farmyard manure or/ and filter mud alone, the highest value observed at 2%. These finding are harmony with those obtained by Eghbal et al.,(2004) and Mohammed (2004)

Data recorded in tables (5 and 6) illustrate that, effect of different organic residue farmyard manure either alone or in with mixed filter mud and different rates and ratios on phosphorus and potassium content and uptake, data showed the obvious increase for different as compare with control. Similar Suggestions was also reported by Barzegar *et al.*,(2002). In contrast, the addition of organic material was effective either individual or mixed with other.

Data indicated that, increased phosphorus and potassium concentration and uptake in grain and straw as compared with the control treatment. These results are in a good agreement that obtained by Nehra and Hooda (2002) and Thangavel and Prabakaran (2003)

Phosphorus and potassium content in wheat plant (grain and straw) increased in sandy soil as compared with calcareous soil, due to the differences in its physiochemical properties. Concerning P and K uptake data illustrated that, the uptake was higher in the sandy soil as compared to the calcareous soil for both P and K.

Data also, indicated that P and K content and uptake in both grain and straw increased continuously with increasing farmyard manure and filter mud rate applied from 1% and 2%. This indicates that, due to the increase in P and K farmyard manure and filter mud amended soil enhanced microbial activates, which increase nutrient availability and their uptake and increasing root distribution. These results are in a good agreement that obtained by Yaduvanshi and Sharma (2008)

Abstract: The present study was designed to investigate the radioprotective efficacy of naturally occurring antioxidants, L - carnitine (LC) and α -Lipoic acid (LA) on radiation-induced bone marrow and liver damages in a rat model. The cellular changes were estimated by evaluation the expression of antioxidant enzymes, superoxide dismutase (SOD) and glutathione peroxidase (GPx), genes using RT-PCR and DNA damage in bone marrow and liver cells. The histopathological and ultra structural changes were also determined. To evaluate the effects of the above antioxidants, adult rats were treated with LC (300 mg/kg b wt) and LA (150 mg/kg b wt) after exposure to whole-body γ-rays (6 Gy) for 10 days, or treated with LC & LA for 7 consecutive days and one hour after the last administration, animals irradiated a single dose of whole-body γ-rays (6 Gy) and received again LC & LA in same dose for 10 days. The obtained data revealed that γ –irradiation significantly decreases the expression of SOD and GPx genes and increases DNA fragmentation in liver cells as well as the incident of micronuclei in bone marrow cells. In addition, different histological and ultra structural alterations in the liver of irradiated animals were recorded. These alterations were varied from hemorrhage, congestion in blood vessels, pyknosis and necrosis as well as complete degenerated area in the liver electron micrographs recorded swollen mitochondria, fragmented endoplasmic reticulum, distorted nuclei and cell membrane. Treatment with LC & LA post-exposure to radiation attenuated most of these changes. Whereas pre- and post- treatment with LC & LA to γ-irradiation normalized the expression of the antioxidant genes enzymes, decreased the DNA fragmentation and micronuclei formation with a normal restoration of histopathologial and ultra structure liver architecture. Thus, our results suggested that pre-treatment with LC & LA offers protection against γ-irradiation induced cellular damage.

1. Introduction

Ionizing radiation (IR) is an important environmental risk factor for various cancers and also a major therapeutic agent for cancer treatment. Radiation toxicity occurs either by direct attack on the genetic material and/or by generating reactive oxygen species (ROS) by radiolysis of water. It also attenuates the endogenous antioxidant enzymes which are considered as first line defense mechanism to maintain redox balance and normal biochemical processes (Parihar *et al.,* 2007). Consequently, the organs become more susceptible to the deleterious effects of ROS that attack various cellular components including DNA, RNA, proteins and membrane lipids, thereby leading to significant cellular damage (Tominaga *et al.,* 2004).

The potential application of radioprotective chemicals in the event of planned exposures or radiation accidents/incidents has been investigated from the beginning of the nuclear era (Weiss and Simic, 1988). It has also been considered possible that radiation therapy for cancer patients could be improved by the use of radioprotectors to protect normal tissue. They include sulfhydryl compounds, antioxidants, plant extracts, immunomodulators, and other agents (Nair *et al.,* 2001).

α-Lipoic acid (LA), a naturally occurring sulphydryl compound found in virtually all plants and animal species that functions as a coenzyme in pyruvate dehydrogenase and α-ketoglutarate dehydrogenase mitochondrial reactions, leading to the production of cellular energy. In human body LA

is rapidly reduced to dihydrolipoic acid (DHLA) after intake into the cellular system (Packer *et al.,* 1995). Both, LA and DHLA are effective against conditions in which oxidative stress has a role (Packer *et al.,* 1999). LA, which is a universal antioxidant functions both in aqueous and membrane phases (Kagan *et al.,* 1992). LA has been shown to quench free radicals, prevent singlet oxygen-induced DNA damage, exhibit chelating activity, reduce lipid peroxidation and protein damage through the redox regeneration of other antioxidants such as vitamins C and E, and by increasing intracellular glutathione (Moini *et al.,* 2002; Biewenga *et al.,* 1997). It shows beneficial effects in oxidative stress conditions because of its synergistic action with other antioxidants (Suzuki *et al.,* 1993).

L-carnitine (LC) is a natural compound known as vitamin B_T (γ-trimethyl amino butyrate) widely distributed in the body. It is mainly required in the transport of activated fatty acids from the cytosol into the mitochondrial matrix for subsequent β-oxidation, and in the transfer of the products of peroxisomal β-oxidation to the mitochondria for utilization in energy generation process (Ramsay *et al.,* 2001; Santoro *et al.,* 2005). It has been shown that LC has a scavenger effect on ROS and a stabilizing effect on damaged cell membranes (Fritz and Arrigoni-Martelli, 1993). Carnitine can also act as a chelator by decreasing the concentration of cytosolic iron that plays a very important role in free radical chemistry (Reznick *et al.,* 1992). LC has a capacity to enhance non-enzymatic antioxidants, such as vitamin E (Arockia Rani and Panneerselvam, 2001).

Several studies demonstrated that both LA and LC protected intact tissues against injurious effects of cancer treatments such as radiotherapy or chemotherapy, without an inhibitory effect against their therapeutic effects (Chang *et al.,* 2002; Pisano *et al.,* 2003; Selvakumar *et al.,* 2006; Prahalathan *et al.,* 2006). Previous study has shown that the combined effect of both these drugs improves mitochondrial enzyme activities (Savitha and Panneerselvam, 2006). Muthuswamy *et al.* (2006) found that co-administration of L-carnitine and DL-α-lipoic acid mitigates ROS-induced oxidative damage to macromolecules such as lipids, proteins and DNA in brain of aged rat.

The aim of the present study was to investigate the radioprotective role of L-carnitine and α-Lipoic acid against γ-irradiation-induced liver and bone marrow damage in rat model.

2. Materials and methods

2.1. Source of chemicals

L-Carnitine and R-α-lipoic acid were a kind gift from EVA Pharma for pharmaceuticals and medical appliances, Egypt. All other chemicals used were of the highest analytical grade.

2.2. Irradiation

Whole-body Gamma - irradiation was performed at the National Centre for Radiation Research and Technology (NCRRT), Cairo, Egypt, using a Gamma Cell-40 biological irradiator. Animals were irradiated at an acute single dose level of 6 Gy delivered at a dose rate of 0.72 Gy/ min.

2.3. Animals

Female albino rats of Wistar strain weighing 150-200 g was obtained from the animals house Colony, National Research Centre, Dokki, Giza, Egypt. The animals were housed in large spacious cages and given food and water *ad libitum*. The animals were well ventilated with a 12-h light/dark cycle, throughout the experimental period.

2.4. Experimental design

A total of (50) rat was randomly divided into five groups (10 animals per group).

Group I: control group, animals were received normal saline (0.5 ml/150 g b wt.) for 10 consecutive days.

Group II: LC&LA group, animals were received LC & LA for 10 consecutive days.

Group III: IR group, rats received the same dose of normal saline as the first group and on day seven, animals were irradiated with a single dose of whole-body γ-rays (6 Gy) and left for 10 days.

Group IV: IR + (LC&LA) group, animals were irradiated with a single dose of whole-body γ-rays then after one hour they administered LC & LA for 10 days.

Group V: (LC&LA) + IR group, animals received LC & LA for 7 consecutive days, then after one hour of the last administration, animals irradiated a single dose of whole-body γ-rays (6 Gy) and received again LC & LA in same dose for 10 days.

L-Carnitine (300 mg/ (kg b wt) day) (Kumaran *et al.,* 2005) was dissolved in 0.89% physiological saline and R -α- lipoic acid (150 mg/ (kg b wt) day)

(Savitha *et al.,* 2005) was dissolved in 0.5% of KOH in physiological saline and administered orally. Animals were killed by cervical decapitation and a part of liver was immediately frozen and stored at - 80°C for RNA extraction and DNA fragmentation analysis. Other part of liver was collected for the histopathological and ultra structural examination.

2.5. Molecular genetics assays

2.5.1. RNA isolation and Reverse transcription (RT)

Total RNA was isolated from liver tissues using Trizol reagent (Invitrogen, Paisley, UK). RNA samples were subjected to DNase1 treatment to remove genomic DNA contamination in the presence of RNase inhibitor. The purity and integrity of the total RNA was determined by spectrophotometry and agarose gel electrophoresis (Sambrook *et al.,* 1989). The first-strand cDNA was prepared from the 5 µg of total RNA using Fermentas kits (Sigma, St. Louis, MO) as per the manufacturer's instructions. The RT-program used was: 60 min at 42^{0}C (cDNA synthesis); 5 min at 94^{0}C (denaturation). Afterwards the reaction tubes containing RT preparations were ash-cooled in an ice chamber until used for DNA amplification through polymerase chain reaction (PCR) (Brun *et al.,* 2006).

2.5.2. Polymerase chain reaction (PCR)

The first-strand cDNA from different rat samples was used as the template for amplification by the PCR with the following pairs of specific primers (from5′to3′):

Cu-ZnSOD forward: GCAGAAGGCAAGCGGTGAAC,
Cu-ZnSOD reverse: TAGCAGGACAGCAGATGAGT,
GPx forward: CTCTCCGCGGTGGCACAGT,
GPx reverse: CCACCACCGGGTCGGACATAC,

that are taken from the literature (Limaye *et al.,* 2003). β-actin, a house-keeping gene, was used for normalizing mRNA levels of the target genes. The PCR cycling parameters were one cycle of 94 ^{0}C for 5min, 35 cycles of 94 ^{0}C for 30 s, 60 ^{0}C (Cu-Zn SOD and GPx gene) for 30 s, 70 ^{0}C for 40 s, and 72 ^{0}C for 5 min. The PCR products were electrophoresed onto ethidium bromide stained a 2.0% agarose gels. The ethidium bromide-stained gel bands were scanned and the signal intensities were quantified by the computerized Gel-Pro program.

2.6. Quantification of fragmented DNA by diphenylamine (DPA)

To measure hepatic DNA fragmentation by spectrophotometry, a portion of the liver was homogenized in hypotonic lysis buffer (0.2% Triton X-100, 10 mM Tris, 1 mM EDTA, pH 8.0) and centrifuged for 15 min at 10,000 rpm to separate intact chromatin in the pellet from fragmented/damaged DNA in the supernatant. Pellets were resuspended in 0.5 N perchloric acid and 5.5 N perchloric acid was added to supernatant fractions to final concentration of 0.5 N. Samples were heated at 90 ^{0}C for 15 min and centrifuged at 10,000 rpm for 10 min to remove proteins. Supernatant fractions were reacted with diphenylamine (DPA) reagent [0.088 M DPA, 98% (v/v) glacial acetic acid, 1.5% (v/v) conc. H_2SO_4 and 0.5% of 1.6% acetaldehyde solution] and the samples were kept at room temperature for 20 h Paradones *et al.* (1993). Absorbance was measured at 600 nm using a UV-double beam spectrophotometer (Shimadzu 160A).The percentage of DNA fragmentation was taken as the ratio of DNA in the supernatant to total amount of DNA in pellet and supernatant.

2.7. Agarose gel electrophoresis for DNA fragmentation

Agarose gel electrophoresis was carried out for the analysis of DNA fragmentation by the method of Yokozawa and Dong (2001). The DNA samples (1 µg) were electrophoresed on 1.4% agarose gel using TBE buffer at 40 V for 5 h. Then the gel was stained with ethidium bromide and viewed under UV transilluminator and photographed.

2.8. Micronucleus assay

Immediately after the animals were sacrificed, bone marrow was collected from each animal for the micronucleus assay as described by Schmid (1975). In brief, the femurs were dissected and washed with 1ml of fetal calf serum, smeared on clean and dry slide, fixed with absolute methanol for 10 min and stained with 5% (v/v) Giemsa stain diluted in phosphate buffer. One thousand polychromatic erythrocytes (PCEs) were analyzed per animal to ascertain the frequency of micronuclei and the micronucleated cells in the bone marrow of each rat in the different treatment groups. The ratio of PCEs to normochromatic erythrocyte (NCEs) was calculated for the determination of the cytotoxicity in bone marrow.

2.9. Histopathological study

After animals dissections, liver were removed immediately and fixed in 10% normal saline and neutral buffered formalin for 7 days, then the tissues were washed and dehydrated in ascending grades of ethyl alcohol cleared in benzene and impregnated in paraffin for 1.5 h in the oven at 55^{0}C. Serial section, 5 µm were cut and stained with

Haematoxylin & Eosin (H&E) as described by Bancrofet and Stevens (1977).

2.10. Electron Microscopic Study

For electron microscopic examination, portion of liver were cut into small pieces, fixed in 2.5% glutaraldehyde in 0.1 M cacodylate buffer (pH 7.3) and post in 1% osmium tetroxide in 0.3 M cacodylate buffer. The specimens were then dehydrated and embedded in Epson 812 (Hayat, 1973). Ultrathin sections were cut and stained according to Reynold (1963). Sections were examined with Joel 100.cx a transmission electron microscope at NCRRT.

2.11. Statistical analysis

Data were analyzed using One-way analysis of variance (ANOVA) using the SPSS 11 program, followed by Post-Hoc test for multiple comparisons. The data were expressed as means ± standard error of the mean. Differences were considered significant at $P<0.05$.

3. Results

3.1. Evaluation of gene expression

Bands produced from amplifying cDNA of GPx, SOD and the house keeping gene β-actin as a control were analyzed and the results of gene expression was based on quantifying the signal intensities in each band. Results were expressed as the ratio between maximum optical density (max OD) for each band of the target amplification product and the corresponding max OD of β-actin. Expression of GPx and SOD mRNA in liver of the different groups of rats are summarized in Figs. (1 and 2). The results show that there was a significant decrease in the expression level of the examined genes in the γ-irradiated group of rats as compared to the other groups. However, treatment with LC & LA resulted in a significant increase in the expression level of GPx and SOD mRNA ($P < 0.05$) versus the control group. As well as treatment of LC & LA prior to γ-irradiation exposure significantly ($P < 0.05$) up-regulated the expression of both genes. Moreover, pre- and post- treatment with LC & LA to γ-irradiation normalized the expression levels of these genes relative to the control level.

3.2. Analysis of DNA Fragmentation

Results of DNA fragmentation are shown in Table (1). γ-irradiated animals produced 33.01 % fragmented DNA in hepatic tissue, whereas control group shows a negligible 6.5 % fragmented DNA, which are associated significantly ($P < 0.05$). Supplementation with LC & LA significantly brought down the levels of DNA damage that reached 22.41 % for post – treated group, and 13.33% in pre- and post-treated group. In addition, the pattern of DNA fragmentation elicited by γ-irradiation showed the characteristic DNA ladder which is significantly restored in the groups treated with LC & LA (Fig.3).

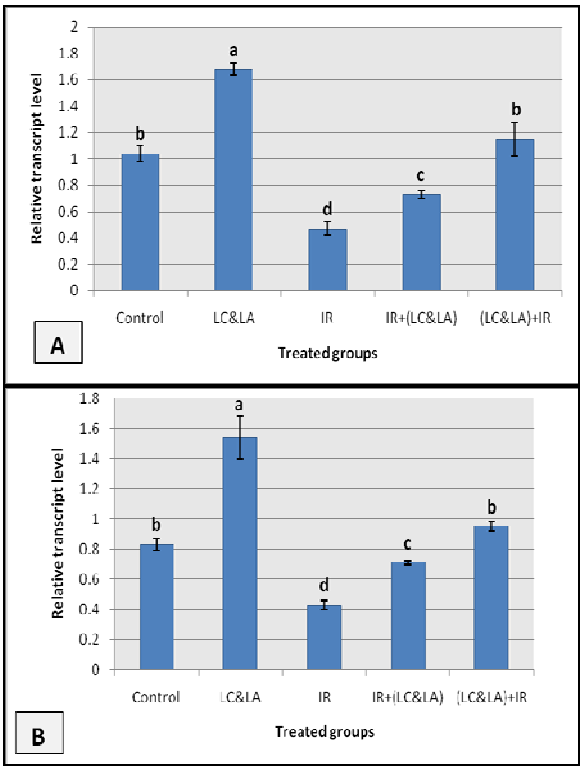

Fig. 1. RNA expression of SOD (A) and GPx (B), in the liver of control and treated rats. The results depicted are normalized to levels of β-actin gene. Data are mean ± S.E. of ratios of intensity for each gene divided by that for β-actin.

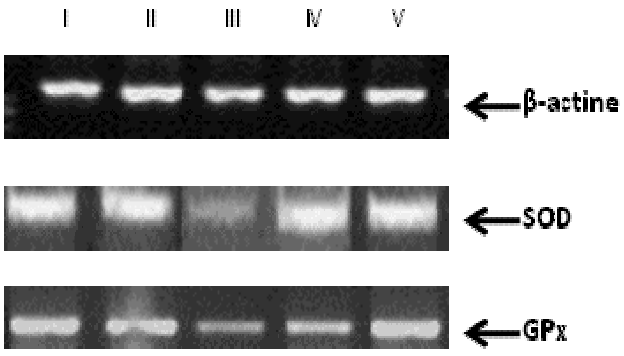

Fig.2. Effects of LC & LA on transcript product of hepatic antioxidant genes in γ-irradiated rats. Agarose gel electrophoresis of SOD, GPx and β-actin RT-PCR products of different groups. Group I: Control, Group II: LC&LA, Group III: IR, Group IV: IR + (LC&LA) and Group V: (LC&LA) + IR.

Table 1. Effects of LC & LA on the percentage of DNA fragmentation in liver of rats exposed to γ- irradiation.

Treated Groups	Percent DNA fragmentation Mean ±S.E.	Change %
Control	6.5±0.64[d]	-
LC&LA	6.0±0.40[d]	0.5
IR	33.01±3.04[a]	26.5
IR+(LC&LA)	22.41±2.22[b]	15.91
(LC&LA)+IR	13.33±1.30[c]	6.83

Within each column, means superscript with different letter are significantly different (*P< 0.05*).

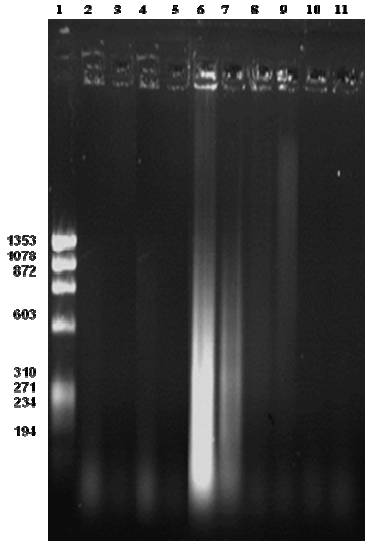

Fig.3. Agarose gel electrophoretic pattern of DNA isolated from liver tissue of control and treated rats. Lane 1: phi x marker; Lane 2-3: control group; Lane 4-5: LC&LA group; Lane 6-7: IR group; Lane 8-9: IR + (LC&LA) group; Lane 10-11: (LC&LA) + IR group.

3.3. Effects of LC and LA on γ-irradiation–induced micronuclei formation

The cytogenetic damage induced by γ-irradiation as well as the antimutagenic effects of treatment with LC and LA were investigated in bone marrow of female rats utilizing micronucleus assay. Table (2) showed that the frequencies of micronucleated polychromatic erythrocytes (Mn-PCEs) as resulted from administration of LC & LA was within the accepted spontaneous range for control. Exposure to γ-irradiation induced a significant increase in the frequencies of Mn-PCEs (26.6 ± 1.44) as compared to the control group (4.2 ± 0.58). Pre - and post- treatments with LC & LA to γ-irradiation was found to decrease the Mn-PCEs (7.0 ± 0.45) significantly when compared to the post – treated group (12.4 ± 0.81). Moreover, the inhibition percentages reached (63.4%) in post-treated group meanwhile, a maximum inhibition (87.5%) was shown in pre- and post- treated group (Fig. 4 A and B). In spite of this reduction, the frequencies of Mn-PCEs were significantly higher than the control group. Our results clearly indicated that animals exposed to γ-irradiation showed severe bone marrow cytoxicity as indicated by the reduction in PCEs percentage and the PCEs/NCEs ratio as compared to the control group. The treatment with LC & LA resulted in an increase in PCEs percentage and the PCEs/NCEs ratio when compared with γ-irradiated rats.

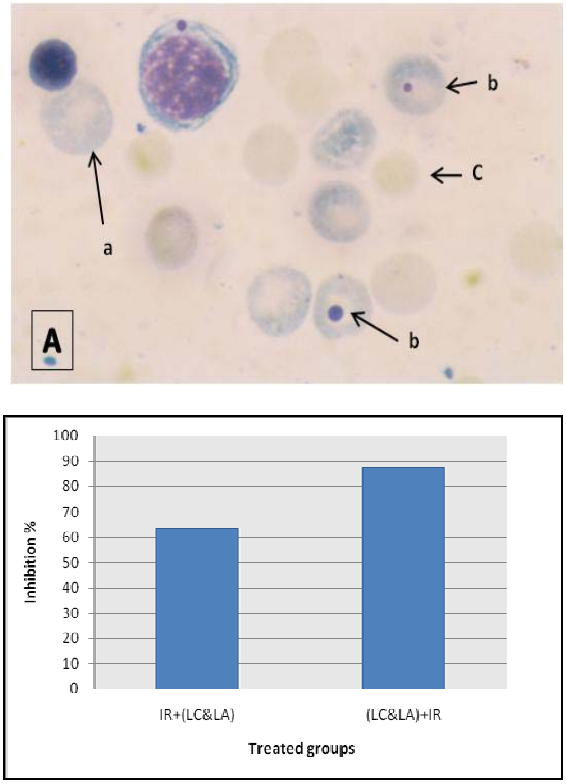

Fig.4. (A) Showing (a) polychromatic erythrocyte (PCE), (b) micronucleated polychromatic erythrocyte (Mn- PCE), and (c) normo chromatic erythrocyte (NCE). **(B)** Histogram showing inhibition of micronuclei incidence – induced by γ-irradiated by LC&LA.

Table 2. Effects of LC&LA on the frequency of Mn-PCEs and PCEs in the bone marrow of rats exposed to γ- irradiation.

Treated Groups	No of Mn-PCEs/5000PCEs (Mean ± S.E.)	PCEs %	NCEs %	PCEs/NCEs ratio (Mean ± S.E.)
Control	21 4.2 ± 0.58^{d}	51	49.0	1.04 ± 0.05^{b}
LC&LA	11 2.20 ± 0.37^{e}	59.8	40.2	1.49 ± 0.08^{a}
IR	133 26.6 ± 1.44^{a}	39.6	60.4	0.65 ± 0.03^{e}
IR+(LC&LA)	62 12.4 ± 0.81^{b}	45.6	54.4	0.84 ± 0.02^{d}
(LC&LA)+IR	35 7.0 ± 0.45^{c}	48.8	51.6	0.94 ± 0.02^{C}

Within each column, means superscript with different letter are significantly different ($P< 0.05$).

3.4. Histopathological evaluation

Examination of H & E stained liver sections obtained from control rats showed a normal lobular architecture with central veins and radiating hepatic cords are separated by narrow blood sinusoids lined with two types of cells, endothelial (with thin, small, rod-like nucleus) and van-kupffer cells (containing oval dense nuclei), the hepatocytes are large spherical cells with spherical nuclei and prominent deeply stained nucleoli (Fig.5 A). The liver sections of rats treated with LC and LP illustrating the hepatic architecture shows no abnormalities. The hepatocytes reveal the same appearance as the normal ones. Also, the hepatic, sinusoids and kupffer cells show no abnormalities (Fig.5 B). However, liver sections of γ-irradiated rats showed radiolesions in the form of dilatation and congestion in blood vessels and appearance of inflammatory cells. The hepatocytes showed vacuolated cytoplasm, dilated sinusoidal spaces, large number of binucleated hepatocytes cells and necrotic cells along with many pyknotic nuclei (Fig. 5 C, D and E). In Fig. (5 F, G and H) liver of rat in group post- treated with LC&LA showed hepatocytes were found in focal hepatic hemorrhage and binucleated hepatocytes wider sinusoidal space, vacuolar degeneration of some hepatocytes, dilated blood vessel were noticed. Nevertheless, other hepatocytes were abnormal with either pyknotic or karyolitic nuclei with noticeable increase of endothelial and of kupffer cells within the tissue. Whereas photomicrograph of liver in pre- and post-treated with LC&LA to γ-irradiation showed lesser damage when compare to post-treated one. Liver sections of these rats almost have normal hepatic architecture as well as mild cytoplasmic vacuolation, binucleated cells were evident in photomicrograph, hemorrhage disappeared, slight dilated blood vessels and dilated blood sinusoids were noticed (Fig. 5 I).

3.5. Ultra structural evaluation

The ultra structural of a normal hepatocyte obtained from control and LC&LA is presented in Fig. (6 A and B). Electron micrographs showed large rounded euchromatic nuclei with prominent nucleoli. The cellular organelles were uniformly distributed throughout the cytoplasm, where numerous mitochondria, cisternae of rough endoplasmic reticulum and electron dense cytoplasm. Electron micrographs showed ultra structural changes in different hepatocyte components after exposure to γ-irradiated revealed focal degeneration of cytoplasmic matrix accompanied by ill defined cytoplasmic organelles, degeneration hepatocytes with lysis cytoplasm matrix, degeneration nuclei with wrinkled nuclear membrane (Fig. 6 C and E). Swelling mitochondria with rupture of its cristae. Also, fragmentation of the rough endoplasmic reticulum (Fig. 6 D). In addition, the blood sinusoids exhibited prominent dilatation with abnormal lymphocytes and also contain numerous R. B. Cs. (Fig. 6 C, E and F). Also, dilated bile canal with abnormal microvillus (Fig. 6 F). Mitosis of the nuclei appears in Fig. (6 A).

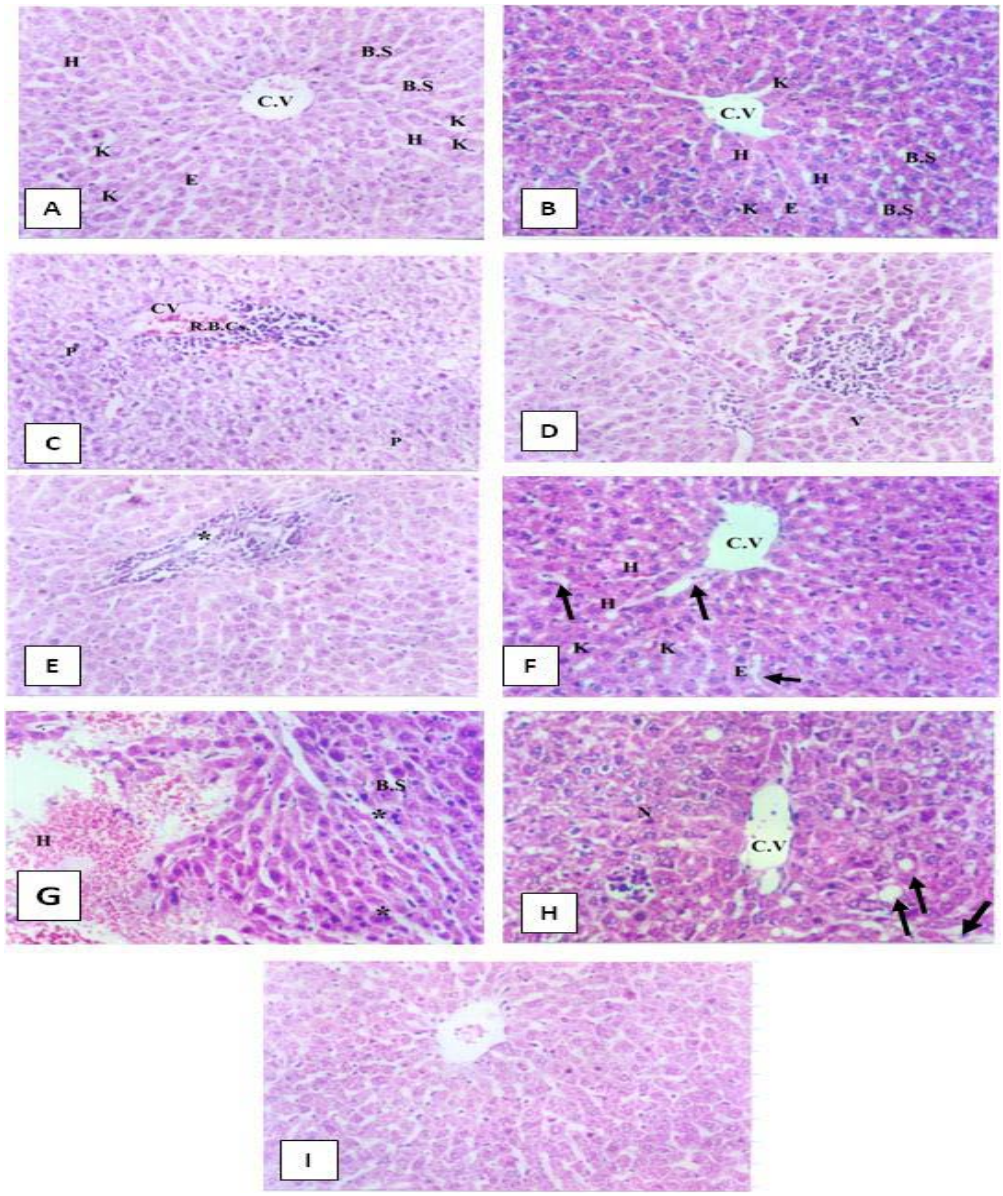

Fig. 5. (A) (Group I-control) Showing normal histological structure of rat liver; hepatocytes (H.), central vein (CV), blood sinusoid (BS), endothelial cell (E) and Kupffer cell (K). **(B) (GroupII-LC&LA)** Showing normal architecture of hepatic cells; the hepatocytes (H). The blood sinusoids (BS) are lined by a layer of endothelial cells (E) as well as Kupffer cell (K). **(C) (GroupIII-IR)** Showing central vein (CV) appears congested with blood cells (RBCs), the central vein (CV); is located at the center of the hepatic lobules. phyknosis in the hepatocytes nuclei (P) and vacuolated hepatocytes cytoplasm, cellular edema and binucleated hepatocytes, necrotic cells portal infiltration with leucocytes. **(D) (GroupIII-IR)** Showing focal area of hepatic necrosis associated with leucocytic cells infiltration and vacuolated hepatocytes cytoplasm (V) binucleated hepatocytes, dilated sinusoidal spaces. **(E) (GroupIII-IR)** Showing portal infiltration with leucocyte (*) **(F) (Group IV- IR+(LC&LA))** Showing dilated blood sinusoids (thick arrow), dilated central vein (CV) normal arrangement of the hepatic cords with invasion of endothelial cells (E) and kupffer cells (K)and haemorrhage (H). **(G) (Group IV- IR+(LC&LA))** Showing focal hepatic hemorrhage (H) and binucleated hepatocytes (*) wider sinusoidal space (B.S). **(H) (Group IV-IR+(LC&LA))** Showing vacuolar degeneration (arrow) of some hepatocytes, dilated central vein (CV), dilated blood sinusoids (thick arrows) and necrosis (N). **(I) (Group V-(LC&LA)+IR)** Showing the arranged hepatic architecture, dissociation of giant hepatocytes with parenchymatous islands. (H & E stain, X -200).

However, electron micrograph of liver from post–treated group revealed that LC & LA minimized most the injuries noticed in the hepatocytes of those rats exposed to γ-irradiated. Improvement in the nucleus and its nuclear membrane and chromatin, normal mitochondria, regeneration in the endoplasmic reticulum mean while, mild irregularity in nuclear membrane and fragmented endoplasmic reticulum were still found in different hepatocytes (Fig. 7 A, B and C). Ultra structurally, the hepatocyte sections of pre- and post-treated group (Figs. 7 D, E, F and G) revealed normal appearance of the liver cell membrane. The hepatocytes showing complete regeneration in the nucleus, nuclear membrane regular appear. Regeneration in the endoplasmic reticulum, the bile canal demonstrated in normal shape normal mitochondria in between rough endoplasmic reticulum.

4. Discussion

The deleterious effects of ionizing radiation in the biological systems are mainly mediated through the generation of ROS, a process called oxidative stress, in a variety of cells as a result of water radiolysis (Kamat *et al.,* 2000). To control the flux of ROS, aerobic cells have developed their own defense system, the antioxidant system, which includes the superoxide dismutase (SOD), the first line of defense against oxygen-derived free radicals, catalysis the dismutation of superoxide anion into H_2O_2. Glutathione peroxidase (GPx) reduces lipidic or nonlipidic hydroperoxides as well as H_2O_2 (Taysi *et al.,* 2002). Antioxidant enzymes are regulated by multiple factors. The oxidative status of the cell is the primary factor regulating gene expression and activity of these enzymes (Rodriguez *et al.,* 2004). Both, endogenous (Nicotera *et al.,* 1989) and exogenous (Yoo *et al.,* 1999) agents act as oxidants and alter cellular oxidative equilibrium and, consequently, antioxidant enzyme gene expression.

In the present study, the expression of GPx and SOD was down-regulatated at the liver of γ-irradiated animals. It is reported that translocation of redox-sensitive transcription factors into the nucleus is influenced by oxidative stress (Sen and Packer, 1996). Besides, elevation of oxidative stress is known to cause destabilization of mRNAs (Mayo *et al.,* 2002). Therefore, the reduction in the mRNA of SOD and GPx in γ-irradiated rats could be either due to the oxidation of transcription factors or due to the decrease in the half lives of mRNAs. In agreement with our results, Mansour *et al.* (2008) recorded a significant decrease in the activities of SOD and GPx in hepatic tissues after whole body γ-irradiation. Ushakova *et al.* (1999) reported that radiation inhibited the expression of SOD gene in splenocytes from control mice.

The down-regulated mRNA of the hepatic GPx and SOD in γ-irradiated rats is alleviated by antioxidant treatments, suggesting the transcriptional control by LC & LA. In additions pre- and post-treatments with LC & LA significantly increased the levels of mRNA expression of hepatic antioxidant enzymes in irradiated rats than the post-treated group. These results are in agreement with that found by Miguel-Carrasco *et al.* (2010) who reported that L-carnitine treatment was able to reverse the down-regulation of cardiac GPx and SOD mRNA expression observed in hypertensive rats, increasing values to the levels observed in control, normotensive animals. Mansour (2006) reported that LC could increase the endogenous antioxidant defense mechanism in rats and thereby protect the animals from radiation-induced organ toxicity. Kocer *et al.* (2007) found that LC protected the lenses of rats against the damage produced by γ- irradiation by increasing the activity of the SOD enzyme and by scavenging free radicals generated by ionizing radiation. In another study, Davis *et al.* (2009) found that LA treatment restored antioxidant levels, reduced cell injury and protected cells against irradiation-induced cytotoxicity. Yang *et al.* (2008) determined that LA ingestion up-regulated the expression of genes related to free-radical scavenger enzymes of mice fed with high fat diet. LA also enhances the decrease of SOD activity and this may be related to its direct scavenger effect (Sundaram *et al*., 2006).

Numerous studies have demonstrated that exposure of mammalian cells to ionizing radiation induces several types of damage to DNA when the capacity of enzymatic and nonenzymatic antioxidant system is inadequate (Ames *et al.,* 1993). They induce a variety of lesions in DNA, including double and single-strand breaks, base and sugar damage, as well as DNA–DNA and DNA–protein cross-links (Barker *et al.,* 2005). Our results clearly showed that γ-irradiation, induces DNA damage in rat liver that was detected by the elevation the percentage of DNA fragmentation and the visualization of DNA ladders upon gel electrophoresis in treated animals. In addition, an increase of micronuclei in bone marrow cells was demonstrated in γ-irradiated rat. The induction of micronuclei was accompanied by cytotoxicity that evidenced through the significant reduction in the number of PCE/1000 cells. This reduction could be a consequence of a direct cytotoxicity or due to the micronuclei formation itself or to heavy DNA damages leading to cell death or apoptosis (Zorgui *et al.,* 2009). An increase in the DNA damage after γ-irradiation has been observed in different studies (Hosseinimehr *et al.,* 2003; Mansour *et al.,* 2008). It has long been known that the damaging effects of ionizing radiation on cellular DNA are brought about by both direct and indirect mechanisms. Direct action produces disruption of chemical bonds in the molecular structure of DNA, while indirect effects result from highly reactive free radicals such as •OH and •H produced during the radiolysis of water, and their subsequent interaction with cellular DNA (Pons and Sullivan, 1994).

Treatment with LC & LA in combination with γ-irradiation was markedly efficient and significantly inhibited the micronucleated PCE in bone marrow cells that reached 63.4% in post-treated and 87.5% in pre- and post- treated groups. Moreover, LC & LA treatment decreases the percentage of DNA fragmentation induced in liver cells as evidenced by the reduction of DNA fragments in agarose gel electrophoresis. The

observed protective effect of LC & LA maybe due to the direct protection against DNA damage by scavenging free radicals generated by ionizing radiation before they induce damage to the genetic material, i.e. the extent of primary damage in cellular DNA may be significantly reduced (Sundaram *et al.,* 2006; Kocer *et al.,* 2007). Secondly, LC & LA may indirectly alter the final level of DNA damage by enhancing the activity of DNA repairing enzyme, poly (ADP-ribosyl) polymerase, a nuclear protein that is intimately linked with the occurrence of DNA strand breaks and also other related repair mechanisms (Boerighter *et al.,* 1993; Szabodos *et al.,* 1999), so that the damage DNA is repaired more rapidly in irradiated cells pre-treated with LC & LA. Other studies have also observed that the LC & LA maintains thiol-containing compound and improves the glutathione redox status, which could protect DNA repairing enzymes, thereby preventing DNA strand break (Savitha and Panneerselvam, 2006). LC & LA treatment was also shown to decrease the levels of oxidative stress mediated DNA damage during aging probably by decreasing the oxidant production and by improving the antioxidant status in aged rats (Savitha and Panneerselvam, 2007). These results are in complete agreement with our reports on the protective effect of the LC & LA against DNA damage induced by ionizing radiation.

The histopathological architecture of the liver in γ-irradiated groups showed radiolesions in various form in liver that included congestion and dilatation in blood vessels, haemorrhage, vacuolation, lymphocyte infiltrations and necrobiotic changes in the hepatocytes. Concomitantly, the ultra structural examination for the same group showed different changes in the hepatocytes of treated rats. These changes were represented as swelling and ruptured mitochondria, fragmentation of the endoplasmic reticulum and nuclear damage with wrinkled nuclear membrane. Aforesaid alterations in the liver tissue showed similarity and conforms those recorded by several authors, with various experimental animals exposed to radiation (Nasr *et al.,* 1993; Zavodnik *et al.,* 2003; Mansour *et al.,* 2008). These histopathological and ultra structural changes in rats liver treated with irradiation were attributed to the direct harmful effect of irradiation on the biological system or indirect effect of free radicals liberated in the body after irradiation (Hagn, 1989).

In the current study, LC & LA were histopathologically and ultra structurally proven to be radioprotective agents by reducing the severity of radiation-induced liver damage. Most of the histopathological lesions observed in γ-irradiated group were disappeared to a large extent; where the normal architecture of the liver was restored in the pre- and post-treated group. whereas, slight dilated blood vessels and blood sinusoids were still found, in photomicrograph of liver sections in post- treated group, hepatocytes were found in focal hepatic hemorrhage and binucleated hepatocytes wider sinusoidal space, vacuolar degeneration of some hepatocytes, dilated blood vessel were noticed. Also, other hepatocyts were abnormal with either pyknotic or karyolitic nuclei. Meanwhile, the results of electron microscopy showed that post - treatment with LC & LA minimized most of the injuries noticed in the hepatocytes of rats exposed to γ-irradiation. While, a complete regeneration in the nucleus, nuclear membrane, endoplasmic reticulum and mitochondrial shape were detected in rats treated with LC & LA prior and post exposure to γ-irradiation.

In the previous studies, Altas *et al.* (2006) found that LC was able to ameliorate radiation-induced cochlear histopathologic damage in guinea pigs. Also, Sezen *et al.* (2008) histopathologically demonstrated that LC has a radioprotective feature by reducing the severity of radiation-induced brain damage. Ucuncu *et al.* (2006) reported that LC had radioprotective properties by delaying the starting day and reducing the severity of radiation-induced oral mucositis. L-carnitine is an endogenous mitochondrial membrane compound (Ueda *et al.,* 2002), these data support the idea that L-carnitine-mediated cytoprotection is due, in part, to inhibition of the mitochondrial apoptotic pathway. Moreover, LC has been shown to act as an important anti-apoptotic mediator (Moretti *et al.,* 2002). Ishii *et al.* (2000) reported that acetyl carnitine has shown to attenuate DNA fragmentation and nuclear condensation in cultured neurons promoting neuronal survival. Similarly, Sayed-Ahmed *et al.* (2004) reported that acetyl carnitine has a protective effect against Bleomycin-induced oxidative stress and energy depletion in lung tissues in rats, through its free radical scavenging properties with the consequent improvement in mitochondrial function and ATP production. Recently, Dadhania *et al.* (2010) have reported that LA pretreatment ameliorates MTX-induced intestinal toxicity in rat as evident from the protection against oxidative stress, decrease in DNA damage and protection of cellular morphology. Similarly, LA pretreatment affected cell death by decreasing the number of apoptotic and necrotic cells induced in cyclophosphamide treated rat (Selvakumar *et al.,* 2006). It has also been demonstrated that LA and DHLA both inhibit the apoptosis of rat thymocytes after exposure to either methylprednisolone or etoposide and this inhibition

was manifested at an early stage in the apoptosis as cell shrinkage, chromatin fragmentation (Bustamante *et al.,* 1995).

In the present study, we chose to co-supplement α-lipoic acid, an antioxidant, with L-carnitine to decrease the damaging effects in rat exposed to irradiation. Previous studies have shown an improvement in mitochondrial functions upon supplementation with these two mitochondrial metabolites (Hagen *et al.,* 2002). Moreover, Savitha and Panneerselvam (2006) have also shown that this feeding regimen improves the activities of mitochondrial enzymes and respiration, thereby improving the ATP levels during aging. Alie *et al*. (2008) demonstrated that feeding LA and acetyl carnitine ameliorated age-associated mitochondrial ultrastructural decay.

Treatment with LC & LA could protect against radiation damage by up-regulation the gene expression of the antioxidant enzymes (GPx and SOD), that is in turn may lead to inhibition of DNA fragmentation in liver cells, micronuclei incidence in PCE (bone marrow cells), and normal restoration of histopathologial and ultra structure liver architecture. It is interesting that being injected prior to irradiation, LC and LA could prevent the development of oxidative attack initiated by irradiation suggesting that LC and LA exhibit an antioxidant activity. Thus we can concluded that LC & LA may protect against the damage produced by radiation by preventing oxidative stress by scavenging ROS directly and increasing those of free-radical scavenger enzymes genes expression indirectly.

Fresh Water (The Nile And Its Branches) As One Of The Ways For The Development Of Fish Protein Sources In Egypt

Saber Mostafa Mohamed, Mahmoud Khalifa Ahmed and l. A. E l Karyony

National Institute of Oceangraphic & fishries (NIoF) Alexandria
saber_mostafa0@yahoo.com

Abstract: This study aimed to identify the freshwater fisheries in Egypt in terms of its evolution of fish production, the economic significance of the geographical distribution of the fish with identifying the seasonal productivity and measuring the impact of effort done on the fish production with emphasis on ways of development of those fisheries. The study had been adopted to achieve its goals on both economic analysis and descriptive statistical. The most important results were as follows: The fish production increased from river Nile fisheries from 57.8 thousand tons in 1995 to 79.7 thousand tons in 2008, after interest in the development of this source to provide fry tilapia and carp used in the development of water bodies.The study has been identified on the most important species and their relative importance, which represents about 72.3% of the average fish production during the study period, estimated at approximately 87500 tons. The tilapia, catfish, carp, and bayad are the most important varieties of high production are estimated the relative importance of 32.5%, 17.8%, 12.7%, and 9.8% respectively. While, the order comes after that in the arrangement, Nile perch, Shelan, (unicornfish) Albesaria, Nile lebeo, Eel, and barbal with an estimated relative importance of 3.9%, 3.6%, 3.3%, 2.1%, and 0.8%, respectively. The 96% of the annual variability production is due to changes in the productivity of varieties perch, catfish and tilapia. The middel Delta region (Desouk, Kafr El-Zayat, Menouf, Qanatier, and Benha) of the most important productive areas for fish in the River Nile, where a production of about 39.1%, followed by the region of the Nile Valley, which includes (Cairo, Giza, Fayoum, Beni Suef, Minya, and Assiut) represents 26.1%, while the production of Aswan region, represent 16.3%, which include (Sohag, Qena, Aswan).With regard to the employment and fishing boats, has decreased from 16400 boats in 1990 to about 11800 boats in 2008. While, the employment of fishing has decreased at high rates, which dropped from 51.5 thousand fishermen in 1990 to about 7.9 thousand fishermen in 2008, mostly working through the primitive ways, which have lacked in the safety manner. Furthermore, the number of boats licensed reflects the non reality where, the manual boat needed two or more person to complete the various operations on the boat, which indicates an increase in employment of fishing, non-licensed in those fisheries. The average production of the boat has increased with an average annual increase of productivity of 0.28 kg, while the average annual increase of productivity of a fisherman about 0.72 kg per year. However, the number and the productivity of boats are affected by 98% due to the annual changes of the production. Regarding, the examining of seasonal productivity and using seasonality index after excluding the effect of the general trend shows that, production is more than the overall average in the months of May, June, August and December. Whilst, the production is lower than of the overall average in the rest of the year months. Now there are a lot of efforts for the development of freshwater fisheries, through a variety of development programs (i.e. protect fisheries from pollution, fishery Seed supply, determine the appropriate fishing effort, and re-evaluate the characteristics and working methods of fishing). The targeted development plans to increase fish production through the overall development and coordination between the various parties to prevent the pollution of water resources and expansion in the construction and clearing waterways of plants, and re-stocking, especially carp fish, the Nile fish varieties, which became extinct with the quiet water stream, and made use of fish production.

[Saber Mostafa Mohamed, Mahmoud Khalifa Ahmed and l. A. E l Karyony. Fresh Water (The Nile And Its Branches) As One Of The Ways For The Development Of Fish Protein Sources In Egypt. Journal of American Science 2010;6(12):880-888]. (ISSN: 1545-1003). http://www.americanscience.org.

Keywords: Fresh water; Fish protein; tilapia, catfish, carp.

1. Introduction

At the moment, the problem of providing food is one the largest and most difficult problems of development in developing countries, especially in Africa. During the past years, a number of Arabs and African countries plans to address the problem of providing food and focused on the exploitation of fishery resources that constitute reserves important to meet the needs of the animal protein. In addition to, create a fundamental basis for the manufacture of fish products and their derivatives. Especially, the countries which have bodies, and waterways large as the Arab Republic of Egypt, which could take advantage of this wealth and make up the shortfall in

animal production, which contain beaches on capture fishery area is estimated by 13.9 million acres, which constitute, and include more than 200 varieties of different fish, 71 species of molluscs and about 14 types of cephalopods to other shrimp, crustaceans and other items, in addition to the varieties of freshwater. The importance of freshwater fisheries (the river Nile and its branches) in being the lifeblood of Egypt, which extends for a distance of about 1600 km, and is divided into two branches in the Delta region, and forks from small branches and channels cover a large area, and empty its waters in Mediterranean sea. Due to the fresh water utmost importance for all agricultural activities and industrial water needs of the Egyptian, as well as being one of the resource Fish Egyptians, which represents production of about 7.5% of the total fish production, the Egyptian in 2008, although the area is estimated at 178 thousand acres represent about 1.3% of the total area of fishery Egyptian according to the evaluation of the General Authority for Fish Resources Development in 2008. [1]

The increase in the fisheries is considered a statistical increase rather than substantive, due to expansion in the scope of registration and registration by the traditional fishing sector so that it includes additional landing sites.

Research problem

The main problem of fish production in Egypt is the inability of fish production, to fulfill the needs of consumer, although the contribution of all sources of production, including fresh water (the Nile and its branches), which exposed many of the changes that have affected the production capacity and hence ecological balance and Chemical composition, varieties and the disappearance of some fish species as a result of these changes as well as the lower contribution of this source in the production, so the strategy for the development of freshwater fisheries (the Nile and its branches) is considered one of the most important axes of fish production in Egypt.

Objective of the study

The aims of this research are to study the Egyptian freshwater fisheries in terms of (1) the development of fish production, (2) the economic importance of these fisheries, (3) the geographical distribution of fish varieties, (4) seasonal productivity of freshwater fisheries, (5) measuring the impact of efforts done on fish production, and (6) ways of development of those fisheries.

2. Material and Methods

Data Source

The study Adopted in achieving its goals on descriptive and quantitative manners in the interpretation and description of economic variables, using the simple statistical methods such as simple percentages and averages, as well as the use of a linear model to estimate rates of production of freshwater fish, in addition to the regression model to measure Fish varieties and effort aspirated on the total production.

Methods

The study relied on two main sources of data; the secondary data are derived from published annual statistical bulletins issued by the Ministry of Agriculture and Land Reclamation represented in the records of the General Authority for Fish Resources Development as well as some references, thesis and scientific research on the subject of study.

3. Results

Economic importance of fish production and development of freshwater aquaculture (the Nile and its branches)

The economic importance of these aquacultures is concerning with productivity, employment, and fishing fleet, as well as the highly productive fish varieties. In spite of the misguided area compared to Egyptian aquacultures area where production is estimated at 37.9 thousand tons in 1990 represents representing 12.8% of the total fish production, including Egyptian equivalent to about 159.1 million pounds representing 9.3% of the total income of fish. Identifying the effectiveness of the five years plans strategy's of the General Authority for Fish Resources Development [2] toward the development of freshwater aquaculture, has been shown that, production was estimated at 67.9 thousand tons in 1995, representing 16.7% value of 305.4 million pounds, which represents 14.4% of the value of fish production, increasing to an estimated 80.3 thousand ton in 2000, accounting for about 11.1% with an estimated value of 483.4 million pounds, which represents about 8.5% of the value of fish production in the same year, while estimated at 83800 tons in 2005 represents 9.4% of the total fish production Egyptian in the same year, worth estimated 559.7 million pounds represent 7.2% of the value of fish production for the same year declined due to changes to about 79.7 thousand tons, representing 7.5% a value of 654.2 million pounds, which represents 9.5% of the value of fish production in 2008. This contribution is a little for the Egyptian fish production and needs attention for the development as shown, relatively low contribution in production in spite of the increase in production, as

well as the low percentage of the successive production values.

Studying the evolution of the production of freshwater aquaculture through the study period was characterized by fluctuations between high and low, when it was estimated at 57.9 thousand tons in 1995 increased until it reached a peak in 2002 to an estimated 120.8 thousand tons, then dropped to 83 800 tons in 2005 and then increased again to an estimated 104 thousand tons in 2006. These aquacultures constitute an important source for the population in the Central Delta and the Nile Valley in reliance on consumption of fresh fish, representing the central area for production also the amount of production based upon the fry and fingerlings used in the development of water bodies in previous years.

With regard to fishing vessels operating in these fisheries has been shown that it is estimated at 16.4 thousand in 1990, mostly boats of the third degree, which is on the decrease until estimated at 11.8 thousand boats in 2008. The employment of fishing has decreased at high rates, as estimated at 51.5 thousand fishermen in 1990 decreased by up to an estimated 7.9 thousand fishermen in 2008, mostly working through the primitive manner which has lacks in safety procedures for the fisherman and production and, hence, the number of boats licensed reflects the non reality where, the manual boat needed two or more person to complete the various operations on the boat, which indicates an increase in employment of fishing, non-licensed in those fisheries.

Study the general time trend for the production of freshwater aquaculture of their respective areas to identify the development and production growth during the period (1995 - 2008). This reflects the impact of Productivity policies for the development and growth of fish production from natural sources.

Form the data, it has been shown from the following equation that fish production from freshwater increasing annually by 31.7 thousand tons. Significantly, the statistical estimate in accordance with the coefficient of determination (R^2) is 36% of the changes to the annual production of fresh water due to factors related to time.

As indicated by the following formula:

$$P^e = 63385.4 + 31743.18\ T_e$$
$$(6.205) \qquad (2.645)\ *$$
$$R^2 = 0.36 \qquad F = 217.3\ *$$

Where:
P^e = the amount of fish production from freshwater per Ton

T_e= time in years 1, 2, 3, ….., 14
* Significant at level of 0.01

The relative importance of the most important fish species

There are many different species and varieties of fish as well as the quantity of production areas as a result of the impact of natural (i.e. the inventory diversity of flora and fauna located in rural water), climatic (i.e. temperature, light and movement of water) and surrounding biological factors. The influence of these factors on quality and quantity of fish has been identified the most important fish species of freshwater aquaculture in accordance with the fishing of different species during the period (1995 - 2008).

Table (1) shows, the most important varieties and their relative importance, which represents about 72.3% of the average fish production during the study period, estimated at 87500 tons. The tilapia, catfish, carp and bayad are the most important varieties of high production, estimated at 32.5%, 17.8%, 12.7%, and 9.8%, respectively and then comes in the arrangement Nile perch, Shelan, Albesaria, lebeo, eel and barbal with a relative importance of 3.9%, 3.6%, 3.3%, 2.1%, and 0.8% respectively. Studying the impact of fish species on the fish production from freshwater aquaculture, shows that the best models estimated is the double logarithmic as the following equation:
Where, the fish production of fresh water identified as a dependent variable (y) on one hand and the production of varieties, on the other hand, in the form of an independent and is in the tilapia (x1), Aqraamit (x2), Schall (x3), perch (x4), bayad (x5), eel (x6), barbal (x7), lebeo (x8), Albesaria (x9) and carp (x10).

$$\text{Log } y^8{}_n = \log 2.686 + 0.143 \log X4 + 0.440 \log X2 + 0.323 \log X1 \text{ (equation 1)}$$
$$(1.847) \quad (0.143)^* \quad (6.747)^* \quad (2.551)^*$$
$$R^2 = 0.96 \qquad F = 61.25$$

Where:
$\mathbf{y^8{}_n}$ = quantitative estimates for the total production of fresh water
X4 = annual production of fish Nile perch.
X 2 = annual production of fish, catfish.
X 1 = annual production of tilapia.
Xn = variable time in years 1, 2, 3 ....., 14.

* Significant at 0.01 level

It is clear from equation (1), change of 10% in the production of Nile perch (x 4) leads to the change OK in the total production is estimated at

10.4%, (2) change of 10% in the production of catfish (x 2) leads to a change approved in the total production estimated at 4.4%, (3) change of 10% in the production of tilapia (x1) lead to a change in the total production estimated at 3.2%, (4) 96% of the changes in annual production of freshwater aquaculture due to annual changes in fish species, according to the coefficient of determination (R^2), and (5) proved to be significant at the level of a probabilistic model better than 0.001.

Table (1) the development of fish production per ton, classified as freshwater fisheries during the period (1995-2008).

Collected and calculated from:
- Central Agency for Public Mobilization and Statistics, Bulletin of fish production, Oaadadmokhtlvp, period (1995-2008).
- Ministry of Agriculture and Land Reclamation, the General Authority for the development of fisheries, fish production statistics (1995-2008).

The relative importance of the most productive areas (the geographical distribution of Nile fish)

To study the relative importance of the production of fish from fresh water (the Nile and its branches), the production areas were divided according to the General Authority for Fish Resources Development, which divided production areas into six areas as follows: the Damietta, includes (Damietta, Mansoura, and Zagazig), Western Region includes (Behaira), the meddle Delta includes (Desouk, Kafr El-Zayat, Menouf, Qanatir, and Benha), the eastern region includes (Al-Salam Canal, Ismailia Canal area), the Nile Valley includes (Cairo, Giza, Fayoum, Beni Suef, Minya, and Assiut area) and Aswan includes (Sohag, Qena, and Aswan).

Table (2) shows, the relative importance of fish production to the average period (1995-2008), it was found that, the meddle Delta is the most important areas of production, producing about 39.4% of the production of fresh water at an average production estimated at 34,183 tons. While, the Nile Valley comes in the second ranked, which estimated at 26% of the fresh water production at an average production estimated at 22,553 tons, whilst the Aswan region comes at a third ranked, producing about 15.3% of the production of fresh water at an average production estimated at 13,325 tons, whereas the Damietta region occupies the fourth ranked, where it produces about 14.4% of the average production of fresh water production estimated at 12,466 tons, while the eastern region came in fifth ranked, where it produces about 2.8% of the average production of fresh water production estimated at 2427 tons, while the western region occupies rank where the final output is estimated at 1.3% of the average production of fresh water production is estimated at 1094 tons, during the study period (1995-2008). From the abovementioned discussion clearly, the productions of fish freshwater are concentrated mainly in the central Delta.

Table (2) the ratio of the important areas of fish production in the River Nile during the period (1995 - 2008).

Table (3) Monthly averages for the fish varieties of fresh water during the period (1995-2008)

Source calculated and collected: collected and calculated from:
- Central Agency for Public Mobilization and Statistics, Bulletin of fish production, Oaadadmokhtlvp, period (1990-2004).
- Ministry of Agriculture and Land Reclamation, the General Authority for the development of fisheries, fish production statistics (1990-2004).

Seasonal production (seasonal ratios after excluding the effect of the general trend)

Seasonal fish production means, all changes in fish production, with systematic successive periods of time less than twelve months, also known as seasonal concentration of production in certain periods of the year or decline or lack in the remaining months of the year, leading to changes in price. These fluctuations are attributable to a number of influences, which is mostly systematic. Study the seasonal production is useful to identify seasonal periods of low or increase production to avoid the effect's changes in productivity for the product and the consumer as well as policy planners [4].

Studying the seasonal fluctuations of fish production to the most important fish species's aquaculture of the Nile during the study period, as shown in Table (4) shows, a fluctuating seasonal pattern, where the production rise and decline from the annual average year, estimated at 7829 tons during the period from January until December, where reach the maximum in January, 8247 tons, then reduced to a minimum during December, to estimated 7214 tones, due to the multiplicity of varieties of fish from River Nile aquaculture and the different patterns of seasonal products to another, which requires analysis of the fluctuations of the most important species for production, especially tilapia, catfish, bayad and carp (Table 4).

The results have been shown that, the seasonal fluctuations of fish tilapia rise and fall as well as the fluctuation of seasonal monthly production during the study period, with reduced production from the total average monthly of the year about 30.2 thousand tons during the period from January to December, culminating in June by seasonal amounted to about 9.2% and then production to fall below during december, as the percentage of seasonal 5%. As it turns out seasonal fluctuations of catfish production, which reduced production from the average monthly year of about 14.4 thousand tons during the period of January to December, where production diminished to below during February, the seasonal rate reached about 8%, while peaked in June by seasonal amounted to about 9.1%.

As for the carp is characterized by a pattern of clearly seasonal and determined by two periods, firstly, start from January to April, where more than production during that period than the average annual year, estimated at 20.8 thousand tons, reached its maximum in January, with average seasonal amounted to 9.5% and then secondly, start from May to December, it is characterized by a decrease of production from the total average annual, reached the lowest level in August by seasonal amounted to 7.9%.

Regarding to the bayad fish, it has been shown, the increase in production for the general average of 8.2 thousand tons during the period from January to December. The production fell to below during the month of February, it reached about 7.5%, while peaked in june by seasonal reached about 9.4 %.

Table (4) Seasonal productivity of the fish Nile

Statement	Average Monthly	Directional values	Average Monthly	Seasonal Guide
January	8247	8166.7	101.0	99.1
February	7711	8105.4	95.1	93.3
March	7809	8044.1	97.1	95.2
April	8098	7982.8	101.4	99.5
May	8138	7921.5	102.7	100.8
June	8150	7860.2	103.7	101.7
July	7717	7798.9	98.9	97.1
August	7995	7737.6	103.3	101.4
September	7809	7676.3	101.7	99.8
October	7676	7615	100.8	98.9
November	7385	7553.7	97.8	95.9
December	7214	6032.0	119.6	117.3
Total	93949	92494.2	1223.2	1200
Average	7829			

$y^n = 8227 - 61.3\ x_n$

(56.4) (- 3.1)* $R^2 = 0.69$ $F = 9.57^*$

Where: y^n= Monthly average fish production from freshwater per ton

x_n = time per months (January .. December)

* Significant at 0.01 level of significance

The decrease in the winter months to drop the fish to the depths as a result of cold, which is difficult to access fishing by the methods used, and explain the increased production of some species in the summer months due to the temperatures rise and the growth of phytoplankton close to the surface of the water, leading the fish to rise and thus increase the chances of fishing. Examining the seasonal productivity of fish production after excluding the impact of general direction and in accordance with the table (3) shows that, the production is more than the overall average in the months of May, June, August and December, down from the average year in the remaining months of the year Fig (1)

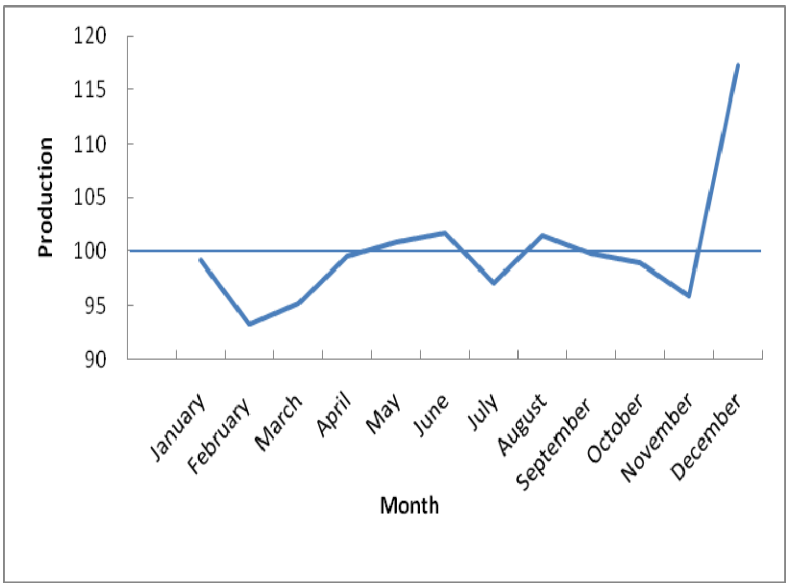

Figure (1) Guide to the interposed seasonal production of fresh water during the period (1995-2008)

The impact of fishing efforts on production: -

The number of workers, number of fishing boats and size of equipment affect largely on the quantity and quality of fish caught in addition to the productivity of the boat and fisherman,

The outcome of production is low, due to the disproportionate between the numbers of boats and the size of fish stocks available for fishing. It is clear from Table (5), the average number of boats operating in fresh water was about 15182 boats, whereas, the average productivity of the boat was about 5.1 tons and the average number of fishermen about 28491 while, the average productivity of a fisherman about 4.8 tons.

Studying the fishing effort on production, according to a model of multiple regression showed that the best models estimated [5] is the linear model in its following were identified as production of fresh water as the dependent variable (y) on the one hand, and the preparation of boats, on the one hand, as an independent variable (x1) and the average productivity of the boat (x 2) and the preparation of the fishermen (x 3) and the average productivity of a fisherman (x 4)

$$Y^8n = -86355.2 + 5.58x_1 + 15216.2\ x_2$$
$$(-10.59) \quad (12.86)^* \quad (26.57)^*$$
$$R^2 = 0.98 \qquad F=363.6$$

Where=

Y^8n = estimated quantity of total production of fresh water

x_1 = number of vessels operating fishing in the fresh water.

x_2 = average productivity of the boats

x_n = variable time in years 1,2,3 ....., 14.

* Significant at 0.01 level of significance

It is clear from the previous model that (1) Change one unit in the number of boats (x1), offset by corresponding change in the total production by 5.6 units, (2) change the amount of one unit in the average productivity of the boat (x2) counteract with change in the total production by (15216.2), (3) the independent variables explain 98% of the annual changes in the total production, and (4) proved to be

significant at the level of a probabilistic model better than 0.001.

Table (5) the average productivity of the boat and fisherman from freshwater fisheries (the Nile and its branches)

Years	Production(ton)	Number of boats (boats/ boat)	Productivity of the boat	Number of fishermen	Productivity of fishermen (ton)

Ways to the development of freshwater fisheries (the Nile and its branches)

Five years plans for economic development, aimed to increase fish production from freshwater sources [6] can only be achieved through the comprehensive development of this source and coordination between the various parties to prevent the pollution of water resources and expansion in the construction and clearing waterways of plants, with re-stocking fingerlings, especially carp, fish Nile, which became extinct with the quiet power, and benefit from the research production of fry fish friendly environment away from pollution, and attention to guidance fish, especially in the area of development for the indirect fish farming in the rice fields, as well as improve the efficiency of freshwater aquaculture as being one of the renewable natural resources, which may dry up if used at rates that exceed natural regeneration, and therefore requires an amendment radical in the methods and systems and the use of freshwater fisheries by avoiding fishing small fish in the seasons of natural spawning with requiring fishermen to use nets legal with mesh wide, and to prevent over fishing, and modifying the licensing boats and fishermen, with the adoption of research on the dates of spawning of different items and regions so as to regulate fishing, and reliance on electronic record for statistical quantities produced so that data can be modified depending on the circumstances available and follow-up of production. Attention to raising the efficiency of workers with the fishery sector in freshwater fisheries through training in the field of limited interest in fish and abide by the laws and regulations of hunting, with regard to fishing boats can be equipped to suit the possibilities of fishing, with attention to fry fish collection sites used in providing those fisheries.

Role of lactic acid bacteria as a biopreservative agent of Talbina

Amal S. Hathout*, Soher E. Aly

Toxicology & Food Contaminant Dept., Food Industries & Nutrition Division, National Research Centre, Dokki 12622, Cairo, Egypt
amal_hathout@hotmail.com

Abstract: Talbina is a mixture of barley flour and milk. The aim of this study is to evaluate the role of probiotic bacteria (*L. gasseri*, *L. reuteri*) compared to yoghurt starter bacteria (*S. thermophilus* and *L. delbreukii* sub sp. *bulgaricus*) as a biopreservative agent of Talbina samples. Shelf life of refrigerated Talbina processed by lower count (ratio 1:3 LAB : Talbina) of *L. gasseri* or *L. reuteri* increased and reached over 21 days at 6±2°C, compared to yoghurt starter bacteria which ranged between 6 and 14 days depending on the type of milk used. Storage temperatures are considered the main factors for biopreservation action of lactic acid bacteria (LAB). Increasing storage temperature to 12±2°C increased total fungal count and greatly changed fungal profile. It could be concluded that the potential of LAB to inhibit the growth of common food spoiling fungi opens up new perspectives for the bio-preservation of food products.

Keywords: lactic acid bacteria; Talbina; barley flour; fungi; bio-preservation

1. Introduction

Bio-preservation has gained increasing attention as natural means for controlling the shelf life and safety of food products. The application of bioprotective cultures to ensure the hygienic quality is a promising tool although, it should be considered only as an additional measure to good manufacturing, processing, and storage and distribution practices (Holzapfel et al., 1995). LAB have shown a major potential for use in bio-preservation because of safety for human consumption (GRAS status) and the prevalent microflora during storage in many foods (Vignolo et al., 2008). LAB can produce a wide range of antimicrobial metabolites, i.e. organic acids, diacetyl, acetoin, hydrogen peroxide and bacteriocins. These antimicrobial activities can contribute in the microbiological safety by controlling the growth of other microorganisms, and inhibition of pathogenic bacteria such as *Listeria monocytogenes*, *Staphylococcus* sp. and *Clostridium* sp. (Stiles 1996; Caplice and Fitzgerald, 1999)

The nutritious and therapeutic benefits of probiotic microorganisms have been most extensively investigated in dairy products such as milk, yogurt (Khalil and Mansour, 1998), and cheese (Ong et al., 2006; Meyer et al., 2007). Vasiljevic and Shah (2008) added that probiotic bacteria have been exploited extensively by the dairy industry as a tool for the development of novel functional products. Probiotics have been also incorporated in edible spreads (Charteris et al., 2002); meat (Arihara et al., 1998); Ras cheese (Abdalla et al., 2008); and beef burger (Mohsen et al., 2009).

In recent years there has been a growing research interest for the utilization of barley in a wide range of food applications (Bilgi and Çelik, 2004) as it can be processed into a number of palatable, nutritious food products. Barley flour is suitable for a wide range of food applications, and it is used in a wide range of traditional Arabic, Kurdish, Persian, and Turkish foodstuffs including *kashkak*, *kashk* and *murri*. In Saudi Arabia, barley soup is traditionally eaten during Ramadan (Long, 2005). Historically, barley has been an important food source in northern and Eastern Europe and Asia (Newman and Newman, 2006).

Talbina is a popular traditional food product in the Arab world prepared by mixing barley flour and milk and cooking for 10 to 15 minutes. In Islam, Talbina was prescribed for seven diseases (Hadith), these include grief, high cholesterol levels, heart disease, treatment of cancer, effects of aging, diabetes and hypertension. Recently Miller et al. (2000) confirmed these facts, whereas Majchrzak et al. (2004) added that barley contains a number of antioxidants that can reduce the incidence of chronic diseases, including cancer. Because dairy products provide the ideal food system for delivery of probiotic bacteria (Shehata et al., 2004), therefore, the objectives of this study are to evaluate the effect of probiotic bacteria compared to yoghurt starter bacteria on the shelf life of Talbina produced and on fungal profile during refrigerated storage period. The viability of LAB was also evaluated.

2. Material and Methods

2.1. Materials

Raw fresh cow milk having 12.26% TS, 3.51% fat, 3.42% protein, 0.17% titratable acidity and pH 6.50 was obtained from a private farm in Calyoubia Governorate, whereas UHT (Ultra Heated treatment) milk as well as barley flour were obtained from supermarkets. Raw milk was pasteurized at 72°C for 15 s before using in the processing of Talbina.

2.2. Cultures

Lactobacillus delbreukii sub sp *bulgaricus* and *S. thermophilus* were obtained from Chr. Hansen's lab. Denmark, while the probiotic bacteria *L. gasseri* LA39 and *L. reuteri* LA6 were kindly donated by Dr. T. Saito, Faculty of Biological Resource Science, Tohoku University, Japan.

2.3. Organism preparation

De Man Rogosa Sharpe (MRS) broth (Difco Labs., Detroit, MI, USA) was used for propagation of the LAB. For each culture, MRS broth was inoculated at 1% using a freshly prepared culture of the desired strain of LAB and incubated at 37°C. Fermented milk was prepared by inoculating the colonies in reconstituted 10% no-fat dry milk (NFDM) until coagulation.

2.4. Preparation of Talbina

Talbina samples were prepared by mixing milk (UHT milk, fresh cow milk) and barley flour (10%) and cooking for 10 minutes. After cooling LAB>10^7 CFU/g was added to the mixture. The LAB added to the Talbina was divided into two different concentrations: Lower count (1:3 LAB: Talbina) and higher count (1:1 LAB: Talbina).

Different treatments (T) used in this study were as follows:-

T 1: *L. gasseri*, lower count, UHT milk
T2: *L. gasseri*, higher count, UHT milk
T3: *L. gasseri*, lower count, fresh milk
T4: *L. gasseri*, higher count, fresh milk
T5: *L. reuteri*, lower count, UHT milk
T6: *L. reuteri*, higher count, UHT milk
T7: *L. reuteri*, lower count, fresh milk
T8: *L. reuteri*, higher count, fresh milk
T9:Yoghurt starter bacteria, lower count, UHT milk
T10:Yoghurt starter bacteria, higher count, UHT milk
T11:Yoghurt starter bacteria, lower count, fresh milk
T12:Yoghurt starter bacteria, higher count, fresh milk
T13: Control Talbina, UHT milk
T14: Control Talbina, fresh milk

All Talbina samples were distributed in plastic cups (100g each) and stored at 6±2 and 12±2°C for 21 days. Samples were prepared in three replicates.

2.5. Microbiological analysis

Samples were prepared for microbiological examination according to ICMSF (1996). Samples were examined for total fungal count (CFU/g); according to American Public Health Association (APHA, 1992). Isolated fungi were identified according to Nelson et al., (1983). Viable cells of Lactobacilli in Probiotic Talbina were determined on MRS agar (Dave and Shah, 1996).

2.6. Titratable acidity and pH

Samples were analyzed during storage for titratable acidity (%) according to the method of AOAC (1990). Samples were also analyzed during storage for pH value using a wireless Mess-Stab 656 pH meter (Knick, Berlin, Germany).

2.7. Statistical analysis

Statistical analysis was performed using SPSS statistical program for windows (Version 16) (SPSS Inc., Chicago, IL, and USA). Standard deviation of mean was used to describe data, and a Student's T-test was used to evaluate the significant differences between control and Talbina samples. P value was considered significant if less than 0.05 at 95%.

3. Results

3.1. Microbiological analysis

Talbina is a new traditional food processed from barley flour, milk and LAB. A specific factor for Talbina shelf life is to prevent fungal growth, therefore, it is necessary to discuss the role of different factors affecting fungal occurrence during refrigeration storage.

3.1.1. Total fungal count

Fungal counts in processed Talbina samples were demonstrated in Figure (1). Lower counts of fungi were isolated from Talbina samples stored at both 6±2 and 12±2°C compared to control. Fungi were not observed in Talbina samples (Figure 1) processed by UHT milk with lower LAB count (ratio 1:3) of *L. gasseri* or *L. reuteri* during the storage period (21 days) at 6±2°C revealing significant difference to control samples. On the other hand, the period reached to 14 days for samples processed by yoghurt starter bacteria. Using higher LAB count (ratio 1:1), (Figure 1a, c) decreased the shelf life period to 14 and 7 days for samples processed by *L.*

gasseri and *L. reuteri* respectively. Increasing storage temperatures to 12±2°C lead to higher fungal count (Figure 1) in processed Talbina.

3.1.2. Occurrence and distribution of fungi

Data in Table (1) showed that increasing the storage temperature to 12±2°C caused a great change in fungal profile, where *Aspergillus* species were the most dominant fungi, whereas *Penicillium* species were the most dominant on those stored at 6±2°C. In addition, *Fusarium* species appeared only on Talbina processed by fresh milk. This variation of fungal species may be due to the difference of optimum temperature for each genus of fungal growth.

The occurrence of *A. parasiticus*, *A. flavus, A. niger* and *A. carbonarius* (Table 2) differed according to the type of milk used. During storage at 6±2°C, *A. flavus* was the most existing fungi followed by *A. niger* and *A. carbonarius* respectively in Talbina samples processed by raw milk. Meanwhile in Talbina samples processed by UHT milk, *A. niger* was the dominant species followed by *A. carbonarius* and *A. parasiticus* respectively. On the other hand, *A. parasiticus* was the most prevailing fungi in both Talbina samples processed by either fresh milk or UHT milk at 12±2°C.

3.1.3. Lactic acid bacteria viable count

Results in Table (3) showed that Talbina processed by either low or high viable count of *L. gasseri* or *L. reuteri* were over 10^7 CFU/g (7.00 $\log_{10}$ CFU/g). Data also indicated that Lactobacilli increased during the development of the storage period at 6±2°C. After 7 days of storage viable count recorded 7.681 and 7.301 $\log_{10}$ CFU/g for *L. gasseri* and *L. reuteri* respectively for the lower starting count (1:3). The viable counts continuously increased during storage period as shown in Table (3).

3.2. Chemical analysis

3.2.1. Titratable acidity (%)

Samples with higher count of bacteria, UHT milk and stored at 6±2°C (Figure 2) showed higher titratable acidity (1.14%) for *L. gasseri* samples at zero time compared with those processed by lower count of bacteria (0.69%). These findings were recorded for all treatments; this may be due to metabolites produced by LAB, which were proportional to the bacterial count in fermented milk.

Figure (2a, b) also revealed that Talbina processed by yoghurt starter bacteria and UHT milk showed the highest titratable acidity (0.96%) followed by *L. gasseri* (0.69%) and *L. reuteri* (0.64%) respectively for samples stored at 6±2°C at zero time. Samples stored at 12±2°C showed that increasing titratable acidity was also recorded for samples processed by fresh milk (Figure 2d) compared to those processed by UHT milk (Figure 2c).

3.2.2. pH value

Table (4) showed that the pH value of control Talbina was similar to that of milk, and that there was no great change in the pH value during storage period. The unchanged pH value of control Talbina during storage is evidence that Talbina is processed under sanitation conditions. On the other hand, the pH values ranged from 5.44 to 5.25 and from 5.11 to 5.00 for *L. gasseri* Talbina processed by UHT milk and fresh milk respectively during storage period at 6±2°C revealing significant difference to control samples. Furthermore, *L. gasseri* Talbina samples had higher pH values than those of *L. reuteri* followed by yoghurt starter. These findings are related to the change in titratable acidity (%).

3.3. Shelf life

Figure (3) revealed that *L. gasseri* and *L. reuteri* Talbina samples stored at 6±2°C showed long shelf life followed by yoghurt Talbina. All samples stored at 12±2°C showed a lower shelf life, which reached up to 7 days (data no shown). Furthermore, the UHT milk (Figure 3) had a long shelf life in all samples compared to fresh milk. Shelf life means that samples are without any unfavourable changes in flavour, taste, appearance and no fungal growth observed, low titratable acidity, high pH values .Results also indicated that probiotic bacteria had a positive effect on the shelf life of samples compared to either control or samples processed by yoghurt starter bacteria. On the other hand, lower bacterial count for both *L. gasseri* and *L. reuteri* showed the best results such as long shelf life (21 days) compared to those of higher bacterial count (Figure 3).

4. Discussion

LAB are considered to be important components of the microbiota, playing a large variety of health-promoting functions. Strains belonging to the *Lactobacillus* genera have traditionally been used as probiotics and added as functional components to various food products. Talbina samples processed by fresh milk were highly contaminated by fungi compared to those processed by UHT milk. These results are in agreement with Brenier-Pinchart et al. (2006) who surveyed different products for fungal contamination and found that UHT milk is not contaminated by filamentous fungi, since UHT milk is heated to 135°C for a couple of seconds to kill harmful bacteria that may be present. In addition UHT milk is sometimes called 'long-life milk,' and it is slightly different from fresh milk and has an extra

treatment that enables it to be stored at room temperature (as long as it is unopened) for extended periods. Meanwhile the heat treatment for fresh milk (pasteurization or boiling) may not be enough to ensure the safety of the fresh milk against microorganisms. The effect of heat treatment of milk was reported by Ismail et al. (2004) who indicated that heat treatment might reduce the curd tension by partial precipitation of calcium salts and changes in protein. On the other hand, local fresh milk may be contaminated with antibiotic residues or preservative agents that can affect the growth of LAB in dairy product (Saneez et al., 1995). In an effort to overcome this problem for home or Simi pilot scale industries, the possibility is considered to replace totally or partially fresh milk in dairy product by UHT milk, which is considered as a preferable consumer's health milk.

The storage conditions, especially temperature, represent an important factor affecting the microbiological quality of foods and feeds, and the improper storage temperature may prolong survival of the microorganisms or even enhance their multiplication (Zmysłowska and Lewandowska 2000). In agreement, Collombo et al. (1992) reported that low temperature was more effective for prolonged cheese storage than high temperature. Therefore, it could be demonstrated that storage temperature is considered the first factor affecting the shelf life of Talbina, thus refrigerating temperature is important to control spoilage or fungal growth of probiotic Talbina.

Our results stated that *L. gasseri* followed by *L. reuteri* were able to delay and/or decrease fungal contamination in Talbina compared to control These findings may be due to the production of the bacteriocins gassericin A and reutericin 6 from *L. gasseri* LA39 and *L. reuteri* LA6 respectively (Kawai et al., 2004). The bacteriocin gassericin A showed the highest antimicrobial activity against gram-positive food borne pathogenic bacteria, *Listeria monocytogenes*, and *Staphylococcus aureus* (Kawai et al., 2006). Arakawa (2008) added that this bacteriocin can be produced in natural media such as milk and milk based media. Arakawa et al. (2009) explained that bacteriocins (gassericin A, reutericin 6) might act on the cytoplasmic membrane of the target cell and cause death of the cell by efflux of potassium ion.

Previously AbdAlla et al. (2008) found that two probiotic bacterial strains (*L. reuteri* and *L. casei*) inhibited the fungal growth of *A. parasiticus* on Ras cheese during 90 days of storage. Recently Mohsen et al., (2009) reported that the use of LAB completely inhibited the pathogenic microorganisms and total fungal count in beef burger during 45 days of storage at 4°C.

Various media have been studied as carriers for probiotic bacteria, such as cheese (Bergamini et al., 2005), and yoghurts (Vinderola et al., 2000), but there is no data for Talbina as probiotic vehicles. Our results stated that when Lactobacilli were inoculated in Talbina, it sustained a cell count at recommended concentrations of probiotic in food (10^7 or 10^8 CFU/g) (Reid, 2001). These results are in good harmony with those recorded by Ishibashi and Shimamura (1993) who reported that food containing such bacteria should contain at least 10^7 live microorganisms per g or per ml at the time of consumption, in order to benefit the consumer. On the other hand, the count of LAB were still in the limit up to day 14 of storage period as recommended by Svensson (1999) who reported that probiotic cultures should be able to withstand food processing and storage conditions encountered during the manufacture of functional foods under industrial conditions.

Results showed that titratable acidity (%) was higher for yoghurt starter bacteria followed by *L. reuteri* and *L. gasseri* respectively in descending order, whereas control samples showed the lowest titratable acidity and no remarkable change during storage. It was also noticed that titratable acidity increased sharply during storage period. Results are in synchronization with those reported by Joshi and Sharma (2009) who revealed that titratable acidity increased with the advancement of fermentation period up to 16 days, meanwhile El Owni and Hamed (2009) added that the titratable acidity of cheese samples stored at room temperature was higher in comparison with those stored at refrigerator temperature. Our results were confirmed by Rivera-Espinoza and Gallardo-Navarro (2010) who indicated that *L. delbreukii* produced significantly more titratable acidity expressed as lactic acid than *L. casei*, and that *L. delbreukii* was capable of surviving at low pH and high acidity. These findings were discussed previously by Carr et al., (2002) who stated that LAB encompass a heterogeneous group of microorganisms, which have a common metabolic property that produces lactic acid from the fermentation of carbohydrates. The decrease in pH of Talbina during storage was related to titratable acidity (%). It is also necessary to know that pH measures free hydrogen ion concentration, thus it is a more direct measurement, as it circumvents "apparent acidity" and is usually less subject to error or misinterpretation than titratable acidity measurement. This may have been due to the production of lactic and organic acids by LAB, which had an effect on lowering pH value as reported by Kuipers et al.

(2000) and Shah (2007). Thus, the pH value of the product was in the range of 6.4 to 4.5, which is the best pH for encouraging lactic acid bacterial growth as reported by Rivera-Espinoza and Gallardo-Navarro, (2010). Therefore, pH value plays an important role for the microbiological growth affecting the shelf life of the products.

Our investigation revealed that LAB play an important role as a preservative agent depending on the type of bacteria and its count during application leading to the increase in shelf life of the Talbina. These findings were confirmed by Shah (2007) who reported that LAB produce some components, which have a bacteriocidal and bacteriostatic effect, and therefore, lead to the delaying and/or disappearance of fungal growth in samples during storage period.

Results also revealed that storage temperature is the most important factor affecting the preserving action of LAB in the product, which is higher at 6±2°C, followed by the type of LAB used depending on the preserving action of bacteriocin. The third factor is the count of bacteria that produce metabolites parallel with the count of bacteria such lactic acid, and organic acid related to titratable acidity during storage.

a) Ratio of LAB: Talbina (1:3 v: v)
b) Ratio of LAB: Talbina (1:1 v: v)
*Indicates real significant differences $P<0.05$

4. Conclusion

LAB provides a high preservative effect especially at low temperature <6°C causing longer shelf life to the product over 21 days. It could also be concluded that the potential of LAB to inhibit the growth of common food spoiling fungi opens up new perspectives for the bio-preservation of food products. Furthermore, Talbina as a dairy product provides the ideal food system for the delivery of these beneficial bacteria to human gut. Further research needed includes studying more LAB as biopreservative agents as well as identifying and isolation of bacteriocins produced by LAB.

Abstract: Psoriasis, a common skin disease in Egypt, has drawn much attention to study the potential role of immunity in its pathogenesis.. Exposure of skin to microbial antigens and other stressful stimuli can induce heat shock proteins (HSPs) expression. HSPs comprise a large number of antigens against which immune responses are directed, owing to their cytokine-like effects and immunomodulatory properties. The potential role of HSP70 in pathogenesis of psoriasis is under investigation. We aimed at evaluating the differential immunohistochemical expression of HSP 70 in psoriatic skin and correlating the results with disease severity ; to elucidate its potential role in pathogenesis of psoriasis. Skin biopsies were taken from 20 patients with different severity of untreated chronic plaque-type psoriasis and from 20 healthy volunteers. Antibodies to HSP70 were analyzed immunohistochemically. Immunoreactivity intensity distribution index (IRIDI) scores including the proportion of immunoreactive cells and their staining intensity were calculated in the basal, suprabasal, superficial as well as the whole epidermal layers of patients and controls. Differential and total IRIDI scores for HSP70 expression showed highly significant higher values in psoriatic patients compared to controls. Statistical differences were found between the different groups of patients; according to their disease severity and controls. Positive correlations also existed between IRIDI scores of patients and disease severity. Based on the findings of the present study, HSP70 is suggested to play a role in the pathogenesis of psoriasis and to correlate with disease severity. Further studies on immunotherapeutic intervention are recommended, aiming at inhibiting events in an ongoing immune response which may provide new therapeutic and perhaps preventive approaches for psoriasis.

1. Introduction

Psoriasis is a common, chronic inflammatory skin disease associated with both genetic and environmental risk factors (Krueger, 2002). There is growing interest in the role of innate and adaptive immunity in inflammatory diseases such as psoriasis (Curry et al,2003). The exposure of the skin to microbial pathogens and other stressful stimuli can induce heat shock proteins (HSPs) expression, as a part of the innate immunity (Boucock and Shannan,2001). Autoimmunological mechanisms triggered by microbial agents have been suggested as playing an important role in the pathogenesis of psoriasis (Jones et al, 2004; Asea et al, 2000). More recently,

HSPs have become a focus for their role in inflammatory and autoimmune diseases owing to their cytokine-like HSPs play a central role in homeostasis by their ability to bind to other peptides and to control their effects and immunomodulatory properties (Asea et al,2000). Based on molecular mass and sequence homology, HSPs are classified into families including ubiquitin, small HSPs of 20 to 28 KDa, HSP60, HSP70 and HSP90 (Curry et al, 2003). The antigenic sites of many pathogenic HSPs, particularly HSP70 are immunodominant and are thus the primary targets for B cell and T cell responses (Palleros et al, 1991). In the HSP70 family are heat shock cognate protein 70 (HSC70), which is constitutively expressed during normal cell development and differentiation (Curry el al, 2003) and the major heat or stress-inducible protein HSP70 (Palleros el al, 1991). They are nuclear and cytoplasmic proteins exhibiting approximately 95% sequence homology and forming stable complex in stressed cells. HSP27, HSP60 and HSP70 and their ligands common HSP receptor CD91 have been reported to be increased in lesional psoriatic skin (Boyman et al, 2005).

The aim of our study was to evaluate the differential immunohistochemical expression of HSP70 in psoriatic skin in comparison with normal skin to elucidate its potential involvement in the pathogenesis of psoriasis and to correlate the results with the disease severity.

2. Material and Methods

Twenty patients with untreated chronic plaque-type psoriasis and of various degree of severity were participated in the present case- control study. They were randomly selected from those attending the outpatient dermatology clinic at Ain Shams University Hospitals and fulfilling the inclusion criteria of the study. They were 13 males and 7 females with mean age 33.6 years ±12.57 (16-53) and mean disease duration 10.5 years± 6.38 (1-24). Twenty age and sex matched healthy volunteers were included as controls. Inclusion criteria included subjects with no concomitant dermatological and/or systemic diseases that could affect the outcome of the study, subjects who did not use any topical or systemic treatment for at least one month before the study. Prior to initiation of the study, every subject was informed about the aim of the study and gave an informed consent.

All subjects were subjected to the followings:

1. Full history taking.
2. General and dermatological examination.
3. Assessment of psoriasis severity using Psoriasis Area and Severity Index (PASI) score (Fredrickson and Patterson, 1978).
4. Skin biopsy: Formalin-fixed paraffin embedded 5 mm skin punch biopsy specimens were obtained from 20 clinically diagnosed and histopathologically confirmed psoriatic lesions and from 20 normal skin controls.

Immunohistochemical staining procedure was applied to all specimens. Sections, 3-4 µm thick, were cut and mounted on positively charged slides (Menzel-glazer-polysine). Monoclonal mouse antibody to HSP70Ab-2 (clone W27;Neomarkers, Fremont, CA, USA) and Ultravision universal detection kit were used. After deparaffinization of the sections in xylene, rehydrated through graded ethyl alcohol and washed with phosphate-buffered saline, endogenous peroxidase activity was prevented by using hydrogen peroxide 0.86%. Microwave treatment (x4 for 10 minutes; sections in 10 mM citrate buffer, pH 6.0) were used for antigen retrieval. Blocking of non-specific binding was done using a universal blocking reagent (ultra V block; Neomarkers). Prediluted primary monoclonal antibody was applied for 1 hour at room temperature within a humidifying chamber. DAB; Neomarkers were used as chromogen. Mayer's haematoxylin was used for counterstaining (Merck, Germany). Sections were mounted and examined under the light microscope (Olympus CX 41 Japan).

Immunohistochemical evaluation was done on light microscopic examination. Epidermis was divided into 3 layers: basal, suprabasal and superficial (stratum corneum). Each layer was evaluated for the proportion of immunoreactive cells as well as their staining intensity. The proportion of the immunoreactive cells in each layer was assessed as 0: no immunoreactive cells, 1: less than 25% of the cells are immunoreactive. 2: 25-50% of the cells are immunoreactive. 3: more than 50% of the cells are immunoreactive. As regards the staining intensity of the cells, it was graded as 0: no staining, 1: light staining, 2: moderate staining, 3: intense staining. Immunohistochemical evaluation was performed semiquantitatively according to Chaiyarit et al,1999). An immunoreactivity intensity distribution index (IRIDI) was calculated for every patient and control. IRIDI score of each layer was calculated by multiplying the score of the proportion of immunoreactive cells by the score of their staining intensity. Total IRIDI score was determined by adding the IRIDI scores of the 3 epidermal layers for every patient and control.

Statistical analysis was carried out using the Statistical Package for the Social Sciences (SPSS) version 15. Comparison of quantitative data was carried out using unpaired t-test and Mann Whitney test. ANOVA and Kruskal-Wallis tests were used to compare more than 2 groups as regards quantitative data. Post Hoc test was used to detect the least significant difference in case of significant ANOVA test. Probability (p) values ≤ 0.05 were considered statistically significant and p ≤0.001 were considered statistically highly significant. Correlation between different parameters was assessed using Pearson's correlation coefficient test. Correlation is considered significant at 0.05 level.

3. Results

The study included 20 patients with chronic plaque-type psoriasis. They were 13 males and 7 females with mean age 33.6 years ± 12.57 (16-53). Twenty age and sex-matched healthy volunteers, with mean age 32.3 years ± 12.54 (15-54) were enrolled as controls. According to PASI score, patients were divided into 3 groups:

Group 1 included patients with mild psoriasis. Their PASI score ranged from 7 to 13 (mean 10.2 ± 3.03). They were 6 patients (3 males and 3 females) with mean age 33.8 years ± 12.19 (24-53) and mean disease duration 10.17 years ± 6.62 (1-20).

Group 2 included patients with moderate psoriasis. Their PASI score ranged from 17 to 24 (mean 18.4 ± 3.09). They were 7 patients (5 males and 2 females) with mean age 39.86 years ± 10.42 (26-53) and mean disease duration 9.0 years ± 7.77 (2-24).

Group 3 included 7 patients with severe psoriasis. Their PASI score ranged from 30 to 65 (mean 50.2 ± 17.41). They were 5 males and 2 females with mean age 41 years ± 12.1 (16-53) and mean disease duration 12.43 years ± 4.99 (4-20).

Immunohistochemical evaluation of HSP70 expression: The mean IRIDI scores of HSP70 expression of psoriasis vulgaris and normal skin in the different epidermal layers (differential IRIDI scores) as well as the whole epidermis (total IRIDI scores) are summarized in Table (1). As regards normal control skin, light HSP70 immunostaining was seen within basal cell layer of the epidermis. Suprabasal cell layer showed light to moderate HSP70 immunostaining in 4 specimens only. Superficial cell layer on the otherhand, showed no HSP70 immunoreactivity. Moreover, HSP70 was not immunohistochemically detected in the dermis of normal skin. The immunohistochemical staining pattern of normal keratinocytes was diffuse; cytoplasmic and nuclear (Fig. 1). In contrast, intense HSP70 immunostaining was found in psoriatic lesions, predominantly in basal and suprabasal epidermal cell layers. In the basal cell layer, keratinocytes tended to be decorated focally and peripherally at basal side of cytoplasm with perinuclear as well as nuclear expression. In the suprabasal cell layer, it was irregularly distributed. Superficial epidermal cell layer showed light HSP70 immunoreactivity as well (Figs. 2 and 3). Only 2 cases from the severe group of psoriasis showed expression of HSP70 within the dermal inflammatory infiltrate as intense perinuclear, granular staining of lymphocytic infiltrate (Fig. 2).

Comparison between patients and controls as regards total and differential IRIDI scores of expressed HSP70: On comparing psoriatic and normal skin specimens, statistically highly significant differences were found between patients and controls as regards mean IRIDI scores of HSP70 expression in basal, suprabasal as well as superficial epidermal cell layers. Similar results were also noted on comparing patients and controls as regards total IRIDI scores (Table 1).

Comparison between different groups of patients and controls as regards total and differential IRIDI scores of HSP70 expression : Statistically highly significant differences were found between the different groups of patients and controls at all epidermal cell layers as well as regarding total IRIDI scores (Table 2). By using the post Hoc test to detect the least significant difference, statistical differences existed according to the epidermal cell layer. In the basal epidermal cell layer, significant differences were found between groups 1 and 2 (p=0.047) and between groups 1 and 3 (p=0.012). Highly significant differences were found between group 2 and controls as well as between group 3 and controls. No significant differences were however, found between groups 2 and 3 (p=0.540) and between group 1 and controls (p=0.317). In the suprabasal epidermal cell layers, significant differences existed between groups 1 and 2 (p=0.046) as well as between groups 2 and 3 (p=0.003). Statistically highly significant differences were found between groups 1 and 3, group 1 and controls, group 2 and controls and group 3 and controls.

In the superficial epidermal cell layer, significant differences between groups 1 and 2 (p=0.008), groups 1 and 3 (p=0.003) as well as between group 1 and controls (p=0.010) were found. Moreover, statistically highly significant differences existed between group 2 and controls and between group 3 and controls. No significant difference was found between groups 2 and 3 (p=0.688). As regards total IRIDI scores, there were significant differences between groups 1 and 2 (p=0.012) as well as between group 1 and controls (p=0.006). Highly significant differences existed between groups 1 and 3 as well as between group 2 and controls and between group 3 and controls. No significant difference was noted between groups 2 and 3 (p=0.072). Significant positive correlations were also found in the patients between PASI score, total and differential IRIDI scores of HSP70 expression in the basal, suprabasal and superficial epidermal cell layers (r= 0.55, 0.53, 0.61 and 0.28 respectively).

Table 1: Mean Differential and Total IRIDI Scores of HSP70 Expression in Psoriasis Patients Compared to Control

	Patients	controls	t-test	p-value
Basal cell layer	4.75± 2.40	2.35±1.04	4.099	0.001
Suprabasal cell layer	6.35±2.45	1.65±0.93	8.002	0.001
Superficial cell layer	1.6± 1.04	0.0	6.839	0.001
Whole epidermis	12.70±5.89	4.0±1.97	7.165	0.001

Table 2: Comparison between Different Groups of Patients and Controls as Regards Differential and Total IRIDI Scores of HSP70 Expression

	Group 1 Mild psoriasis	Group 2 Moderate psoriasis	Group 3 Severe psoriasis	controls	F-test	p-value
Basal cell layer	3.16±1.33	5.14±2.73	5.14±2.73	2.35±1.04	8.94	0.001
Supra Basal cell layer	4.33±0.82	6±2.24	6±2.24	1.65±0.93	43.86	0.001
Superficial cell layer	0.83±0.41	1.86±1.22	1.86±1.22	0.0	23.49	0.001
Whole epidermis	8.33±2.56	13±6.19	13±6.19	4.0±1.97	31.64	0.001

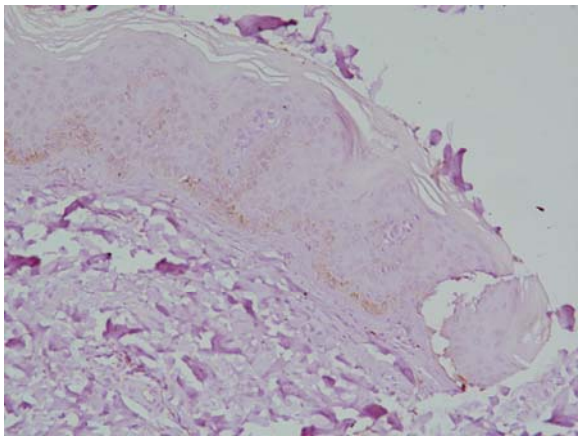

Figure 1: Normal skin: light HSP70 imunostaining in basal epidermal cell layer with negative immunoreactivity in suprabasal and superficial epidermal layers (immunoperoxidase X200)

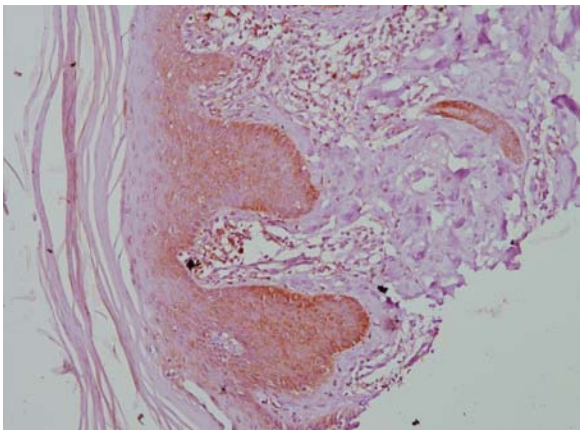

Figure 2. Psoriasis vulgaris: intense HSP70 immunostaining in basal and suprabasal epidermal cell layers with light superficial layer immunostaining and dermal inflammatory infiltrate immunoreactivity. (immunoperoxidase X 200).

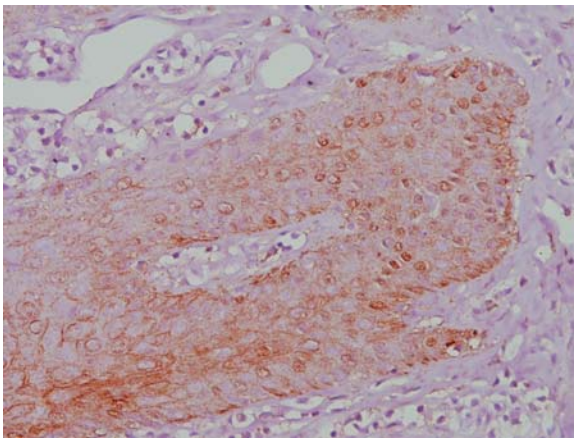

Figure 3. Psoriasis vulgaris: intense HSP70 immunostaining (nuclear and focally cytoplasmic (immunoperoxidase X 400).

4. Discussions

The differential expression of HSP70 may be related to the different expression of the stress inducible HSP70 depending on the differentiation state of keratinocytes. Expression of HSP70 may be also related to the extent of keratinocytes alteration. The following proposed scenario may explain HSP70 contribution in the development of psoriasis. Minor skin lesion(s) caused by microbial infection or physical stimuli lead(s) to stimulation of keratinocytes and secretion of cytokines, HSP70, (auto-)antigens and HSP-(auto-)antigens complexes.

Dendritic antigen presenting cells (APCs), expressing common HSP receptor CD91, bind HSP and HSP-antigen complexes. This is followed by the activation and translocation of NF-κß into the nucleus leading to the production of proinflammatory cytokines (Basu et al,2001; Boyman et al, 2004). HSP70 also facilitates the activation of dendritic APCs with IL-12 production. Presentation of processed HSP and HSP-antigen complexes, stimulation of T lymphocytes and secretion of TH-1

type cytokines then follow (Nestle et al, 1994). On the basis of this, enhanced epidermal proliferation, aberrant epidermal differentiation, recruitment of more immune cells, new blood vessel formation and finally formation of a psoriatic plaque develop. The potential role of HSP70 in the development of psoriatic lesions may therefore be attributed to its primary effect on innate system through immunomodulatory properties.

Based on the findings of the present study, we conclude that HSP70 may play an important role in the aetiopathogenesis of psoriasis, although one cannot exclude the possibility of its up-regulation secondary to inflammation. It seems that psoriasis represents a genetically determined skin disease probably initiated by hyperactivity of the triggered state of otherwise dormant cutaneous innate immunity. Recognition of the potential contribution of HSP70 in the pathophysiology of psoriasis may help clarify the mechanisms underlying the development and maintenance of psoriatic lesions with its different severity. However, further studies are recommended to determine the interplay between innate and adaptive immune responses in psoriasis and to search for immunotherapeutic intervention, aiming at inhibiting events in an ongoing immune response which may provide useful therapeutic and perhaps preventive approaches for psoriasis.

ABSTRACT: One of the most popular mushrooms in the World is the Shiitake mushroom. In the present study *lentinula edodes (L. edodes)* mycelia were grown in submerged culture and the polysaccharides were extracted from culture broth. The structure of polysaccharides was elucidated using NMR spectra, which indicated that the polysaccharide is highly branched glucan containing mainly 1, 3 and 1, 6 linkages. The results showed that the polysaccharides posses anticancer activity against human esophageal cancer cell line. The potential of the internal transcribed spacer (ITS) region as a tool for studying molecular systematics and population genetics is significant. The results also showed that the polysaccharides enhance the immune-responses of human body thereby increasing resistance to cancer disease. Mycelia formed by growing pure cultures in submerged conditions are of constant composition, and submerged culture is the best technique for obtaining consistent and safe mushroom product.

Key words: Mushroom, polysaccharides, immune-responses, submerged culture, cancer.

INTRODUCTION:

Consumption of edible mushrooms has been suggested to improve health. There are thousands of different mushroom species and about 700 species have been reported to have significant pharmacological properties (Chang, 1996). Medicinal mushrooms have a long history of use in traditional Oriental therapies. Hot-water-soluble fractions of medicinal mushrooms have been used as medicine in the Far East (Wasser, 2002).

In the last three decades, numerous polysaccharides and polysaccharide-protein complexes have been isolated from mushrooms and used as a source of therapeutic agents. The most promising biopharmacological activities of these biopolymers are their immunomodulation and anti-cancer effects.

They are mainly present as glucans with different types of glycosidic linkages such as (1-->3), (1-->6)-beta-glucans and (1-->3)-alpha-glucans, and as true herteroglycans (figure 1), while others mostly bind to protein residues as polysaccharide-protein complexes (Chihara *et al.*, 1987 and Zheng *et al.*, 2005). The β-glucans have been shown to inhibit tumor growth *in vitro* and *in vivo*.

The β-glucans lentinan from *L. edodes*, schizophyllan (sonifilan) from *Schizophyllum commune*, grifolan from *Grifola frondosa*, and extracts from *Sclerotinia sclerotiorum* all have anti-tumor activity. Intratumor injection of an acid-treated fraction of *Agaricus blazei* inhibited tumor growth of that tumor as well as other tumors at remote sites [Fujimiya et al., 1998]. An extract from the *Phellinus rimosus* mushroom extended the life span of mice by 96% following injection of tumor cells in an experimental Dalton's lymphoma ascites model [Ajith and Janardhanan, 2003].

L. edodes is the first medicinal macrofungus to enter the realm of modern biotechnology. It is the second most popular edible mushroom in the global market which is attributed not only to its nutritional value but also to possible potential for therapeutic applications. *L. edodes* is used medicinally for diseases involving depressed immune function (including AIDS), cancer, environmental allergies, fungal infection, frequent flu and colds, bronchial inflammation, heart disease, hyperlipidemia (including high blood cholesterol), hypertension, infectious disease, diabetes, hepatitis and regulating urinary inconsistencies. It is the source of several well-studied preparations with proven pharmacological properties, especially the polysaccharide lentinan, eritadenine, shiitake mushroom mycelium, and culture media extracts (LEM, LAP and KS-2). Antibiotic, anti-carcinogenic and antiviral compounds have been isolated intracellularly (fruiting body and mycelia) and extracellularly (culture media). Bisen et al., 2010.

During the last 15 years the internal transcribed spacer (ITS) of nuclear DNA has been used as a target for analyzing fungal diversity in environmental samples, and has recently been selected as the standard marker for fungal DNA barcoding. Bellemain et al., 2010. The potential of

ITS region as a tool for studying molecular systematics and population genetics is significant.

Hearst et al., 2009, previously suggested that it is required to isolate and identify active compound(s) in L. edodes. They stated that once these have been identified, suitable pharmaceutical delivery systems should be explored to allow concentrated extracts to be prepared and delivered optimally, rather than crude ingestion of raw material, which could promote further bacterial resistance.

The aims of the present study were to 1- growing *L. edodes* mycelia in submerged culture and extracting the polysaccharides from culture broth. 2- to elucidated the structure of polysaccharides was using NMR spectra, and 3- to generate the phylogenetic tree of this isolate compared to other isolates. And finally 4- to posses the biological activity of the isolated polysaccharides both as antimicrobial and as anticancer (against human esophageal cancer cell line)

MATERIAL AND METHODS:

Microorganism and media

A culture of *L. edodes* was isolated from local forest in La Crosse USA. The culture was maintained on a yeast complete medium and subculture every 1 month, and the slants were incubated at 27ºC for 7 days and then stored at 4ºC. The seed cultures were grown in 250ml flasks containing 100 ml of medium containing (g/l) : glucose 10, yeast extract 1, peptone 2, KH2 PO4 0.5 , Mg SO4 0.5 at 27ºC on a rotary incubator at 150 rpm for 7 days.

Fermentation

L. edodes was initially grown on yeast complete medium in Petri dish, and then transferred to the seed culture medium by punching out 2.5mm of the agar plate culture with a sterilized cutter. After 7 days of growing in shake flasks .The fermentation medium was inoculated by 3 % of the seed culture. A 15 liters Stirred tank fermentor (BIOFLO 3000 New Brunswick, USA) was used in the experiment, the cultivation in the fermentor for 10 days. The temperature was adjusted for 27ºC and the rpm 150. Fermentation experiment was performed in duplicate.

Extraction of the polysaccharide

The fermentation broth was filtered and then centrifuged at 5000 X g for 15 minutes, and the resulting supernatant was concentrated using rotary evaporator .The concentrated supernatant was mixed with two volume of absolute ethanol, stirred vigorously and left overnight at 4ºC. The purified polysaccharide is then pooled and lyophilized.

Estimation of mycelial growth and polysaccharide production

Samples collected from the fermentor at various intervals were centrifuged at 5000 X g for 15 minutes. Polysaccharide was separated from supernatant and lyophilized until constant weight was confirmed. The dry weight of mycelia was measured after repeated washing of the mycelial pellets and drying overnight at 70ºC to a constant weight.

NMR

The ^{13}C NMR spectra were recorded on an INOVA-600 spectrometer (Varian, Palo Alto, CA, USA) at ambient temperature.

MTT assay

Human esophageal cancer cell line was kindly obtained from university of Cape Town.

The amount of yellow MTT (3- (4, 5-Dimethylthiazol- diphenyltetrazolium bromide) reduced to purple formazan is measured spectrophotometrically by a spectrometer. This reduction takes place only when mitochondrial reductase enzymes are active, and thus conversion is directly related to the number of viable cells. The production of purple formazan in cells treated with an agent is measured relative to the production in control cells, and a dose-response curve can be generated (Mosmann, 1983).

Antimicrobial Activity assay

Muller-Hinton agar medium was used as an assay medium. The agar medium at 45ºC was mixed with 0.1ml bacterial suspension. The mixture was powered into 9cm petri dish and allow to ceritified. Sterile paper diskes were placed on the dried surface of the medium. Each disk received 20ml of the culture filtrate. Perti dishes were incubated at 37ºC for 18hs. The inhibation zone was measured mm. diameter (Amade *et al.,* 1994).

DNA Extraction

DNA extraction was done using C-TAB Lysis buffer and 70% ethanol precipitation. DNA clean up via Geneclean III kit by Q-biogene Ten microlitres of each of the extracted DNA solutions were checked by an electrophoresis on a one percent agarose gel.

PCR Analysis

Total DNA was subject with primers specific to the ITS-domain (5'-CTTGGTCATTTAGAGGAAGTAA-3'), (5'-CCTCCGCTTATTGATATGC-3') (White *et al.,* 1990). DNA amplifications were carried out in a thermocycler Eppendourf PCR system with denaturing step at 95ºC for 5min and the step cycle

program set for 35 cycles (with a cycle consisting of denaturing 94ºC for 30s, annealing at 45ºC for 30s and extension step at 72ºC for 30s), followed by a final extension step at 72ºC for 10 min.

Cloning and sequencing of PCR fragments

Expected PCR-amplified fragments were excised from agarose gel and purified using Qiagen Gel Extraction kit (Qiagen, Germany) and then cloned with TOPO TA cloning kit (invetrogen, USA) in the competent E. coli strain TOPO 10. Plasmid DNA was isolated using Qia Spin mini-prep kit (Qiagen, Germany). Plasmid DNA was sequenced in both directions using BigDye Sequencing kit and Applied Biosystems 3730xl automated DNA sequencing Instrument at the University of Wisconsin, USA. Biotechnology Center.

Alignment and phylogeny

Pairwise and multiple DNA sequence alignment were carried out using CULSTALW (http://align.genome.jp). The phylogenetic tree was generating using MUSCALE 3.7 (http://www.phylogeny.fr/) according to Dereeper *et al.,* 2008). To obtain the phylogeny tree, 10 different strains were used, including ours, as illustrated in table (1).

RESULTS AND DISCUSSION

Shiitake (L. edodes (Berkeley) Pegler) is one of the most consumed mushrooms, for both therapeutic purposes and as food, therefore, the study of its biological properties is of great interest for producers and consumers. L. edodes mycelia have an excellent nutritional value. Their raw mycelia were found to include 88–92% water, protein, lipids, carbohydrates as well as vitamins and minerals. On a dry weight basis, they have a relatively high nutritional value when compared to commonly consumed vegetables. Dried shiitake mushrooms are rich in carbohydrates and protein. They contain 58–60% carbohydrates, 20–23% protein (digestibility of 80–87%), 9–10% fiber, 3–4% lipids, and 4–5% ash (Data not shown). Shiitake is one of the best-known and best-characterized mushrooms used in medicine. It is the source of several well-studied preparations with proven pharmacological properties, especially the polysaccharide. Using methods of fractionation and purification of polysaccharide reported by Chihara (1969 and 1992) exo-polysaccharides were isolated from shiitake, Chihara was one of the first to report on the anti-tumor properties of the mushroom, stating that lentinan a polysaccharide isolated from the fruit bodies ‘‘was found to almost completely regress the solid type tumors of Sarcoma 180 and several kinds of tumors including methylchloranthrene induced fibrosarcoma in synergic host–tumor system Wasser (2002).

The potential of the ITS region as a tool for studying molecular systematics and population genetics is significant (Boyer *et al.,* 2001). We compared our ITS r-RNA *L. edodes* sequence with another sequences on GenBank to detect the similarity of this region with other *L. edodes* isolates (figures 3, 4) (Hibbett *et al.,* 1995; Miyazaki *et al.,* 2007, Gao et al., 2008, Yu, 2008, Jiang et al., 2008 (a), Jiang et al., 2008 (b), Jiang et al., 2009, Cao & Bao, 2009, and Le et al., 2010).

The H NMR Spectra (Figure5) of the exopolysaccharides exhibited signals at different resonance which represent the anomeric proton and protons of the different hydroxyl groups. The C13 NMR Spectra showed the presence of 6 carbon atoms the proton magnetic resonance is the most accurate spectroscopic method used to determine the structure of new compounds. The obtained NMR spectra could be compared with those reported by Gorin (1981) for lentinan polysaccharides, a potent antitumor agent extracted from shiitake.

Mushroom polysaccharides were tested for antibacterial activity in vitro against gram positive and gram negative bacteria. The minimum inhibitory concentration reported in Table (2) shows that mushroom polysaccharide has a potent antibacterial effect against different kind of bacteria. Only a few studies have explored shiitake’s antibacterial components, and these have concentrated on their potential in terms of bacteria of oral origin. Anti-bacterial activity is an exciting result, with increasing bacterial resistance to antibiotics, improving host immunity may be the way forward in fighting bacterial infection. But, these results should be viewed with caution because the published papers in this area are confined to only one or two journals, and although these have reliable IF scores, this fact does not lend support to them being credible results. There is a lack of significant studies in this area; and none that were from researching the anti-caries aspect of anti-bacterial activity.

A postulated mechanism of lentinan’s anti-bacterial activity was by the induction of increased levels of complement C3 and C3b formation (Shouji *et al.,* 1999). Although, modulation of the non-specific immune system has also been displayed in numerous studies, and may be the potentiator of lentinan’s anti-bacterial activity.

Cytotoxic activity of isolated polysaccharides was examined using esophageal cancer cell line in vitro. Results showed that polysaccharides inhibited tumour cell growth .This result are with the conclusion of other investigators (Hibasami et al., 2003 and Zhang et al., 2007) who stated that these

polysaccharides could arrest the cell cycle and generate apoptosis. Also Miyaji et al., 2006, evaluated the aqueous extracts of the shiitake mushroom (*L. edodes* (Berkeley) Pegler) in HEp-2 cells in vitro.

Extracts of multiple varieties of mushrooms have been shown to be protective in experimental cancer models; presumably because in part they boost anti-tumor immunity. These polysaccharides and polysaccharide-protein complexes are suggested to enhance cell-mediated immune responses in vivo and in vitro and act as biological response modifiers (Borchers *et al.,* 1999). Potentiation of the host defense system may result in the activation of many kinds of immune cells that are vitally important for the maintenance of homeostasis. Polysaccharides or polysaccharide-protein complexes are considered as multi-cytokine inducers that are able to induce gene expression of various immunomodulatory cytokines and cytokine receptors (Okamoto *et al.,* 2004).

Some interesting studies focus on investigation of the relationship between their structure and antitumor activity, elucidation of their antitumor mechanism at the molecular level, and improvement of their various biological activities by chemical modifications. Israilides *et al* (2008) demonstrate cytotoxic and cell growth inhibitory (cytostatic) effect of aqueous extracts of the shiitake mushroom on MCF-7 human breast adenocarcinoma cell line. Such effect was demonstrated with fruit body and mycelial extracts, the difference being that there was no significant suppression on normal cells with the latter. Furthermore mycelial extracts did not induce any cytostatic effect in both cancer and normal cell lines based on a DNA synthesis assay. The significant suppression of the proliferation of cancer cells was reflected by the comparatively low IC (50) values and the simultaneous higher respective values on normal fibroblast cells.

There is a lot of evidence to support the anti-tumour assertions made of lentinan. A number of valuable studies have been conducted on the consequence of lentinan administration, and its acceptance into clinical medicine in Japan should perhaps highlight its efficacy. The researchers in Japan have covered much ground in the area of neutraceuticals from mushrooms and have unearthed the potential of *L. edodes*. At the moment there is not enough credible information to warrant the marketing of lentinan in the world, further investigations, look to be promising, while isolated purified shiitake constituents have received appropriate scrutiny investigations into the anti-tumour potentials of shiitake consumption are limited. There is a lack of epidemiological data as to the prophylactic effects of mushroom intake on the development of spontaneous tumours and the evidence that suggests shiitake consumption elicits anti-tumour effects are only found in murine systems. Therefore, the claim that shiitake consumption has anti-tumour effects is not fully substantiated.

CONCLUSIONS:

This study shows the potential the efficacy of the given method to isolate a highly branched glucan containing mainly 1, 3 and 1, 6 linkages. Biological examinations revealed its antimicrobial, cytotoxic activity against esophageal cancer cell line. Further research is needed to establish content and bioactivity of the many compounds present and the effect of preparation and consumption differences on their medicinal activity.

Abstract: The effective removal of HM ions from aqueous wastes is among the most important issues for many industrialized countries. The present work has been carried out to study the adsorption of Cd(II), Al(III), Co(II) and Zn(II), by adsorption technique using CKD which, are both wastes and are pollutants. The sorption process was examined in terms of its equilibria and kinetics. Batch adsorption experiments were conducted to evaluate the removal of Cd(II), Al(III), Co(II) and Zn(II), onto CKD waste over a wide range of operating conditions of sorbat concentration, pH, contact time, sorbent dose. The batch experiments showed that the most effective pH range was found from 5.5 to 8. Time-dependent experiments for the removal efficiency of HM ions showed that Al(III) required a shortest contact time, for Zn(II) and Cd(II), binding to the CKD was rapid and occurred within 20 to 40 min and completed for Co(II) within 4 hrs. High sorption capacities were observed for the four HM ions. The binding capacity experiments revealed the following amounts of HM ions bound per gram of CKD: 165.994 mg/g, 75.389 mg/g, 64.296 mg/g and 108.875 mg/g for Zn(II), Al(III), Co(II) and Cd(II), respectively. The equilibrium data for HM ions fitted both Langmuir and Freundlich models and based on Langmuir constant. The adsorption isotherm studies clearly indicated that the adsorptive behavior of HM ions on CKD satisfies not only the Langmuir assumptions but also the Freundlich assumptions, i.e. multilayer formation on the surface of the adsorbent with an exponential distribution of site energy.

Key words: Sorbat, Sorbent, Adsorption, Freundlich, Langmuir and Neutralization. Cement kiln dust (CKD).

1. Introduction:

Industrial and mining waste waters are the major source of pollution by heavy metals. Furthermore, in developing countries, many industries are operated at small or medium scale, or even as a family business within the residential premises of the owner. These smaller unties can generate a considerable pollution load, which, in many cases, is discharged directly into the environment without any facilities for waste-water treatment. This is because the capital investment, turnover and profit for these industries are also small. Heavy metals can pose health hazards if their concentrations exceed allowable limits. Even when the concentrations of metals do not exceed these limits, there is still a potential for long–term contamination, since heavy metals are known to be accumulated within biological systems. In recent years, increasing awareness of the environmental impact of heavy metals has prompted a demand for the purification of industrial waste water prior to discharge into natural waters. This has led to the introduction of more strict legislation to control water pollution. In this study several metal ions have been investigated such as Zinc that is present in waste water stream from steel works, rayon fiber manufacture, production and recalculating of cooling water system employing cathodic treatment also in electroplating process (Ismail, 2003). Cadmium causes intoxication of liver, kidneys, brain, lungs, heart and testicles. It is a carcinogen. Cobalt is a microelement involved in such essential processes as nitrogen fixation. The lack of cobalt can lead to abnormal angiogenesis and dangerous diseases in cattle; it is a vital component of cobalamine. On the other hand, despite of the fact that it is an essential microelement, at higher concentrations cobalt can have dangerous effects on living organisms. Cobalt compounds are classified as class II, which means they are not extremely toxic. However, one of the main potential effects of cobalt compounds is decrease of natural ability of rehabilitation of water reservoirs. In plants, cobalt becomes toxic at a concentration of 0.1 – 0.3 mg / l. People exposed to cobalt compounds were reported to suffer from defective metabolism of proteins and carbohydrates, anemia, Basedow's disease, carcinogenic and mutagenic effects (Dalia Virbalyte, 2005). Treatment

processes for metals contaminated waste streams include chemical precipitation, membrane filtration, ion exchange, adsorption, and electro deposition. Cost effective alternative technologies or sorbets for treatment of metals contaminated waste streams are needed. However, most of the methods suffer from some drawbacks as high capital and/or operational cost or the disposable of the residual metals sludge (Mohammad Aimal, 1996). Adsorption processes for heavy metals contaminated wastewater have been proved to be successful by many researchers (Bailey, 1999; Juang, 1999). In this regard the use of abundant low cost and effective adsorbent materials is of interest. Activated carbon has been recognized as a highly effective adsorbent for the treatment of heavy metals in waste water (Reed, 1994). However, it is relatively expensive to produce. Therefore, there is increasing research interest using alternative low–cost adsorbents. Many such materials have been investigated, including microbial biomass, peat, compost, leaf mould, palm press fibre, coal straw, wool fibre and rice milling by- products (Singh, 1997; Wase Daj, 1997) not all of these are effective. Therefore, it is still important to identify suitable low cost adsorbents for heavy metal removal. In this study we have investigated the interaction of CKD with Cd(II), Al(III), Co(II) and Zn(II). The cement industry in Egypt applies dry processes in cement manufacture and releases a large amount of by-pass cement kiln dust (CKD) , is both a waste and a pollutant Therefore, it was desired to make use of this waste and to save the environment.

2. Experimental

2.1. Adsorbent CKD

CKD generated in large quantities for example in Tourah Portoland Cement Factory, the production of CKD is around 5.35% of the total production of the dry kilns, which is about 9000 tons/day. So the amount of CKD about 477 tons/day. In this company 205 tons of the total CKD produced may be recycled to the wet process but the residual amount is discharged in the desert after granulation by using water. The amount of water needed to granulate this amount of CKD, was about 304m^3 /day, this calculation based only on CaO only. These big amounts of CKD produced and the amount of water needed cost the company a lot of unprofitable money and effort. As received CKD was kept all the time on a dessicator to a void the conversion of CaO to $CaCO_3$. CKD has average particle size 3µ during the adsorption process .the pH of 4g/l suspended CKD in deionized water was 10. X-ray florescence, Micromeritics GEMINI 2360 surface area analyzer, Micromeritics SEDI-GRAPH 5100 particle size analyzer and Micromeritics ACCUPYC 1330 density analyzer are devices were used for the physical and chemical analysis of CKD.

2.2. Chemicals

Analytical grade reagents were used for heavy metal solution, ACS reagent grad concentrated hydrochloric acid, NaOH and buffer solutions (E.Merck) were used to adjust pH values of samples. In all experimental work, demineralised water was used.

2.3. Adsorbate solution

Synthetic stock solution of heavy metals was prepared by dissolving required quantity of Analar grade salts in the demineralised water. The salts used are Cadmium chloride, Zinc nitrate, Cobalt chloride, Aluminum nitrate, as sources for Cd(II), Zn(II), Co(II), Al(III), respectively, for the preparation of stock solution. The stock solution was further diluted with demineralised water to desired concentration for obtaining the test solutions.

2.4. Batch mode adsorption experiments

The adsorption of heavy metals on cement kiln dust was studied by batch technique. The general method used for this study is described as below**:**

A known weight of adsorbent (e.g. 0.5–1.5 g) was equilibrated with 50 ml of the heavy metals $CdCl_2$, $CoCl_2$, $Zn(NO_3)_2$ and $Al(NO_3)_3$ with a known starting concentration in a plastic bottles at a fixed temperature (24+1) C° in a thermostatic mechanical shaker (WIDSONS Scientific) for a known period (5 min–24 h) of time. After equilibrium, the suspension of the adsorbent was separated from solution by filtration using Whatman filter paper No. 1. The concentration of heavy metal ions remaining in solution was measured by Inductive Coupled Plasma–Atomic Emission Spectroscopy (ICP-AES). The effect of several parameters, such as pH, concentrations, contact time and adsorbent dose on the adsorption was studied. The pH of the adsorptive solutions was adjusted using hydrochloric acid, sodium hydroxide and buffer solutions when required. Adsorption of metal ions on the walls of glass flasks determined by running the blank experiments was found negligible. The results of these studies were used to obtain the optimum conditions for maximum heavy metals removal from aqueous solution.

2.5. Removal and adsorption of heavy metals

The percent heavy metal removal was calculated using the following equation:

$$\%R = \frac{C_o - C}{C_o} * 100 \qquad (1)$$

Where: C_o: Initial heavy metal ion concentration of test solution, mg/l.

C : Final equilibrium concentration of test solution, mg/l.

The adsorbed phase concentration was calculated using the following equation

$$q = (C_o - C) * \frac{v}{m} \quad (2)$$

where:

q: Amount of heavy metal ions adsorbed per unite mass of adsorbent, mg/g

V: is the volume of the solution in, L

M: is the weight of dry CKD in, gm

Quality Control (QC) aspect: To insure the accuracy, reliability, and reproducibility of the collected data, all the batch experiments were carried out in duplicate and the mean values of two data sets are presented. When the relative error exceeded the relative stander deviation by more than 1.0%, the data were disagreed and a third experiment was conducted until the relative error fell within an acceptable range.

3. Results and Discussion

CKD was utilized to remove heavy metals such as: Zn (II), Co (II), Cd (II), and AL (III) from wastewater. Therefore, the parameters affecting heavy metals removal from synthetic solution such as; the effect of residence time, the effect of pH, the effect of variation sorbent amount added, the effect of variation initial sorbate concentration (Zn, Co, Cd, and Al ions) and finally studying the effect of temperature on the adsorption of these heavy metal ions. Inductive Coupled Plasma –Atomic Emission Spectroscopy (ICP-AES): It is used for analysis of trace elements in a wide range of samples and samples types.

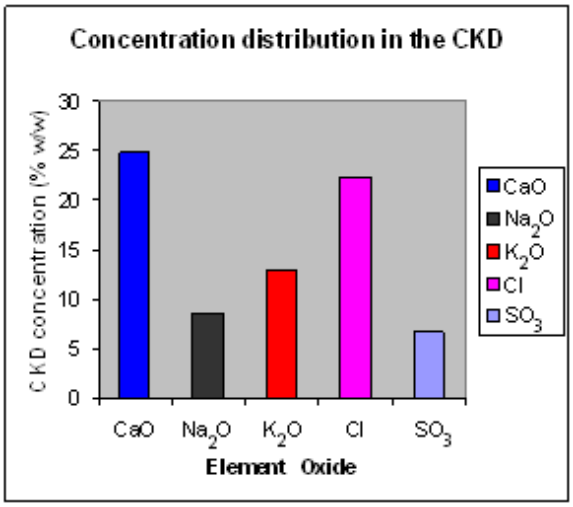
3.1. Analysis of CKD

The sample of CKD obtained from companies was analyzed by X-ray fluorescence (XRF), the percent composition of the CKD are shown in Table (1) the main ingredients or the major components of CKD are calcium oxide, besides sodium oxide, potassium oxide, sulfur-tri-oxide, silicate and chloride. The alkalinity nature of the dust makes it a good neutralizing agent for acidic wastewater stream.

Table (1): X-ray Fluorescence analysis of CKD

Ingredients	% Average Percent
SiO_2	3.14
TiO_2	0.05
Al_2O_3	0.38
Fe_2O_3	0.61
MnO	0.01
MgO	0.22
CaO	24.85
Na_2O	8.61
K_2O	12.95
P_2O_5	0.04
Cl	22.35
SO_3	6.71
L.O.I*	19.45

* loss of ignition



3.2. Effect of initial concentration of heavy metal ions

The effect of initial concentration on the percentage removal of heavy metals by CKD is shown in figure (1) It can be seen from the figure that the percentage removal decreases with the increase in initial heavy metal concentration. For Zn(II), it is seen that the percentage removal is almost complete (nearly 90-100%) throughout the initial metal ions concentration range (384.55-1825.8) mg/L for 10 g/L adsorbent dose, at pH 5.89 and equilibrium contact time. For Cd(II) and Al(III) at same adsorbent dose and equilibriums contact time, there are gradually drop in percentage removal at higher initial concentration, whereas for Co(II) the percentage removal is highly effective >80% below 600 mg/l initial concentration after which percentage removal decreases sharply to below 70%. At higher initial concentrations, Cd(II) shows greater percentage removal than Al(III). At lower initial metal ion concentrations, sufficient adsorption sites are available for adsorption of the heavy metals ions. Therefore, the fractional adsorption is independent of initial metal ion concentration. However, at higher concentrations the numbers of heavy metal ions are relatively higher compared to availability of adsorption sites. Hence, the percent removal of heavy metals depends on the initial metal ions concentration and decreases with increase in initial metal ions

concentration. The difference in percentage removal of different heavy metal ions at the same initial metal ions concentration, adsorbent dose and contact time may be attributed to the difference in their chemical affinity and ion exchange capacity with respect to the chemical functional group on the surface of the adsorbent.

The percentages of removal of Zn(II), Al(III), Co(II) and Cd(II) solutions, in which concentrations were 100–2000 mg/L, were evaluated by using CKD showed high removal efficiency for all metals. These results are shown in figure (1) in these adsorbants, high removal efficiency (95%) was obtained over the Zn(II), Cd(II) and Al(III) concentration range 100-800mg/L. However, the removal percentage gradually decreased with increasing the concentration (>800 mg/L).

3.3. Effect of adsorbent dose

The results for adsorptive removal of heavy metals with respect to adsorbent dose are shown in figure (2) over the range 10–30 g/L, at pH 5.89 and 6.17 for Al (III) and Cd (II), respectively and 8 for Zn(II) and Co(II), the percentage removal of heavy metals is seen to increase with adsorbent dose. From (Fig.2.), the percentage removal of Al (II) ions show 100% removal throughout the range of concentrations studied (within initial concentration 803.10 mg/L). It is observed that there is a sharp increase in percentage removal with adsorbent dose for Zn (II) and Cd (II) ions but in case of Co (II) ions, there is gradual increase in percentage removal with increasing dose. It is apparent that the percent removal of heavy metals increases rapidly with increase in the dose of the adsorbents due to the greater availability of the exchangeable sites or surface area. Moreover, the percentage of metal ion adsorption on adsorbent is determined by the adsorption capacity of the adsorbent for various metal ions.

3.4. Batch contact time studies

Figure (3) indicates that removal efficiency increased with an increase in contact time before equilibrium is reached. Other parameters such as dose of adsorbent, pH of solution and agitation speed was kept optimum, while temperature was kept at 30^{o}C .It is observed that for Al (III) ions, the percentage removal is nearly 100% even throughout the all contact times. Hence the Al (III) requires a shortest contact time. In case of Zn(II) and Cd(II) ions showed sharp rise in percentage removal with increasing contact time. It can be seen that Zn and Cd removal efficiency by using CKD increased from 80% to 95% when contact was increased from 20 to 40 min. On other hand, percentage removal of Co (II) increases gradually with contact time, reaching nearly 95% removals only at around 4 h. It is evident from the results that the contact time required to attain equilibrium is dependent on the initial concentration of heavy metals. For the same concentration, the percentage removal of heavy metal increases with increase of contact time till equilibrium is attained. The optimal contact time to attain equilibrium with CKD was experimentally found to be about 40 min for Zn(II), 5 min. for Al(III), 1 h for Cd (II) and 4 h for Co(II). These results are important, as equilibrium time is one of the important parameters for an economical wastewater treatment system.

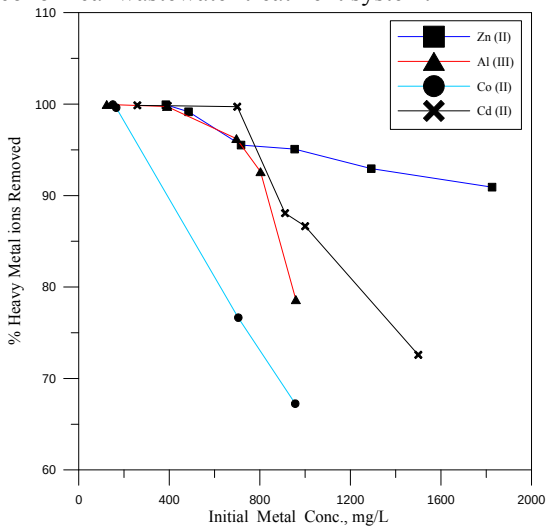


Fig. (1): Effect of initial concentration on the percent removal of heavy metal ions by using CKD.

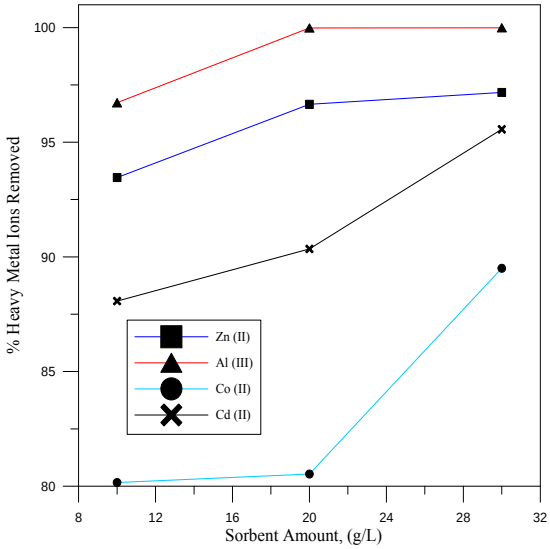

Fig. (2): Effect of variation sorbent dose on heavy metal ions removal by using CKD,at 130 rpm and temp.30^{o}C.

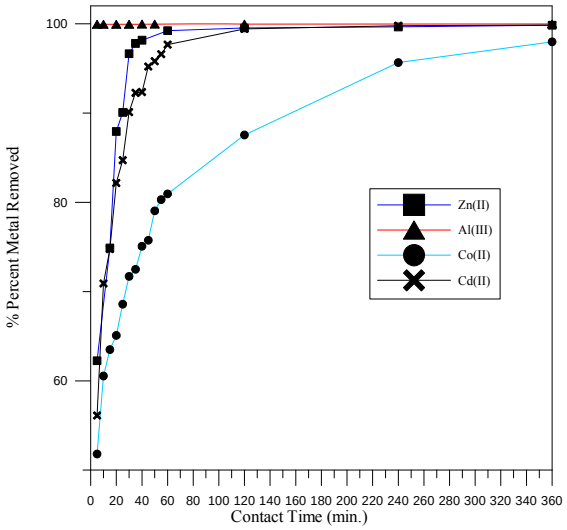

Fig. (3): Effect of contact time on the percent heavy metal ions removal by using CKD.

It has been observed that (Gardea, 1998; Panday, 1985) the mechanism of metal removal from the aqueous metal involved four steps: (i) migration of metal ions from the bulk solution to the surface of the adsorbent; (ii) diffusion through boundary layer to CKD surface; (iii) adsorption at a binding site and (iv) intra particle diffusion into the interior of the CKD. The boundary layer resistance will be affected by the rate of sorption and increasing the agitation time will reduce this resistance and increase the mobility of the ions. However, because the process is time dependent, after about 40 min, 5 min, 1 hr and 4 hr for Zn(II), Al(III), Cd(II) and Co(II), respectively of agitation, adsorption remains slightly or relatively constant. This observation is in agreement with the proposed mechanism obtained from the sorption characteristic study.

3.5. Effect of pH

pH is one of the most important parameters controlling uptake of heavy metals from wastewater and aqueous solutions. Figure (4) shows the percent removal of the four heavy metals as a function of pH at heavy metal concentrations of 384.55, 123.60, 150.40, 258.51 mg/l for Zn(II), Al(III), Co(II), Cd(II), respectively and a CKD concentration of 10 g/L. In general, the amount of heavy metal removed increased as pH increased, and sharply reached over 90% removal at a specific pH value. As shown in diagram given (Heechan , 2005), indicating that the removal of the metals was mainly accomplished by adsorption. As pH increased from 5.5 to 8, it can be expected that the CKD surface becomes more negatively charged. Thus, more favorable electrostatic attraction forces enhanced cationic metal ion adsorption as pH increased. However, the dependence of heavy metal adsorption on pH was different for each metal. The removal of zinc was about 80% at pH 6.5 and it increased to 99% at pH 8. For Aluminum, 85% was removed at pH 5 and it increased to 99% at pH 6. For cadmium, 90% was removed at pH 5.5 and it increased to 99% at pH 6.2 .For Cobalt, removal increased proportionally with increasing pH from 50% at pH 6–90% at pH 8. The percentage adsorption increases with pH to attain a maximum at pH 6-8 and thereafter it decreases with further increase in pH. The maximum removal of Zn (II) and Co(II) at pH 8 were found to be nearly 99 and 90%, respectively, whereas, for Al (III) 99% removal at pH 6 and for Cd(II) 99% removal at pH 6.2. A sharp decrease in removal percent of Al(III) was observed at very high pH values. In case of aluminum, the possible presence of species Al^{3+} and the hydroxyl forms $Al(OH)_2^+$, $Al(OH)_2^+$, $Al(OH)_3$, and $Al(OH)_4^-$. Aluminum is precipitated for pH between 4 and 10. Depending on the pH of the solution, different hydroxyl complexes: $Al(OH)_2^+$, $Al(OH)_2^+$, $Al(OH)_3$, and $Al(OH)_4^-$ can be formed by the aluminum ions Al^{3+} (Bates,1986). In all cases, over 99% of all the four metals were removed except cobalt reached 90% at pH 8. It is often suggested that the tendency of metal cations to adsorb to oxide surfaces is highly correlated with their tendency to undergo hydrolysis reactions in solution (Freundlich 1939). Metal cations in aqueous solutions hydrolyze according to the generalized expression for divalent metals.

$$M^{2+}(aq.) + nH_2O = M(OH)^{2-n} + nH^+ \qquad (3)$$

Explanation of mechanism of adsorption.

The maximum adsorption at pH 8 may be attributed to the partial hydrolysis of M^+, resulting in the formation of MOH^+ and $M(OH)_2$. $M(OH)_2$ would be adsorbed to a greater extend on the non-polar adsorbent surface compare to MOH^+.With increase of pH from 4 to 8, the metal exists as $M(OH)_2$ in the medium and surface protonation of adsorbent is minimum, leading to the enhancement of metal adsorption. At higher pH, that is, above optimum pH of 8, increase in OH^- ions cause a decrease in adsorption of metal ions at adsorbent–adsorbate interface (Langmuir, 1918). Lower solubilities of hydrolysed metal ions species may be another reason for the maximum adsorption at pH 8. Since, in lower pH range, metal is present predominantly as metal ions in the adsorptive solution, there is a competition between$^+$ and M^+ ions for adsorption at the ion-exchangeable sites, leading to a low removal of metal. The extensive repulsion of metal ions due to

protonation of the adsorbent surface at lower pH may be another reason for decrease in adsorption of metal in lower pH range.

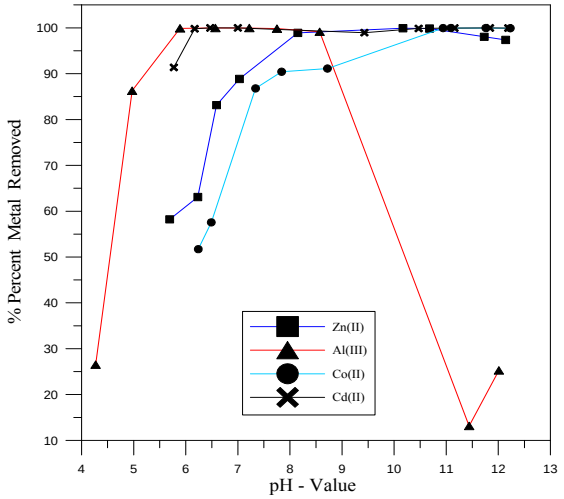

Fig. (4): Effect of different pH - values on heavy metal ions removal by using CKD.

3.6. Adsorption isotherms

The adsorption studies were conducted at fixed initial concentration of heavy metals by varying adsorbent dosage. The equilibrium data obtained were analyzed in the light of Langmuir and Freundlich isotherms.

Freundlich equation is given by (McKay, 1982).

$$q_e = K_f \; C_e^{\frac{1}{n}} \qquad (4)$$

Taking the logarithmic form of the equation

$$Log(q_e) = Log(K_f) + \tfrac{1}{n} Log(C_e) \qquad (5)$$

Langmuir equation is given by (Slejiko, 1985).

$$q_e = \frac{abC_e}{(1+bC_e)} \qquad (6)$$

The linearized expression of this equation is

$$\frac{1}{q_e} = \frac{1}{a} + \frac{1}{abC_e} \qquad (7)$$

This equation is called the **"Double-Reciprocal Langmuir Equation"** and more suitable for situations in which the distribution of equilibrium concentrations tends to be skewed towards the lower end of the range of the equilibrium concentrations. where q_e is the amount of heavy metal ions adsorbed per unit mass of adsorbent in mg/g, **Ce** the equilibrium concentration of heavy metal ions in mg/l, K_f and n are Freundlich constants, **'a'** is a Langmuir constant which is a measure of adsorption capacity expressed in mg/g, **'b'** is also Langmuir constant which is a measure of energy of adsorption expressed in l/mg. The parameters **'a'** and **'b'** have been calculated from the slope and the intercept of the plots.

Figure (5) gives the Freundlich adsorption isotherm plot of **log q_e** versus **log*C*e**. The values of K_f and **1/*n*** obtained from intercept and slope of the plot are given in Table (2). The Langmuir adsorption isotherm plot for **$1/q_e$** versus **1/Ce** is shown in figure (6) and the plots show two distinct regions, one for low $1/C_e$ values up to about 25 l/mg and another for higher $1/C_e$ values.

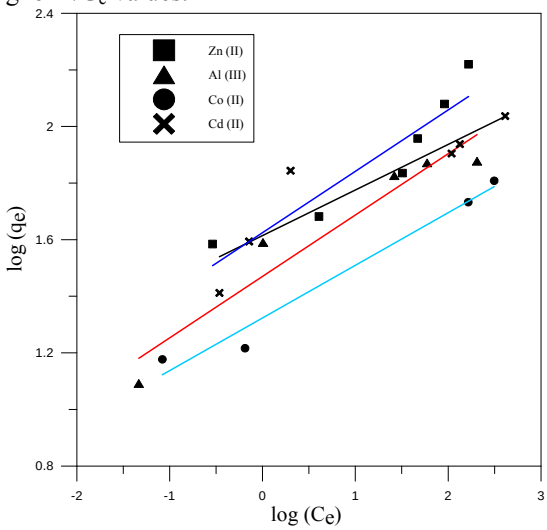

Fig. (5): Freundlich adsorption isotherm of heavy metal ions by using CKD at 30°C.

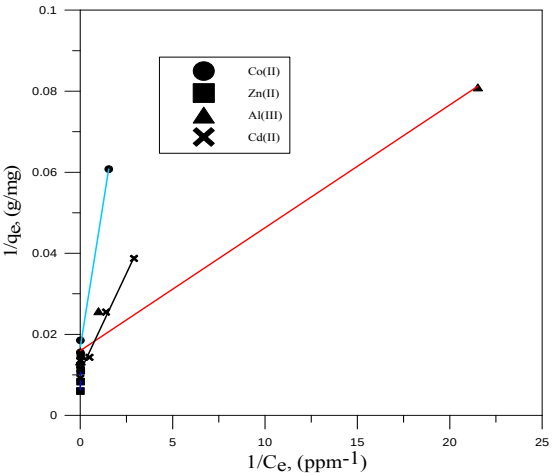

Fig. (6): Langmuir adsorption isotherm of heavy metal ions by using CKD at 30°C.

The essential characteristics of Langmuir isotherm can be described by a separation factor or equilibrium constant R_L, which is defined as,

$$R_L = \frac{1}{1+bC_i} \quad (8)$$

where C_i is the initial concentration of heavy metal ions (mg/l) and b is Langmuir constant which indicates the nature of adsorption. The separation factor R_L indicates the isotherm shape and whether the adsorption is favourable or not, as per the criteria given below.

Table 2.

R_L – values	Adsorption / Type of isotherm
$R_L > 1$	Unfavorable
$R_L = 1$	Linear
$0 < R_L < 1$	Favorable
$R_L = 0$	Irreversible

The values of Langmuir constants ***'a', 'b'*** and R_L are presented in (Tables 3, 4.) Since R_L values lie between 0 and 1 for all four adsorbants studied, it is seen that the adsorption of heavy metal ions is favourable. Adsorption capacity as indicated by value of ***'a'*** is seen to be maximum for CKD, i.e. Zn(II) (233.18 mg/g), Cd(II) (92.35 mg/g), Al(III) (62.64 mg/g), and Co(II) (58.77 mg/g) with a much lower capacities. The energies of adsorption, as indicated by ***'b'*** are seen to be highest for Al (III) (5.26 L/mg), Co(II) (4.12L/mg), Cd(II) (1.12 L/mg), and Zn(II) (0.013 L/mg) in that order. A comparison of the Freundlich adsorption isotherms for the metal ions show that ***n*** in that order Cd(II) > Co(II) > Al(II) > Zn (II). The values of **n** lie between 1 and 10 indicating favourable adsorption. K_f seen to be Zn(II) >Cd(II) >Al(II) >Co(II). This gives a similar inference as that obtained from Langmuir isotherms.

Table 3. Values of langmuir isotherm constants for adsorption of heavy metal ions by using CKD.

Metal ions	**slope**	a(mg/g)	**intercept**	b(L/mg)	R^2	R_L
Zn(II)	0.328784528	233.1785	0.004288560825	0.013044	0.992037	0.0950
Al(III)	0.003033405	62.63779	0.01596480332	5.262996	0.982052	0.0015
Co(II)	0.004133276	58.77456	0.01701416256	4.116386	0.997344	0.0016
Cd(II)	0.009701566	92.35398	0.01082790419	1.116098	0.986492	0.0034

Table 4. values of Freundlich isotherm constants for the adsorption of heavy metal ions by using CKD

Metal ions	**slope**	K_f	**intercept**	n	R^2
Zn (II)	0.2169544939	42.1260480	1.624550719	4.609262	0.862792
Al (III)	0.2168382642	29.5201782	1.470118976	4.611732	0.925075
Co (II)	0.1859835242	21.0527929	1.32330972	5.37682	0.974276
Cd (II)	0.1610804879	41.1513419	1.614384002	6.208077	0.818879

The adsorption isotherm studies clearly indicated that the adsorptive behavior of heavy metal ions on CKD satisfies not only the Langmuir assumptions but also the Freundlich assumptions, i.e. multilayer formation on the surface of the adsorbent with an exponential distribution of site energy.

On the basis of regression analysis of the experimental data on the adsorptive behavior of metal ions on CKD, it may be inferred that the adsorption behavior of metal ions on CKD is in good agreement with Langmuir model. These can be attributed to three main causes (i) the formation of monolayer coverage on the surface of CKD with minimal interaction among molecules of substrate (ii) immobile and localized adsorption and (iii) all sites having equal adsorption energies. The shapes of isotherms suggest that there are high-energy adsorption sites to favor strong adsorption at low equilibrium concentrations for the CKD.

4. Conclusions

In this study, batch adsorption experiments were performed to evaluate the use of CKD particles as an adsorbent for heavy metal ions. It was found that Aluminum required a shortest contact time 5 min, while equilibrium was reached for Zinc and cadmium within 40-60 min and completed for Cobalt at 4 hrs.

It was found that pH of the solution has a significant impact on the percentage removal of heavy metals. Between pH 5.5 and 8, where the influence of precipitation is negligible, the percent removal was 80% - 99% for zinc, 85% - 99% for Aluminum, 90% - 99% for cadmium and 50% - 90% for cobalt. The percent removal of the heavy metal

ions increased as the pH increased. Most of the metal ions had a 99% removal when the pH was 8 except cobalt had a 90% at this pH.

The adsorption isotherm studies clearly indicated that the adsorptive behavior of HM ions on CKD satisfies not only the Langmuir assumptions but also the Freundlich assumptions, i.e. multilayer formation on the surface of the adsorbent with an exponential distribution of site energy.

The results of this study have shown that CKD a cheap by- processes of cement industrial (CKD which is both a waste and a pollutant) was effective in the removal of Cd(II), Zn(II), Al(III) and Co(II) metals in wastewater.

Evaluation of Avian Influenza Vaccines used in Broiler Flocks in Egypt.

Lebdah, M.A and *Shahin, A.M.

Avian and Rabbit Medicine Department; Faculty of Vet. Med.; Zagazig University
*abeer.shahin@gmx.de

Abstract: This study was carried out to investigate the efficacy of different types of commercial Avian Influenza Vaccines (H5N1 &H5N2) used in Egypt. Three – hundred and fifty day-old broiler chicks were divided into 7 groups. Six groups of chickens were vaccinated with H5N1 and H5N2 AI vaccines at 1, 7, and 14 days-old. The chickens of group 7 were kept as negative control. All groups were fed adlibtum and kept under observation. Serum Samples were collected at day-old to evaluate the maternal immunity and after 7 weeks post vaccination with both types of vaccines from all chickens. This study revealed that, the challenge virus was highly pathogenic for control group as causing 100 % mortalities 24 hours after challenge with 10^6 EID_{50}/ 0.2 ml intranasal. Challenge of other groups showed difference in pathogenicity of the virus and immune response of the chickens according to type of vaccine and age of birds at vaccination. It could be concluded that H5N2 AI vaccine was more protective than H5N1 AI vaccine as the protection percentage and GMHI titer of experimentally broiler chicks vaccinated at day-old and fourteen days-old with H5N2 higher than chicks vaccinated with H5N1. Moreover, the vaccination of the chicks at seven days-old showed higher GMHI titer and protection percentage than vaccination at one day-old.

1. Introduction:

Avian Influenza Virus (AIV) is a type A Orthomyxovirus and produces a variety of disease syndromes in various poultry species. On the basis of serological reactions to surface glycoprotein (hemagglutination and neuraminidase), AIV is subtyped into 16 hemagglutinin (H1-H16) and nine neuraminidase (N1-9) subtypes (Kawaoka et al., 1990; Rohm et al., 1996 and Easterday et al., 1997).

Avian Influenza become the most important disaster threat to the poultry industry all over the world after the occurrence of highly pathogenic AI (HPAI) outbreaks in many parts of the world (Alexander, 2000 and Swayne, 2003) such as H5N2 in Pennsylvania and H7N1 in Italy (Capua et al., 1999; Capua and Mutinelli, 2001; Capua and Alexander, 2004 and Manvell et al; 2000).

Beside the biosecurity and monitoring infection particularly in the densely populated poultry areas, the vaccination represents an option for control. From this point of view, the evaluation of different types of Avian Influenza Vaccines (H5N1 and H5N2) used in Egypt may provide effective vaccination strategy.

Conventional Inactivated AI vaccines are widely used all over the world. Vaccination has been shown to increase resistance to field challenge and reduce virus shedding levels in vaccinated birds and subsequently reduce transmission. Despite of wide uses of different inactivated AI vaccines program, outbreaks of AI still threat poultry flocks in Egypt. Abd El Aziz (2008) concluded that single dose of vaccination at 12 days-old have better effect on chicken immune response and protection against lethal challenge with HPAIV than one day-old vaccination which need booster vaccination for initiation of humoral immune response and maximal protection rate. The aim of this study was to obtain new insights into evaluation of Avian Influenza Vaccines used in Egypt.

2. Materials and methods

A. Materials

A.1. Experimental Chickens:

A.1. Broiler chickens: Three – hundred and fifty, day – old, Ross broiler chicks were obtained from Commercial Hatcheries-Egypt

.

A.2. Avian Vaccines:

A.2.1. ND vaccines:

a. Hitchner B1 vaccine, batch No. 0151V and titer $10^{6.5}$ EID_{50}

b. La Sota vaccine, obtained, batch No. 719 u/2 and titer $10^{6.5}$ EID_{50}

A.2.2. IB vaccines:

H120 vaccine, obtained, batch No.6m5f/3 and titer $10^{3.5}$ EID_{50}

A.2.3. AI Vaccines:

A.2.3.a. an inactivated oil emulsion H5N1 Avian Influenza vaccine, A/Goose/Guangdong/16(H5N1), batch No. 009088, and titer $10^{8.5}$ EID_{50}.

A.2.3.b. an inactivated oil emulsion H5N2 Avian Influenza vaccine, obtained from EGA Vet. Company, batch No. 0901150A, and titer $10^{8.5}$ $EID_{50.}$

A.3 Local isolated AI virus (challenge AI virus).

Locally isolated H5N1virus isolate kindly supplied by Dr. Adel Abd El-Aziz, Vet. Clinic, Faculty of Veterinary Medicine, Zagazig University with titer of 10^6 EID_{50}.

A.4. Equipments

A.4.1. Instruments and Equipments:

a. Eppendorf cups

b. Microtiter Plates

c. Automatic pipettes

A.5. Reagents: Washed RBCs 10%; sterile saline, Sterile Distilled water and Phosphate Buffered saline (PBS)

A.6. Antigen: Inactivated H5N1 antigen, obtained from Veterinary laboratories Agency, New haw, Addlestone, surrey KT153 NB, UK. Prep. Date: dec05. Lot No: 3/05. It was provided kindly by Dr. Adel El-Gamal, Animal Health Research Institute, Zagazig, Egypt.

A.7. Embryonated chicken eggs (ECE): One hundreds SPF ECE (9-11 days- old) were used for titration of the viral isolates. They were obtained from Kom-Oshim Company, El Fayoum Governorate, Egypt

B. Methods:

B.1. Experimental design:

For evaluation of both AI H5N1 and H5N2 vaccines in broilers, three hundred and fifty, day- old, Ross broiler chicks, were divided into seven groups (1-7), each group containing 50 chicks. Chicks of groups 1 and 2 were vaccinated with H5N1 and H5N2 respectively at one – day old via subcutaneous injection with dose 0.5 ml / chick. Meanwhile, chickens of group 3 and 4 were vaccinated with H5N1 and H5N2 vaccines respectively, at seven days-old, via subcutaneous injection with dose 0.5 ml /chick. In addition, chicks of group 5 and \6 were vaccinated with H5N1 and H5N2 vaccines respectively, at fourteen days-old, via subcutaneous injection with dose 0.5 ml / chick. Meanwhile, chicks of group 7 were remained non - vaccinated as non vaccinated control. All experimental chickens were challenged with H5N1 via intranasal route with dose of 106EID50/0.2ml at 28 days post vaccination with both types of AI vaccines. Blood samples were taken at were collected at day-old, 7 days, 7 weeks post vaccination and three weeks post challenge, sera were extracted for determination the level of specific antibodies against Avian Influenza by using HI test. All experimental chickens were observed for clinical signs, morbidities and mortalities. All freshly dead chickens were examined for recording PM lesions.

Table 1: Experimental design for evaluation of AI vaccines in broiler

Group No.	Type of used vaccine	No. of exp. birds	Age and route of vaccination	Serum samples collection age per day							Challenge		
				1	2	3	4	5	6	7	Age / day	route	dose
1st	H5N1	50	Day – old S/C	7	14	21	28	35	42	49	28	I/N	**0.2ml X10^6 EID_{50}**
2nd	H5N2	50	Day – old S/C	7	14	21	28	35	42	49	28	I/N	
3rd	H5N1	50	7days – old S/c	14	21	28	35	42	49	56	35	I/N	
4th	H5N2	50	7days – old S/C	14	21	28	35	42	49	56	35	I/N	
5th	H5N1	50	14 days–old S/C	21	28	35	42	49	56	63	42	I/N	
6th	H5N2	50	14days– old S/C	21	28	35	42	49	56	63	42	I/N	
7th	----	50	control	14	21	28	35	42	49	56	35	I/N	

B.2. 1. Hemagglutination inhibition (HI) test:

HI test was carried out in U bottomed microplates withantigen to contain 4 HA units according to OIE (2005).

B.3. Statistical analysis:

The statistical analysis of data of different experiments was carried out according to the statistical analysis system (SAS, 1987).

3. Results

Evaluation of avian influenza vaccines:

A- Protection %, morbidity % and mortality %:

The rate of protection, morbidity and mortality differ according to breeds and age of vaccination. The non-vaccinated, challenged control chickens of all breeds and ages were dead within 24 hours post challenge. In addition, morbidities and mortalities were 100% in non-vaccinated challenged control chickens, thus the protection % was 0%. The groups vaccinated at day-old show high mortality rate than groups vaccinated at seven days old and visa versa the groups vaccinated at day-old show low protection rate than groups vaccinated at seven days old. The protection %, mortality % and morbidity % of different groups are summarized in table (2).

Table (2) Protection, mortalities and morbidities percentage of birds.

Group No.	Type of vaccine	Age of vaccination	Protection		Protection		Mortalities %	
			%	%				
Broiler (1)	H5N1	Day - old	80%	40/50	20%	10/50	20%	10/50
Broiler (2)	H5N2	Day – old	90%	45/50	20%	10/50	10%	5/50
Broiler (3)	H5N1	7 day – old	90%	45/50	0%	0/50	10%	5/50
Broiler (4)	H5N2	7 day – old	90%	45/50	0%	0/50	10%	5/50
Broiler (5)	H5N1	14 day – old	90%	45/50	10%	5/50	10%	5/50
Broiler (6)	H5N2	14 day – old	92%	46/50	2%	1/50	8%	4/50
Broiler (7)	control	-	0%	0/50	0%	0/50	100%	50/50

The protection percentage of all experimentally vaccinated chickens with either H5N1 or H5N2 AI vaccines was arranged from 80-92 %. The broiler chicks vaccinated at day - old with H5N1 AI vaccine showed lowest protection percentage (80%). Meanwhile, broiler chickens vaccinated at 14 day-old with H5N2 AI vaccine were showed highest protection percentage (92%).

B-Serological results:

1-Mean HI titer of broiler chicks vaccinated at day-old with AI H5N2vaccine showed high titer than broiler chicks vaccinated at day-old with H5N1 vaccine. The HI titer of broiler chicks were vaccinated at day-old was summarized in table (3).

Table(3): HI titer of broiler chickens vaccinated against AI at day-old.

Group	Maternal immunity	1st week*	2nd week*	3rd week*	4th week*	5th week*	6th week*	7th week*

C. Statistical analysis of HI titer:-

1-**Evaluation of AI (H5N1 and H5N2) vaccines of broiler chickens at day-old:**

Treatment	Mean ± Std. Error
Pre vaccination	1.4048 ± 0.1003^{b}
After vaccination	1.8187 ± 0.1017^{b}
After challenge	2.6758 ± 0.05^{a}

Means within the same column carrying different titer were significant at ($P \leq 0.05$). There was significant between after challenge and other treatment and there was no significant between pre vaccination and after vaccination

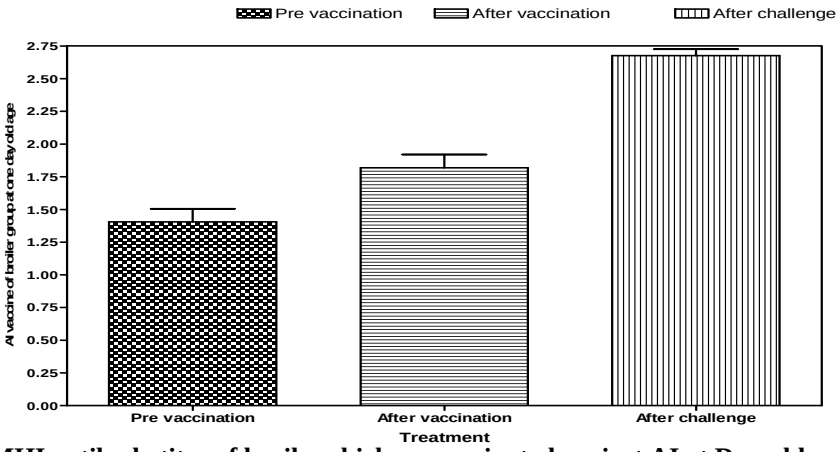

Fig (4): GMHI antibody titer of broiler chickens vaccinated against AI at Day-old.

2- Evaluation of AI (H5N1 and H5N2) vaccines of broiler chickens at seven day-old:

Treatment	Mean ± Std. Error
Pre vaccination	1.4048 ± 0.1003^{c}
After vaccination	1.9191 ± 0.1172^{b}
After challenge	2.7594 ± 0.07^{a}

Means within the same column carrying different titer were significant at (P≤0.05). There was significant between pre vaccination, after vaccination and after challenge

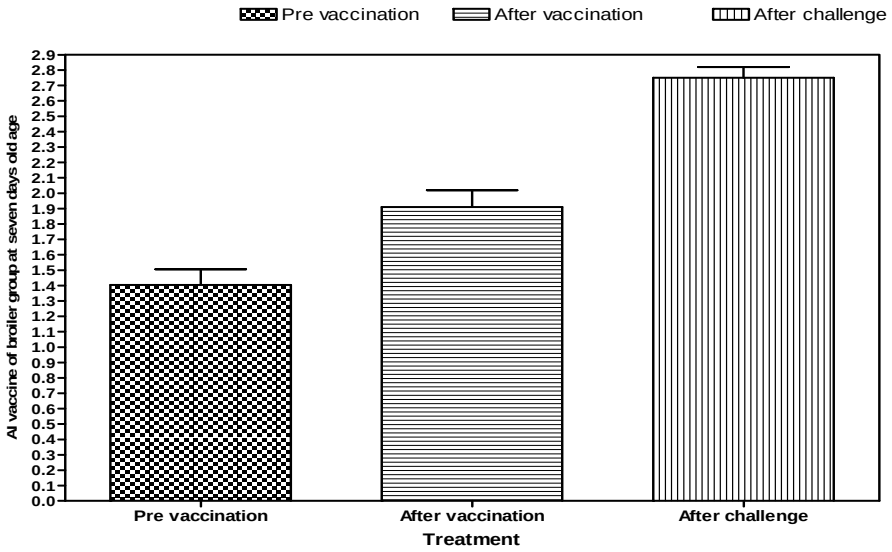

Fig (5): GMHI antibody titer of broiler chickens vaccinated against AI at seven days-old.

3- Evaluation of AI (H5N1 and H5N2) vaccines of broiler chickens at fourteen days-old:

Treatment	Mean ± Std. Error
Pre vaccination	1.4048 ± 0.1003^{c}
After vaccination	1.8940 ± 0.1064^{b}
After challenge	2.6591 ± 0.06^{a}

Means within the same column carrying different titer were significant at (P≤0.05). There was significant between pre vaccination, after vaccination and after challenge

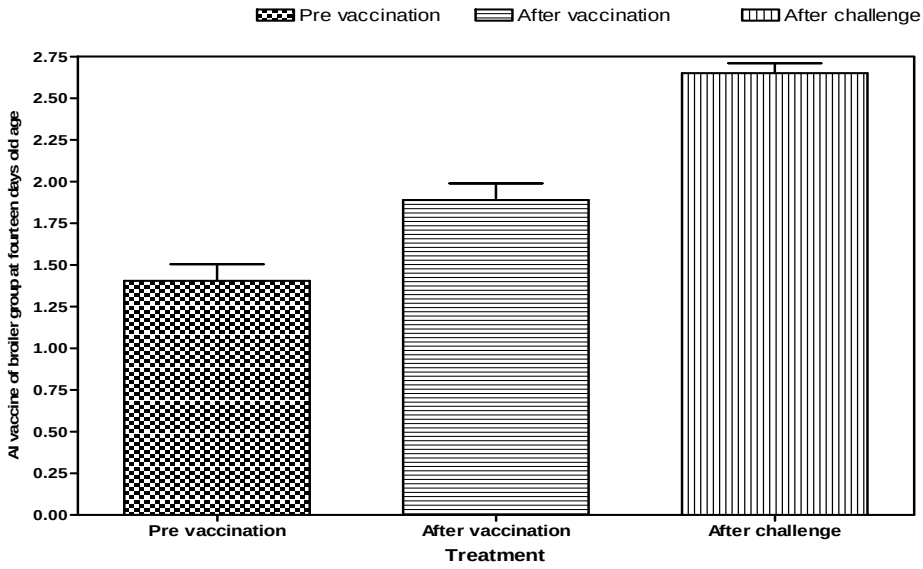

Fig (6): GMHI antibody titer of broiler chickens vaccinated against AI at fourteen days-old.

4- Evaluation of H5N1 vaccine of broiler chickens at day-old, seven day-old and fourteen days-old:

Treatment	Mean ± Std. Error
day-old	2.1861 ± 0.09[a]
seven day-old	2.2792 ± 0.09[a]
fourteen day-old	2.2219±0.08[a]

Means within the same column carrying different titer were significant at (P≤0.05). There was no significant between different treatments.

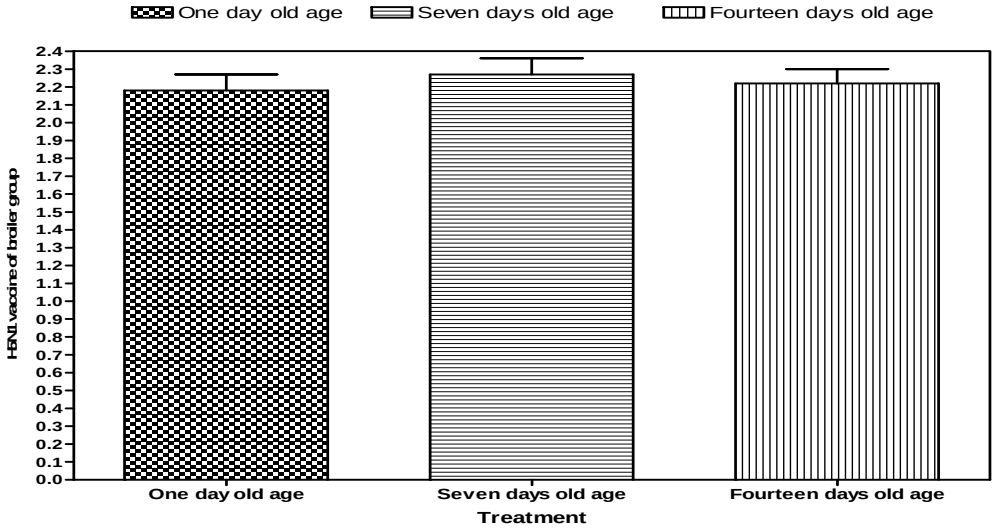

Fig (7): GMHI antibody titer of broiler chickens vaccinated against H5N1 vaccine at day-old, seven days-old and fourteen days-old.

5- Evaluation of H5N2 vaccine of broiler chickens at day-old, seven day-old and fourteen day-old:

Treatment	Mean ± Std.Error
One day old age	2.1861 ± 0.09[a]
seven days old age	2.2792 ± 0.09[a]
fourteen days old age	2.2219± 0.08[a]

Means within the same column carrying different titer were significant at (P≤0.05). There was no significant between different treatments

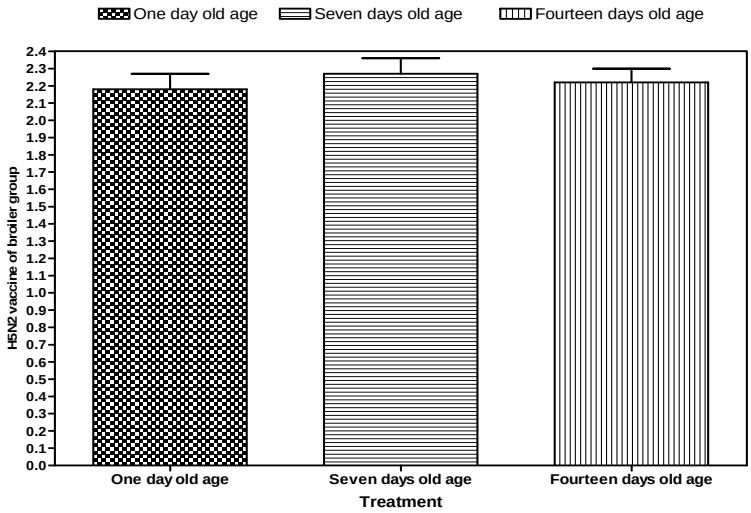

Fig (8): GMHI antibody titer of broiler chickens vaccinated against H5N2 vaccine at day-old, seven days-old and fourteen days-old.

4. Discussion:

In the present work, the effect of Avian Influenza (AI) vaccines on the chickens of different ages was recorded. In Egypt, vaccination of broilers against AI represents for now and the foreseeable future, the central strategy for prevention and control of AI.

The obtained results indicated that GMHI titer of broiler chicks vaccinated at day-old with H5N2 vaccine showed high titer than broiler chicks vaccinated at day-old with H5N1 vaccine, while mean HI titer of broiler chicks vaccinated at seven day-old with H5N1 showed high titer than broiler chicks vaccinated at seven day-old with H5N2 vaccine, but the other groups showed similarity of mean HI titer of chicks vaccinated with H5N2 or H5N1 vaccine. These results agreed with the results of Ellis et al., (2004 b) who stated that the use of killed H5N2 vaccine in the face of HPAI H5N1virus challenge was able to protect chickens from disease and can reduce virus transmission. Also, these finding were agreed with Guobin Tian et al., (2005).

Who generated a high – growth H5N21/ PR8 virus by plasmid –based reverse genetics. When chickens were immunized with 0.3 ml of the vaccine, the hemagglutinin inhibition (HI) antibody become detectable at 1 week post-vaccination and reached to the peak at 6 weeks post-vaccination then slowly declined at 43 weeks post-vaccination. When challenge test performed at 2, 3 and 43 weeks post vaccination; all the chickens were completely protected from disease signs and death. Revaccination after three weeks from the primary vaccination at saso and

Layer groups increase the GM antibody titer in both H5N1 and H5N2 vaccines leading to complete protection (100%) in some groups after lethal challenge with H5N1 virus. These results agreed with the results of Webster et al., (2006) who concluded that revaccination increase the HI antibody by about ten fold. Also these results were agreed with Abdel-Aziz (2008) who concluded that revaccination after 7 days from the primary vaccination at one day old increase the GM antibody titer about 3 folds in both H5N1and H5N2 AI vaccines, and agreed with Lee et al., (2007) who stated that one dose of 128 hemagglutinin (HA) unit of homologous H5N1 vaccine able to induce 100% protection in mortality and prevent viral shedding completely after lethal dose virus challenge, whereas one dose of 64 HA unit of heterologous H5N3 vaccine only induce50% protection in mortality, and it did not prevent viral shedding. However, two doses of 64 HA unit of heterologous H5N3 vaccine as well as one dose of 1024 HA unit of heterologous H5N3 vaccine induced 100% survival rate and could prevent viral shedding completely.

The rate of protection, morbidity and mortality after infection with the isolated H5N1Avian Influenza viruses differ according to breeds and age of vaccination. The control groups in any breeds and at any age which kept without AI vaccines, all birds of these groups died within 24 hours. The groups of chicks vaccinated at day-old showed high mortality rate (20%). On the other hand the chickens vaccinated at seven day-old showed low mortality and high protection rate (90%). These agreed with Ellis et al., (2004 a) who recorded that, when the infection spread to the recently vaccinated birds, low rate of H5N1 mortality when the chickens were between 9 and 18 days post- vaccination. However after 18 days post-vaccination, no more deaths from H5N1 AI occurred and intensive monitoring by virus isolation from these farms showed no evidence of asymptomatic shedding of the virus. This provides evidence that avian influenza vaccines can interrupt virus transmission in the field.

These results also agreed with Beato et al., (2007) who reported that the recent outbreaks of Avian Influenza were worldwide and have highlighted the difficulties in controlling this disease. Vaccination has become a recommended tool to support the eradication efforts and to limit the economic losses due to AI. The vaccination system in the poultry farms based on the use of vaccine containing a heterologous neuraminidase to the field virus. This has been shown to be very effective in reducing the viral shedding, clinical symptoms and differentiating vaccinated from infected birds. Also our results were in agreement with Bublot et al., (2007) who reported that all unvaccinated challenged birds died within 2 days, whereas 90% and 100% of chickens vaccinated with H5N9WI and H9N9It respectively were protected against morbidity and mortality. Both vaccines prevent cloacal shedding and significantly reduce oral shedding of the challenge Asian HPAI H5N1virus

It could be concluded that H5N2 vaccine gives higher protection percentage than H5N1 vaccine, and the more preferable age for vaccination is seven days-old.

Abstract: The aim of the current study was to assess Her2/neu protein on paraffin tissue sections and serum VEGF in carcinoma of the urinary bladder in a cohort of Egyptian patients. Furthermore, they were correlated to the schistosomal-associated and non-schistosomal associated bladder cancer as well as tumor types and disease stages. Immunohistochemical (IHC) procedure for Her 2/neu, FISH for detection of Her2/neu gene and serum level of VEGF by EIISA were performed in 35 patients with chronic cystitis (10 patients with nonschistosomal chronic cystitis and 25 patients with chronic schistosomal cystitis), 135 were schistosomal-associated malignant patients (75 cases of squamous cell carcinoma and 60 cases of urothelial carcinoma) and 50 cases of non schistosomal-associated urothelial carcinoma. In addition to 20 normal blood donor volunteers act as control. IHC results for Her 2/neu was overexpressed in malignant group compared to control and chronic schistosomal cystitis groups ($p<0.01$). In malignant group it was 1^+ in 33 (30%), 2^+ in 45 (40.9%) and 3^+ in 32 (29.09%). Her 2/neu incidence was significantly higher in urothelial carcinoma group 80/110 (72.2%) compared to SCC 30/75 (40%) with ($p<0.01$) and in high grade tumors than low grade tumors with ($p< 0.01$). FISH results in SCC showed that the signal ratio were 0-1.0 in 2 (6.6%), 1.1-2.0 in 18 (60%), and ≥2.0 in 10 (33.35%), which were considered positive for Her 2/neu gene amplification. In urothelial carcinoma the signal ratio was 0-1.0 in 10 patients (12.5%), 1.1-2.0 in 25 (22.3%), and ≥2.0 in 45 (58.2%). Overexpression of Her2/neu gene was significantly higher in high grades; 31 (63.6%) than in low grades; 14(56%) tumor with ($p< 0.01$), also Her2 /neu gene was significantly ($p< 0.01$) higher in invasive tumors; 45 cases (78.9%) than in non invasive tumors 10 (43.3%) with high significance ($p< 0.01$). The serum VEGF levels showed higher levels for SCC, urothelial carcinoma patients, chronic cystitis patients compared to normal controls, they were 94.7% (71/75), 89% (98/110), and 22.9% (8/35), 5% (1/20) respectively. Our results suggest that Her 2/neu overexpression might provide additional prognostic information in patients with bladder carcinomas. Because 50% of our patients harbor Her 2/neu overexpressing those patients may potentially benefit from molecular targeted therapy targeting Her 2/neu for bladder carcinoma and they should be identified by gene amplification analysis using FISH in IHC 2+ patients. In addition association between increased serum VEGF levels with high grades and invasive bladder cancer patients indicates that serum VEGF may play a role in the invasion and metastasis of cancer and may serve as an indicator of tumor progression and future recurrence and may be a candidate as a new noninvasive diagnostic tool.

Key Words: Her 2/neu protein; Her 2/neu Gene; IHC- FISH; Serum VEGF.

1. Introduction:

In Egypt, bladder cancer accounts for about 30% of all cancers, where it is the most common malignancy in men and the second most common malignancy in women after breast cancer (El-Mawla *et al.* 2001, Jemel *et al.* 2005). It has been associated with many pathogenetic factors most commonly bilharzial infestation, which is an endemic infection in the Nile River Valley (El Sebaie *et al.* 2005). In countries with a long history of schistosomiasis, research studies have identified the following risk factors for infection with S haematobium: male gender, an age < 20 years, living in smaller rural communities, exposure to canal waters, reagent strip detected hematuria and proteinuria, and a history of burning micturation (El-Harvey *et al.* 2000, Gabar *et al.* 2000). Most investigators have accepted the association between schistosomiasis and bladder cancer since the work of Ferguson 1911. The development of bladder cancer in a younger age group affects males more and is usually associated with schistosomal infection. Also it is accompanied with a high mortality rate and clinicopathologic features of schistosomal-associated bladder cancer (SABC) (Mostafa *et al.* 1999). The high frequency of squamous cell carcinoma (SCC) is due to schistosomiasis-infested bladders that frequently show squamous metaplasia and dysplasia of the

transitional epithelium (El Bolkainy *et al.* 1981). Recently, however, a relative increase in the frequency of transitional cell type in schistosomiasis-associated bladder cancer has been noted (Gouda *et al.* 2007, Felix *et al.* 2008, Heyns and van der Merwe 2008). The neoplastic changes in the urothelium of bladder are a multistep phenomenon (Carroll 1995). The exact genetic events leading to urothelial transformation involve the activation of oncogenes, inactivation or loss of tumor suppressor genes and alterations in the apoptotic gene products (Sandberg and Berger 1994).

The Human epidermal growth factor receptor 2 (Her 2/neu) oncoprotein, also known as (NEU, EGFR2, or ErbB2) is one of the members of the Epidermal Growth Factor Receptor (EGFR) family, which includes EGFR or (ERBB1), EGFR3 or (Her3/ErbB3) and EGFR4 or (Her4/ErbB4), is known to contribute to physiological mechanisms of cell proliferation by intrinsic tyrosine-kinase-activity (Wülfing *et al.* 2005). Binding of ligands, such as epidermal growth factor and transforming growth factor alpha (TGFα), to their extracellular ligand-binding domain initiates intracellular signaling cascades, leading to progression, proliferation, migration and survival of cancer cells (Yarden and Sliwkowski 2001).

EGFR and Her 2/neu are dysregulated in many human cancers (Slamon *et al.* 1978). Recent studies indicate the role of Her2/ neu in the development of numerous types of human cancer. Her 2/neu overexpression and/or amplification have been detected in a variety of cancer types, including non–small cell lung cancer, pancreatic carcinoma and gastric carcinoma (Gravalos and Jimeno 2008), colonic carcinoma (Schuell *et al.* 2006) ovarian carcinoma (Des Guetz *et al.* 2006, Tabernero 2007), bladder cancer (Eltze *et al.* 2005) and 10%-34% of invasive breast cancers and correlates with clinical outcome, poor prognosis, and constitute a predictor factor of poor response to chemotherapy and endocrine therapy. Her 2/neu overexpression is associated with shortened disease-free and overall survival compared with patients who have Her 2/neu-negative tumors (Kaptain *et al.* 2001).

Superficial bladder cancer (SBC) is a precursor of muscle-invasive, potentially life-threatening bladder cancer. Given the field cancerization effect and the risk of recurrence and progression, SBC appears the most suitable target for bladder cancer systemic chemoprevention. However, new risk biomarkers are demanded to select at-risk subjects and to conduct efficient clinical chemoprevention trials. Angiogenesis represents a key step for tumor progression and metastatic spread in solid tumors. Vascular Endothelial Growth Factor (VEGF) is the most known angiogenic factor and is involved in early stages of bladder carcinogenesis (Nicholson *et al.* 2001). Also expression of VEGF either as tissue or soluble form, has been reported to have prognostic significance in several cancers (Mohammed *et al.* 2007). Overexpression of Tyrosine–kinase receptors, including VEGF, and Her 2/neu, has been associated with the progression of cancer and poor prognosis in urothelial tumors (Bolenz and Lotan 2008). It is worth mentioning that all of these studies were limited to transitional cell carcinoma which was not schistosomiasis-associated. The aim of the current study was to assess Her 2/neu protein and gene and soluble VEGF in carcinoma of the urinary bladder in a cohort of Egyptian patients, and both markers were correlated to the schistosomal status as well as tumor types and disease stages.

2. Materials and methods

Materials:

This study was conducted on 220 patients (156 males and 64 females having mean age of (65.5± 11.2) patients admitted to the Urology Department at Theodor Bilharz Research Institute (TBRI) Hospital. In addition, 20 age and sex matched healthy subjects as a blood donor control group and 5 cases of cystoscopic biopsies during prostatectomies as control group for IHC & FISH; upon patient's consent were included in this investigation. Tumor specimens were taken by cystoscopy (Transurethral resection (TUR) biopsies) and cystectomies. Only cystoscopic biopsies containing muscle tissue were included, so that muscle invasion by the tumor could be assessed. The study protocol was approved by the ethical committee of TBRI according to the institutional committee for the protection of human subjects and adopted by the 18th world medical assembly, Helsinki, Finland and informed consent from all patients underwent cystoscopy and biopsy from apparent growth and lesions was taken. Patients were subjected to full clinical examination, routine laboratory investigations, complete urine analysis, abdominal and pelvic ultrasonography, general and abdominal examination, digital rectal examination (DRE), bimanual examination under anesthesia, plain x-ray of the urinary tract, intravenous urography (IVU), cystoscopy and TUR biopsies were taken from apparent growth. Accordingly they were grouped into:

- Group I: Five male patients (age range 25-50), with normal bladder urothelium, subjected to prostatectomy served as normal controls after taking their consent.
- Group II: Thirty five patients with chronic cystitis classified as:

- 10 patients with nonschistosomal chronic cystitis.
- 25 patients with chronic schistosomal cystitis, which include:

12 patients with dysplastic changes, 4 patients with squamous metaplasia and 9 patients with simple chronic schistosomal cystitis.

- Group III: One hundred and eighty five malignant patients:

- 135 were schistosomal-associated include 75 cases of SCC and 60 cases of schistosomal-associated urothelial carcinoma.
- 50 cases of non schistosomal-associated urothelial carcinoma.

Urothelail carcinoma (110 cases): Are categorized according to pathological stages into: 40 Non invasive tumors (pTa+pT1) and 70 invasive tumors (pT2+pT3) and according to pathological grades into: 46 low grade urothelial carcinoma and 64 high grade urothelial carcinoma.

Methods:

Histopathological Study

Tissues were fixed in 10% buffered formalin, paraffin embedded and processed routinely. Hematoxylin and Eosin stained slides were used to evaluate the pathological diagnosis of all bladder lesions and to assess urothelial carcinoma [transitional cell carcinoma (TCC)] cases for pathological grades according to World Health Organization (WHO) (Mostofi *et al.* 1988) and pathological tumor stage, in accordance with WHO Classification of tumors (Eble *et al.* 2004). Diagnosis of schistosomal infestation was based on detection of Schistosoma eggs in tissues and/or detection of circulating Schistosoma antibodies in sera of patients by enzyme linked immunosorbent assay (ELISA).

Immunohistochemical (IHC) procedure for Her 2/neu

For IHC, a standard 3-layer protocol was used, as previously described by

Hsu and Raine (1981). Unstained sections were processed for immunostaining with Her 2 monoclonal antibody, Endogenous peroxidase was blocked by 0.3% hydrogen peroxide for 30 minutes. The antibody-binding epitope of the antigen was retrieved by microwave treatment for 15 minutes in citrate buffer at 700°C. We used Her 2 primary antibody at a dilution of 1:50, and incubated for 24 hours in a humid chamber (Dako, Copenhagen, Denmark). The sections were then incubated with the secondary biotinylated antibody followed by avidin peroxidase complex according to the manufacturer's instructions (Universal Detection Kit, Dako, Denmark). A brown color was developed with 3,3 diaminobenzidine for 5 minutes, and counterstained with Mayer's hematoxylin. Negative controls in which the primary antibody was omitted and replaced by phosphate buffered saline were also used. Breast cancer known to express Her 2 /neu was used as a positive control.

Urothelial cells in entire sections were examined in ten consecutive fields under light microscopy at magnifications x 400 with the highest expression and the percentage was calculated from their mean. A negative staining was defined as the absence of cells expressing the marker (zero %). The intensity of reactivity was scored according to Ooi *et al.* (2004).

Fluorescence in situ hybridization (FISH) to detect Her 2/neu gene

The technique of FISH to detect Her 2/neu gene was performed according to Matsubara *et al.* (2008), after usual processing for remove of wax and hydration of the slides, we use enzymic digestion by 5 µg/ml proteinase K (Boehringer Mannheim; Mannheim, Germany) in 0.1 M Tris-HCI (pH 8.0) containing 50 mM EDTA. Disodium salt for 45 minutes at 45°C before incubation with the slides. Then incubate slides with DIG – labelled DNA probe (Zymed Lab-Sa system, USA) for 10 minutes at 95°C. Then incubate slides in humid chamber at 37°C for 45 minutes with mouse anti DIG, then add on slides goat anti mouse Cy3 at 3°C for 45 minutes. Put DAPI at 37°C for 60 seconds at 37°C for nuclear stain (blue nucleus). To preserve fluorescent labelling, sections were mounted using DABCO antifade (Sigma, Missouri, USA). Each section was mounted in approximately 5 µl of mounting medium and the slide cover is sealed with entallin. In each preparative run, positive controls (Probe Check control slides supplied by the manufacturer) were included.

An Olympus BX 61 microscope equipped with appropriate filters for DAPI, Spectrum Green and Spectrum Orange was used to score the number of signals per nucleus under magnification power x600. Images were captured using a CCD digital camera and Quips FISH imaging software (Meta Cyte scanning image cytometer, Meta Systems, Altlussheim, Germany). The number of fluorescent signals was counted in 60 urothelial cell in each case. The mean number of signals per nucleus was determined.

Serum VEGF was done using EIA technique:

From the studied subjects five milliliter of venous blood samples were collected under complete aseptic conditions, delivered into a clean tube and left to clot. Serum was separated by centrifugation at 3000 rpm for 15 min. , sera were separated and divided into small aliquots for assay of liver function tests {serum bilirubin, alanine

aminotransferase (ALT), aspartate aminotransferase (AST) and serum albumin}, kidney function tests (serum creatinin and blood urea) using autoanalyzer (Hitachi 736, Hitachi, Japan) and Determination of serum level of VEGF using quantitative sandwich enzyme immunoassay technique (ELISA). (using R&D system, USA).

Statistical Analysis

For statistical analysis, Statistical Package for the Social Sciences (SPSS, Chicago, IL, USA) version 10.0 for Windows software was used. The chi-square test was used to detect statistically significant differences between the groups, with a significance level of ($p<0.05$). Comparison between means of different groups was done using one way ANOVA. Comparison between percent of positive cases was calculated by Chi-square test.

3. Results

Clinico-pathological data and immunostaining results for the cases exhibiting overexpression of Her 2/neu are illustrated in (Table 1).

Assessement of Her 2/neu protein using IHC technique

In control cases no Her 2/neu expression was detected. Her 2/neu- positive immunostaining was limited to the cell membrane. It was overexpressed ($p<0.01$) in malignant group compared to control and chronic schistosomal cystitis groups. In malignant group it was 1^+ in 33 (30%), 2^+ in 45 (40.9%) and 3^+ in 32 (29.09%). Her 2/neu incidence was significantly ($p<0.01$) higher in urothelial carcinoma group 80/110 (72.2%) compared to SCC 30/75 (40%).

On classifying urothelial carcinoma cases on the basis of their histopathological grades into low and high grades; the numbers of cases showed overexpression of Her 2/neu were found to be significantly ($p< 0.01$) higher in high than low grade tumor.

On classifying urothelial carcinoma cases on the basis of their histopathological stages into non muscle invasive and muscle invasive urothelial carcinoma; we found Her 2/neu overexpressed in ($p< 0.01$) 23/40 (55.5%) in non muscle invasive urothelial carcinoma compared to 57/70 (81.4%) (Table 1, Figs 1A &B & C).

Assessment of Her 2/neu gene using FISH technique

In primary tumors, in SCC the signal ratio was 0-1.0 in 2 patients (6.6%), 1.1-2.0 in 18 (60%), and ≥2.0 in 10 (33.35%)., which was considered positive for Her 2/neu gene amplification. In Urothelial carcinoma the signal ratio was 0-1.0 in 10 patients (12.5%), 1.1-2.0 in 25 (22.3%), and ≥2.0 in 45 (58.2%).

According to the classification of grade, the number of cases showed over- expression of Her 2/neu gene were found to be significantly ($p< 0.01$) higher in high 31 (63.6%) than low grade 14(56%) tumor.

According to the classification of stage, we found Her 2/neu overexpressed ($p< 0.01$) in 10(43.3%) non muscle invasive urothelial carcinoma compared to those with muscle invasive 45(78.9%) (Table 1, Figs 2A&B&C).

Determination of positive VEGF rates

According to the mean level of VEGF in normal human serum (123.53 pg/ml),the normal level of VEGF was calculated as 227.20 pg/ml. Taking this as the standard, the VEGF expression positive rates for SCC, urothelial carcinoma patients, chronic cystitis patients and normal controls were 94.7% (71/75), 89 % (98/110), and 22.9% (8/35), 5% (1/20) respectively, (Table 2).

Relationship between VEGF and Schistosomiasis:

Of the 35 chronic cystitis patients, 10 were found without schistosomal infestation and 25 were chronic cystitis with schistosomiasis. There was a significant ($P< 0.01$) difference in serum VEGF level between the two groups. Of the 60 patients with schistosomal associated urothelial carcinoma, the positive rate of VEGF was 91.7% (55/60), whose VEGF level (584.77± 443.87 pg/ml), which was significantly ($P< 0.01$) higher than that of non schistosomal associated urothelial carcinoma where the positive rate of VEGF was 84% (42/50) and VEGF level was (429.41± 289.83 pg/ml) (Table 3).

Relationship between VEGF and histopathological grades

According to histopathological grades, 46 patients were classified as having low grade tumor with a VEGF level of 329.68 ± 228.45pg/ml. Sixty-four patients were classified as having high grade tumor with a VEGF level of 558.42± 370.10 pg/ml. In the two groups, the serum level of VEGF expression was significantly ($P< 0.001$) higher in histopathologically higher grade tumors, compared to lower grades, and there was a positive correlation between the serum level of VEGF and tumor grades (Table 3).

Relationship between VEGF and Histopathological stages

Superficial bladder cancer (SBC) is a precursor of muscle-invasion, potentially life-threatening bladder cancer. In this study, the levels of VEGF in the patients with non muscle invasive-

urothelial carcinoma were significantly (P< 0.001) lower than those with muscle invasive-urothelial carcinoma (418.21 ± 243. 25 pg/ml and 550.10 ± 436.60 pg/ml respectively). This finding suggested that high-level expression of VEGF predicts a higher level of muscle invasiveness and higher metastastatic tendency of the tumor (Table 3).

Table 1: Expression of Her2/neu protein using IHC and Her2/neu gene using FISH in the bladder tissue in the studied cases

Parameters	No of positive cases with Her2/neu in bladder tissue by IHC No (%)	No cases with normal expression of Her2/neu gene by FISH	No cases with over-expression of Her2/neu gene by FISH No (%)

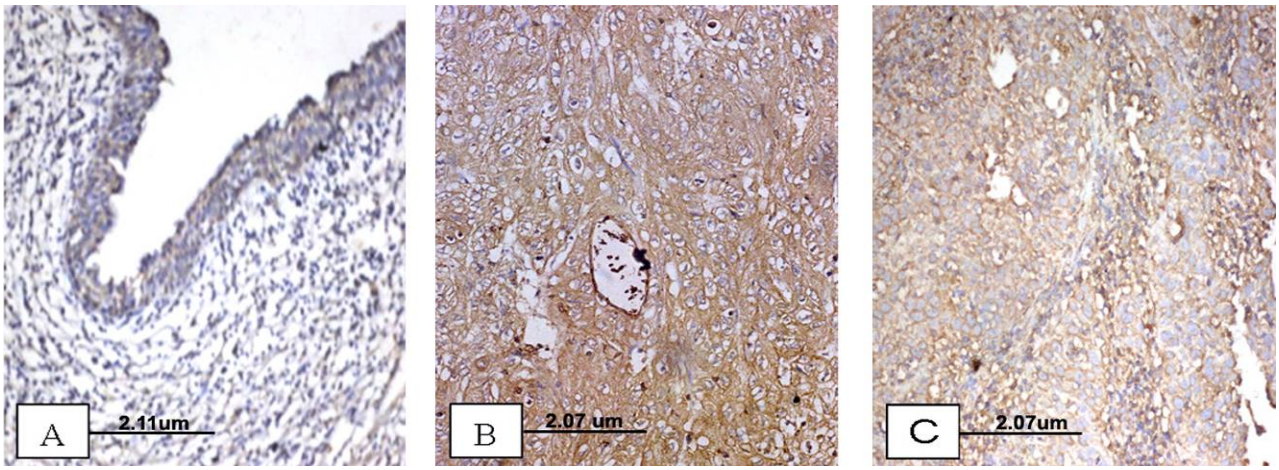

Figure 1: A) A case of chronic schistosomal cystitis, showing mild memranous expression of Her 2, involving the whole layers of the urothelium (IHC, Her2, DAB, x20). B) A case of schistosomal-associated moderately differentiated squamous cell carcinoma showing moderate membranous expression of Her 2 in about 70% of the malignant squamous cells (IHC, for Her 2 DAB, x40). C) A case of invasive urothelial cell carcinoma, high grade, showing marked membranous expression of Her2 in the majority of malignant urothelial cells (IHC for Her-2, DAB, x40).

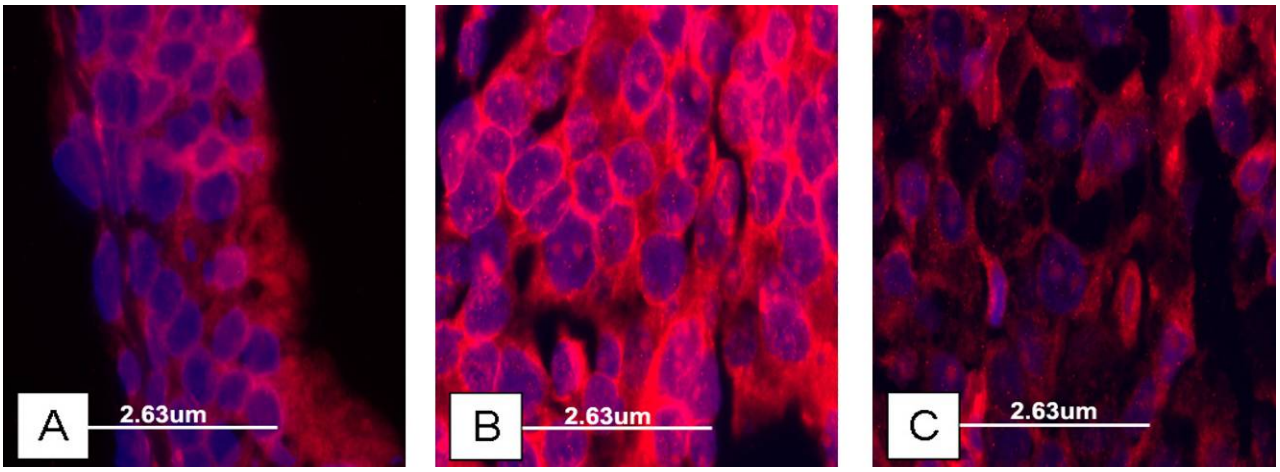

Figure 2: A) A case of chronic schistosomal cystitis, showing mild number of red signals in the nuclei of urothelial cells for Her 2 gene in the urothelium (FISH, Her2 gene, x60). B) A case of schistosomal-associated moderately differentiated squamous cell carcinoma showing moderate number of red signals in the nuclei of urothelial cells for Her 2 gene in about 50% of the malignant squamous cells (FISH, Her 2 gene x60). C) A case of invasive urothelial cell carcinoma, high grade, showing marked red signals in the nuclei of urothelial cells for Her 2 gene the majority of malignant urothelial cells (FISH, Her-2 gene, x60).

4. Discussion:

Bladder cancer is a major health problem in Egypt. The two major types of bladder cancer in Egypt are bilharzial and non-bilharzial bladder cancer. The present study included 135 bladder cancer patients infected with bilharziasis and revealed high VEGF levels compared to non-bilharzial cases. Recently, bilharzial bladder cancer was found to be positively correlated with over- expression of Bcl-2 (apoptotic marker) (Swellam *et al.* 2004a) that enhance the angiogenesis process and induced increase of VEGF protein secretion as reported by Biroccio *et al* (2000). These findings may hypothesized that molecular changes occurring in bladder cancer patients infected with bilharziasis can undergo the phenotypic (angiogenic) switch therefore able to induce phenotypic changes in endothelial cells, leading to angiogenesis (Swellam *et al.* 2004a). Our study reported significantly higher VEGF levels in SCC compared to TCC types. Previously, it was reported that SCC components are more genetically unstable and had alterations not present in TCC cases (Swellam *et al.* 2004b). Accordingly, it is possible to postulate that SCC of the bladder stimulates angiogenesis by directly secreting angiogenic substances or by activating and releasing angiogenic compounds stored within the extracellular matrix (Campbell 1997). Moreover, significantly high levels of VEGF were observed in high grade compared to low grade bladder tumors, suggesting that VEGF production increases as tumors become more anaplastic. Shinoda *et al.* (1999) and Tuttle *et al.* (2002) observed similar findings in other tumors. Our result also revealed significant association between increased VEGF levels and tumor invasion. Association between increased VEGF levels with high grade and tumor invasion in bladder cancer patients indicates that VEGF may play a role in the invasion and metastasis of cancer and may serve as an indicator of tumor progression and future recurrence.

Oncogene amplification is a common mechanism of disease progression in many solid tumors and it may be used as a prognostic marker for aggressiveness of growth and behavior in some of these malignancies (Menard *et al.* 2001).

Studies have shown that Her 2/neu overexpression induces cell transformation and that Her2/neu positive tumors are more aggressive (Eltze *et al.* 2005). With regard to the distribution of Her 2/neu in normal tissues, Her 2/neu is slightly expressed only in the liver, bile duct, gastrointestinal tract, skin, genital organs and urinary tract, with limited expression in most normal tissues (Natali *et al.* 1990, Matsubara *et al.* 2008). The methods to analyze Her 2/neu in tissues include analysis of gene amplification, mRNA overexpression, and protein overexpression; however, possible methods for use on formalin-fixed paraffin sections are IHC and FISH. It has been indicated that examination of gene amplification rather than antigen expression is a more reliable method to identify patients with Her 2/neu positive breast cancer (Mass *et al.* 2005, Matsubara *et al.* 2008).

In the present study, IHC results for Her 2/neu was overexpressed ($p<0.01$) in malignant group compared to control and chronic schistosomal cystitis groups. In malignant group it was 1+ in 33 (30%), 2+ in 45 (40.9%) and 3+ in 32 (29.09%). Her 2/neu incidence was significantly ($p<0.01$) higher in urothelial carcinoma group 80/110 (72.2%) compared to SCC 30/75 (40%). While Her 2/neu overexpression was observed in 12% (Lipponen *et al.* 1991) to 71% of urothelial cancers (Gandour-Edwards *et al.* 2002) it correlated with grade and stage in some studies (Miyamoto *et al.* 2000) but not in others (Ioachim *et al.* 2000). Several hypotheses could explain these wide variations, as well as the relatively low rate of Her 2 overexpression reported here. One of the major issues is the variability in IHC assays, related to the heterogeneity between kits, antibodies, protocols, interpretations or cut-off values, in their study performing this analysis using both IHC staining and FISH, Her 2/neu overexpression was observed in 33.3% (10), 58.2% (45) of SCC and urothelial carcinoma respectively (Lae *et al.* 2010) while Aly and Khaled, (2004) found that 9/21 (43%), and 3/16 (19%) of cases with squamous and transitional cell carcinoma had C-erb-B2 gene amplification, respectively.

In the present study, overexpression of Her2/neu gene was significantly ($p< 0.01$) higher in high 31 (63.6%) than low grade 14(56%) tumor and in high than low grade tumor with ($p< 0.01$, we found that overexpression correlate with grade, and stage, while Aly and Khaled, (2004), found that no significant association was observed between C-erb-B2 amplification and tumor grade. They suggest that relative C-erb-B2 gene amplification is associated with aggressive bladder cancer and may play an important role in tumor progression.

On comparison between IHC and FISH, Sauter *et al.* (1993) reported that Her 2/neu gene amplification was detected in only 7% (10/141) of patients with urothelial cancer (36 pTa, 42 pT1, 67 pT2-T3/20 G1, 39 G2, 46 G3 and 6 with grade and stage unknown), whereas 43% (61/141) of tumors were Her 2/neu positive by IHC. In addition, Kruger *et al.* (2002) studied 203 patients with urothelial cancer and reported that 37% (76/203) of patients were Her 2/neu positive by IHC, whereas Her 2/neu gene amplification was detected in only 5% (2/42) of

patients. Moreover, de Pinieux *et al.* (2004) reported that 23% (15/64) of patients with invasive urothelial cancer were Her 2/neu positive, while Her 2/neu gene amplification was detected in 28% (6/21) of patients.

In the current study, FISH results in SCC Her 2/neu gene amplification, was 10 (33.35%). In Urothelial carcinoma Her 2/neu gene was overexpressed in 45 (58.2%). Lae *et al.* (2010), found Her 2/neu overexpression in 9.2% of tumor samples. In comparison of Her 2/neu expression between IHC and FISH, it was suggested that the dissociation between gene amplification and overexpression could be related to a point mutation that leads to protein overexpression, translocation or transcriptional up regulation (Sauter *et al.* 1993)

Evidence from breast cancer indicates that only tumors with Her 2/neu gene amplification respond to an anti-Her 2/neu targeted therapy, such as trastuzumab. Using the same principle, 78% of muscle-invasive urothelial bladder carcinomas should be suitable for such treatment. The potential involvement of Her /neu in the proliferation of urothelial carcinoma led to the initiation of anti-Her 2/neu targeted therapy protocols in advanced disease. Single-agent data with trastuzumab in urothelial cancer are not available or limited to case reports (Peyromaure *et al.* 2005). The efficacy of molecular targeting therapy for various molecules including EGFR/VEGF/Her 2/neu has been proved clinically in a wide range of cancers (Yoon *et al.* 2004).

In the running study we found that Her 2/neu protein was expressed in 68% of cases of schistosomia associated urothelial carcinoma compared to 43.3% in nonschistosoma associated urothelial carcinoma, also in SCC in 33.3% of the cases. The study examined the prognostic value of C-erb-B2, among other markers, in bilharzial related bladder cancer (Haitel *et al.* 2001), has also suggested that C-erb-B2 expression was associated with poor prognosis.

5. Conclusion:

Her 2/neu overexpression might provide additional prognostic information in patients with muscle-invasive bladder carcinomas; Because 78.9% of our patients harbor Her 2/neu overexpressing those patients may potentially benefit from molecular targeted therapy targeting Her 2/neu for invasive bladder carcinoma and they should be identified by gene amplification analysis using FISH in IHC 3+ patients. In addition, serum VEGF levels are increased in patients with bladder carcinoma and may be a candidate as a new noninvasive diagnostic tool.

Ultrasonic Comparative Assessment for Biodiesel Production from Rapeseed

N.N. Ibiari*, S.A. Abo El-Enin, N.K. Attia and G. El-Diwani

Chem. Eng. and Pilot Plant Dept., National Research Centre, Egypt

Abstract: The application of ultrasound during extraction and trans-esterification of oil from rapeseed was evaluated. Two methods of extraction were used, batch wise extraction and soxhlet extraction. In batch wise extraction procedure, ground rapeseeds were added to solvent and ultra-sonicated either by cleaning bath or ultrasonic generator. Conventional soxhlet extraction assisted in the soxhlet chamber by ultrasound has been developed. Ultrasonic technique reduced time required to extract oil. Using batch wise extraction procedure, percent recovery of oil increased almost 17.83% and 20.99% by using cleaning bath and ultrasonic generator respectively rather than control after 2hrs.While in using soxhlet extraction percent recovery reached 85% after 1.5 hr in case of ultrasonic and after 4 hrs without using ultrasonic. Physical and chemical properties of rapeseed oil were tested. Then the alkaline trans-esterification of rapeseed oil with methanol and potassium hydroxide for production of biodiesel was studied, using ultra-sonication and magnetic stirring. In trans-esterification the use of ultra-sonication and magnetic stirring led to similar high yields of 90% of methyl esters after approximately 10 min. of reaction time. Comparison between biodiesel obtained and standard biodiesel and diesel fuel was done.

Keywords: Ultrasound, extraction, biodiesel, rapeseed oil, transesterification.

1. Introduction:

Diminishing fossil fuel resources coupled with the steady increase in energy consumption have spurred research interest in alternative and renewable energy resources. Bio-diesel is a promising nontoxic and biodegradable renewable fuel comprised of mono-alkyl esters of long chain fatty acids, which are derived from vegetable oils (edible and non-edible)(Hanna 1999) . Seeds of high oil content such as sunflower, soybean and canola as edible oils, and jatropha and rapeseed as non-edible oils used as feed stock for bio-diesel production.

Extraction is one of the key processing steps in recovering oils contained in seeds. Mechanical pressing (Abu- Arabi 2000) is the simplest method of extraction, however, needs no extraction medium. It has been traditionally applied to the extraction of oils from oil seeds; the only equipment needed is a hydraulic press.

Traditional extraction processes may be classified as follows: extraction with organic solvents: percolation, maceration, and extraction using a Soxhlet apparatus; and extraction with water: infusion, decoction, and steam distillation (Silva 1998). An old method also worth mentioning is extraction with cold fat, called effleurage, used mainly for extraction of fragrances from flowers (Starmans 1996) These techniques are often time consuming and require large volume of organic solvent.

In last decade, alternative extraction techniques (non conventional extraction methods) that introduce some form of additional energy to process in order to facilitate the transfer of analysts from sample to solvent have been considered. These methods include ultrasound assisted extraction, pressurized liquid extraction, microwave extraction and supercritical fluid extraction {Huie 2002, Flores 2006, Garcia 2004, Vinatoru 2001} ,as well as vertical (turbo) extraction. The main advantage of these non-conventional methods compared to conventional methods is the increased extraction efficiency, which leads to increased yield and/or shorter extraction time.

The ideal approach would be one retaining the advantages of soxhlet extraction (namely, sample fresh solvent contact during the whole extraction step, no filtration step, simple manipulation) while circumventing its short comings by accelerating the process and minimizing environmental pollution.
With this aim, an ultrasound-assisted soxhlet extractor has been designed and constructed. The device is based on the same principles as the conventional soxhlet extractor but modified in order to allow location of the soxhlet chamber in a bath through which ultrasounds are applied by means of an ultrasonic probe. The same approach was done with the wise batch extraction.

The interest in the use of renewable fuel started with the direct use of vegetable oils as a substitute for diesel (Demirbas 2003). However, their

direct use in compression ignition engines was restricted due to high viscosity, low volatility and polyunsaturated character (Ramadhas 2005). To overcome these constrains there are at least four ways in which oils and fats can be converted into bio-diesel (Ghadge 2006), transesterification, blending, micro emulsion (Fukuda 2001)and pyrolysis. Out of these methods, trans-esterification is the most viable process. The trans-esterification process is achieved by reaction of triglyceride molecule with an excess of alcohol in the presence of a catalyst to produce glycerin and a fatty acid methyl esters "FAME" which is the bio-diesel.

Stochiometrically, three moles of alcohol are required for each mole of triglyceride, but in general, a higher molar ratio is often employed for maximum ester production depending upon the type of feed stock, amount of catalyst, temperature etc. However, the yield of bio-diesel is independent of the type of the alcohol used (methanol, ethanol, propanol and butanol) (Sharma 2008) and the selection of one of these depends on cost and performance. Methanol is preferred over others due to its low cost (Ramadhas 2005) and its physical and chemical advantages such as polar and shorter-chain alcohol (Hanna 1999). The conventional catalysts used are acid and alkali catalysts depending on the nature of the oil used (free fatty acids FFA content in the raw oil) (Fukuda 2001, Freedman 1986). FFA should not exceed a certain amount for trans-esterification to occur by an alkali catalyst (Canakci 1999, 2001).In case of high free fatty acid, acid esterification using H_2SO_4 as a catalyst was done to reduce the FFA prior to alkaline transesterification [Ramadhas 2005, Veljkovic 2006, Sahoo 2007, Shanna 2007) . The common catalyst employed during alkaline transesterification includes homogeneous catalyst such as sodium hydroxide, potassium hydroxide and sodium methoxide (CH_3ONa) (Leung 2006). Sodium methoxide proved to be more effective than NaOH, which produces a small amount of water by mixing NaOH and methanol. However, NaOH and KOH are widely used in the industrial biodiesel production process owing to its low cost (Jeong 2004). The amount of alkali catalyst was calculated on the basis of the amount needed to neutralize the unreacted acids plus 0.35% for virgin oil which came out to be 0.55% w/v KOH (Tiwari 2007).

Presence of sufficient amount of methanol during the transesterification reaction is essential to break the glycerin-fatty acid linkages (Widyan 2002). But excess of methanol should be avoided. Increasing the molar ratio of methanol/oil beyond 6:1 neither increases the product yield nor the ester content, but rather makes the ester recovery process complicated and raised its cost.

Lifka and Ondruscka (Lifka 2004) said that since basic transesterification showed no significant temperature dependence, energy required for thermo starting the reaction mixture can be saved. From the energy balance of the three mixing methods (magnetic stirrer, ultrasound and ultra turrax) employed, it was determined that energy costs are lower for ultrasonic mixing.

The main objective of the present work is to compare classical extraction techniques of oil (Soxhlet, batch wise extraction) with ultrasound-assisted extraction method, and to apply the biodiesel production technology using an alkaline catalyst to the transesterification of rapeseed oil and particularly to study the effect of ultrasonication versus mechanical stirring on methyl esters yield and reaction time.

2. Materials and methods

2.1 Materials:

- Rape Seeds used in this work were supplied by Cultivation and Production of Medicinal and Aromatic Plant Dept. at National Research Centre of Egypt.
- Solvent used for oil extraction was commercial hexane, obtained from Alexandria Petroleum Company of Egypt.
- Methanol of 99.8% analytical reagent.
- Potassium hydroxide pellets of 98% purity as catalyst.

2.2 Rape Seed Preparation:

The rape seeds were milled in an electric mill, sieved and classified into three different particle size groups ≤234, ≤600 and ≤850 µm. Moisture content of rape seeds was determined.

2. 3 Analytical Methods:

Moisture and oil content in seeds were determined gravimetrically. The fatty acid composition of rapeseed oil was determined using gas chromatographic analysis of the oil ethyl esters. Modification of the oil to its ethyl esters was made using 2% H_2SO_4 as catalyst in the presence of dry ethyl alcohol in excess. The chromatographic analysis was made using Hewlett Packard Model 6890 Chromatograph. A capillary column 30 m length and 530 µm inner diameters packed with Apiezon® was used. Detector temperature was 280°C, injection temperature was 300°C and the column temperature was programmed from 100 to 240°C at 15°C/min.

Viscosity was measured using Brookfield Viscometer Model DV-II+. The acid values are milligrams of KOH necessary to neutralize the free acidity in 1g of oil sample.

Acid Value = {(Titration (ml) *5.64) /wt of sample used} (mg KOH/g)

2.4 Extraction Procedure

Extraction was done by two different methods as shown in Fig.1 .

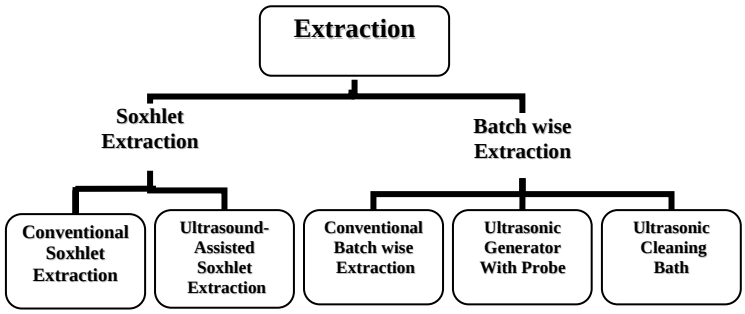

Fig (1): Extraction Methods

2.4.1 Soxhlet Extraction:

As shown in Fig. 2, the apparatus of conventional soxhlet extraction was modified by adding a water bath with an orifice at the bottom in order to enable connection with a distillation flask. A titanium alloy ultrasonic probe (2.75 mm diameter) was immersed in the water bath and used to accelerate the extraction process.

2.4.2 Batch –Wise extraction process:

2.4.2.1Conventional Extraction

Ground rape seeds are mixed in an glass reactor with hexane. Suspensions were continuously stirred at constant temperature and stirring rate (using a magnetic stirrer) for different time intervals. Suspension is filtered and extracted oil was separated from the solvent using rotary vacuum evaporator.

2.4.2.2 Ultrasonic Generator with Probe Assisted Extraction

Same steps as in conventional method except that the suspension was ultra-sonicated during extraction time using ultrasonic generator probe which was submerged in the suspension. Temperature was kept constant during sonication and extraction.

2.4.2.3 Ultrasonic Cleaning Bath Assisted Extraction

Ground rape seeds and hexane as extracting solvent were mixed in a closed flask. The sonication was performed at constant temperature for different time intervals using an ultrasonic cleaning bath.

A rotary – evaporator was used to release the solvent after each extraction.

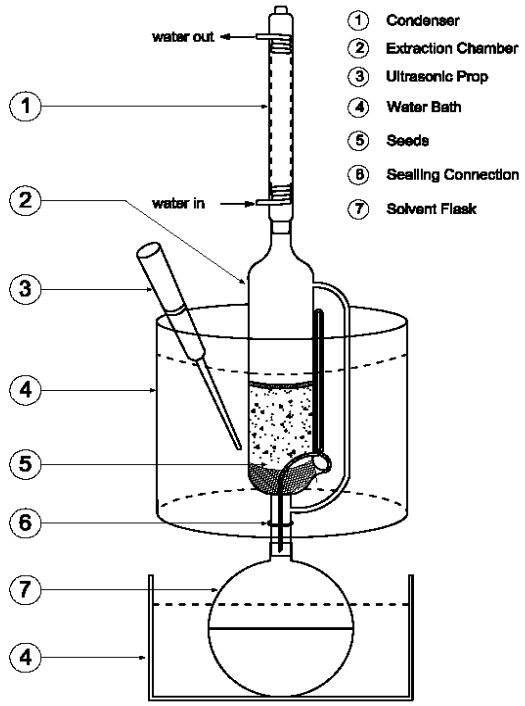

Fig (2): Soxhlet extraction apparatus

2.5 Transesterification Procedure:

Rapeseed oil produced, methanol corresponding to 6:1 molar ratio of alcohol to oil and KOH (1% w/w) were refluxed together in a glass reactor placed in water bath. Heating was achieved by means of hot plate with temperature controller. The

temperature was raised to 65°C and the mixture was stirred either using a magnetic stirrer or an ultrasonicator (ultrasonic generator with probe or ultrasonic cleaning bath).

After different reaction time intervals, the reaction was stopped and the mixture was allowed to stand for phase separation in a separating funnel. The esters mixture formed the upper layer and glycerin formed the lower layer (Stavarache 2005)

3. Results ands Discussion:

3.1. Effect of moisture content on the percentage yield of extracted oil

No significant effect in the percent oil extracted from dried seed (38.16%) and non dried seed (38.68%) using soxhlet extraction. This may be attributed to the moisture content range from 5.86 to 6%, which is less than the moisture level between 8 and 20% for optimum yield when harvesting (Loren 2007)

3.2. Effect of particle size on the percentage yield of extracted oil

The effect of seeds' particle size on the oil yield was studied by soxhlet extraction of three classes of ground rape seeds using hexane.

As can be seen from Table (1) the highest oil yield was obtained from the higher class of the ground rape seeds. Thus in the further research, the higher class of ground rape seeds were used.

Table (1) Effect of Particle Size on Extracted Oil Yield

Class	*Particle Size, mm*	*%Yield of oil*
Largest	**0.6-0.85**	**36.52**
Medium	**0.6**	**31.3**
Smallest	**0.234**	**26**

3.3. Effect of Time on the percentage yield oil extracted:

3.3.1. Using Soxhlet Extraction

The percent oil recovery by conventional soxhlet extraction and ultra-sonic assisted soxhlet extraction (UASE) with hexane using different extraction time are compared in Fig. (3). It is clear that using UASE reduces the time of extraction from about 4hr to 1.5 hr, but the percent recovery is slightly lower and this is due to the high frequency (800 KHz) ultrasound employed. When the high frequency ultrasound is employed the extraction yield did not increase significantly, however the degradation of the seed constituents was diminished. In case of low frequency sonication degradation becomes more important (Vinatoru 2001).

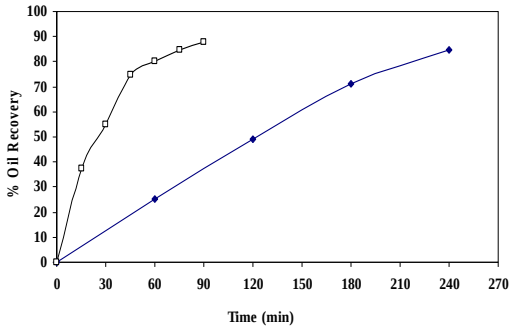

Fig (3):Effect of time on percentage recovery using soxhlet and UASE

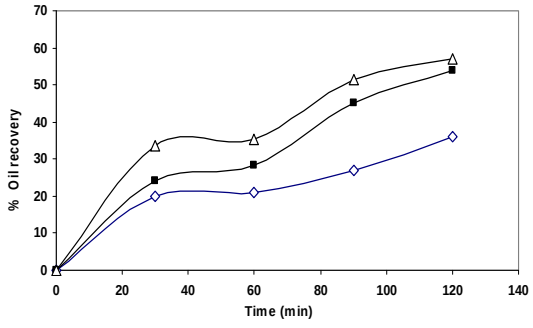
3.3.2. Using Batch Wise Extraction Process

The oil extraction capabilities of three different methods (control, ultrasound cleaning bath and ultrasound probe) using hexane (seed: solvent (1:10 ratio)) at different extraction time are shown in Fig (4). The percentage of oil recovery is increased with application of ultra-sound. But the relative increase in the percent of oil recovery of the two methods of ultrasound differed. For sonic bath, the percent recovery increased by 4.35% at an extraction time of 30 min and 17.83% at an extraction time of 2 hr. While in case of using probe, the percent recovery increased by 13.47% at an extraction time of 30 min and 20.99 at an extraction time of 2 hr.



Fig(4):Effect of time on percent recovery using batch wise extraction process

It is interesting that the higher yield of extracted oil achieved using soxhlet extraction technique either with or without ultrasonic than using batch wise extraction process. This can be attributed not only to a higher operating temperature and much

longer extraction time, but also to a higher seed – solvent ratio applied in the Soxhlet extraction.

3.4 Effect of type of extraction on the properties of rapeseed oil

In order to evaluate if the oil composition was affected during ultrasound assisted extraction, gas liquid chromatography analyses were carried out on two different extracted samples using UASE and soxhlet. Table (2) shows that no appreciable differences in the extracts composition. This indicates that the oil composition is not affected by the use of ultrasound, and these results agree with Luque-Garcia J.L. et al (Luque 2004).

Table (2) Fatty acid composition of rapeseed oil

Constituent	% composition using UASE	% composition using soxhlet extraction
Palmitic (16:0)	4.34	4.39
Stearic (18:0)	1.55	1.67
Oleic (18:1)	60.0	60.95
Linoleic (18:2)	20.0	19.04
Linolinec (18:3)	12.5	11.78
Eicosic (20:1)	27.0	27.1
Erucic (22:1)	0.9	0.9

Average molecular weight =882.6 k.mol/kg

Characterizations of rapeseed oil are shown in Table (3).

Table (3) Characterization of rapeseed oil

Viscosity, (c.ps) at 40 °C	46.5
Free fatty acid, %	1.5
Acid value, (mg NaOH/1gm oil)	0.3

3.5 Transesterification:

A set of experiments was carried out to determine the effect of magnetic stirring and ultrasonication on the transesterification reaction. After 10 min, conversions of more than 90% were obtained. So no significant influence due to the mixing method was observed. Percent conversion to ester values is higher than those of Lifka and Ondruscka [26] who reported more than 85% conversion of rapeseed oil to methyl esters after 10 min. at 45°C, on the alkaline transesterification of rapeseed oil using NaOH at a concentration of 1 % w/w, using different mixing methods (magnetic).

Table (4): Comparison of different standard of biodiesel in worldwide with produced biodiesel from rapeseed and conventional diesel.

Property	Units	Biodiesel (Rapeseed)	US National Biodiesel	German Biodiesel	Conventional Diesel
Flash point	° C	163	100	110	54
Pour point	° C	-6			
Cloud point	° C	-3			
Kinematics viscosity at 40° C	mm^2/s	6.08	1.9-6	3.5-5	2.3
Density at 15° C	Kg/m^3	884	860	875-900	800
Carbon Residue	% (w/w)	0.258		0.3	0.3

Table (4) represents the characterization of biodiesel obtained from rapeseed and standards of biodiesel and diesel fuel in worldwide.

Flash point is the lowest temperature at which the vapor realized by a liquid, can form an ignitable mixture with air. Flash point of a fuel is a security parameter, with great importance for its transport and storage. The flash point of biodiesel is one of its main advantages (163 ° C) in our case when compared to diesel fuel (54° C).

Cloud point data consistently over predict the cold temperature limit at which start-up or performance problems may be expected to occur. The temperature at which crystal agglomeration is extensive enough to prevent free pouring of fluid is determined by measurement of its pour point

(Hochauser 1994).Feed stocks with relatively low concentrations of saturated long-chain fatty acids generally yield biodiesel with much lower cloud point and pour point. Thus, feed stocks such as linseed, olive, rapeseed, and safflower oils tend to yield biodiesel with CP ≤ 0°C; our results agree with Kalligeros (2003) and Peterson (1987).

4. Conclusion:

In this study the application of ultrasound during extraction and transesterification of oil from rapeseed was evaluated. Extraction was done by two methods, batch wise extraction (conventional and ultrasonicated) and Soxhlet extraction (conventional and ultrasound). Ultrasonic technique reduced time required to extract oil. The oil composition is not affected by the use of ultrasound. The alkaline transesterification of rapeseed oil with methanol and potassium hydroxide for production of biodiesel was studied, using ultrasonication and magnetic stirring. It is concluded that a conversion of 90% was obtained for both ultrasonicated and magnetic stirred reactions after 10 min. The characterization of biodiesel obtained is in agreement with the standard biodiesel and diesel fuel worldwide.

Abstract: Pregnancy is the more prevalent stress in under feeding small ruminant with multiple bearing. Fifty Ossimi ewes of two years old and their body weight ranging between 35 and 50 kg were allotted into three groups; Group I: contains ten non pregnant non lactating ewes were used as control group. Group II: contains twenty single pregnant ewes* and Group III: contains twenty twin pregnant ewes used as experimental animals. Our study focused on the comparison between single and twin bearing ossimi ewes in the last four weeks of pregnancy and the day of parturition by measurement of reduced glutathione (GSH) level and the activities glutathione peroxidase (GSH-Px); glutathione reductase (GR-ase); glutathione-S-transferase (GST) and total superoxide dismutase (t-SOD) in erythrocytic haemolysate. In addition, glucose, non esterfied fatty acid (NEFA), Beta hydroxyl butyric acid (BHBA), cortisol, insulin and protein electrophoric patterns were measured in serum. Our results concluded that, In erythrocytic haemolysate the mean values of GSH-Px and GST in group II and III during the period of 2nd and last week before parturition and at the day of parturition were high significantly increased. While, GSH and t-SOD were high significantly decreased ($P<0.01$) and GR-ase activities were significantly decreased. While serum insulin level decreased while serum NEFA, BHBA and cortisol were increased in single and twin but in twin the values is more significant. The data showed that twin bearing ewes are more susceptible to pregnancy toxemia than single bearing that may be influence the productivity and performance of those animals.

Keywords: pregnancy, glutathione, single bearing, twin bearing, ewes

1. Introduction:

Pregnancy, parturition, and lactation represent a physiological load to the female body. Where pregnancy toxemia (gestational ketosis) caused by negative energy balance in late gestation is commonly observed in ewes and does (Kulcsar et al, 2006), in beef cows (Rook, 2000), and also in monogastric species as rabbits, guinea pigs, dogs and in ferrets (Lewington, 2007). The background of the disease is the result of the fetal carbohydrate- or energy-demand exceeding maternal supply during the last trimester of pregnancy.

In ruminants, dietary carbohydrates provide well over one half of the energy needs for maintenance, growth and production. Glucose is a primary energy source for certain animal tissues and a precursor for lactose synthesis in the mammary gland. Consequently, understanding carbohydrate digestion and absorption, dietary glucose availability, and the involvement of gluconeogenesis in the regulation of glucose homeostasis is essential for the manipulation of the production and quality of agricultural foods (Rafael and Donald, 2007). Lipid digestion in ruminants is unique in that after ingestion feed lipids are placed into a hydrolytic and reductive environment. The result is that glycerol from triacylglycerols and phospholipids are fermented to VFA and those unsaturated fatty acids which are hydrogenated to mostly saturated fatty acids before absorption (Van Saun, 2000). In ewes, number of fetuses plays role in keeping the homeostasis. The last trimester of pregnancy is very demanding for that homeostasis, because fetuses gain over half of their weight in this period (Seidal et al., 2006). Pregnancy toxemia is a metabolic disease that commonly affects pregnant ewes with multiple fetuses and does during late gestation. It is characterized by hypoglycemia, increased concentrations of ketone bodies in the blood and elevated plasma concentrations of free fatty acids is the result of energy demand exceeding maternal supply during the last trimester of pregnancy (Kulcsar et al., 2006).

The endocrine system especially the pancreas probably is involved in the development of ruminant ketosis. Insulin inhibits ketogenesis when free fatty acids levels are high, as well as growth hormone secretions inhibited by cortisol and free fatty acids. Insulin also appears to be important in regulating the

utilization of ketone bodies as the uptake of *β*-hydroxybutyrate and acetate (Abd-Elghany et al., 2010).

Cortisol is a regulator of glucose in ruminants, which acts to increase gluconeogenesis from amino acids. In starving ruminants the gluconeogenesis is maintained by elevated levels of glucocorticoids (Azab and Abdel-Maksoud, 1999). In lactating ruminants the rate of hepatic gluconeogenesis and the relative concentrations of glycogenic precursors regulate the level of milk production (Huntington, 1990).

Ketone bodies serve as an alternative fuel for many tissues, but they probably do not or only to a minor extent contribute to the energy supply of the fetus (Battaglia and Meschia, 1988). Glucose remains the most important metabolite for fetal and placental growth. The ability of the ewe to provide a sufficient amount of glucose to the fetus from dietary sources is limited because about 70 to 75% of the dietary carbohydrate is converted in the rumen into nonglucogenic products. The remaining fraction of digestible carbohydrate provides 40 to 60% of the circulating glucose through propionate. During periods of a negative energy balance and increased demand for glucose, up to 23% of the glucose may be synthesized from liberated glycerol from the adipose tissue. Along with this glucogenic precursor, a larger amount of fatty acids is released into the circulation that may give rise to an increased rate of ketone body formation (Schlumbohm and Harmeyer, 2004). Our study aimed to investigate carbohydrate and fat metabolic changes in single and twin bearing ossimi sheep.

2. Materials and methods

A. Experimental design

The present study was carried out in field farm of Veterinary medicine, Moshtohor, Banha University. Fifty apparently healthy, multiparous Ossimi sheep, of two years old and their body weight ranging between 35 and 50 kg. All animals were kept at the same environmental and nutritional conditions. All over the experimental period, the ewes were allotted into three groups as following:

Group I: included ten ewes (non pregnant non lactating) were used as control group.

Group II: included twenty single pregnant ewes used as experimental animals.

Group III: included twenty twin pregnant ewes used as experimental animals.

Animals were fed free in feedlot. Concentrate feed mixtures were adjusted to the changing of body weight every two weeks. Concentrate mixtures were given twice daily at 10 a.m. and 2 p.m. while wheat straw was offered (*ad lib*.).

B. Blood samples

The blood samples were collected from jugular vein of all animals in the examined groups in the early morning with one week interval during the last month of pregnancy and the day of parturition. Blood samples were divided into two portions; The first portion was collected in heparinized Tube contained 20 I.U. heparin for one mL blood for preparation of haemololysate by using digitonin and washing by physiological saline according to (Kornburg and Korecker 1955).

Table (1) Chemical and cell wall constituents of feed concentrate mixture and corn stalks (on DM basis)

Items	Feed concentrate mixture ϴ	Wheat straw
Chemical composition		
DM	91.51	93.48
OM	89.64	89.58
CP	14.34	3.26
CF	8.47	40.23
EE	2.24	1.32
NFE	64.59	44.77
ASH	10.36	10.42
Cell wall constituents		
NDF	34.62	78.24
ADF	16.24	54.13
Hemi cellulose	18.38	24.11
NFC*	38.44	6.76

*NFC: Non fibrous carbohydrates= 100 - % (CP+ NDF + EE + ASH) (Calsamiglia et al., 1995).

ϴ Feed concentrate mixture consists of 18% undecorticated cotton seed meal, 4% soybean meal, 36% yellow corn, 36% wheat bran, 3% Vinass, 1.5 % limestone, 1.4% sodium chloride and 0.1% common salts.

This was used for estimation of erythrocytic GSH (Sedlak and Lindsay, 1968); t-SOD (Misra and Fridovich, 1972); GSH-Px (EC: 1.11.1.9) (Chiu et al., 1976); GR-ase (EC: 1.6.4.2) (Bergmayer, 1983); GST (EC: 2.5.1.18) (Vessey and Boyer, 1984). The second one was collected without anticoagulant for obtaining a clear non-hemolyzed serum by centrifugation of the blood sample at 3000 r.p.m for 5 minutes. The clear sera were freshly used for determining of blood glucose (Trinder, 1969), non esterified fatty acid (NEFA) and Beta hydroxyl butyric acid (BHBA) (Duncombe, 1964), Commercial radioimmunoassay kits were used to measure concentration of cortisol and insulin (Tietz, 1968 and Wilson and Miles, (1977).

C. Electrophoretic pattern of serum protein by SDS-PAGE which performed according to the method of (Laemmli, 1970).
D-Statistical analysis was done by (SAS, 1996).

3. Results

The data presented in (Table 2) revealed a high significant increase (P<0.01) in the mean values of GSH-Px and GST in group II and III during the period of 2nd and last week before parturition and at the day of parturition. In contrast, GSH and t-SOD were high significantly decreased (P<0.01) and GR-ase activities were significantly decreased (P<0.05) at the same period of experiment.

Serum glucose level (Table 3) of single pregnant ewes showed significant (P<0.05) decrease than control during the last 3 weeks of pregnancy. But of twin pregnant ewes was decreased significantly (P<0.05) during the last 4 weeks of pregnancy.

Concentration of serum non esterified fatty acid (Table 3) of single pregnant ewe showed significant (P<0.05) increase than the control during the last 3 weeks of pregnancy as well as at the day of parturition. But of twin pregnant ewes showed significant (P<0.05) increase during the last 4 weeks of pregnancy.

Serum BHBA level (Table 3) of single pregnant ewes showed significant (P<0.05) increase than the control during the last 3 weeks of pregnancy and the day of parturition. And twin pregnant ewes showed significant (P<0.05) decrease than the control during the last 4 weeks of pregnancy and the day of parturition. Serum insulin level (Table 3) of single and twin pregnant ewes showed significant (P<0.05) decrease than the control during the last 4 weeks of pregnancy and the day of parturition.

Serum cortisol level (Table 3) of single and twin pregnant ewes showed significant (P<0.05) increase than the control during the last 2 weeks of pregnancy as well as the day of parturition.

The electrophoretic pattern of serum protein revealed that albumin, alpha (α)-1-globulin, alpha (α)-2-globulin and gamma (γ) globulin of single pregnant ewes (Table, 4 and Figure, 1) were significantly decreased during the last week of pregnancy and the day of parturition. But, the concentration of serum beta (β) globulin showed significant (P<0.05) decrease during the last week of pregnancy as well as the day of parturition.

Figure (1): show the electrophoretic serum pattern of Control (A), the last week of pregnancy (B) and the day of parturition (C). In each picture, bands were arranged Albumin, Alpha (α)-1- globulin, Alpha (α)-2- globulin, Beta (β) globulin and Gamma (γ) globulin (From left to right).

4. Discussion

Our study revealed a high significant increase in the mean values of GSH-Px and GST in group II and III during the period of 2nd and last week before parturition and at the day of parturition. Also, showed high significantly decreased in GSH and t-SOD and a significant decrease in GR-ase. This result indicated that t-SOD activity decreased as it is a first line in antioxidant enzymes defense. In the second line, GSH-Px and GST were consuming GSH as a reductant cofactor. For that reason GSH-Px and GST activities were increased and GSH level was decreased. In addition, GR-ase activities were decreased because of GR-ase enzyme generates GSH (Mandour and Abou-El-Ela, 1999 and Abdel-Maksoud et al., 2000). As the glutathione assumes pivotal roles in bioreduction, protection against oxidative stress, detoxification of xenobiotics and endogenous toxic metabolites, transport, enzyme activity, and sulfur and nitrogen metabolism. Its biological significance comes from the free sulfhydryl moiety of the cysteine residue and nucleophilic properties. In cells, glutathione mainly exists in the reduced form (GSH), as the oxidized form (GSSG) (Taisuke et al., 2009). Erythrocytes are permanently in contact with potentially damaging levels of oxygen, but their metabolic activity is capable of reversing this injury under normal conditions. Erythrocytes are equipped by many defence systems representing their antioxidant capacity. This protective system includes superoxide dismutase (SOD), catalase (CAT), reduced glutathione, glutathione peroxidase (GPx), glutathione-S-transferase, and glutathione reductase (GR). However, the cellular antioxidant action is reinforced by the presence of dietary antioxidants (Nakbi et al., 2010).

The present study showed that a significant decrease in the mean values of glucose of single and twin that lower plasma glucose levels came in accordance with (Seidal et al., 2006 and Balikci et al., 2007). The observed decrease in serum glucose level may be due to the, negative energy balance increases lipid mobilization, which results in hepatic lipidosis with subsequent impairment of hepatocellular function, glucose deficiency with intermittent hypoglycemia and accumulation of ketone bodies. The hypothesis that cows suffering from stress and/or painful diseases have elevated blood glucose levels due to an increase in serum cortisol (Forslund et al., 2010).

NEFA and BHBA concentrations in single and twin pregnant ewes were significantly increased than control but in twin were more significantly increased; these results were proved by (Nazifi et al., 2002 and Moghaddam and Hassanpour, 2008).

Serum cholesterol level of single and win pregnant ewes showed significant increase than the control during the last 2 weeks of pregnancy as well as at the day of parturition. The high cortisol level inhibits the growth of the axial skeleton in the sheep fetus during the late pregnancy which enhances the parturition process (Fowden et al., 1996).

Serum insulin level of single and twin pregnant ewes showed significant decrease than the control during the last 4 weeks of pregnancy as well as at the day of parturition. The decrease of insulin level may be attributed to negative energy balance which leads to decrease in glucose level and increase the liploysis (Faulkner and Pollock, 1990). The shift of energy metabolism in a catabolic direction is characterized by a wide range of endocrine changes, such as insufficient pancreatic β-cell function with a coinciding increase in insulin resistance.

The data illustrated in table (3) showed significant increase in cortisol level than the control during the last 2 weeks of pregnancy as well as the day of parturition in Single and twin pregnant ewes. This observation may be due to a hypothesis that the known relation between stress and/or painful diseases in high yielding dairy cows and pregnant ewes may be mediated through a concurrent increased cortisol secretion leading to hyperglycaemia (Rohrbach et al., 1999). On the other hand, Forslund et al., (2010) reported significantly low levels of cortisol in Cows with ketonemia (BHBA > 1.5 mmol/l). The significant increase in cortisol and presence of significant negative correlation between plasma glucose concentration and cortisol level and the significant positive relationship with β-hydroxybutyrate may be due to increased adrenal output or to impaired ability of the fatty liver, which was a consistent finding in pregnancy toxemia, to mobilize and excrete the hormone (Ford et al., 1990 and Abd-Elghany et al., 2010).

The concentrations of serum albumin, alpha-1-globulin, alpha-2- globulin, beta globulin and gamma globulin of single pregnant ewes showed significant decrease than the control during the last week of pregnancy as well as the day of parturition. These results may attributed to consequence increase in the mother's basal metabolic rate, the maximal nutrient requirements of the placenta and the growing fetus, together with the transfer of serum albumin, immune globulins, and amino acids from the blood stream to the mammary gland for synthesis of colostrums (Batavani et al., 2006).

5. Conclusion

Late pregnancy in ewes is a very stressful period specially the late period in which in erythrocytic haemolysate the mean values of GSH-Px

and GST were high significantly increased; GSH and t-SOD were high significantly decreased (P<0.01) and GR-ase activities were significantly decreased. While, serum glucose, total protein, albumin, globulin and insulin were decreased while serum NEFA, BHBA and cortisol were increased in single and twin but in twin the values is more significant. Our research results recommended that twin bearing ewes need a special care during pregnancy and after parturition by supplementation of ewes by a demands of appositive energy balance.

Economic Return of Recycling the Agricultural Wastes in Egypt and Spain

Mohamed G.M. Abou El- Azayem* and Salah S. Abd El-Ghani

Department of Agricultural Economics, National Research Centre, Dokki, Cairo, Egypt.

Abstract: Animal wastes and plant wastes are an important resource in Sustainable Agricultural Development and organic crops production for healthy food for life, when it is recycled to produce organic fertilizer (compost). It is clear that through the study of The economic returns to rotate some animal wastes and plant wastes in Egypt and Spain, And to identify. The quantity and value of losses in the content of animal wastes and plant wastes fertilizer elements (N, P, K) And also to identify Economic returns to recycling plant wastes for the production of industrial organic fertilizer (compost). Sustainable waste management means using resources efficiently to cut down on the amount of waste produced and where waste is generated, dealing with it in a way that contributes to the economic, social and environmental goals of sustainable development.

[Mohamed G.M. Abou El- Azayem and Salah S. Abd El-Ghani. **Economic Return of Recycling the Agricultural Wastes in Egypt and Spain**. Journal of American Science 2010;6(12):960-970]. (ISSN: 1545-1003). http://www.americanscience.org.

1. Introduction:

There are many complex economic and policy issues related to nutrient management. Before farmers can be convinced about applying a purchased input such as mineral or organic fertilizer, they need knowledge about such inputs and their effects on crop yield in both agronomic and economic terms. Once convinced of using fertilizers, in principle, they have to make the complex decision on how much and which fertilizer to use. Their decision on whether to use fertilizer on a particular crop is generally based on some form of economic judgment that includes experience from using such inputs, the cash or credit available, and probable produce prices. While the calculation of the economics of applying fertilizers is relatively straightforward, the economics of using nutrient sources such as animal manure, compost, crop residues, green manure crops and urban wastes is more complex. Critical elements in the calculation of the economics of using these products are their variable nutrient composition, their residual effect and the cost and availability of labour to access, process and apply them. These factors are often overlooked when advocating different nutrient management strategies.

For practical use, all agronomic data on crop responses to nutrients should always be subjected to economic analysis in order to account for differences in input and output prices and to address the basic issue of whether and to what extent fertilizer application will be profitable to the farmer. The discussion here uses mineral fertilizers as an example but the issues are also applicable to the other nutrient sources. Information on the factors that affect the returns from nutrient application is equally valuable in decision-making.

2. Material and Methods

Data sources: The study relied on sources of essential and secondary data through.

The annual statistical bulletins, periodicals, and some studies academy previous thesis of the masters and doctoral research.

Research and analytical method:

Study adopted the method of statistical analysis of descriptive and quantitative and averages, percentages, and measures of financial for the economic importance of recycling of some agricultural wastes, animal and plant through the production of organic fertilizer manufacturing in Spain, was also used some conversion factors to find out what rewards or draw the waste from the major fertilizer elements (N, P, K) in order to facilitate the economic valuation of these wastes and converted to the values of physical cash.

Reference review

Organic waste composting techniques (Julia et al., 2009) have been extensively developed in recent decades in response to the increasing concern about the amount and management of waste. Most studies focus on a specific stage or aspect in the life cycle of compost. The aim here is to determine the environmental impacts associated to the use of compost, from the collection of organic municipal solid waste to its application to tomato crops, and to compare these results with mineral fertilizer application, using life cycle assessment. Three systems were considered, depending on the fertilizing

treatment applied. The data was obtained experimentally in pilot fields and in an industrial composting facility, both located in the Mediterranean area. Treatments with compost have higher impacts than treatment with mineral fertilizer as a result of the high impact of compost production.

Growing concerns for environmentally friendly goods and services are being expressed together with those related with risks derived from intensive agriculture and broader environmental problems. This was, for example, a major issue at the World Summit on Sustainable Development held in Johannesburg in September 2002. In a recent survey (European Commission, 2005), citizen of the European Union answered that their main priorities in terms of agricultural policy were, listed in order of importance: ensuring stable and adequate incomes for farmers (36%), ensuring that agricultural products are healthy and safe (30%), promoting respect for the environment (28%), favoring and improving life in the countryside (26%) and favoring organic production (20%).

In the study for (Josep. 2006), this paper conducts an empirical study on output, costs and incomes in organic farming with a sample of Spanish firms. Financial accounting data reveals that organic and partly or transitional to organic farming do not get significantly different output than intensive farming. Farms in transition to organic farming bear significantly higher costs and obtain significantly lower income than intensive farming. Costs were recalculated incorporating opportunity costs of family work. Organic and transitional farming displayed significantly higher costs and lower relative income. However, organic farming plays a social role generating more employment than intensive farming and avoiding environmental and health damages. The article recalls for the necessity for accounting to broaden its scope and contents. It should disclose social and environmental data, as well as transactions that are not marketed, registered or valued but yield social profits and costs.

In the study for (salah, 2006) showed that maize wood was of the first rank as organic fertilizer on the total level of Egypt with L.E. 904.98 million annually and expected net return L.E. 687.78 million annually Rice straws came as second rank with total value of organic fertilizer L.E. 2317.29 million annually and total expected net returns L.E. 1761.14 million annually on Egypt's level. As for Fayoum Governorate, corn wood came in the first rank as a value of organic fertilizer L.E. 51.37 million annually and expected net return L.E. 39.04 million annually. Maize wood came in the second rank, the total of Fayoum Governorate of organic fertilizer quantity was L.E. 144.55 million annually and the total of expected net return was L.E. 109.86 million annually with 6.24% of the total Republic. As for Maize wood, it came in the first rank of quantity equivalent to Nitrogen and Rice straw came as second rank. Maize would come as first rank of quantity equivalent to phosphorous and rice straws came as second rank. Rice straws registered the first rank of equivalent quantity of potassium and corn woods were in the second rank. As for the economic retunes of organic fertilizers from agricultural wastes it was of 18% as an average according to 2004 statistics.

(Salvador et. al., 2007) Concern for the environment on a world scale is affecting all economic activities, and agriculture is not an exception. The Common Agricultural Policy (CAP) and the Policy for the Environment of the European Union (EU) have been introducing during the last years different environmental laws through their various legislating offices to facilitate the obtaining of community funding. The fundamental principles on which their measures are based are the following: "those who contaminate will have to pay", "conservationists will be paid" or "internalization of environmental costs". At present, the EU is involved in a configuration process reforming the totality of its budget policy for the programming period 2007-2013. Within this process, the community structural funds have been reviewed to conform to the new EU cohesion policy. Within this area, the new European Agricultural Fund for Rural Development (EAFRD) has been created, in which the basic lines regarding to rural development policy for the next few years are being defined. This is one of the pillars of the CAP. In this way, at least 25% of community expenditure is envisaged to be destined to environmental issues. Based on these principles, it is necessary to integrate agriculture environmentally by practicing the kind of agricultural management that respects and benefits from the opportunities offered by the environment.

3. Results and Discussion:

First: The economic returns to rotate some animal wastes in Egypt and Spain.

Can be identified on the efficiency or economic returns that accrue when to rotate some of the animal wastes and by using some conversion factors can be illustrated through the following points.

The quantity and value of losses in the content of animal waste fertilizer elements (N, P, K).

Loss occurs in the content of animal waste fertilizer elements (nitrogen, phosphorus and potassium) when these wastes are used in the production of non-conventional energy by burning them directly without the benefit with the pollution of

the environment, and can even explain it should first clarify the average content of animal waste fertilizer of these elements, which illustrated in tables (1,2) where shows the average percentage of the content of each waste of animal wastes into the study based on dry weight of the waste.

To determine the value of the content of animal waste from these elements must know the average price in euros per ton of the three fertilizer elements (nitrogen, phosphorus and potassium), and through the prices of mineral fertilizers for these items on the market (at February 2009). It can be explained prices as the price of nitrogen around (345) euros/ton, the price of some phosphorus (510) euros/ton and the price of some potassium (840) euros/ton. (www.coag.org).

Table No. (1): characteristics of the residues produced from animals

Category	*Average Weight (Kg)	*The amount of waste Dry (Kg / day)	**The number of animals in Egypt 2007	***The number of animals in Spain 2007
cattle	400	4	8974466	5740557
Horses	350	5	65714	276987
Sheep	200	0.48	5467469	18758512
Goat	50	0.24	4210714	2475710

Third: Economic returns to recycling plant wastes for the production of industrial organic fertilizer (compost):

There is no doubt that reliance on mineral fertilizers under the regime of intensive agriculture leads to pollution of soil, plants and water and here endorse a need for the presence of organic matter to soils of high level of production, quality and relevance of consumer tastes and conditions of public health, so the quantities of the waste plant were considered a waste of high value-added income national agriculture as a result of the loss of organic matter and fertilizer elements, in addition to being a source of contamination of the environment in the absence of their correct use.

From this perspective, increased attention to the expansion in the production of organic fertilizers and consequently organic agriculture programs can be achieved to maintain soil fertility and improve the physical and chemical properties and biological weapons, which would lead to the production of crops with good specifications to suit the needs and requirements of foreign markets, thus providing opportunities for export of those products.

What is meant by the term organic fertilization of agricultural land is organic fertilizers made from agricultural wastes for recovery of fertilizer elements taken from the soil during various stages of plant growth, so as to maintain the fertility and vitality and restore the ecological balance of the soil, which is achieved with the reduction of environmental pollution resulting from rationalization of consumption of mineral fertilizers pesticides and other chemicals, as well as by not burning waste for disposal and the production of clean safe healthy food for both humans or animals and to obtain a high quality product and reduce the costs of agricultural production and create jobs through non-conventional stages of the production of organic fertilizers and maintain the integrity of the sources of irrigation and drainage and the economy the expenses of the clean canals, banks and reduce the chances of insect and rodent pests and harmful and increase national income through an attractive economic return.

Due attention to organic agriculture to environmental restrictions to protect humans from pollution and the difficulty of disposal of agricultural wastes, leading to increased health and environmental problems, in addition to health conditions to be met through global conventions when exporting agricultural products to world markets. All that was important to provide industrial compost (manure compost), an organic fertilizer resulting from aerobic fermentation of mixtures of plant and animal waste.

And to identify the quantity and value of industrial organic fertilizer (compost) and economic returns that can be achieved when the plant waste recycling for the production of agricultural fertilizer industrial organic (compost) for each waste of agricultural waste under study in Egypt and Spain. Can rely on the following data in the table (11,12) to determine the conversion factor which can be used is as follows:

Table No. (11): characteristics of the waste produced from crops and various plants in Egypt and Spain (2008). .

Type of waste		Area in thousand hectares	***Average production per Ha Wet tons	The total amount of waste is wet a thousand tones/year
*Egypt	Rice straw	745.1	4.8	3576.44
	Cotton Stalks	131.3	4.3	564.75
	Maize Stalks	821.8	4.8	3944.41
	Sorghum Stalks	154.1	5.0	770.51
	Sugar beet Thrones	108.2	9.5	1028.09
	tomato Thrones	240.2	10.0	2401.74

4. Conclusion:

Sustai:nable waste management means using resources efficiently to cut down on the amount of waste produced and where waste is generated, dealing with it in a way that contributes to the economic, social and environmental goals of sustainable development.

The following table No. (15) shows the most important economic returns that can be obtained from the recycling of agricultural wastes in Egypt and Spain.

Country	**Egypt**			**Spain**		
Waste type	**Animal wastes**

5. Recommendations:

1) Promoting cooperation between research bodies and industrial enterprises in order to facilitate the identification of problems and sources of bottlenecks and constraints that limit the optimum utilization of agricultural wastes and thus lead to the scientific and practical solutions to these problems.
2) provide the necessary support for the issuance of an annual statistical bulletin of the two countries on the types and quantities of agricultural waste.
3) Provision of machinery and equipment necessary for the establishment of small projects in the field of recycling of agricultural waste.
4) Training and employment for the construction of these projects.
5) Work to raise awareness of environmental and health among the citizens through seminars and conferences to discuss important economic, social, environmental and health resulting from the recycling of agricultural waste.

Encourage the use of organic fertilizers (compost) as alternatives to economic and safe for the production of healthy food and safe compared to chemical fertilizers are detrimental to health and environmentally.

Abstract :Background: Phenylketonuria (PKU) is a metabolic disorder characterized by high phenylalanine (Phe) levels in blood. Tissue accumulation of L-phenylalanine (Phe) is the biochemical hallmark of human phenylketonuria (PKU), an inherited metabolic disorder clinically characterized by mental retardation and other neurological features. The mechanisms of brain damage observed in this disorder are poorly understood. S-100B protein is highly specific for nervous tissue where its role is not yet fully understood. **Objective:** The aim of our study was to determine the diagnostic value of measuring S-100b in the serum of PKU patients as a marker for brain lesion. Additional validity should be acquired by a comparison with plasma levels of phenylalanine. **Methods:** Nineteen PKU patients from 15 families were selected from the clinic for special needs at the National Research Centre. Their age ranged between 2 and 20 years in addition to 15 healthy controls with same age. Blood samples were drawn to investigate circulating serum levels of S-100b using ELISA technique for all the studied cases. **Results:** Statistical significant increase of serum S-100B concentrations was present in PKU patients compared to controls. Regarding sensitivity and specificity, PKU patients, serum neural protein S-100b showed high sensitivity and specificity values. In addition, there was non significant negative correlation between S100B and Phe **Conclusion:** we concluded that serum S-100B blood could be a useful peripheral marker of nervous system damage in patients with phenylketonuria.

Key Words: Phenylketonuria, Serum neural protein S-100B

1. Introduction

Phenylketonuria is a rare metabolic disorder with an estimated prevalence of 1:10,000, i.e. an orphan disease. Inheritance is autosomal recessive caused by mutations in the phenylalanine hydroxylase gene. This enzyme converts phenylalanine to tyrosine which is also a precursor for dopamine. Partial or complete enzyme inactivity results in the accumulation of phenylalanine in tissues, blood (hyper-phenylalaninemia) and other body fluids (Albrecht *et al.,* 2009).

Untreated phenylketonuria causes severe neurological impairment, mental retardation and behavioral difficulties. Although there is no doubt that blood phenylalanine has a detrimental effect in the brain (Scriver, 2007), the ultimate causes for this effect remain hypothetical (Hoeksma *et al*., 2009). If left untreated from birth, this results in rapid accumulation of toxic concentrations of Phe in the blood, leading to severe brain damage and microcephaly (van Spronsen *et al.,* 2009). The vast majority of cases are now identified via neonatal screening programmers, allowing timely intervention to avoid severe consequences. However, insufficiently controlled Phe concentrations may still result in neuro-cognitive symptoms, such as a decrease in intelligence quotient (IQ), attention, executive function (such as planning, working memory, inhibition, flexibility and behavioral issues), and psychosocial effects in later childhood, continuing into adulthood (DeRoche et al., 2008; Waisbren *et al.,* 2007).

A low-Phe diet currently forms the principal strategy to limit Phe accumulation in the blood and, therefore, in tissues such as the brain (MacDonald and Asplin. 2006). The low-Phe diet restricts the intake of high-protein foods, and the remaining nutritional requirements must be obtained from Phe-free amino acid supplements (protein substitute) and special or natural foods that are low in Phe, the nature

and availability of which can vary geographically (Weetch and MacDonald, 2006).

The term S-100B refers to members of a multigenic family of calcium-modulated proteins (S100 proteins), mostly of low molecular mass (≅10 000 Da), that were first identified (on the basis of methods available at the time) as a protein fraction detectable in brain but not in non-neural extracts and called S100 because of their solubility in a 100%-saturated solution with ammonium sulfate (Moore, 1965). At present, at least 20 proteins have been identified as belonging to the S100 protein family, the members of which are characterized by the presence of a pair of so-called EF-hand (i.e., helix-loop-helix) calcium-binding motifs (Kawasaki *et al.,* 1998), first discovered in the crystal structure of parvalbumin (Kretsinger and Nockolds, 1973), that induce conformational changes of the protein after binding to calcium (Donato, 2001; Heizmann, 1999). This conformational change may facilitate the interaction of S100 proteins with secondary effectors: S100 proteins are generally thought to be calcium sensor proteins that modulate biological activity via calcium binding (Ikura, 1996). In addition, some S100 members (Schafer *et al.,* 2000; Nishikawa *et al.,* 1997) have been shown to bind Zn^{2+} and Cu^{2+}, suggesting the possibility that their biological activity in some cases might be regulated by Zn^{2+} and/or Cu^{2+}, rather than by Ca^{2+} (Heizmann and Cox, 1998).
Aim of this study: Since S-100B protein is a biomarker of neural tissue damage and PKU is a neurodegenerative disease, we aimed to investigate whether S-100B is related to CNS damage of PKU patients and to their blood Phe levels.

2. Material and methods

Patients screening

The present study was carried out on 19 PKU patients (12 males and 7 females) from 15 families selected from the children with Special Needs Clinic and Clinics Department, National Research Centre. Their age ranged between 2 and 20 years. In addition, 15 healthy matched subjects of age and sex were ascertained as control group.

All selected cases were selected at the time of the diagnosis of the index cases by elevation of serum levels of Phenylalanine (Phe) which was done by an enzymatic colorimetric assay (Scriver *et al.,* 1989) for all studied cases.

Participants were classified into three age groups: children with mean age below 13 years, adolescents with mean age between 13years and 18 years, and adults older more than 18 years.

All PKU patients were managed with low phe diet the time they diagnosed

Clinical Investigation: All PKU patients were on low phe diet.

- 3 patients had abnormal EEG and received Carbamazepine in addition to low phe diet
- Also 6 patients received Sodium valproate.
- On the other hand 5 patients had autistic features receiving Risperidone.

Intelligence quotient (IQ):

All the patients were tested using Stanford-Binet Intelligence scale: Fourth Edition (Thorndike et al., 1986) according to their age. The degree of mental retardation (MR) was evaluated according (Menon et al., 2003): normal ~80, borderline =70-90, mild = 51-70, moderate = 36-50, severe = 21-35, profound = 0- 20.

Clinical Investigation

Collection of Blood Samples

Blood samples were collected from (controls and PKU patients) by venous arm puncture into tubes, The tubes containing blood without adding anticoagulant were centrifuged after 30 minute at (3000 r.p.m for 10 minutes at 4^{o} C) to separate the serum. The serum samples were divided into small aliquots and kept frozen until analysis.

Laboratory Investigations

- Serum concentrations were performed by using a commercially available the RD 192090100 Human S100B ELISA Kit.
- Total serum protein was assessed by colorimetric method using commercially Stanbio Total Protein Loiqui-Color Kit. This method is based on the reports of Weischeslbaum (1946) and Gornal et al.,(1949).
- Determination of Total Calcium in serum by colorimetric method using commercially available Kit from STANBIO Company. The procedure presented is based essentially on the micro-method of Saker and Chauhan (1967).
- Ionized calcium was calculated according to Zeisler Formula (1954)

Statistical analysis of data, Package for

Social Science (SPSS for Windows Release 11; SPSS Inc., Chicago, IL, USA) was used. Data were analyzed by two-way ANOVA. As no variable was simultaneously Gaussian in the groups of study, differences were tested with the Mann–Whitney U test. Correlation coefficients were estimated with the Spearman test. For the evaluation of categorical variables, Chi square test was used. All tests were

two sided and P values < 0.05 were considered significant.

3. Results

Among the 19 patients with PKU studied, PKU was proved to have high level of Pha concentration. The diagnosis of Mental retardation was based on IQ Score (Table 1)

Table 1. Demographic and clinical data of the studied group

		#N
No. of Family groups		15
Gender	Females	7
	Males	12
	Total	19

	Not available	1

#N.: no of cases

The results of the S100B in PKU showed that S100B level was significantly increased in PKU cases when compared to healthy control group (F=43.771, P<0.0001). In addition, Total calcium (Ca) and ionized Calcium (Ca^{+2}) were significantly decreased in PKU when compared to healthy controls (F=35.121, P<0.0001 and F=27.155, P <0.0001 respectively).In addition the results of the Total Protein (TP) in PKU Showed that there was no statistical variation between the mean values of TP in PKU (7.71±0.22gm/dL) when compared to healthy controls(7.54+ 0.19gm/dL) (F=0.333, P=0.568) (Table 2)

The best Cut off value of S100B was 1866 pg/ml (the sensitivity and PPV values were 100 % and 86.4% respectively but the specificity and NPV were 80% and 100 % respectively(Table 3) The area under the curve of S100B was 0.942 (Table 4, Fig.1). The predictive value of S100B for discriminating between individuals with and without PKU was assessed by calculating the area under the ROC curve.

Correlation between S100B and Phe, IQ, TP, Ca and ionized Ca^{+2} in PKU Cases:

There was no significant positive correlation between S100B and both of IQ, Ca and ionized Ca^{+2} (r=0.368, P=0.133, r=0.256, P=0.290 and r=0.272, P=0.260 respectively) in PKU Cases. In addition, there was non significant negative correlation between S100B and both of Phe and TP (r=0.173, P=0.479 & r=-0.157, P= 0.521 respectively) in PKU Cases (Table 5).

Table 2. Summarized for data Age, Pha Conc., IQ Score, Total Protein (TP)(g/dL), Total Calcium (Ca), Ionized Calcium (Ionized Ca^{+2}) mg/dL) and S100B (Pg/ml) in Control and PKU Groups.

* P values < 0.05 were considered significant.
** P values < 0.0001 were considered very high significant.

According to the different ages group

There were no statistical variations in S-100B between different age groups [F=.050, P>0.05(P=0.826)](Fig.2). In the group of age (0-12yrs), there was no significant negative correlation between S100B and both of Phe, Ca and ionized Ca^{2+} (r=-0.0.222, P=0.0.607, r=-0.237, P=0.651 and r=-0.0.590, P=0.217 respectively) However, there was no significant positive correlation between S100B and IQ and TP (r=0.575, P=0.232 and r=-0.411, P= 0.419 respectively).

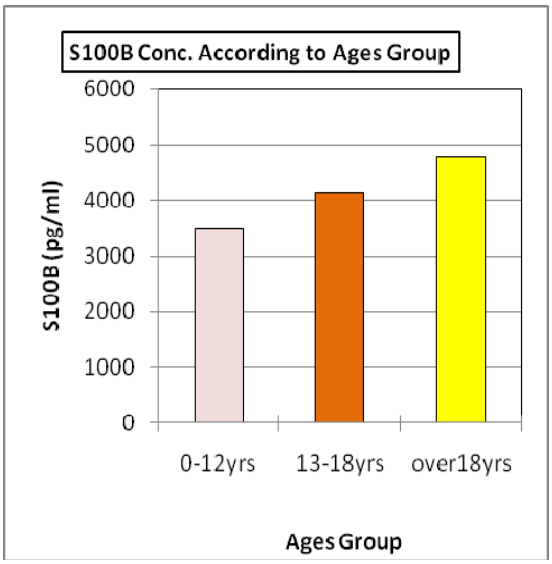

Fig. (4): Mean Values for S100B Conc. in Different Age group s of PKU

According to Severity of PKU:

The results revealed that there was no variation between different severity of PKU groups (F=2.998, P=0.104).

In Classic Phe severity. There was no significant positive correlation between S100B and both of Phe, IQ, Ca and ionized Ca^{2+} (r=0.251,P=0.0.484,r=317, P=0.373, r=0.330, P=0.352 and r=0.463, P=0.0.178 respectively). As well as in Moderate Phe severity, there was non significant positive correlation between S100B and both of Phe and IQ (r=0.490, P=0.262 and r=-0.0.233, P= 0.615 respectively), but there was non significant negative correlation between S100B and both of Ca and ionized Ca^{+2}(r=-0.083-, P=0.859 and r=-0.146-, P= 0.754 respectively)

According to Degree of Mental Retardation (Depended on IQ Score) in PKU:

The results indicated that the mean values ± SE of S100B in Borderline (B), Moderately (Mod) retarded and Severely (S) retarded of Mental retardation in PKU were 4898.5±112.5, 3941.9±252.71and 3380.1±411.26 pg/ml respectively with ranges of 4786-5011,3162-5128 and 1995-5248 pg/ml respectively, Statistically, there was no significant changes between these groups (F=0.05, P=0.826).

As well as the result showed one case have Mild Mental retardation and another one haven't IQ score.

4. Discussion

Phenylketonuria (PKU) is the most common inherited disorder of amino acid metabolism that arises from a single enzyme deficiency of phenylalanine hydroxylase, which converts the essential amino acid phenylalanine to tyrosine. Failure of this conversion results in the accumulation and elevation of phenylalanine in blood and tissues. Elevated concentrations of phenylalanine and its metabolites interfere with normal development of the central nervous system, leading to severe mental retardation. In PKU, plasma Phe concentrations may reach 400–1800 μmol/L and are harmful especially during the first year of life (Leader *et al.,* 2008).

Our study showed a significant negative correlation between concurrent Phe level (ranged from 7 to 37 mg\dl) and IQ score (ranged from 21 to 80) for the affected individuals' .Our results agreed with previous investigators (Antshel *et al*., 2003; White *et al*., 2002).

It is generally accepted that early-treated children with classic PKU suffer loss of IQ scores if the diet is discontinued, and children who are maintained on phe- restricted diet are more likely to achieve higher IQ scores and greater school achievement than those who discontinue the dietary management (Sharman *et al.,* 2009; Susan *et al.,* 2007).

On the other hand, another longitudinal study of intelligence among early-treated patients with PKU concluded that for each 300 µmol/l (5mg\dl) increase in phe level, IQ measured during pre-school years decreased by 0.5 SD (approximately 7 points) up to 10 years of age, after which time IQ remained reasonably stable (Burgard, 2007).

The measurement of biomarker of neural tissue damage such as S-100B protein may offer an alternative and direct indicator of cell damage in the nervous system when clinical and radiologic signs are not yet fully manifest and it is recommended to additional advantage of providing a quantitative

indicator of the extent of brain lesion (Steiner *et al.,* 2010).

Several reports have been published regarding the expression of S100B in patients with Phenylketonuria, Down's syndrome, in children with cerebral palsy or delayed development (Steiner *et al.,* 2010).

Previous authors reported that higher concentrations of serum S-100B protein in normal neonates and children compared to adults could reflect the ongoing central neuro-developmental processes occurring during these different stages of life (Mori *et al.,* 2009) the proliferation and maturation of glial cells, growth of neuritis and formation of synapses have been documented to be the most important functions of S-100B in morphogenesis (Tateihi *et al.,* 2006).

Our results showed a significant increase in S-100B levels in the affected cases and a significant correlation between S-100B and phe and total protein (TP) .Our data are in agreement with corresponding data reported by other investigators (Boneh *et al*., 2006; Alarcon *et al*., 2005; Foerch *et al.*, 2005; Marchi *et al*., 2004; Park *et al.,* 2004; Schulpis *et al.,* 2004).

Marchi *et al.,* (2004) reported that serum S100B is an ideal marker of blood-brain barrier integrity, because with a molecular weight of 21 kDa (S100B dimer) it may not penetrate through an intact blood-brain barrier. Furthermore, its concentration is high in central nervous system fluids and normally low in blood. Indeed, serum levels of S100B were directly correlated with an experimental damage of the blood-brain barrier.

One hypothesis is that S-100B accumulates in the extracellular space after astrocyte death or due to increased release by activated astrocytes, or after cellular disintegration of the damaged parenchyma. Under these conditions, the S-100B concentration may be in the micromolar range and the protein may become toxic due to its stimulatory effects on nitric oxide (NO) production by astrocytes and microglia. It interacts with receptor for advanced glycation end product (RAGE) on neurons and RAGE mediated neuronal apoptosis, or stimulates of interleukin-6 (IL-6) secretion by neurons (Alarcon *et al*., 2005). In this regard, it is noteworthy that RAGE is up regulated in many tissues including brain, during development and in the course of pathologic states i.e., under conditions in which many cells are destined to die by apoptosis. RAGE therefore may be an important progression factor in several disease states, and S-100B might be one crucial RAGE ligand in the brain (Alarcon *et al*., 2005).

Similarly, it was suggested that elevated S-100B levels are involved in the development of Down's syndrome; its expression was also correlated with the density of dystrophic neuritis with over-expressed β-amyloid precursor proteins (AβPP) (Medana *et al.,* 2007). Recent evidence indicates that high levels of S-100B in cerebrospinal fluid CSF increase the risk of repeated seizures in children with severe infection due to axonal injury (Medana *et al*., 2007).

Our results showed a significant negative association between S-100B and both Total Calcium (Ca) and Ionized Calcium (Ca^{2+}) in the affected cases although S-100B plays an important role in Calcium homeostasis. Our data agree with previous studies that reported similar findings (Wojda *et al.*, 2008; Mattson *et al*., 2004; Petzold *et al.,* 2003).

S-100B is involved in calcium homeostasis. For example, glial cells from mouse S100B null cerebellar cultures have been reported to display enhanced calcium transients in response to potassium chloride (KCl) or caffeine suggesting a role of S-100B in cytosolic calcium buffering. This observation is difficult to reconcile with the relatively low affinity of S-100B for calcium in vitro but one cannot exclude the possibility that normally S-100B modulates the activity of one or more effect or proteins (calcium channels/endoplasmic reticulum ATPase) that regulate the levels of cytosolic calcium with ensuing abnormality in calcium handling in the absence of S100B (Petzold *et al.,* 2003).

In conclusion, our findings support the hypothesis of a positive relationship between serum S-100B level and Phe blood level in PKU patients, and estimation of S-100B blood could be a useful informative peripheral marker monitoring the toxic effect of phe on central nervous system and direct indicator of cell damage in nervous system. Moreover, the combination of this marker with other diagnostic techniques may the way forward to improve the clinical assessment of patients with PKU.

Our study emphasized the correlation between early-dietary intervention and IQ score improvement in children with classic PKU.

Further studies with increase number of cases are highly recommended.

[1]Bio Chemistry Department, Faculty of Agriculture, Cairo University, Giza,Egypt
[2]Department of Seed Technology, Horticulture Research Institute, A R C, Ministry of Agriculture, Giza, Egypt

Abstract: The aims of this work was to study some changes in the total content of storage components of watermelon (*citrullus lanatus*) seeds during accelerated ageing technique and its relation to seeds viability. **Materials and Methods**: Before the experiment, seeds were stored for two years in store house at 25C° in the start experiment, ageing at 50°C with 17% moisture up to 24, 48, 72, and 96 hours respectively. Germination percentage was decreased, a reduction in the total content of storage components such as proteins, carbohydrates, in addition, increasing oils and decreases in the activities of various esterase enzymes under the same condition were observed. **Results:** It was clearly that 50°C with 17% moisture content could be used as a good ageing seed testing condition for watermelon seeds In the present study The treatments watermelon seeds could be identified by Biochemical analysis (Esterase isozyme and Protein) banding pattern.

Key words: Watermelon, accelerated ageing seed, seed germination.

1. Introduction:

Watermelon (*citrullus lanatus)* is one of important horticultural crops belonging to the family cucurbitaceae mainly propagated by seeds. Ageing tests have been developed to predict emergence performance , seed vigor and comparing seed lost quality **(Yanmaz *et al.*, 1999; Matthews, 1994; McDonald, 1980).** The deterioration of the stored seed is a natural phenomenon and the seeds tend to loose viability even under ideal storage conditions **(Ayyappan *et al.*, 2006; Bhatti and Sata, 1997).**

The seeds with low viability are rejuvenated /multiplied. Frequent multiplication results in genetic drift due to which genetic integrity is impaired, it also involves high risk of out crossing and mechanical mixture during multiplication, so it is very important to prolong the seed longevity. There are number of factors that affect seed longevity in storage **(McDonald, 1999; Powell, 1998)**. Among these factors are temperature and seed moisture content/relative humidity. There are some other factors which can decrease seed longevity, e.g. varietal differences in seed viability.. Therefore, it is important to assess seed vigour and viability during storage. Seed ageing as an important parameter to assess /estimate the seed viability and vigour accelerated ageing which is a good vigour test for various crop seeds **(Anonymous,1983)** and could be used to predict storability of seed lots **(tyagi,1992)**.

Accelerated ageing treatments involve exposing seeds to severe adverse storage conditions, i.e.-raised temperature and high moisture contents for specific periods of time.

The aims of this work was studying the changes in the total content of storage components of watermelon seeds during accelerated ageing technique and its relation to seed viability, in order to reduce the time of storage experiments (which took a long time) to know the extent of changes in content of storage components of seeds.

2. Materials and Methods:

21. Materials

1) Plant material and ageing conditions:-

Watermelon (*citrullus lanatus l.cv giza1*) seeds were collected from plants grown in Moshtohr field at Horticulture Research Institute, 2007.

Seeds were stored for 2 years in store house at 25±-2°C before the experiment started. They were soaked in water for 24 hours at 4°C then air dried for 4 hours. During the experiment, seeds were aged at 50°C and 17% moisture content, stored up to 96 hours (4 days).

Samples of watermelon seeds were collected every 24 hours.

2.2. Methods:

2.2.1. Germination tests:

Germination tests were carried out on four replicates of 25 seeds. The seeds were set to germinate in between moistened paper towels. Seeds were kept at 25°C±2 for 14 days. The numbers of germinated seeds were counted daily up to 14 days in watermelon seeds. At the final count the number of normal and abnormal seedling. Then survival curves were constructed from these results, germination percentage, were recorded.

2.2.2. Determination of the total carbohydrate:

Total carbohydrates were extracted according to **A.O.A.C. (1990)** 0.1 g of air-dried sample was hydrolyzed with 1 N HCl by refluxing for 6 hrs in a boiling water bath. The obtained solution was filtered, neutralized and the total volume was made up to 100 ml with distilled water. Resulted total reducing sugars was determined calorimetrically using 1 ml of sample with alkaline potassium ferricyanide reagent. The amount of total carbohydrates was determined according to the standard curve of glucose**.**

2.2.3. Determination of total protein:

The dried parts of the plants were used. Total nitrogen in plant was determined based on micro-Kjeldahl method accorded to **Markaham (1942)**, using boric acid modification as described by **Ma and Zuazage (1942),** under steam distillation using Buchii 320 unit, and was calculated as nitrogen percent.

The protein content was calculated as follows: Protein% = Nitrogen% x 6.25.

2.2.4. Determination of total oil:

Seed Oil percentage in dry seeds was determined using Soxhlet apparatus and petroleum ether as a solvent according to **A. O. A. C. (1970).**

2.2.5. Biochemical Markers

2.2.5.1. Protein analysis

SDS-Polyacrylamide gel electrophoresis was performed in 12 % acrylamide slab gels following the system of **Laemmli (1970)** to identify their protein profiles. Young fresh leaves were collected from all studied plants and immediately ground in a mortar using liquid nitrogen. The seeds were grounded to a fine powder using a mortar and pestle, homogenized with 1 M Tris-HCl buffer; pH 6.8 in clean eppendorf tube, left in refrigerator over night, then, centrifuged at 10000 rpm for 10 min. The supernatant of each sample (contains protein extract) was kept in deep-freeze until use for electrophoretic analysis, then boiled for 5 minutes in water bath before loading in the gel.

2.2.5.2. Isozymes Electrophoresis

Native polyacrylamide gel electrophoresis was used to study isozyme variation among the ten populus accessions. The staining solution was composed of 50 ml of 1M Na-Acetate; pH 4.7, 50 ml of Methanol, 50 ml 3,3,5,5 tetra-methylbenzidine (TMBZ) and 2 ml of 30% H_2O_2 while for esterase (Est.) the staining solution composed of 50 ml of 100 mM Na – Phosphate; pH 6.0, 25 mg of α – Naphthyl Acetate and 50 ml of fast blue RR salt according to **Scandalios (1964).**

4. Results:

4.1. Effects of an Accelerated Ageing Technique on chemical Components of Watermelon seeds on total protein ,total carbohydrates, and total oil contents are illustrated in table (1) and figures (1, 2 and 3)

Table (1): Effect of Ageing on total protein (%), total carbohydrate (%) and total oil (%) in watermelon seeds.

Treatment	Total protein (%)	Total carbohydrate (%)	Total oil (%)
Untreated treatment	43.75 a	4.06 a	49.34 c
50 °C with 17% moisture for 24 hours	41.15 b	3.75 b	50.6 b
50 °C with 17% moisture for 48 hours	40.35 b	3.52 c	51.4 b
50 °C with 17% moisture for72 hours	38.9 c	3.34 c	52.4 a
50 °C with 17% moisture for 96 hours	37.75 d	3.08 d	53 a

Values in the same column followed by the same letter(s) do not significantly differ from each other according to Duncan's multiple range tests at 5% level.

Data in table 1 and Fig (1) showed high significant differences in watermelon seeds between untreated treatment seeds and accelerated ageing treatment seeds total protein was significantly decreased in ageing seeds for 50 C° with 17% moisture for (4 days) from 43.75% to 37.75%.

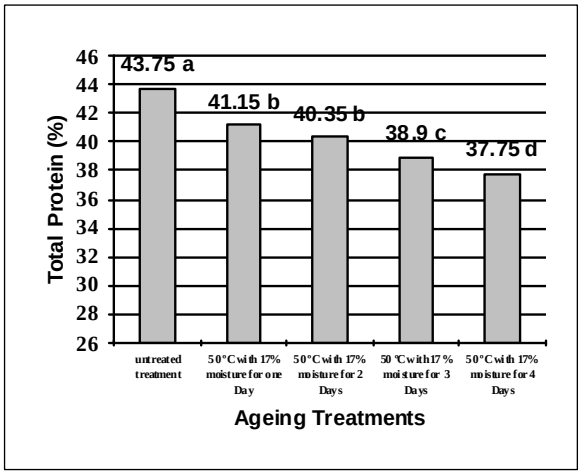

Fig 1: Changes in total protein of watermelon seeds before and during accelerated ageing technique.

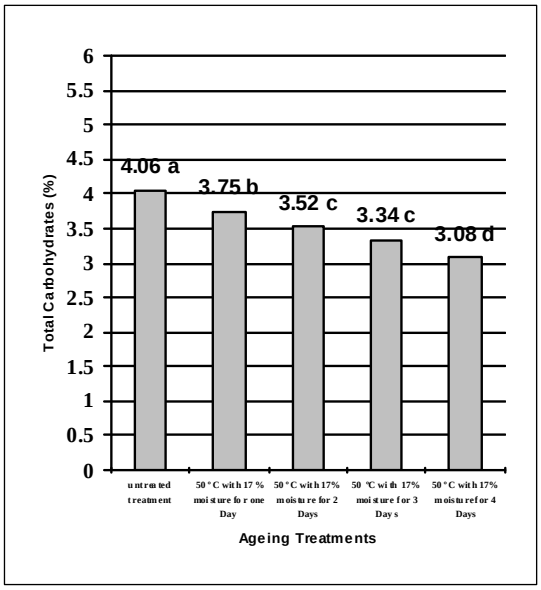

Fig 2: Changes in total Carbohydrate of watermelon seeds before and during accelerated ageing technique.

It is obvious from results shown in fig (3) that significant increase in total oil were detected due to accelerated ageing of watermelon seeds compared with untreated treatment. Total oil (53 %) were obtained from the high level of 50 ºC with 17% moisture for 4 Days while the lowest level (49.34 %) were obtained from untreated treatment.

4.2. Effects of an Accelerated Ageing Technique on Germination percentage of Watermelon Seeds.

Table (2) shows that the germination percentage of watermelon seeds decreased from 60% in untreated treatment seeds to 24% for aged seeds, after 96 hours (4 days).

Treatment	Germination (%)
Untreated treatment	60 a
50 ºC with 17% moisture for 24 hours	48 b
50 ºC with 17% moisture for 48 hours	37 c
50 ºC with 17% moisture for72 hours	30 d
50 ºC with 17% moisture for 96 hours	24 e

4.3. Effects of an Accelerated Ageing Technique on Electrophoretic banding patterns of proteins of Watermelon seeds. "Biochemical markers"

4.3.1. Watermelon seeds protein electrophoresis.

The watermelon seeds protein banding profile which was separated by using SDS-PAGE are illustrated in fig. (4). The total number of bands was 14 with molecular weights ranged from 18.4 KDa to 116 KDa. The highest number of bands was 13, detected in clone no. 1 (control) and clone no. 2 (while the lowest number of bands was 11, identified in *clone* no 4 and clone no. 5.

Fig. (4), is a dendrogram which demonstrated the distance between watermelon seeds under investigation.It showed that treatments of seeds watermelon were separated into two major groups at a distance of 2.5.

The first group included clone no. 4.

The second group involved each clone no. 1 and clone no. 2 was delimited from the first group at a distance of 10.75, while clone no. 3 was delimited, as well, from clone no. 1 and clone no. 2 at a distance of 6.75.

Demonstrative analysis of the presence and absence of bands were assessed with (1) and (0), respectively, are illustrated in Table (3). It is observed that 10 bands were mono-morphic (106.886, 85.898, 75.31, 59.478, 53.786, 44.411, 76.495, 71.709 and 70.015KDa), while 4 bands were polymorphic, giving 28.57% polymorphism. The matrix of similarity index for watermelon seeds is presented in Table (4). The

highest coefficient was 95.2 recorded between *clone no. 4 and clone no. 5* followed by 88.9 recognized between clone no.1 (control) and clone no. 2, followed by 84.2 between clone no.1 (control) and clone no.3 and clone no. 2 and clone no.3 On the other hand, the lowest coefficient value was 60 observed between clone no.1 (control) and clone no.4.

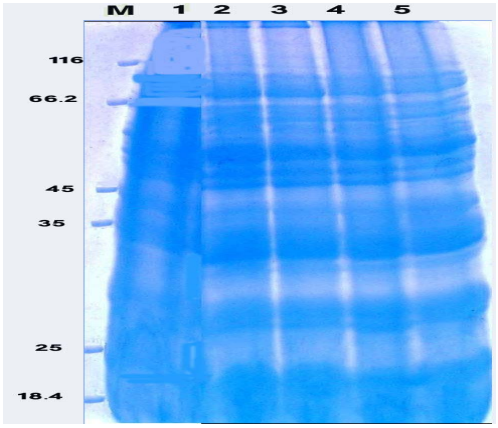

Fig. (3): SDS-protein banding patterns of seeds proteins
Clone no 1- untreated treatments
Clone no 2- ageing at 50C° with 17% moisture for one day
Clone no 3- ageing at 50C° with 17% moisture for two day
Clone no 4- ageing at 50C° with 17% moisture for three day
Clone no 5- ageing at 50C° with 17% moisture for four day

Table (3) Data matrix illustrating the presence or absence of bands in the seeds protein electrophoresis *banding patterns*.

No. bands	MW	Untreated treatment	Ageing at one day	Ageing at two day	Ageing at three day	Ageing at four day
1	106.886	1	1	1	1	1
2	85.898	1	1	1	1	1
3	75.31	1	1	1	1	1
4	68.765	0	0	0	1	1
5	60.64	1	1	0	0	0
6	59.478	1	1	1	1	1
7	53.786	1	1	1	1	1
8	44.411	1	1	1	1	1
9	33.483	1	1	1	0	0
10	76.495	1	1	1	1	1
11	76.444	1	1	1	1	1
12	71.709	1	1	1	1	1
13	70.015	1	1	1	1	1
14	18.064	1	1	1	0	0

Table(4) Proximity Matrix of protein results

	Untreated treatment	Ageing at one day	Ageing at two day	Ageing at three day	Ageing at four day
Untreated treatment		0.889	0.842	0.600	0.632
Ageing at one day	0.889		0.842	0.700	0.737
Ageing at two day	0.842	0.842		0.762	0.700
Ageing at three day	0.600	0.700	0.762		0.952
Ageing at four day	0.632	0.737	0.700	0.952	

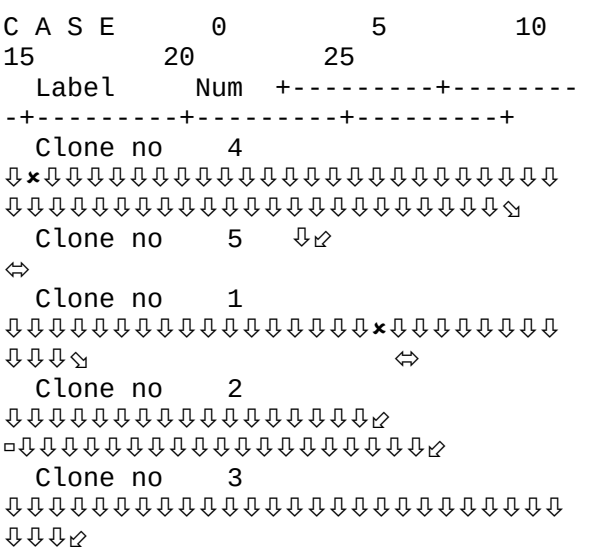

Fig (4) Dendrogram for the seeds treatment and untreated treatment of the protein data using UPGMA and Similarity matrices computed according to Dice coefficients.

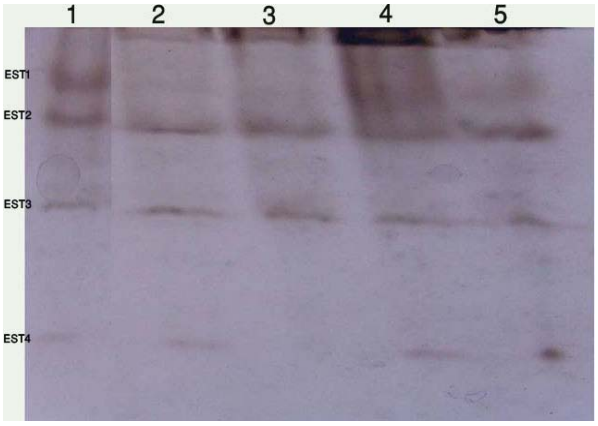
Based on the similarity matrix developed by analyzing only the common bands between the different accessions representing each seeds a dendrogram (Fig. 5) was constructed. The obtained dendrogram was divided into two main clusters; one cluster included. clone no. 4 and 5, while the other one included 1, 2, and 3, the cluster no. 2 divided to two subcluster one of them included clone no. 3 while the other subcluster included clone 1 and 2 .the highest relationships was between clone no. 4 (ageing at 50C° with 17% moisture for three day) and clone no. 5 (ageing at 50 C° with 17% moisture for four day). It was found. The highest variation between clone no 1(untreated treatment) and clone no 4, 5 that indicate to the effects of accelerated ageing on banding patterns of proteins of watermelon seeds.

4.3.2. Esterase banding patterns:

Esterase banding patterns was illustrated in Fig. (6) and dendogram in fig (7).

Fig (6) represents esterase electrophoretic banding patterns among examined seeds, a total of 4 bands were identified in this study, which were presented in some seeds treatment and absent in some others. The analysis of data showed 3 bands were polymorphic with 75 % polymorphisms.



Clone no 1- untreated treatments
Clone no 2- ageing at 50C° with 17% moisture for one day
Clone no 3- ageing at 50C° with 17% moisture for two day
Clone no 4- ageing at 50C° with 17% moisture for three day
Clone no 5- ageing at 50C° with 17% moisture for four day

Fig. (6) Electrophoretic profiles of the esterase enzyme system

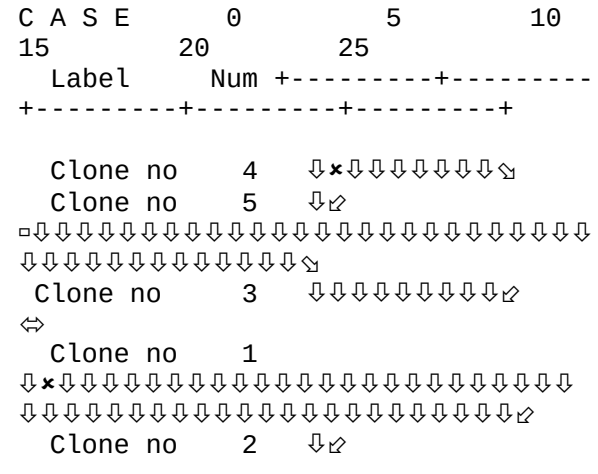


Fig. (7) Dendrogram for seeds treatment and untreated treatment of the esterase data using UPGMA and Similarity matrices computed according to Dice coefficients.

Estrase isoenzyme polymorphism detected in seeds watermelon (Fig.6), was represented by four zones of estrase activity Est.1, Est.2, Est.3 and Est.4 (in the order of increasing mobility from cathodal end). Results of seeds watermelon treatments showed that Est.1 was appeared in all treatments, results of zone Est.2 , Est.3 showed that new isoenzyme bands appeared and other disappeared, the highest close was between clone 1 (control) and clone 2, Est.3 showed decrease in its band between clone 3 and clone 4 with control.

Finally, the results obtained suggest that, the clone no. 1 (control with very close with clone 2 (Ageing at one day).

Based on the similarity matrix developed by analyzing only the common bands between the different accessions representing each seeds treatment and untreated treatment a dendrogram was constructed. The obtained dendrogram was divided into two main clusters; one cluster included. clone no. 1 and 2, while the other one included 4, 5, and 3 , the cluster no. 2 divided to two subcluster one of them included clone no. 3 while he other subcluster included clone 4 and 5. The highest relationship was between clone no. 1 (untreated treatment) and clone no. 2 (ageing at 50c with 17% moisture for one day). It was found. The highest variation between clone no 1(untreated treatment) and clone no 4, 5 that indicate to the effects of accelerated ageing on Esterase banding patterns.

4. Discussion:

The process of deterioration which occurs under these special ageing conditions is assumed to be similar to those which occur during natural ageing **(Delouche and Baskin, 1973; Perl *et al.*, 1978)**. The main difference being the speed at which these changes occur. A reduction in the total content of storage components such as proteins and carbohydrates **(Ayyappan *et al.*, 2006 and Agnieszka. *et al*., 2010)**. Increase in total oil were detected due to accelerated ageing (**Maqsood *et al.*, 2000).**

Results recorded high significant differences in watermelon seeds between untreated treatment seeds and accelerated ageing treatment seeds .Concerning total protein and total carbohydrate values, it was significantly decreased in ageing seeds for 50 C° with 17% moisture for (4 days). These results were in agreement with **Ayyappn *et al.*, 2006)** who found that total protein was decreased to half of initial content in cucumber seeds at 8th day of ageing as previously reported (**Ravikumar *et al.*, 2002)**, while the amount of free amino acids increased

gradually as previously reported (**Coolbear *et al.*, 1984**; **Ravikumar *et al.*, 2002)**. This increase in the amount of the free amino acids may be due to the hydrolysis of proteins during ageing.

Feeney and **Whitaker,(1982)**; **Ayyappn *et al.*, (2006)** who reported that the reduction of sugar content might be due to hydrolysis proved by Amadori and Maillard reactions. Starch. As well as wheat seed did not increase total carbohydrate levels as a result of accelerated ageing, on the contrary the amount of carbohydrates in these seeds slightly decreased **(Agnieszka., *et al* 2010)**.

In contrast, our results showed significant increase in total oil were detected due to accelerated ageing of watermelon seeds compared with untreated treatment. These results were harmony with (**Crowe *et al.* 1989**) who showed that addition of total fatty acids increased fusion of plant vesicles which led to an increase in membrane leakage. (**Copeland** and **McDonald 1995**) reported that continual accumulation of total fatty acids culminates in a reduction of cellular pH and is determined to normal cellular metabolism. Further more, it denatures enzymes resulting in loss of their activity. Individual cotton seeds containing 1% or more of free fatty acid usually will not germinate. The germination percentage of watermelon seeds decreased from 60% in untreated treatment seeds to 24% for aged seeds, within 4 days. The results were in agreement with **Yanmaz *et al.*, 1999** and **Alsadon *et al.* (1995)** found that cucumber seeds showed 82% of germination after storing at 24% moisture content and 45°C for 72 hours. In our experiment, at 17% moisture content and 50°C, cucumber seeds lost viability after the same period. Obviously, little variation in moisture and temperature had great effect on viability as pointed by **(Ellis and Roberts 1980)**.

Enzyme activity of esterase isozyme was parallel with the extent of germination of those seeds, since these activates owes mainly to esterase of endosperm. It was suggested that the endosperm of aged seed retains normal responsibility to the growth of seedling even if it was 2 years old (**Momotani, *et al.*, 1989**).

Abstract: Purpose: In this study the therapeutic low-power laser (LPL) and Betamethasone (as an anti-inflammatory) were compared in terms of their effects on edema and trismus associated with surgical removal of impacted mandibular third molars. **Material and methods:** 20 healthy patients divided into two equal groups were included in the study. Group (I) received LPL irradiation (energy output 6 J/cm^2 with constant power density of 100 mW, wavelength 980 nm) on the 1st and 3rd postoperative days. Group (II) received a single dose of 4 mg systemic intramuscular Betamethasone Sodium Phosphate (Diprofos) into the gluteal region immediately after suturing of the surgical wound. Both groups received the usual medical and physical postoperative recommendations. **Results:** LPL irradiation (group 1) showed remarkable reduction of postoperative edema on the 3rd postoperative day. In addition, no significance difference resulted on comparing this effect between both groups. Postoperative trismus was nearly the same in both groups. No adverse effects of the procedure or medication were observed. **Conclusion**: LPL therapy is effective than systemic Betamethasone in reducing postoperative edema after third molar surgery without statistical significant differences. However both treatment modalities have the same effect on postoperative trismus.

Key words: edema, trismus, low power laser therapy, Betamethasone.

1-Introduction:

Postoperative trismus and edema are consequences of tissue injury during surgery. The raising of muscular attachments results in reflexive cramp of the masticatory muscles, Jovanovic (1998), and direct trauma to the blood and lymph vessels, Petkovic and Bukurov (1987).

These conditions cause limitation of the mouth opening and fluid accumulation in the interstitial area as a result of its transudation from injured blood vessels and fibrin obstruction of lymph drainage Petkovic and Bukurov (1987). The destruction of the local tissues and severity of surgical intervention are in direct proportion to the presence of these postoperative sequelae, Gonzalez-Santana et al., (2005). These complications reach their maximal at 12–48 h after surgery, but may completely resolve in 5-7 days, Sowray (1986).

Several trials have been used to prevent the occurrence of these complications by means of preoperative and postoperative administration of corticosteroids, as they reduce the leakage of lymph and thereby the transudation of liquid. Also, non-steroidal anti-inflammatory drugs were administrated postoperatively as well as cold compresses and analgesics, Carrillo et al., (1990); Honmura et al., (1992); Tuner and Hode (1996).

The use of low power lasers (LPLs) had attracted attention. As it induces primary (photochemical, photoelectrical, and photoenergetic) and secondary biostimulation (stimulation of cell metabolism and microcirculation), Berns et al., (1990); Abt (1995); Barabash et al., (1995) and Miserendino et al., (1995). Thus it has a direct effect on lymph and blood vessels, with no adverse effects of irradiation, Lievens (1991).

So the aim of this study was to compare the effectiveness of LPL and intramuscular anti-inflammatory; Betamethasone, in minimizing postoperative edema and trismus after surgical removal of impacted lower third molars under local anesthesia (2% Mepevacaine hydrochloride/1:20,000 Levonordephrine).

2. Material and Methods

2.1. Materials:

2.1.1. Samples:

Twenty patients with the same difficult condition of mandibular third molar teeth composed the sample of this study. They were of both sex, aged 25-30y.

Clinical investigations of the LPL and Betamethasone anti-edematous and anti-trismus effects were conducted at the Oral Surgery Clinic, Faculty of Oral and Dental Medicine, Cairo University, Egypt.

The patients were divided into two equal groups.

2.2. Methods:

2.2.1. Surgery

Surgical odontectomies were performed by only one, experienced surgeon and the duration of surgery was similar in the two investigated groups, being most frequently 30 min on average.

2.2.2. Low-power laser (LPL) treatment

Patients of group (I) received GaAlAs LPL (Quanta system, Italy) sessions on the first and third postoperative days. The laser tip was directed intra-orally from a distance of 1 cm away from the surgical wound, at the buccal, distal and medial surfaces of the extraction sockets. Each surface was stimulated for 3min. The energy output was 6 J/cm^2, with constant power density of 100 mW, and wavelength of 980 nm.

2.2.3. Systemic intramuscular Betamethasone treatment

Group (II) received a single dose of 4 mg systemic intramuscular Betamethasone Sodium Phosphate (Diprofos) into the gluteal region immediately after suturing of the surgical wound. Both groups received the usual medical and physical postoperative recommendations.

2.2.4. Measurements:

The size of postoperative edema and trismus were registered in cm on the third and seventh postoperative days (the baseline level was recorded preoperatively).

2.2.4.1. Measurements of edema coefficient (Ec)

The distance between the tip of tragus and the lip commissure at the same side was measured using a graduated tape and the edema coefficient (Ec) calculated using modified formula of Carrillo et al., (1990).

Ec = postoperative distance - preoperative distance /preoperative distance x 100.

2.2.4.2. Measurements of trismus coefficient (Tc)

The trismus was determined by measuring the maximum interincisal mouth-opening ability of the patients by a sliding caliper and the trismus coefficient (Tc) calculated using Carrillo el al., (1990 formulae.

Tc= preoperative distance - postoperative distance /preoperative distance x 100.

2.2.5. Statistical analysis

Statistical analysis of edema and trismus coefficient differences between both groups was performed using the non-parametric Wilcoxon rank test.

3. Results

None of the patients showed any adverse reactions to the applied treatments.

From (Table 1) it was observed that, the average value of edema coefficient in laser stimulated patients on the 3rd postoperative day was noticeably lower than its correspondence in the Betamethasone injected ones, being 1.59 and 10.39 cm respectively. On the 7th postoperative day the average edema coefficients of both groups were almost the same.

Table 1: Comparative survey of postoperative edema coefficients in the investigated groups of patients.

Follow up intervals	Average edema coefficient in Laser group	Average edema coefficient in Betamethsone group	p-value
3rd postoperative day	1.59	10.39	0.5553
7th postoperative day	2.68	3.40	0.2538

It was noticed from table (2) that the average postoperative trismus coefficient did not show remarkable difference between both groups on the 3rd and 7th postoperative days.

Statistical analysis of edema and trismus results (Wilcoxon rank test) pointed to a non significant difference between both groups on the 3rd and 7th postoperative days.

Table 2: Comparative survey of postoperative trismus coefficients in the investigated groups of patients

Follow up intervals	Average trismus coefficient in Laser group	Average trismus coefficient in Betamethsone group	p-value
3rd postoperative day	23.47	26.33	0.7114
7th postoperative day	13.91	16.78	1.0000

4. Discussion

It is well known among oral surgeons that empirically, postoperative edema and trismus can always be expected after impacted lower third molar surgery. Operative trauma could be presumed to be fairly similar in all the study groups with regard to the need for tooth separation, drilling in bone, and duration of surgery. Both groups received their medical and physical postoperative rescue therapy, it seems reasonable to attribute the favourable results in reduction of postoperative edema or trismus primarily to the effectiveness of the treatment methodology.

Regarding the efficiency of LPL and steroids in reducing postoperative sequelae, many studies proved their anti-edematous and anti-trismus effects on experimental and clinical conditions Goldman(1980); Honmura et al., (1992). LPL is believed to induce an increase in number and diameter of lymph vessels, with a simultaneous decrease of blood vessel permeability Lievens (1988; 1991). The use of steroids, aid in inhibition of phospholipase A2 enzyme, which reduces the release of arachidonic acid in the cells of the inflamed focus. This will consequently decrease prostaglandins and thus reduces these postoperative complications, Huggman (1977). It is believed that single parenteral use of steroids, regardless of the dose, does not exert an undesired effect on the adrenal-pituitary regulation of natural steroid secretion, Montgomery (1990) ,thus implicating their safe use for this indication. The course of our investigation showed that although Wilcoxon rank test proved insignificant, yet the LPL therapy is more efficient in reducing average postoperative edema on the day of its peak occurrence. But both treatment therapies did not establish a noticeable anti-trismus effect through the follow up intervals.

The beneficial LPL irradiation effects seem to be dose-dependent. Roynesdal, 1992 verified that lasers with 3 J/cm^2 energy output or less produce no significant effects after impacted lower third molar surgery, Roynesdal (1992). In our study, we followed his recommendation and used a higher therapeutic dose (6 J/cm^2, with constant power density of 100 mW, and wavelength 980 nm). It exerted a significant anti-edematous effect on the 3rd postoperative day in comparison to the Betamethasone group.

The LPL therapy appeared to be non-invasive and without any adverse effect on the patients. This clinical finding disagreed with results of Jovanoic et al., (2004) who expected a thermal insult to tissues stimulated with 100mW power density or more Jovanovic (2004), but as we shortened the stimulation time, no adverse thermal effects was encountered. The repeated dose on the 3rd postoperative day proved unnecessary, as its' outcome on the 7th postoperative day was not notable in comparison to the results of the Betamethasone group.

It could be concluded that within the limitation of this study, LPL therapy is effective than systemic Betamethasone in reducing postoperative edema after third molar surgery. However both treatment modalities showed no statistical significant difference and have the same effect on postoperative trismus.

[2]Department of Science Laboratory Technology, University of Jos, Nigeria.
[3]Department of Pharmacognosy, University of Jos, Plateau State, Nigeria.
istifanuschindo@yahoo.com

Abstracts: The oil quality parameters of the seed and condiment oil of *Adansonia digitata* were evaluated. The Iodine value, Peroxide value, Saponification value and percentage Free Fatty Acid (FFA) were 98.07g/100g, 1.4mEq/Kg, 122.60mg/g and 0.21% respectively for seed oil and 71.06g/100g, 10.20mEq/Kg, 142.80mg/g and 6.37% respectively for the condiment oil. The variation in the parameters from seed oil to condiment oil observed include increased in peroxide value, FFA and Saponification value and decreased in Iodine value. The changes have been interpreted to be due to some structural changes in the Triglyceride leading to the formation of new chemical properties and products. The Infra Red (IR) spectra have also given an identification of Rancidity of the condiment oil due to bands observed at 3400- 2700 and 1705 cm^{-1} indicating the possible formation or absence of acid and aldehyde respectively; which are products of oxidative Rancidity.

[I.Y Chindo, J.S Gushit, P.N Olotu, J. Mugana and D.N. Takbal. **Comparism Of The Quality Parameters Of The Seed And Condiment Oil Of *Adansonia Digitata***. Journal of American Science 2010;6(12):990-994]. (ISSN: 1545-1003). http://www.americanscience.org.

Key words: Rancidity, *Adansonia digitata, seed oil, condiment oil, Saponification & Infra Red.*

1. Introduction

Adansonia digitata (baobab) is a tree found in the savanna areas of Africa and Asia. In Nigeria it is found in the northern part of the country. The leaves are the major ingredient for a variety of food preparations. The pulp is also used for cooling drinks, used as an appetizer for seasoning food or curdling milk, used as a coagulant of rubber, and as a fumigant for domestic animals (Nkafamiya, 2007). The leaves, pulp and seed are used in traditional medicine for the treatment of kidney diseases, dysentery and fever, the bark of the tree is used as a substitute for quinine bark in the treatment of malaria fever. The ashes made from the seeds are rich in potash and phosphate and are used as fertilizers. The outer part of the bark is used for making packing materials and the spongy wood for making wide canoes **(**Otto, 1989**)**.

The seed oil content is about 33% of the seed bulb which consist of oleic, and linoleic acids as the major fatty acid constitute and other fatty and non fatty substances (Theodore, 1989). The high content of the linoleic and oleic acids helps in softening skin, restore and moisturize the epidermis and helps in regenerating epithelial tissues which gave the seed oil a very good carrier and useful in the cosmetic industry (Theodore, 1989).

2. Material and Methods

Sample Collection and Preparation

The seed sample of *Adansonia digitata* was obtained from Bayara village in Bauchi State, Nigeria on the 1st January, 2010. The seed coat was stone-cracked in order to collect the seeds and then crushed into powder subsequently referred to as powdered sample and was kept for condiment preparation.

Condiment Preparation

The powdered sample was made into a thick paste by mixing it in a beaker with water (100g powdered sample in 10ml of water). The resulting solution was covered with aluminium at normal room temperature and pressure for five (5) days. And was then dried at room temperature and crushed into powder subsequently referred to as condiment sample.

Oil Content Determination

The condiment sample (100g) was defatted exhaustively with petroleum ether (60- 80^{OC}) in a soxhlet apparatus and concentrated in-vacuo to produce a dark brown mass (50g). The marc was then left in the fume cardboard for about twelve hours in order to remove any spill over petroleum ether and the percentage extract recovery expressed as the weight of oil (g) divided by the weight of sample on dry mass and the resultant multiplied by one hundred percent.

***Moisture Content* Determination**

An evaporating dish was heated to a constant weight in an oven at 105^0C and its constant weight noted. 3g of the powered drug was accurately weighed into the dish. The dish with its content was then put in the oven at 105^0C and the content dried to a constant weight at 30 minutes interval after the initial drying of one hour. Two consecutive same weights confirm a constant weight. The total loss in weight (weight of the moisture) was determined by subtracting the constant weight of the dish and powered drug after heating from the weight of the dish and its content before heating. The percentage of the moisture contents with reference to the initial weight of the powered drug was then calculated.

This was achieved by dividing the weight of the moisture by the weight of the drug (condiment & oil) taken and multiplied by a hundred. Three different determinations were carried out and the average of the three gives the moisture content of the drug (Evans, 1996).

Iodine Value (IV) Determination

The method described by Marshall (2005) was adopted**.** Oil sample (0.5g) was placed in a 250ml conical flask and 10ml of anhydrous chloroform was added. This was followed by 30ml of Hanus solution and the flask was Stoppard and allowed to stand in the drawer for 30 minutes after which Potassium iodide (10ml 0f 15% v/v) was added to the content of the flask so as to wash down any iodine that might be present on the Stoppard. The resulting solution was titrated with sodium thiosulphate solution (0.14M) until the light yellow color formed disappeared. The determination for the blank was conducted in the same manner but without the oil. The iodine value was calculated as:

IV = (B - S) × M × 12.69/ sample weight (g). {Where: M = molarity of sodium thiosulphate (0.14M), 12.69 = conversion factor from Meq. Sodium thiosulphate to gram iodine, B = blank titre value, S (ml) = sample titre value}

Peroxide Value (PV) Determination

The method described by Nkafamiya et al (2007) was adopted. The oil (5g) was placed in 30ml glacial acetic acid: chloroform (3:2 v/v %) and saturated solution of potassium iodide (0.5ml) was added to liberate iodine by reacting with the peroxide. The resulting solution was titrated against sodium thiosulphate (0.01M) using starch solution (1%) as indicator, until the yellow color just disappeared. The peroxide value was calculated as follows:

PV (meq/Kg) = (S-B) × M× 1000/ sample weight (g). {Where: B = blank titre value, S (ml) = sample titre value M = molarity of sodium thiosulphate solution (0.01M)}.

Percentage Free Fatty Acid (%FFA) Determination

Nkafamiya et al (2007) procedure was used. Oil sample (2 g) was weighed into a 250 ml conical flask and 10ml of ethanol (95%) was added, the resulting mixture was titrated with sodium hydroxide (0.1 M) using phenolphthalein as indicator. The titration was done with constant shaking until a pink color persisted for 30 seconds. The %FFA was then calculated from the following equation:

%FFA = V × M × 2.82 mg/sample weight (g). {Where V (ml) = volume of sodium hydroxide solution used M = molarity of sodium hydroxide solution used, 2.82 = conversion factor for oleic acid}.

The acid value AV = % FFA × 1.99

Saponification Value (SV) Determination

The method described by Nkafamiya et al (2007) was used. The Oil sample (2 g) was added to alcoholic potassium hydroxide (4g of KOH dissolved in 100 ml of ethanol); the resulting solution was heated at 60^{o}c with constant stirring for two minutes to saponify the oil. The unreacted KOH was back titrated with HCl (1 M) using phenolphthalein as indicator. The titration took place until the solution turned pink. The Saponification value was then calculated as follows:

SV = (B-S) × M× 56.1/sample weight (g). {Where B = blank titre value, S (ml) = sample titre value M = molarity of HCl (0.1 M) and 56.1 = molecular weight of potassium hydroxide}.

PHYSICAL AND PHYSICOCHEMICAL PARAMETERS DETERMINATION

The physical parameters used include: colour, odour and specific gravity. The specific gravity is given by: weight of oil sample divided by weight of equal volume of water. Infrared (IR) analysis was performed on the oil samples and the absorption bands (cm^{-1}) showing the functional groups present in the oil was collected from the spectra.

Preparation of Reagents

All reagents used were of technical grade.
Preparation of Hanus solution

The method described by (Marshall, 1975) was adopted. Iodine crystal (3.3 g) was dissolved in small quantity of glacial acetic acid (about 10 ml) and the volume was made up to 250 ml in a volumetric flask with glacial acetic acid. The solution was then stored in brown Stoppard bottle.

Preparation of starch solution

Starch powder (1 g) was dissolved in 100 ml of distilled water, and the mixture agitated to ensure complete dissolution.

3. Results

Oil Extraction and Physical Parameters

Adansonia digitata seed oil and condiment oil were extracted by hot solvent extraction method using petroleum ether. The color, texture, odour, moisture content (%), specific gravity and oil yield and percentage recovery are shown in Table 1 below.

Table 1: Extract Recovery and Physical Quality

Sample	Oil yield of extract (ml)	Oil yield of extract (g)	Percent-age recovery (%)	Percent-age moisture content (%)	Spec-ific gravity
Seed oil	35	33	35.9	8	0.943
Condime-nt oil	33	30	31.6	5	0.909

From the Table 1, it can be seen that the seed oil has higher percent recovery and moisture content and also slightly denser than the condiment oil (which indicates possible oxidation or hydrolysis reaction of the oil during the condiment preparation). The sharp odor of the condiment oil may be due to the presence of aldehyde of medium molecular weight(heptylic or nonoic aldehydes), such compounds may be formed by oxidation and rapture of fatty acid chain which might have taken place during fermentation in the condiment preparation. The oxidation will also lead to reduction of oil content. The infrared spectroscopy analysis is shown in Fig 1, Fig 2 and Table 2.

Table 2: Samples Infrared Spectroscopy Information

Seed Oil		
Absorption (cm-1)	Absorption intensity	Inference
3000	narrow absorption	=C – H Stretching
	medium absorption	C – H Stretching
1750	medium absorption	C=O Stretching
1640	medium absorption	C = C Stretching
1250 – 1150	broad absorption	C – O – C Stretching
Condiment oil		
3400 – 2700	Broad absorption	O – H Stretching
3000	narrow absorption	=C – H Stretching
2980 – 2820	medium absorption	C – H Stretching
1750	Medium absorption	C = O Stretching
1705	Medium absorption	C = O Stretching
1640	Medium absorption	C = C Stretching
1250 – 1150	Broad absorption	C – O – C Stretching

Table 3: Sample Titre Values

Parameter	Blank titre value (ml)	Seed oil sample titre value (ml)	Condiment oil sample titre value (ml)
Iodine value	40.2	12.4	20.2
Saponification value	3.2	46.9	54.1
Peroxide value	2.0	2.7	7.1
%FFA		1.5	45.2

Table 4: Results of Chemical Parameters

Sample	PV (mEq/Kg)	IV (g/100g)	SV (mg KOH/g)	Acid value	%FFA
Seed oil	1.4	98.068	122.6	0.421	0.2115
Condiment oil	10.2	71.064	142.8	12.68	6.3732

4. Discussion

From Tables 3 and 4, the Peroxide value, the Saponification value, the %FFA are higher in the condiment oil than those of the seed oil except the iodine value which is higher for the seed oil as shown in table 4. The decrease in iodine value of the condiment oil (71.064) compared to the seed oil (98.068) is an indication of lipid oxidation, since there is a decrease in unsaturation during oxidation. The value of %FFA for the condiment oil (6.3732%) indicates a high level of free fatty acids in comparison to the seed oil (0.2115%), the increase in free fatty acids indicates that free fatty acids are formed during fermentation in the condiment preparation, and the high free fatty acid content of the condiment oil makes it unsuitable for food preparation. The higher Saponification value of the condiment oil (142.8) indicates the formation of lower molecular weight oxidation products for example aldehyde and carboxylic acids; it also explains the use of the oil as an ingredient in tooth paste. Peroxide value is also increased for the condiment oil (10.2) which indicates oil deterioration in the formation of hydro peroxide. The infrared spectra of the seed and condiment oils indicate the presence of unsaturated fatty acid and unsaturated oils. Infrared Absorbance (Table 2) at 1705 cm^{-1} in the condiment oil spectra, which is absent in seed oil spectra indicates the presence of an aldehyde in the condiment. The O – H broad absorbance (3400 – 2700cm^{-1}) for carboxylic acid in the condiment oil indicates the presence of free fatty acid in the condiment oil component.

5. Conclusion

The seed oil is very good for soap preparation due to its high Saponification value. The condiment oil is not good for use as food due to it's the high free fatty acid content, which is above the maximum acid value for edible oils; therefore it is used mainly in the preparation of soap and as an ingredient in tooth paste.

Abstract: A portable HPGe spectrometer has been employed to characterised, *in-situ* gamma activity concentration from the primordial Radionuclides ^{238}U, ^{232}Th ^{40}K in the soil at 12 monitoring points (MPs) in the environment in and around the Centre for Energy Research and Training (CERT), Ahmadu Bello University, Zaria, Nigeria. The MPs were marked-out using Global Positioning System (GPS) navigation. The measured activity concentrations due to ^{238}U range from 4.8 ± 3.0 to 11.9 ± 2.0 Bq kg^{-1} with an average of 8.3 ± 2.6 Bq kg^{-1}, ^{232}Th range from 15.5 ± 4.3 to 46.4 ± 3.5 Bq kg^{-1} with an average of 34.3 ± 3.4 Bq kg^{-1} and ^{40}K range from 317.2 ± 8.4 to 985.3 ± 7.0 Bq kg^{-1} with an average of 641.8 ± 7.3 Bq kg^{-1}.

Keywords: In-situ gamma, activity concentration, primordial Radionuclides

1. Introduction

Ionising radiation and radioactive substances are natural and permanent features of the environment, and thus the risks associated with radiation in all its forms can only be restricted, not eliminated. Moreover, the use of man-made radiation is widespread. The largest contribution to the radiation field is of natural origin: it is due to cosmic rays, the natural radioactivity generated by the decay of unstable, naturally occurring elements and the radioactive decay products of radon in the air (UNSCEAR, 1988). Artificial radioactivity may be released into the environment during the normal operations of nuclear facilities and installations such as nuclear ore processing, uranium enrichment, fuel fabrication, reactor operations, and application of radioisotopes in the fields of nuclear medicine, research, industry and agriculture (Eisenbud, 1987). These emissions are very small in normal operation, although large amounts of radioactivity could be released to the environment through accidents. The total amount of radioactivity in an environment should be accurately known and kept to a level as low as reasonably achievable (ALARA). Exposures from natural radiation are the largest component of all exposures for most people, and form the baseline

upon which exposures from manmade sources are added (UNSCEAR, 2000).

Gamma-ray spectroscopy system provides practical way to characterize dispersed Radionuclides in or on the soil to ascertain possible changes in the environmental radioactivity. Both laboratory and *in-situ* gamma spectroscopy are often used for monitoring and assessment of radioactivity and radiation dose rates in the environment due to both natural and anthropogenic sources. (Beck *et al.,* 1972; Nikl *et al*., 1988; ICRU, 1994; Othman *et al.*, 1994; Tzortzis *et al.*, 2003; Clouvas *et al*., 2004).In large-scale environmental radioactivity measurement, *in-situ* gamma spectroscopy is much favoured compared to laboratory soil analysis because of time and problems associated in cross contamination involved in the laboratory methods. It also gives the opportunity to obtain information not only of the activity concentration but also of the relative contribution of the various nuclides to activity concentration. *In-situ* techniques for measuring the activity concentration, resulting from the gamma radiation and characterizing its sources, with gamma ray spectrometer have been used successfully in the outdoor environment (Beck *et al*., 1972; Clouvas *et al*., 2001; Petalas *et al*., 2005; Auwal,M.M. 2005)

For radiation monitoring near nuclear facilities, baseline data, are indispensable for various purposes: they provide documented reference base; for the assessment of actual or potential consequence of radioactivity on health, and on the environment, due to radioactive materials or radiation fields in the environment from normal operations and accidental releases. The present work has been conducted in the Centre for Energy Research and Training (CERT), and some selected settlements within 2km radius from NIRR-1, using high-resolution portable gamma spectrometry system. The Centre is a nuclear energy (radiation) based research centre, thus, dealing with substantial quantities of artificial radioactive materials, such as neutron generator, Am-Be isotopic neutron source, a nuclear research reactor code named Nigeria Research Reactor-1 (NIRR-1); among others.

The present work puts forward a systematic method for determining environmental activity concentrations levels from *in-situ* measurements, and shows the distribution and intensities of important natural and artificial radionuclides within the studied area. It complements previous studies reported by other authors (Ibeanu *et al.,* 2002) by providing *in situ* gamma spectrometry based, baseline data, for operational and post operational monitoring, of the Centre for Energy Research and Training (CERT).

2. Materials and Methods

2.1 ***Site***

The study site is located at 007°38.523'–007°40.822'E and 11°07.830'–11°09.790' N within the Zaria sheet 102.The number of monitoring points (MPs) includes; eight locations within the Centre for Energy Research and Training (CERT), Ahmadu Bello University, Zaria, and four other locations at selected settlements around CERT within 2Km radius. Table 1 gives the description of the monitoring points (MP) with respect to the Nigeria Research Reactor 1 (NIRR1) as reference point. The chosen sites were undisturbed with little or no surface features and modest vegetation. These sites were marked-out using Global Positioning System (GPS).
