**Abstract :** This paper presents the effect of climate conditions in sprinkler irrigation design, the objective from the study is getting the effect of climate change related by lateral and sprinkler spacing in order to achieve minimum cost required to construct irrigation in which solid-set alignment. A computer model was developed to simulate pressure and flow rate distribution along pipes of pressurized irrigation systems in operation. The software made by VISUAL BASIC and runs in a Windows environment and is capable of simulating irrigation systems having pump station, sprinkler irrigation. The input data of the model are: soil type, climate condition, water salinity, land dimensions and slopes. The model according to soil type and water salinity gives the available types of crops can be cultivated, and according to climate conditions gives the amount of water needed. The model gives complete analysis of the system including hydraulic design of main pipe, laterals, selecting suitable sprinkler, pump power and finally get the system which need minimum cost to be constructed.

**Key words:** minimum cost; rectangle field; climate; sprinkler; solid-set.

### Introduction:

Prescreening process is one of matching the capabilities of the potential irrigation systems to physical site conditions and the goals and impacts of the project. The necessary field factors to design an irrigation system are the soil characteristics, climate conditions, water supply characteristics, field shape, topography, obstructions, and crop characteristics (Awadallah, 2002).

Soils have been classified for agricultural purposes by the U.S. department of Agriculture. For the common arable soils, suitable crops (Doorenbos and Kassam, 1979) and the basic intake rates (Pair C. H., 1983). Basic intake rate of soil and characteristics of the grown crop affect the irrigation method selection. Field crops may be irrigated by sprinkle methods. Solid-set for densely spaced crops are expensive and must avoid for low value crops [Doorenbos and Kassam, 1979].

Climate conditions and soil texture and land slope determine the recommended minimum water application rate (USDA, 1964) and maximum water application rate (Keller and Bliesner, 1990) for sprinkle to overcome evaporation and run-off losses, respectively. Sprinkle irrigation should be avoided if the recommended minimum application rate due to

climate is greater than the recommended maximum application rate due to soil and land slope.

Farm size, shape, and topography must consider in the selection process. For small and irregular farms, there is no need for automated systems. For large and regular farms, the use of a mechanized system is the right choice especially on coarse soils when high frequency irrigation gifts are required. For sloping fields, some systems require a degree of leveling to produce the desired application uniformity.

Some of physical conditions that must be considered for both selection and design process are: crops and cultural practices; farm size and shape; topography; soil type; climate; water supply; and water quality (Jensen M. E., 1990; Bliesner and Merriam, 1988; Keller and Bliesner, 1990; and Hlavec, 1995).

### Cost estimation:

Cost of system is calculated using 2015 price list of roxyplast company which its products according to din specifications (roxyplast.com, 2015). Fittings price 20% from system cost, maintenance 15% from system cost, pump cost 500 E.P per K.watt and K.watt price 0.40 P.E.

**Table 1:** Minimum Application Rate for Sprinkler Systems. [USDA, 1964]

Climatic Zone	Climate Shortcut	Recommended Minimum AR (mm/hr)
Cool maritime	C1	2.54 - 3.81
Warm maritime	C2	3.81 - 5.08
Cool dry continental	C2	3.81 - 5.08
Warm dry continental	C3	5.08 - 7.62
Cool desert	C4	7.62 - 12.70
Hot desert	C5	12.70 - 19.05

**Model description:**

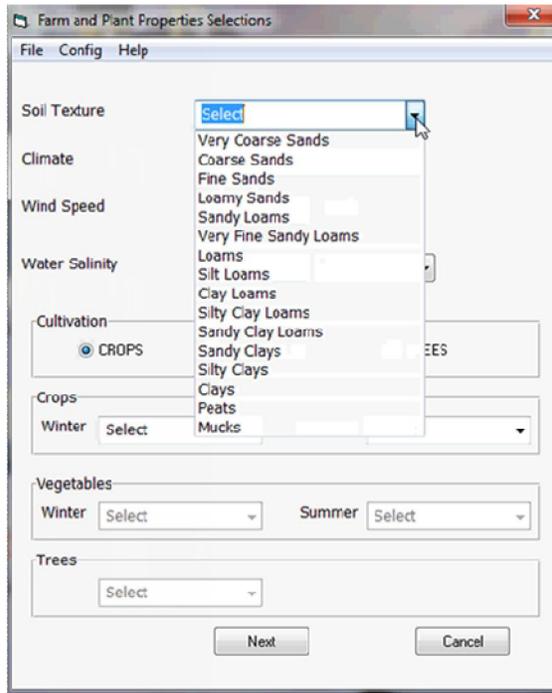

1. Selecting type of soil, climate zone, water salinity and wind speed affects the suitable crops, water needs and sprinkler specifications.
2. The selected crops guide to select the suitable irrigation system whether sprinkler or trickle.
3. The model try the selected system using all variables needed in the design such as Application rate range, Sprinkler spacing and lateral spacing, and Sprinkler operating head.
4. And by every change in the above data the model gives complete analysis and results for the irrigation system according to the inputs.
5. The output results in excel sheet showing all details for the system such as:

Application rate used, sprinkler and lateral spacing, sprinkler operating head and nozzle size,

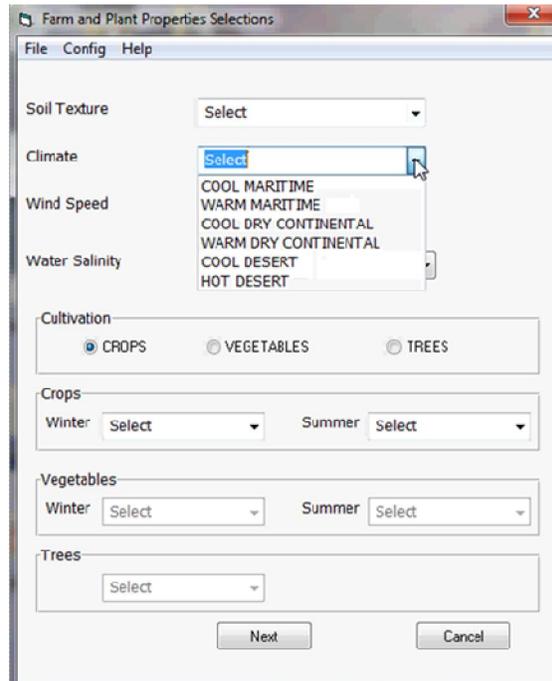

riser height, uphill and downhill lateral lengths, diameters, head loss and inlet pressure, main pipe length, diameter, head loss and inlet pressure on each reach, pump head, discharge of system, pump power and cost of system.

630	998.4

**Fig. 1:** selecting soil type

**Fig. 2:** selecting climate zone

Selecting soil type and water salinity will give the suitable cultivation according to them.

And the wind speed will affect the sprinkler and lateral spacing which preferred less than 2.1 m/s (4.7 mph) to achieve better CU value (Dechmiet al, 2003).

Minimum application rate is varies according to climate condition.

Maximum application rate is known according to soil type and land slopes.

In the runs the program is trying many application rates starting from  $AR_{min}$  up to  $AR_{max}$  then select the sprinkler and lateral spacing to achieve the suitable uniformity coefficient (Keller and Bliesner, 1990), then select the suitable sprinkler specifications discharge, nozzle diameters and operating head

(Keller and Bliesner, 1990) (table 4), the sprinkler discharge is calculated as  $qs=AR * SS * SL$ .

**Application design example:**

The soil in the study is loam. Climate is the changing factor, and field dimensions are 500x500, 750x750 and 1000x1000m, water salinity 2000 ppm, cultivated crops are Barley and Soybean, wind speed are tested as 4.0 mph, bigger land slope (DZ = 2%) parallel to farm length and smaller land slope (Z = 1%) parallel to farm width and main pipe H shape with pump at side of field.

The model will make design according to the above data and according to sprinkler and lateral spacing the results shown in figure (7).

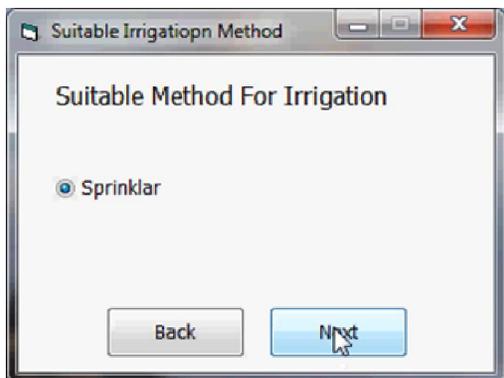

Climate shortcut is indicated in table (1).

**Table 3:** Basic Intake Rates for Different Soils, [Pair, C. H., 1983]

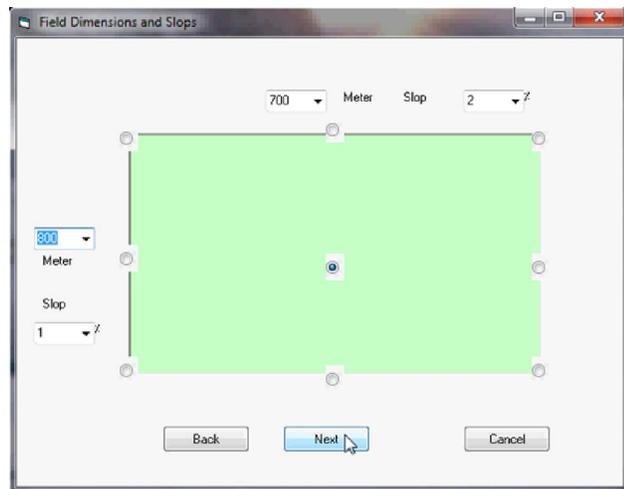

Soil Type	Basic intake rate (inch/hr)	Reduced for poor conditions (inch/hr)
Coarse sand	0.75 - 1.00	0.35
Fine sands	0.50 - 0.75	0.25
Fine sandy loams	0.35 - 0.50	0.20
Silty loams	0.25 - 0.40	0.12 - 0.15
Clay loams	0.10 - 0.30	0.05 - 0.01

**Table 4:** Maximum Application Rate for Sprinkler Systems, [Keller and Bliesner, 1990].

Soil Structure and Profile	Slope %			
	0 - 5	5 - 8	8 - 12	12 - 16
	Recommended Maximum, AR, (mm/hr)			
Coarse sandy soil to 1.8 m	50	38	25	13
Coarse sandy soil over more compact soils	38	25	19	10
Light sandy loams to 1.8 m	25	20	15	10
Light sandy loams over more compact soils	19	13	10	8
Silt loams to 1.8 m	13	10	8	5
Silt loams over more compact soil	8	6	4	2.5
Heavy textured clays or clay loams	4	2.5	2	1.5

(soil texture sandy loams, water salinity = 2000 ppm., DZ=2%, Z=1%, wind speed 4.0 mph, cultivated crops are Barely and Soybeans, Main pipe are H shape and pump on center of field)

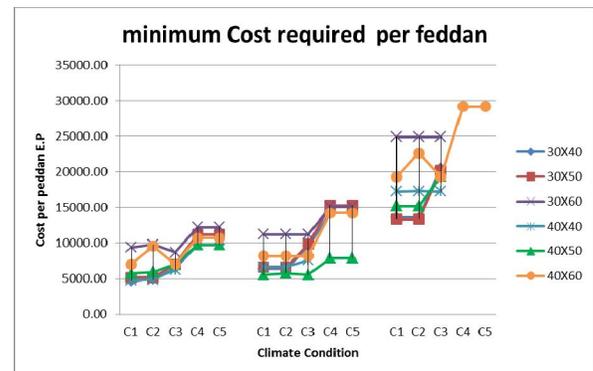

**Fig(8):** Minimum cost of system according to input data in field area (500x500)m<sup>2</sup>

**Fig(9):** Minimum cost of system according to input data in field area (750x750)m<sup>2</sup>

**Fig(10):** Minimum cost of system according to input data in field area (1000x1000)m<sup>2</sup>

**Fig(11):** Minimum cost of system (soil texture sandy loams, water salinity = 2000 ppm, DZ=2%, Z=1%, wind speed 4.0 mph, cultivated crops are Barely and Soybeans, Main pipe are H shape and pump on center of field)

### Conclusion:

The study presents that sprinkler and lateral spacing affects the cost of system as well as the climate condition, the cost of pipe system is the most of any land reclamation project. The cost of system is minimum per feddan, which consider pipe, fittings, maintenance and pump station almost between 4654 E.P to 24926 E.P. according to the climate zone, other data in the example and lateral and sprinkler alignments.

Alignment 40x50 is the best when field area (750x750)m<sup>2</sup> than any other alignment in all climate zones, where all other alignments give minimum cost per feddan when the field area (500x500)m<sup>2</sup>. The cost increases according to field area with the same climate zone by 15% to 47% comparing field (750x750) m<sup>2</sup> by field (500x500) m<sup>2</sup>. And increases by 137% to 260% comparing field (1000x1000) m<sup>2</sup> by field (500x500) m<sup>2</sup>.

So for minimum cost in solid set sprinkler irrigation system the most suitable field area about 60 feddan. In which the field area is more than this, field should be divided to achieve minimum cost.
