#### Abstract

The research aimed at analyzing whether or not there is an impact of climate change? On the net yield of the most important medicinal and aromatic plants during the period (2000-2021) through the study of the effect of maximum and minimum temperatures, average humidity, precipitation rate and time on the net yield of the most important medicinal and aromatic plants (anise, cumin, caraway, chamomile). Using descriptive and quantitative statistical methods and general temporal direction of area, production, productivity and net yield, Ricardo's method was also used to assess the economic impact of climate. The research concluded that the most important medicinal and aromatic plants (cumin, anise, caraway, and chamomile) are sensitive to climate changes. [Sayeda Hamed Amer Abdeljawwad, Shahira M. Reda, Nagwa M. Ahmed, Taher M. Saied Kadah. An analytical study for the impact of climate changes on the most important medicinal and aromatic plants. J Am Sci 2023;19(4):50-69]. ISSN 1545-1003 (print); ISSN 2375-7264 (online). http://www.jofamericanscience.org 05.doi:10.7537/marsjas 190423.05 .

Key Words: Climate changes, medicinal and aromatic plants, Ricardo Approach.

## Introduction:

The phenomenon of climate changes is one the most important universal phenomenon, and these changes occur due to the dynamic processes such as volcanoes or as a result of external forces such as the change in the intensity of solar radiation or large meteorites, and recently because of the human activities and paying attention to the development of industry in the past 150 years and burning billions of tons of fossil fuels to generate energy, which released the greenhouse gases such as carbon dioxide, which is one of the most important causes of climate change, as these gases led to raising the temperature with approximately 1,2 Celsius Degrees compared to the time before the industrial revolution. The climate change is defined according to the United Nations Framework Convention on Climate Changes as the change resulting directly or indirectly from the human activities that lead to a change in the formalization of the global atmosphere, which is observed at similar time intervals. Among the features of the climatic changes that occur at the present time are the severe drought that invades some regions, the devastating floods and torrential rains, the melting of ice in the north and south poles in addition to the increase in the water level in the seas and oceans, the matter which
leads to the possibility of drowning parts of the world, especially the lowlands ${ }^{(1)}$.

The agricultural production activities are the most sensitive and affected by the climate change among all sectors ${ }^{(2)}$, and the spatial differences did not emerge as an influence on the severity of the effects of climate change, as there is evidence that the tropical regions are the most vulnerable to the negative impact, while it is likely that the productivity increases due to the global warming phenomenon in the mild climates ${ }^{(3)}$, and many efforts were exerted to measure the economic impact of climate change on agriculture, which mainly focuses on the United States and other developed countries ${ }^{(4)}$, while some studies were conducted to evaluate the impact of climate change on the agriculture in the developing countries ${ }^{(5)}$, as the agricultural production systems in the developing countries such as Africa are deemed more vulnerable to the climate change because they have the lowest capital intensity and technological flexibility to adapt, as most of them are in the areas of hot climates, and it is likely that the temperatures will be higher beside the frequent drought waves and irregular rainfall ${ }^{(6)}$.

The medicinal and aromatic plants are of great economic value and importance, as the demand for them is increasing globally and locally ${ }^{(7)}$. Egypt has a huge economic wealth of medicinal and aromatic
plants, as it occupies the fifth place among the Egyptian crops for exploration; as the importance of these plants is due to the fact that they are the future of alternative medicine on the global level, where the world currently tends to use the herbs to treat some diseases. The medicinal and aromatic plants are also used in the manufacture of medications, perfumes, cosmetics, food and pesticides, which support the Egyptian economy; especially with the increase in the modern universal trend to shift to everything that is natural. Egypt's exports of medicinal and aromatic plants are about $90 \%$, which reflects their economic importance; where they are being cultivated in five main governorates within Egypt, namely Fayoum, Beni Suef, Minya, Assiut and Gharbia; as they represent $80 \%$ of the land area cultivated with the medicinal and aromatic plants within the Arab Republic of Egypt. The areas of medicinal and aromatic plants reach 120 thousand feddan; and the value of medicinal plant exports with their cultivation is about 8 to 10 billion pounds per year ${ }^{(8)}$.

## Problem:

The agricultural production activity is one of the most sensitive and affected activities by the climate change, and it is expected that the agricultural sector in general will be affected and the agricultural crops in particular because they are closely related to the climatic conditions. This research pays attention to the medicinal and aromatic plants as crops of value and economic importance within the Arab Republic of Egypt. Consequently, the research problem is represented in whether the climate change phenomenon affected the net yield of the most important medicinal and aromatic plants (Cumin, Anise, Caraway, Chamomile) during (2000-2021) or not? what are the percentages of these effects? Are they negative effects? or are some of them having positive effects on the net yield of medicinal and aromatic plants?

## Objective:

The research aims to analyze whether there is an impact of climate change or not? on the net yield of the most important medicinal and aromatic plants during (2000-2021), through studying the effect of maximum and minimum temperatures, average humidity percentage, rainfall rate and time on the net yield of the most important medicinal and aromatic plants (Anise, Cumin, Caraway, Chamomile).

## Method and Data sources:

This research uses the statistical analysis methods such as percentages and averages, in addition to some of the statistical analysis models such as Multiple Regression in the linear form and the
exponential form. Ricardo Approach was also used to evaluate the economic impact of climate change, as Ricardo Model takes either equation (1) or equation (2) according to whether the data is available for the annual net yields or the net capital returns (land value $\mathrm{V}_{\mathrm{L}}$ ).

$$
\begin{equation*}
\Delta W=W\left(E_{B}\right)-W\left(E_{A}\right)=\sum_{i=1}^{n}\left(P_{L B} L_{B i}-P_{L A} L_{A A}\right) \tag{1}
\end{equation*}
$$

Where: each of $P_{L A}, L_{A}$ at $E_{A}$, and each of $P_{L B}, L_{B}$ at $\mathrm{E}_{\mathrm{B}}$
The present value of welfare change is as follows:

$$
\begin{equation*}
\int_{0}^{Q_{B}} \Delta W e^{-r t} d t=\sum_{i=1}^{n}\left(V_{L B} L B_{B i}-V_{L A} L_{A i}\right) \tag{2}
\end{equation*}
$$

The research used the Ricardo Approach, where the net yield per feddan was used for the crops of Cumin, Anise, Caraway, and Chamomile in the most important governorates as a dependent variable, which is regression on the independent variables. The nonlinear model of second degree was chosen because it is easy to be interpreted ${ }^{(9)}$. The data were obtained from the secondary sources represented in the Central Administration of Agricultural Economics in the Economic Affairs Sector and the Central Laboratory of Climate at the Agricultural Research Center during (2001-2021). In addition to depending on some scientific references, research and studies closely related to the subject of the research.
The following scenarios were conducted to predict the extent of the climate changes impact on the study crops:

- The first scenario: the estimated average of net yield at maximum temperature increase with $0.5^{\circ} \mathrm{C}$.
- The second scenario: the estimated average of net yield at maximum temperature decrease with $0.5^{\circ} \mathrm{C}$.
- The third scenario: the estimated average of net yield at minimum temperature increase with $0.5^{\circ} \mathrm{C}$.
- The fourth scenario: the estimated average of net yield at the minimum temperature decrease with $0.5^{\circ} \mathrm{C}$.
- The fifth scenario: the estimated average of net yield at relative humidity increase with $0.5 \%$.
- The sixth scenario: the estimated average of net yield at relative humidity decrease with $0.5 \%$.

## The results of the most important previous studies of climate changes in the agricultural sector:

The most important social and economic effects of climate changes are represented in: the effects related to land resources, where the Island States are expected to disappear, the effects related to water, where it is expected that the areas suffering from drought and
water scarcity will increase and effects related to food production, where the production is expected to decrease with about $30 \%$ in the developing countries ${ }^{(10)}$.

The negative impact of climate change in 2030 in some Arab countries on the productivity of wheat, corn, barley, rice and sorghum, compared to a year (without climate change), while there is only a positive effect on the cotton crop. There are other effects caused by the climatic changes, including the pests and diseases, as it is expected that the leaf rust disease of wheat will increase in the future compared to the yellow rust disease because it needs high temperatures $\left(18-22^{\circ} \mathrm{C}\right)$ and humidity ( $70-80 \%$ ), in addition to the increase in rates of evaporation, which will double the pressure on the productivity and negatively affect the water resources ${ }^{(11)}$.

Egypt is one of the areas vulnerable to risks, including the drowning of parts of the Delta due to the rise of sea levels resulting from the melting of ice in the polar areas and the rise of water levels in the seas and oceans. The changes negatively affect the productivity of many agricultural crops, in addition to their impact on the crop patterns, increasing the desertification rates, increasing the need for water as a result of high temperatures, increasing the evaporation rates and the high temperatures that lead to an increase in soil erosion rates by 2050 . Some of the regionalization strategies to overcome the negative effects of climate changes are represented in developing new varieties that tolerate heat, salinity, drought and have a short growing season to reduce the necessary water needs for them, changing the dates of cultivation to suit the new climatic conditions, and reducing the area of crops that are extravagant in consumption and cultivating alternative crops whose growing season and water consumption is lower, in addition to reducing the emissions through increasing the means of absorbing carbon dioxide via the afforestation and forestry, while utilizing of the treated wastewater ${ }^{(11)}$.
It was found that there is a possibility of losing about $12 \%, 15 \%$ of the high-quality agricultural area in the Delta region as a result of salinization or drowning with the rise of sea level. It is expected that the climate changes will affect negatively on the self-sufficiency rate and the field crops productivity. Among these changes in 2030 is the expectation of two scenarios, the first is the optimistic scenario, that no parts of the Delta will be submerged, but the second scenario is the possibility of submerging about $15 \%$ of the Delta lands, as the cultivated area will be decreased with about 9,0 million feddan, thus the cropped area will decrease with about 406,1 million feddan, equivalent to about $25,6 \%$ of the cropped area if parts of the Delta are not submerged ${ }^{(12)}$.

The future climatic changes will negatively affect the agriculture and food system in general and the most agricultural crops in particular, and this will increase the average net yield per feddan of the wheat crop with a significant growth rate estimated at about $65,20 \mathrm{EGP} / \mathrm{fed} d \mathrm{an}$ during (2000-2017). There are also negative implications for the rising of maximum and minimum temperatures and the relative humidity (with the exception of the high average humidity with about $5 \%$, as the effect is positive on the net feddan yield of the wheat crop). While the effects were positive and increasing due to the decrease in the minimum and maximum temperatures and the relative humidity ${ }^{(13)}$.

It is expected that the rise in temperature will lead to future changes in the prevailing cropped patterns within Egypt. Although it is expected that there will be a decrease in the yield of some crops, an increase in the yield of others is expected. By 2050, it is expected that the output of wheat and corn will decrease with percentage of $18 \%$ and $19 \%$ respectively, compared to the current situation. On the other hand, the climate changes are expected to lead to an increase in the yield of the cotton crop ${ }^{(14)}$.

When measuring the economic impact of climate change on the summer maize crop, show research the sensitivity of the net feddan yield of the summer maize crop due to the change of the maximum temperatures whether with decrease or increase, while it is sensitive to the decrease in the minimum temperature and the relative humidity ${ }^{(15)}$.

A study concluded that there is a long-term significant relationship between average temperatures and productivity of maize and wheat crops, as the temperature greatly affects the productivity of the two crops in the long term more than in the short term and that the average rainfall did not have a significant effect, either in the long or in the short term ${ }^{(16)}$.

The "medicinal plants" in Sinai were not spared from the effects of climatic changes, as they are threatened with extinction. These plants have contributed to the treatment of many chronic diseases, which the Bedouin of Sinai consider as their means of healing from all diseases. Dr./ Mohamed Saleh, the chief sheikh of St. Catherine and an expert of the medicinal plants and medicine in Sinai, says that Sinai contains 472 medicinal plants, including 19 varieties and species, among which there is no place in the world except St. Catherine, and 42 species that are threatened with extinction due to the effects of climate change. He also explained that Sinai, especially its southern region is characterized by clear changes in the nature of the climate. In that one region, there is more than one nature of weather that ranges from below zero to high temperatures at the same time of the year, indicating that 17 species of them are endangered with extinction, as they are rare and most
of which are found in Sinai, and the continuation of climate change threatens their existence and continuity (17).

## Results and discussion

The relative importance of the area of medicinal and aromatic plants from the cropped area:

Table (1) shows The average area of medicinal and aromatic plants during (2016-2017) was about 98,2 thousand feddan, which representing about $61,0 \%$ of the cropped area to be estimated at about 16.1 million feddan, and this clarifies the low economic importance of medicinal and aromatic plants from the percentage of the area they represent in the cropped patterns.

Table (2) shows the order of the most important medicinal and aromatic plants in terms of area and the net yield for 2021. It was found that chamomile occupies the first place in terms of area, as it was about 13,2 thousand feddan with percentage of about $23,5 \%$ of total area of medicinal and aromatic plants, while Caraway occupies the second place with percentage of about $19,29 \%$, then Anise, Rose Geranium and Cumin with percentage of about $15,24 \%, 10,04 \%$ and $6,36 \%$, while the Caraway occupies the first place in terms of the net yield which was about 22,5 thousand EGP per feddan with percentage of about $23,7 \%$, followed by Cumin with about 16,5 thousand EGP with percentage of about $17,3 \%$, then Anise with percentage of about $15,9 \%$.

Table (1): The relative importance of the area of medicinal and aromatic plants from the cropped area during (20162021)

| Year | Crop <br> area | medicinal and aromatic plants <br> area | \% Medicinal and aromatic plants area of crop <br> area |
| :---: | :---: | :---: | :---: |
| $\mathbf{2 0 1 6}$ | 15.8 | 80.7 | 0.51 |

The directional relationship of the variables of the most important medicinal and aromatic plants during (2000-2021):

Through studying the directional relationship of the medicinal and aromatic plants variables, it is obvious from Table (1) that:

## The development of the Cumin crop productivity variables:

- Area: It is evident from the data of Table (1) in the annex that the area of Cumin within Egypt ranged between 1611 feddan in 2015 as a minimum and about 7817 feddan in 2002 as a maximum, and through estimating the equation of the General Temporal Trend of the Cumin area during the study period, it was found that the linear image is the best mathematical form suitable for the nature of the data, as the results indicated an increase in the area
of the Cumin crop with statistically significant annual rate estimated at about 6332,519 feddan per year and represent about $156,7 \%$ of annual average of the Cumin crop which was about 4042,5 feddan, and the significance of the model as a whole was also proven, and the results showed that about $17,6 \%$ of the changes occurring in the Cumin crop area during the study period is due to the time.
- Productivity: It is evident from the data of Table (1) in the annex that the average productivity of the Cumin crop was about 0,593 tons/feddan during the study period and ranged between 0,459 tons/feddan in 2001 as a minimum and about 0,839 tons/feddan in 2019 as a maximum, and via estimating the General Time Trend equation for the Cumin productivity during the study period, it was found that the exponential image is the best mathematical form suitable for the nature of the data, as the results indicated an increase in the productivity of the Cumin crop with a rate of about $3 \%$ annually, and the significance of the model as a whole was proven, and the results manifested that about $64 \%$ of the changes occurring in the productivity of the Cumin crop during the study period is due to the time.
- Production: It became clear from the data of Table (1) in the annex that the average production of the Cumin crop was about 2317,8 tons during the study period, and it ranged between 986 tons as a minimum in 2015 and about 3787 tons in 2002 as a maximum. By estimating the General Temporal Trend equation for the Cumin crop production, it was found that the linear image is the best mathematical form suitable for the nature of the data, as it the results calrified that the Cumin crop production increased at a statistically significant annual rate estimated at about 3021,922 feddan per year and represents about $130,4 \%$ of the annual average of the Cumin crop production, which is about 2317,8 feddan and the significance of the model as a whole was proven, and the results indicated that about $19 \%$ of the changes occurring in the Cumin crop production during the study period is due to the time.
- Net yield: It became evident from the data of Table (1) in the annex that the average net yield of the Cumin crop was about $6931,5 \mathrm{EGP} /$ feddan during the study period and ranged between 2549 EGP/feddan in 2001 as a minimum and about 18233 EGP/feddan in 2019 as a maximum, and through estimating the General Time Trend equation for the net yield of the Cumin crop during the study period, the results showed that the exponential image is the best mathematical form suitable for the nature of the data, as the results indicated an annual increase in the net yield of the Cumin crop with a rate of $8 \%$ per year, and the significance of the model as a whole
was also proven and the results indicated that about $75 \%$ of the changes occurring in the net yield of the Cumin crop during the study period is due to the time.

## The development of the Anise crop productivity variables:

- Area: It is clear from the data of Table (1) in the annex that the area of Anise within Egypt ranged between 996 feddan in 2001 as a minimum and about 8544 feddan in 2021 as a maximum, and through estimating the General Temporal Trend equation for the area of Anise during the study period, it was found that the linear image is the best mathematical form suitable for the nature of the data, where the results indicated an increase in the Anise crop area with statistically significant annual rate of 225,65 feddan annually and represent about $7,7 \%$ of the average annual area of Anise crop area which is about 2923 feddan, and the significance of the model as a whole was also proven and the results clarified that about $39 \%$ of the changes occurring in the Anise crop area during the study period is due to the time.
- Productivity: It is obvious from the data of Table (1) in the annex that the average productivity of the Anise crop productivity was about $0,725 \%$ tons/feddan during the study period and ranged between 0,489 tons/feddan in 2000 as a minimum and about 1,146 tons/feddan in 2019 as a maximum, and throug estimating the General Temporal Trend equation for the Anise productivity during the study period, it was found that the exponential image is the best mathematical form suitable for the nature of the data, as the results indicated an increase in the Anise crop productivity with statistically significant annual rate of $3,7 \%$ annually and the significance of the model as a whole was also proven and the results clarified that about $87 \%$ of the changes occurring in the Anise crop productivity during the study period is due to the time.
- Production: It became clear from the data of Table (1) in the annex that the average production of the Anise crop was about 2503 tons during the study period, and ranged between 541 thousand tons as a minimum in 2001, and about 9738 tons in 2019 as a maximum, and by estimating the General Time Trend equation for the Anise production during the study period, it was found that the exponential image is the best mathematical form suitable for the nature of the data, as the results indicated an increase in the Anise crop production with a rate about $9,5 \%$ annually, and the significance of the model was proven as a whole, where the results manifested that about $53 \%$ of the changes occurring in the
production of the Anise crop during the study period is due to the time.
- Net yield: It is evident from the data of Table (1) in the annex that the average net yield of the Anise crop was about $6552 \mathrm{EGP} /$ feddan during the study period and ranged between 1664 EGP/feddan in 2000 as a minimum and about 15354 EGP/feddan in 2019 as a maximum, and through estimating the General Time Trend equation for the net yield of the Anise crop during the study period, it was found that the exponential image is the best mathematical form suitable for the nature of the data, as the results indicated an increase in the net yield of the Anise crop with a rate of about $10,5 \%$ per year, and the significance of the model as a whole was also proven and the results indicated that about $92 \%$ of the changes occurring in the net yield of the Anise crop during the study period is due to the time.

## The development of the Caraway crop productivity variables:

- Area: It is clear from the data of Table (1) in the annex that the area of Caraway within Egypt ranged between 1496 feddan in 2000 as a minimum and about 19254 feddan in 2019 as a maximum, and through estimating the General Temporal Trend equation for the area of Caraway crop during the study period, it was found that the exponential image is the best mathematical form suitable for the nature of the data, where the results indicated an increase in the Caraway crop area with a rate of $8,3 \%$ annually and the significance of the model as a whole was also proven and the results manifested that about $83 \%$ of the changes occurring in the Caraway crop area during the study period is due to the time.
- Productivity: It is obvious from the data of Table (1) in the annex that the average productivity of the Caraway crop was about 0,894 tons/feddan during the study period and ranged between 0,731 in 2008 as a minimum and about 1,092 tons/feddan in 2021 as maximum and throug estimating the General Temporal Trend equation for the Caraway productivity during the study period, it was found that the linear image is the best mathematical form suitable for the nature of the data, as the results indicated an increase in the Caraway crop productivity with statistically significant annual rate of 0,809 tons/feddan annually and represented about $90,5 \%$ of the annual average of the Caraway crop productivity which is about 0,894 ton/feddan and the significance of the model as a whole was also proven and the results clarified that about $25 \%$ of the changes occurring in the Caraway crop productivity during the study period is due to the time.
- Production: according to the data of the attached schedule (1) that the average of Caraway Yield reached around 6173 ton during the survey period, and ranged from 1355 ton as a minimum in 2000 to 17333 ton as a maximum in 2019 by the evaluation of the general time trend equation for the Caraway Yield during the survey period, was shown that the exponential function is the best functions suitable for the nature of the plants. The results indicated the annual increase in the Caraway Yield at a rate of $9.0 \%$ as well as the whole significance test and the results were shown that a percent of approximately $70 \%$ of the changes in the Caraway Yield during the survey period are due to the process of time.
- Net return: pursuant to the data of the attached table (1), was shown that the net return average of the Caraway Yield reached approximately 6006 pound/ feddan during the survey period and ranged from 58.5 pound/ feddan as a minimum in 2016 to approximately 22391 pound/ feddan in 2020 as a maximum. By the evaluation of the general time trend equation for the Caraway net return during the survey period was shown that the linear function is the best functions suitable for the nature of the plants. The results indicated the annual decrease in the Caraway net return at a rate of 3565.2 pound/ feddan represented a percentage of $59.5 \%$ of the Caraway net return annual average that represents approximately 6006 pound/ feddan as well as the whole significance test and the results were shown that a percent of approximately $45 \%$ of the changes in the Caraway net return during the survey period are due to the process of time.

## The development of the Productive variables for Chamomile Yield:

- Area: according to the data of the attached schedule (1) that the space area designated for the Chamomile Yield in Egypt ranged from 7198 feddan as a minimum in 2000 and approximately 16567 feddan as a maximum in 2019. By the evaluation of the general time trend equation for the space area designated for the Chamomile Yield during the survey period was shown that the exponential function is the best functions suitable for the nature of the plants. The results indicated the annual increase in the space area designated for the Chamomile Yield at a rate of $3.3 \%$ as well as the whole significance test and the results were shown that a percent of approximately $71 \%$ of the changes in the space area designated for the Chamomile Yield during the survey period are due to the process of time. (table 3)
- Productivity: pursuant to the data of the attached schedule (1) that the average of Chamomile yield reached around 0.891 ton/ feddan during the survey
period，ranged from 0.760 ton／feddan as a minimum in 2001 to 1.390 ton／feddan as a maximum in 2019. By the evaluation of the general time trend equation for the Chamomile Yield during the survey period was shown that the exponential function is the best functions suitable for the nature of the plants．The results indicated the annual increase in the Chamomile Yield at a rate of $1.3 \%$ as well as the whole significance test and the results were shown that a percent of approximately $42 \%$ of the changes in the Chamomile Yield during the survey period is due to the process of time．（table 3）
－Production：according to the data of the attached schedule（1）that the average of Chamomile Yield reached approximately 9633.4 ton during the survey period，ranged from 5562 ton as a minimum in 2001 to 23035 ton as a maximum in 2019．By the evaluation of the general time trend equation for the Chamomile Yield during the survey period was shown that the exponential function is the best
functions suitable for the nature of the plants．The results indicated the annual increase in the Chamomile Yield at a rate of $4.6 \%$ as well as the whole significance test and the results were shown that a percent of approximately $69 \%$ of the changes in the Chamomile Yield during the survey period are due to the process of time．（table 3）
－Net return：according to the data of the attached table（1）was shown that the net return average of the Chamomile Yield reached approximately 1164.5 pound／feddan during the survey period and ranged from 1321.8 pound／feddan as a minimum in 2016 to approximately 4110 thousand pounds／feddan in 2019 as a maximum．By the evaluation of the general time trend equation for the net return average of the Chamomile Yield during the survey period was shown that the statistical significance isn＇t proven regarding the different significance levels；this means that it is relatively stable around the annual average for the period indicated．

Table（3）：The general time trend for the productive variables of the medical and aromatic plants During the period of（2000－2021）

| Statement |  |  | Index | General temporal trend equation | R2 | F | Change rate（\％） |

Whereas： $\ln \mathrm{Y}, \mathrm{Y}=$ estimated value of the study variables， $\mathrm{Xi}=$ time variable whereas $21, \ldots \ldots .2,1=\mathrm{i}$
Resource：calculated and collected by the data of Ministry of Agriculture and Land Reclamation，Economic Affairs Sector，Central Administration of Agricultural Economics and the bulletin of the agricultural statistics during the period of（2000－2021）．

The impact of the climate changes on the most important medical and aromatic plants during the period of (2000-2020):

Table (4) has shown the average of Cumin net return reached approximately 8597 pounds, as it reached its maximum in 2020 estimated approximately by 26.3 thousand pounds at the level of the Republic, while it reached its maximum for Minya Governorate estimated approximately by 10.3 thousand pounds, by the statistical significance growth rate reached annually approximately $9.2 \%$ during the period of (2000-2020). The average of maximum and minimum temperature, relative humidity and the rainfall amount reached approximately respectively $28^{\circ} \mathrm{C}, 17^{\circ} \mathrm{C}, 58 \%$ and 0.9 mm and by the statistical non-significance growth rate.

While, the average of Anise net return reached approximately 7101 pounds, as it reached its maximum in 2012 estimated approximately by 13.4 thousand pounds at the level of the Republic, while it reached its maximum for Al Sharqia Governorate estimated approximately by 8.7 thousand pounds, by the statistical significance growth rate reached annually approximately $5.7 \%$ during the same period. The average of maximum and minimum temperature, relative humidity and the rainfall amount reached approximately respectively $29^{\circ} \mathrm{C}, 16^{\circ} \mathrm{C}, 52 \%$ and 0.6 mm and by the statistical non-significance growth rate. While, the average of Caraway net return reached approximately 6151 pounds, as it reached its maximum in 2018 estimated approximately by 24.7 thousand pounds at the level of the Republic, while it reached its maximum for Beni Suef Governorate estimated approximately by 12 thousand pounds, by the statistical significance growth rate reached annually approximately $13.2 \%$ during the same period. The average of maximum and minimum temperature, relative humidity and the rainfall amount reached approximately respectively $29^{\circ} \mathrm{C}, 16^{\circ} \mathrm{C}$ (by the statistical significance growth rate), $55 \%$ (the statistical significance growth rate) and 0.8 mm and by the statistical non-significance growth rate.

While, the average of Chamomile net return reached approximately 1522 pounds, as it reached its maximum in 2019 estimated approximately by 4547 thousand pounds at the level of the Republic, while it reached its maximum for Minya Governorate estimated approximately by 5432 pounds, by the statistical significance growth rate reached annually approximately $2.54 \%$ during the same period. The average of maximum and minimum temperature, relative humidity and the rainfall amount reached approximately respectively $29^{\circ} \mathrm{C}, 16.7^{\circ} \mathrm{C}$ (by the statistical significance growth rate), $51.3 \%$ (the
statistical significance growth rate) and 0.7 mm and by the statistical non-significance growth rate.

The table (5) has shown that the Ricardo model mentions to the impact of the climate changes on the net return of the survey yields during the period of (2000-2020), and was shown that the cumin yield variables, subject of the survey, explain about $62 \%$ of changes in the dependent variable, and the significance of the impact of all variables, subject of the survey, was shown except the impact of relative humidity average, rainfall amount, relative humidity square, the average of maximum temperature $x$ average of relative humidity, the average of minimum temperature in average of relative humidity, rainfall amount in average of relative humidity .

While, it has been shown that the Anise Yield variables, subject of the survey, explain about $76 \%$ of changes in the dependent variable, and has been shown the significance of the impact of all variables, subject of the survey, except the impact of the process of time.

While, it has been shown that the Caraway Yield variables, subject of the survey, explain about $61 \%$ of changes in the dependent variable, and has been shown the significance of the impact of all variables, subject of the survey, except the impact of each of the average of minimum temperature and rainfall amount square.

While, it has been shown that the Chamomile Yield variables, subject of the survey, explain about $37 \%$ of changes in the dependent variable, and has been shown the significance of the impact of all variables, subject of the survey, except the impact of the average of minimum temperature, the average square of minimum temperature, the average of minimum temperature in and relative humidity.

## The simulations of the climate change impacts on the most important medical and aromatic plants:

The simulation of the climate change impact, the estimated functions of the model contained in table (6) in order to calculate the impacts of change in the temperature, relative humidity and rainfall amount on the survey yields net return, whereas the increase and decrease in each of maximum temperature and minimum temperature were calculated by approximately $0.5^{\circ} \mathrm{C}$ and the average of relative humidity was calculated by approximately $0.5 \%$ and the impact of the rainfall amount wasn't calculated as the rainfall is natural and the farmer can overcome their effects by reducing or increasing irrigation.

It was shown by table (6) and figure (1) of the Climate change scenario, the negative effect of the high maximum and minimum temperature $0.5^{\circ} \mathrm{C}$ and high and low relative humidity on the cumin yield net return at a rate reached approximately 298.8 \%, $357,7 \%, 32.7 \%$ of the current revenue net return, and
approximately $396 \%, 483.1 \%, 0.01 \%$ of model calculated revenue net return, the impact of the low maximum and minimum temperature (approximately $0.5^{\circ} \mathrm{C}$ ) on the Cumin Yield net return at a rate reached approximately $234.5 \%, 290,1 \%$ of the current revenue net return, and approximately $397.3 \%, 479.9 \%$ of model calculated revenue net return average.
It was shown the negative effect of the high maximum temperature and low minimum temperature of $0.5^{\circ} \mathrm{C}$ and high relative humidity $0.5 \%$ on the Anise Yield net return at a rate reached approximately $1717.1 \%$, $326.1 \%, 1.27 \%$ of the current revenue net return average, and approximately $1703.1 \%, 324.2 \%$, $17917 \%$ of model calculated net return average, the impact of the low maximum and minimum temperature (approximately $0.5^{\circ} \mathrm{C}$ ) and the relative humidity on the anise yield net return at a rate reached approximately $1718.8 \%, 327.9 \%, 2.9 \%$ of the current revenue net return, and approximately $1703.1 \%$, $324.2 \%$, $2 \%$ of model calculated revenue net return average.

It was shown the negative effect of the high maximum temperature of $0.5^{\circ} \mathrm{C}$ on the Caraway Yield net return at a rate reached approximately $10.89 \%$ of the current revenue net return average, and approximately $15.6 \%$ of model calculated net return average, the impact of the low maximum temperature and high minimum temperature (approximately $0.5^{\circ}$ C) and the high and low relative humidity $0.5 \%$ on the Caraway Yield net return at a rate reached approximately $18.64 \%, 19.64 \%, 6.11 \%, 5.67 \%$ of the current revenue net return average, and approximately $14.94 \%, 11.78 \%, 0.40 \%$ of model calculated revenue net return average.

It was shown the negative effect of the high and low maximum temperature, high minimum temperature of $0.5^{\circ} \mathrm{C}$ and the high and low relative humidity $0.5 \%$ on the Chamomile Yield net return at a rate reached approximately $10.38 \%, 0.69 \%, 18.25 \%$, $10.82 \%, 10,82 \%$ of the current revenue net return average, and approximately $34 \%$ (positive effect), 11.16 (positive effect), $7.61 \%, 0.12 \%, 0.14 \%$ of model calculated net return average, the impact of the low minimum temperature (approximately $0.5^{\circ} \mathrm{C}$ ) on the Chamomile Yield net return at a rate reached approximately $5.03 \%$ of the current revenue net return average, and approximately $19.23 \%$ of model calculated revenue net return average.
Therefore, it was shown from the above- mentioned:

## Cumin Crop:

- The effect was negative in case of the high maximum and minimum temperature, low and high relative humidity.
- The effect was positive in case of the high maximum and minimum temperature.

## Anise Crop:

- The effect was negative in case of the high maximum temperature and low minimum temperature and high relative humidity.
- The effect was positive in case of the low maximum temperature and high minimum temperature and low relative humidity.

## Caraway Crop:

- The effect was negative in case of the high maximum temperature.
- The effect was positive in case of the low maximum and minimum temperature and high minimum temperature, high and low relative humidity.

## Chamomile Crop:

- The effect was negative in case of the high and low maximum temperature, high minimum temperature, high and low relative humidity.
- The effect was positive in case of the low minimum temperature.
Consequently, the feddan net return of the survey yields is sensitive to the climate change.

## Conclusions:

The research aimed at analyzing whether or not there is an impact of climate change? On the net yield of the most important medicinal and aromatic plants during the period (2000-2021) through the study of the effect of maximum and minimum temperatures, average humidity, precipitation rate and time on the net yield of the most important medicinal and aromatic plants (anise, cumin, caraway, chamomile). Using descriptive and quantitative statistical methods and general temporal direction of area, production, productivity and net yield, Ricardo's method was also used to assess the economic impact of climate change.

Analysis of sensitivity to the effects of change in the climatic factors on the Chamomile crop during the period (2000-2020)

Source: Table (6) The rate of change of the calculated net return from the current

## The most important results of the study:

- The average area of medicinal and aromatic plants during the period (2016-2021) was about 98.2 thousand Feddan, representing about $0.61 \%$ of the crop area, estimated at about 16.1 million Feddan, which shows the low economic importance of medicinal and aromatic plants from the percentage of the area they represent in the crop structure.
- Chamomile occupies the first place in terms of area, reaching about 13.2 thousand Feddan, with about $23.5 \%$ of the total area of medicinal and aromatic plants, while caraway occupies the second place with about $19.29 \%$, followed by anise, green tar, cumin, with about $15.24 \%$, $10.04 \%, 6.36 \%$, while caraway occupies the first place in terms of net yield, with a net yield of about 22.5 thousand pounds per feddan, with about $23.7 \%$, followed by cumin with about 16.5 thousand pounds, with about $17.3 \%$, and then anise with about $15.9 \%$.
- The net yield of the cumin and anise crop increased at a rate of about $8 \%, 10.5 \%$ annually, while the yield of the caraway crop decreased at a statistically significant annual rate, representing about $59.5 \%$ of the annual average, while the net yield of chamomile was relatively stable around the annual average.
- For cumin, the effect was negative on the net feddanage yield for the increase in the maximum and minimum temperature rise $\left(0.5{ }^{\circ} \mathrm{C}\right)$ and relative humidity ( $0.5 \%$ ), while it was positive for maximum and minimum temperature drop ( 0.5 ${ }^{\circ} \mathrm{C}$ ).
- Anise had a negative effect on the net feddanage yield at the increase of maximum temperature ( 0.5 ${ }^{\circ} \mathrm{C}$ ) and relative humidity ( $0.5 \%$ ), while it was positive at the decrease maximum temperature ( 0.5 ${ }^{\circ} \mathrm{C}$ ) and negative at the decrease minimum temperature $\left(0.5{ }^{\circ} \mathrm{C}\right)$.
- Caraway had a negative effect on the net feddanage yield at the increase of the maximum temperature $\left(0.5^{\circ} \mathrm{C}\right)$, while it was positive at the increase of the minimum temperature $\left(0.5^{\circ} \mathrm{C}\right)$ and increase and decrease of relative humidity ( $0.5 \%$ ).
- Chamomile diathesis had a negative effect on the net feddanage yield at the increase of maximum and minimum temperatures $\left(0.5{ }^{\circ} \mathrm{C}\right)$ and increase and decrease of relative humidity ( $0.5 \%$ ), while it was positive at the decrease of minimum temperatures $\left(0.5^{\circ} \mathrm{C}\right)$.
- The sensitivity of the net cumin yield is affected by the change of the maximum and minimum temperature either by the decrease or the increase,
while it is not affected by the increase or decrease of the relative humidity.
- The sensitivity of anise net yield is affected by the change of the maximum and minimum temperature either by the decrease or the increase.
- The sensitivity of the net yield of the caraway is affected by the change of the maximum and minimum temperature either by decrease or increase.
- The sensitivity of the net chamomile yield is affected by the change of the maximum and minimum temperature either by the decrease or the increase, while it is not affected by the increase or decrease of the relative humidity.

## Recommendations:

- Studying regionalization to find out the means through which it is possible to overcome or alleviate the shortage in crop productivity that has been negatively affected by climate change.
- Establishing a database to complete the lack of available data on the adverse effects of climate change.
- Encourage scientific and technological research on all issues related to climate change, develop specific plans and clear funding, and follow policies and programs that support climate-smart agriculture.
